To describe 2 cases in which the hypothesis of MODY was considered during pregnancy. Case 1: Woman, 35 years old, G1P0A1, BMI 25 kg/m^2. At 5 weeks of gestation, she developed polyuria and polydipsia, prompting blood glucose measurement: glucose 293 mg/dl, A1C 9.3%. She started metformin 1.5 g/day. At the first Diabetes appointment, she demonstrated inadequate glycemic control. C-peptide was 3.9 ng/ml (reference range 1.1-4.4) and anti-GAD, and anti-IA2 antibodies were negative. Insulin therapy was initiated with progressive titration, and adequate glycemic control was achieved at 13 weeks. At the end of pregnancy, she was on metformin 2 g/day, detemir 28 U/day, and lispro 5U at dinner. Fetal macrosomia was identified without other ultrasound abnormalities. She underwent cesarean section at 38 weeks, with no complications; live birth with a weight of 4365 g, without malformations. She has maintained euglycemia without therapy in the 3 months postpartum. Due to a significant family history of Diabetes *mellitus* (DM), a genetic study for MODY was performed, revealing a result of uncertain significance - c.31A> G p.(Thr11Ala) in heterozygosity in the PDX1 gene (unreported variant). Case 2: Woman, 37 years old, G3P0, BMI 27 kg/m^2, diagnosed with DM in 2019, with no complications. Several maternal relatives with history of DM. She was referred to the Diabetes clinic for preconception assessment: HbA1C 5.6% on glargine 16U/day. Analytically: C-peptide 1.26ng/ml (reference range 1.1-4.4), anti-GAD and anti-IA2 antibodies were negative. At 12 weeks of gestation, she started prandial insulin, with no significant dosage increase since then. Currently, she is in the third trimester, with good glycemic control under glargine 24U and aspart 5U/day; fetal ultrasounds and echocardiogram without abnormalities. Genetic study for MODY revealed an inconclusive result - c.-152C>A in heterozygosity in the promoter region of the INS gene (reported variant).
Conclusion
In the described cases, the pre-existing DM/early diagnosis during pregnancy, the need for IT, significant family history of DM, and the exclusion of pancreatic autoimmunity, raised MODY suspicion. Pregnancy is associated with insulin resistance and may reveal pre-existing dysfunction in individuals with mutations associated with MODY. Genetic studies may provide a better understanding and classification of hyperglycemia during pregnancy.

Flash glucose monitoring: is it having a real impact on our patients' quality of life?

Víctor Siles-Guerrero, Juan Manuel Guardia-Baena, Araceli Munoz-Garach & Martín López-de-la Torre Casares
Hospital Universitario Virgen de las Nieves, Servicio de Endocrinología y Nutrición, Granada, Spain

Introduction and Objectives
Despite the many known advantages of Flash Glucose Monitoring (FGM), very few studies have shown a real improvement in the patient's overall quality of life. Therefore, our aim is to assess, using the validated Diabetes Mellitus Specific Quality of Life Questionnaire: Spanish version (EsDQOL), whether these differences really exist in our population.
Methods
An observational, prospective study was conducted comparing quality of life in patients with T1D prior to FGM and after 6 months of its use in a cohort of 89 patients from 1 January 2021 to 31 December 2022 employing the EsDQOL questionnaire which measures four variables: satisfaction, impact, social concern and concern about diabetes. The total score ranges from 43 to 215, with a higher score corresponding to a poorer quality of life. Kolmogorov-Smirnov test, Student's *t*-test and Wilcoxon test were used.
Results
89 patients were studied with 63% of women with a mean age of 42 ± 14.1 years with 10.8 ± 8.3 years of T1D evolution obtaining an improvement ($P<0.05$) in quality of life comparing each of the 4 items separately and globally in the questionnaire (96 [63-125] vs 79 [58-101]).
Conclusions
In addition to the already known advantages in glycaemic control variables, we can conclude that the implementation of the FGM has led to an improvement in the quality of life of our patients with T1D, reducing their concerns about social and occupational aspects and about the future effects of diabetes while improving the impact and satisfaction with the treatment received.

Cost of managing complicated diabetic patients in tunisia: a retrospective study in a hospital setting

Souhir Maalej, Fatma Mnif, Abdel Mouhaymen Missaoui, Siddiqa Soomauroo, Khouloud Boujelben, Mouna Mnif, Dhouha Ben Salah, Mohamed Abid & Nabila Rekik
Hedi Chaker University Hospital, Endocrinology, Sfax

Background
Diabetes mellitus presents a pervasive global health challenge, and Tunisia grapples with a concerning upswing in the prevalence of type 2 diabetes (T2D). Cardiovascular and renal complications stand out as prevalent and severe outcomes linked to T2D. Evaluating the costs associated with managing these complications in T2D patients is pivotal for improving care quality, optimizing resource allocation, and ultimately mitigating the escalating economic and social burden of this chronic disease.
Materials and Methods
We conducted a retrospective descriptive study to gather data on diabetic patients with chronic cardiovascular and renal complications. The study included patients hospitalized in the Endocrinology Department of Hedi Chaker University Hospital in Sfax from January 1 to December 31, 2022. The aim was to assess the

costs associated with managing cardiovascular and renal complications in our hospitalized patients.
Results
Our study comprised 114 patients, with cardiovascular and renal complications being the predominant category, affecting 53 individuals (46.5%). Cardiovascular complications alone were observed in 37 patients, constituting 32.5%, while renal complications alone were present in 24 patients, accounting for 21% of the sample. In our patient sample, the vast majority (93%) had social coverage, with 71% insured through the National Health Insurance Fund (64.9%) or the National Social Security Fund (6.1%). Additionally, 22% were considered indigent, benefitting from social coverage provided by the Ministry of Social Affairs. Only 7% of our study population lacked any social coverage. The average hospitalization duration was 7.2±4.5 days, with a minimum stay of 2 days and a maximum stay of 26 days. The overall direct cost of hospital management for cardiovascular and renal complications of diabetes in our population amounted to 256,096.18 TND, equivalent to 81,300.37 USD. This translated to an average cost per patient of approximately 2,246.46 TND, or 713.16 USD for an average hospitalization duration of 7 days. The daily cost was 320.92 TND or 101.88 USD. On a global scale, cardiovascular explorations represented the most significant portion of direct costs, encompassing 69.65% of the overall expenses. Conversely, glycemic monitoring was the least expensive, accounting for only 0.63% of the total costs.
Conclusion
Our comprehensive cost analysis of managing cardiovascular and renal complications in diabetic patients reveals significant economic implications. Optimizing healthcare strategies is imperative to alleviate the financial burden and enhance patient outcomes.

Hypomagnesemia in type 2 diabetics and its impact on glycemiccontrol and diabetes chronic complications

Yosra Hasni, Oumayma Zarrouk, Hamza Elfekih, Nassim Ben Hadj Slama, Molka Chadli Chaieb & Koussay Ach
University Hospital of Farhat Hached, Endocrinology Departement, Sousse

Introduction
Several studies have incriminated hypomagnesemia in the pathophysiology of diabetes, as the prevalence of this deficit in type 2 diabetics is high, and as it is correlated with glycemic control and chronic diabetic complications.
Aims
Studying the prevalence of hypomagnesemia in type 2 diabetics and assessing its impact on quality of life, glycemic control and chronic diabetic complications. Patients and methods: We conducted a descriptive cross-sectional study over a period from November 01, 2022 to January 31, 2023, including type 2 diabetic patients followed at the endocrinology department of CHU FARHAT HACHED. Data were collected from careful questioning, physical examination and medical records. Missing biological parameters were performed at the biochemistry laboratory of CHU FARHAT HACHED.
Results
We included 190 type 2 diabetics (sex ratio M/F 1.09), with a mean age of 60±9.9 years and a mean diabetes duration of 11.9±9.1 years. Diabetic retinopathy was present in 43.5% of our subjects. Diabetic nephropathy and diabetic peripheral neuropathy were present in 33% and 23.6% of patients respectively. 15.3% of our population had a coronary syndrome and 14.2% had a history of stroke or transient ischemic attack. Hypomagnesemia was present in 45.3% of our population, with a mean magnesemia of 0.74±0.09 mmol/l. It was statistically correlated with fasting blood glucose ($P=0.004$, OR=2.27) and HbA1c ($P=0.047$, OR=1.53); for a FPG >8.95 mmol/l and for HbA1c values >8.25%, the prevalence of hypomagnesemia increases significantly. However, we found no correlation between magnesium and quality of life, nor with chronic diabetic complications.
Conclusion
Hypomagnesemia is a frequent biological abnormality in type 2 diabetics and is significantly correlated with glycemic control. Therefore, its screening in these patients is recommended for possible supplementation.

Evaluation of glycemic balance in diabetic patients with mental disorders: about 68 cases

Bassiratou Hamza Maliki, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
CHU Ibn Rochd - Casablanca, Morocco, Casablanca, Morocco

Introduction
Mental disorders are frequent in diabetic patients and this makes care difficult.
Objective
Evaluate the repercussions of psychiatric pathologies on glycemic balance and complications of diabetes and show the need to detect them systematically and treat them in these subjects.
Patients and methods
Analytical retrospective study from 2016 to 2023 on 68 diabetic patients also with mental disorders hospitalized in the Endocrinology Service of the Ibn Rochd CHU of Casablanca, HBA1C and diabetes complications have been evaluated.
Results
The average age of our patients was 44 years, 44 DT1 and 24 DT2, sex ratio ½, the average duration of diabetes was 13.42 years (1-25 years), the average duration of evolution of psychiatric disorders 5.7 years (1-9 years), the average HBA1C 8.9 % (7.9- 12.4). Among our patients 20 (29.41%) have an emotional disorder, 16 (23.53%) had a driving disorder and 32 (47.05%) had an anxious disorder. The HBA1 was higher with depression. All patients had poor therapeutic observance both for the treatment of diabetes and for psychopathology, 40 patients (58.82%) had been hospitalized for diabetic ketosis, 14 (20.58%) in the aftermath of an acido ketose and 14 (20.58 %) for serious hypoglycemia. In our series: 14 patients (20.58%) had diabetic retinopathy, 18 (26.47%) had an albumin report on positive urinary creatinine, 32.35%($n=22$) had peripheral neuropathy. Low socio-economic status and mental disorders were associated with an elevation of HBA1C ($p\leq 0, 05$).
Conclusions
Psychiatric disorders in diabetic patients are associated with a glycemic imbalance and an increase in the risk of acute and degenerative complications.

Precocious puberty and skyrocketing obesity rates among children: a contemporary clinical perspective on the co-occurrence

Teona Nutsubidze[1], Ketevani Obolashvili[1], Tekle Bakhtadze[1], Tamta Sharadze[1] & Mariami Bakhtadze[2]
[1]National Institute of Endocrinology, T'bilisi, Georgia, [2]Tbilisi State University, Tbilisi, Georgia

Introduction
Puberty is a crucial period, marking the transition from childhood to adulthood with significant physical and psychological changes. (1) In girls, when puberty begins before the age of eight, it is considered precocious. (2) While multiple factors influence individual differences in pubertal timing, the interactions between hormones and nutrition during critical growth periods, like puberty, are crucial. (3) Girls with a higher BMI experienced early menarche compared to those who did not have excess weight. (4) In recent years, there has been a global increase in both obesity rates among children and early pubertal maturation. (6,7,8,9) By analysing the correlation between precocious puberty in girls and their weight, the study aims to provide insights that contribute to the ongoing discourse on the intertwined rise of obesity and precocious puberty among children, offering valuable information on the dynamics over the past years.
Methods and Materials
A retrospective study was conducted on children aged 4-7 years with an established diagnosis: precocious puberty (PP). Data was obtained from medical records of children who visited the National Institute of Endocrinology, Georgia, during 2020-2023. BMI-for-age percentile was calculated based on CDC growth charts for children. (10)
Medical history of Children with congenital disease, type 1 diabetes, steroid intake history and malignancy was excluded.
Results
We analysed medical records for 165 patients aged 4-7 years, of whom 88 were girls and 22 were boys. 2021 - from 18 evaluated patients, 33.33% ($n=6$) had healthy weights, 33.33 ($n=6$) were overweight, 33.33% ($n=6$) were obese and 0% ($n=0$) had severe obesity. 2022 - from 39 evaluated patients, 23.07% ($n=9$) had healthy weights, 38.46% ($n=15$) were overweight, 23.07% ($n=9$) were obese and 15.38% ($n=6$) had severe obesity. 2023 - from 108 evaluated patients, 19.44% ($n=21$) had healthy weights, 25% ($n=27$) were overweight, 19.44% ($n=21$) were obese and 36.11% ($n=39$) had severe obesity.
Conclusios
Early sexual maturation can have an enormous impact on both the mental and physical. Children with PP often have more psychological difficulties than their non-PP peers. (11) Based on the findings, it is evident that there is a rapidly growing trend of two variables among children: Obesity and sexual precocity, prompting the need for more controlled studies. Our team intends to conduct further preclinical research into identifying the most effective dietary interventions for managing precocious puberty in obese children.

Environmental endocrine disruptors and obesity: what is the causal link?

Mennani fatima ezzahra[1], Hind Ouakrim[1], Sana Rafi[1], Ghizlane El Mghari[2] & Nawal El Ansari[2]
[1]Centre Hospitalo-Universitaire Mohammed VI Marrakech, Endocrinolgy, marrakech; [2]Centre Hospitalo-Universitaire Mohammed VI Marrakech, Endocrinolgy, Marrakech

Introduction
Endocrine disruptors are natural or chemical molecules capable of interfering with the endocrine system, as well as disrupting the signaling pathways of carbohydrate and lipid metabolism.
Materials and methods
This is a retrospective study of 85 patients with a BMI greater than 30 kg/m^2 followed in the endocrinology department of CHU Mohamed VI; we studied exposure to endocrine disruptors.
Results
85 patients were included, mean age 41.96 years, with a predominance of female sex. Mean BMI was 38.24 kg/m^2. 67 patients, 78.82% had been exposed to endocrine disruptors either via inhalation, ingestion or transdermal absorption. 69.41% of patients had been exposed to bisphenol A (plastic), 36.47% to alkyl phenols and phthalates (household products), 31.77% to organochlorines (pesticides), 12.94% to thiocyanates (active or passive smoking).
Discussion
Endocrine disruptors have the ability to interfere with hormone regulation by binding to membrane and nuclear receptors normally occupied by natural hormones; they mimic or disrupt the action of certain hormones on organs such as adipose tissue, pancreas and skeletal muscle. The Endocrine Society described the toxicity of endocrine disruptors; their effects on various diseases including obesity in 2015 they can act directly or indirectly as obesogens, by altering basal metabolic rate, by altering gut microbiota favoring food storage, and by altering hormonal control of appetite and satiety.
Conclusion
The rapid increase in the prevalence of obesity cannot be explained solely by overeating and a sedentary lifestyle. Endocrine disruptors can affect adipocyte differentiation and endocrine function, and disrupt metabolic processes.

Intentional insulin overdose in a type 2 diabetic patient and depressive disorder

Daniel Cosma[1], Cristina Alina Silaghi[2] & Horatiu Silaghi[3]
[1]Horezu City Hospital, Diabetes, Nutrition and Metabolic Diseases Outpatient Clinic, Horezu, Romania; [2]"Iuliu Hatieganu" University of Medicine and Pharmacy, Endocrinology Department, Cluj-Napoca, Romania; [3]"Iuliu Hatieganu" University of Medicine and Pharmacy, 5th Department of Surgery, Cluj-Napoca, Romania

Intentional insulin overdose in diabetic patients is a rare critical situation. The severity is due to numerous neurological complications, electrolyte disturbances, liver and lung damage or death. A 59-year old female, under treatment for depressive disorder, diagnosed with type 2 diabetes since 2016 and treated with glargine (20 IU/day), lispro (30 IU/day) insulin and Metformin (500 mg/day) was admitted to the Internal Medicine department via ER (emergency room) for repetitive episodes of severe hypoglycemia in the ER after administration of 280IU of glargine insulin. Found unconscious, dyspneic with a glycemic value (Gl) of 26 mg/dl, she was brought to the ER approximately 9 hours after overdose with a Gl of 97 mg/dl after 70 ml of 33% glucose. At admission: altered general status, Gl = 130 mg/dl, BP = 160/90 and QT prolongation. Labs exams revealed: Gl = 35.46 mg/dl, hyperamylasemia, hypokalemia and A1c = 5.96%. An infusion of 5% glucose was begun at 250 ml/h. The glucose infusion rhythm and concentration was adjusted according to the glycemic profile while trying to maintain values around 150 mg/dl. Hypokalemia was corrected by oral supplementation. Calcium and magnesium remained within normal limits during hospitalization but phosphorus could not be determined. Psychological and psychiatric consults revealed the trigger of the overdose (a health problem of a newborn grandson) and recommended hospitalization in a psychiatric facility, but the patient refused. The last hypoglycemic episode (Gl = 62 mg/dl) was registered 24h after admission. In the 4th day of hospitalization, the oral treatment with Metformin was resumed and she was discharged in the 5th day with only metformin and glargine insulin. Insulin overdose requires intensive and prolonged glycemic monitoring to prevent recurrent hypoglycemia due to an early cessation of i.v. therapy. The dose is not correlated with the severity of hypoglycemia but with a prolonged hypoglycemic risk higher than that deduced from the pharmacokinetics of insulin analogue administered. This case represents the first insulin overdose treated in our hospital.

Effect of hypoglycemics on lipid parameters in patients with diabetes mellitus and ischemic heart disease

Gulnora Artykbaeva & Talat Saatov
Institute of Biophysics and Biochemistry, Mirzo Ulugbek National University of Uzbekistan, lab of metabolomics, Tashkent, Uzbekistan

2 type diabetes mellitus (2DM) determines high risk of cardio-vascular disorders and pathologies of cardio-vascular system, to name arterial hypertension, ischemic heart disease and hypercholesterolemia. In addition, prolonged insufficient DM compensation results in onset of macrovascular complications eventually causing adverse effects. UKPDS findings demonstrated that intense glycemia control significantly reduced the risk of microvascular diabetic complications, but produced no significant effect on the macrovascular ones and total mortality. The conclusions confirm necessity for the complex control of glycemia, arterial pressure and blood lipids. In our study, patients received metformin as the first line therapy in 2DM. The work was initiated to study lipid profiles of the 2DM patients with IHD and its correction with metformin. We examined 38 2DM patients with IHD to analyze concentrations of triglycerides (TG), total cholesterol (TC), HDL C, LDL and VLDL. 20 donors were included in the control group. Lipid profile in 2DM is characterized with 'lipid triad' including increase in TG, reduction in HDL cholesterol and predominance of small dense particles of LDL. In diabetes, the latter prevail. Due to higher atherogenicity of the particles in question, the risk of atherogenicity is higher in the diabetics with the similar LDL C. The LDL levels were proved to be a risk factor for IHD. In our patients, levels of TG and TC were significantly increased, while those of LDL and VLDL were significantly reduced, as compared to the controls. In contrast, the HDL C was significantly reduced. Metformin therapy results in positive changes in the lipidogram. In the patients, TC significantly reduced, as compared to the pre-therapy values (219.6 ± 8.3 vs 2317 ± 10.7 mg%, $P < 0.05$). TG were found to decrease to 280.0 ± 34.1 mg%, as compared to the initial values (394.6 ± 29.0 mg%, $P < 0.001$). Post-therapy total sum of LDL and VLDL was reduced to 735.0 ± 48.3 mg% vs 948.2 ± 52.4 mg% ($P < 0.001$) before therapy. The therapy insignificantly increased HDL C concentrations (31.4 ± 5.03 vs 28.0 ± 2.7 mg%). Despite reduction in atherogenic lipids and increase in anti-atherogenic ones, all parameters under study were found not to reach the levels in the controls. Metformin significantly reduced atherogenic lipoproteins; the anti-atherogenic ones tended to increase. As in metformin therapy the parameters under study in our experiments did not reach the control values, it can be concluded that statins are necessary to be added to the hypoglycemics in therapy of the dislipidemia in DM.

Healthcare system and current treatment of type 2 diabetes in Uzbekistan

Jamolkhon Kayumov & Otabek Akhunbaev
Fergana Medical Institute of Public Health, Endocrinology, Fergana, Uzbekistan

Background
Diabetes mellitus (DM) is increasing because of urbanization, aging, growth in population, physical inactivity, and excess body weight. The management of diabetes is an important issue for Uzbekistan both from medical and socio-economic points of view due to the increase in the number of patients with type 2 diabetes (T2DM), resulting in disability and premature mortality. This study aims to summarize the recent status of diabetes care in Uzbekistan and to analyze the current treatment of diabetes in the Fergana region.
Materials and methods
To describe the current healthcare for DM in Uzbekistan, recommendations for diabetes treatment in Uzbekistan, reports from international organizations, and research papers were used. Besides, the treatment of T2DM in the Fergana region, 2022, was analyzed.
Results
In 2022, a total of 230,610 patients with DM, composed of 18,349 type 1 diabetes and 212,261 T2DM were registered in the National Registry of Diabetes. Among patients with T2DM in the Fergana region, monotherapy was the most common (71.0%),

followed by dual combination therapy of two anti-diabetic drugs (28.1%). Only 0.9% of the patients with T2DM received no medications. Among monotherapies of DM, insulin (25.3%) was the most common, followed by biguanides (23.4%), sulfonylureas (20.8%), and thiazolidinediones (1.5%). Among dual combination therapies, biguanides + sulfonylureas (24.5%) was the most common.
Conclusion
Insulin monotherapy, biguanides, sulfonylureas, and biguanides + sulfonylureas were the most common medications for T2DM in the Fergana region. Insulin monotherapy was the most common in the older age groups and patients with longer durations of T2DM.

Metformin-induced vitamin b12 deficiency and its impact on neurological health

Souhir Maalej[1], Nadia Charfi[1], Abdel Mouhaymen Missaoui, Siddiqa Soomauroo, Faten Hadjkacem, Mouna Elleuch[1], Mohamed Abid & Nabila Rekik
Hedi Chaker University Hospital, Endocrinology, Sfax, Tunisia

Introduction
Metformin, the primary treatment for type 2 diabetes, is renowned for its positive effects on carbohydrate metabolism, weight management, and vascular health. Despite these well-established benefits, prolonged use of metformin has been linked to potential adverse reactions, including a decrease in serum vitamin B12 levels and the development of anemia[1]. This case further emphasizes the complexities associated with metformin use by introducing an unusual yet consequential complication: severe neurological manifestations stemming from vitamin B12 deficiency.
Case Report
We present an intriguing case involving a 64-year-old woman managing type 2 diabetes through the extended use of insulin analogs, vildagliptin, and metformin. The patient exhibited a frontal syndrome, progressive gait instability, cognitive disruptions, frequent falls, and paroxysmal episodes associated with urinary incontinence. Thorough investigations, including normal imaging and a temporal artery biopsy excluding inflammatory origins, were conducted. The electroencephalogram revealed moderate diffuse cerebral distress with a metabolic component. Despite the absence of dietary deficiencies, gastric surgery, or Biermer's disease, a significant vitamin B12 deficiency was identified at 50 pg/ml. A meticulous examination uncovered a connection between extended metformin use and the observed vitamin B12 deficit. Following intramuscular vitamin B12 supplementation and discontinuation of metformin, despite the authors' suggestion to "search, treat the deficiency, and continue metformin"[2] we decided to discontinue it due to the absence of clear directives. The subsequent progress yielded positive outcomes, including symptom regression, the restoration of normal ambulation, and the resumption of daily activities, accompanied by the normalization of vitamin B12 levels.
Conclusion
This case highlights the critical importance of regular monitoring for individuals on metformin, especially those with identifiable risk factors, underscoring the potential for vitamin B12 deficiency. The intricate relationship between metformin and vitamin B12 deficiency necessitates continuous scrutiny and consideration in clinical practice. This emphasizes the need for heightened awareness and vigilance in managing complications related to diabetes.

The role of the hybrid closed loop subcutaneous insulin pump system in patients with weakness in the management of type 1 diabetes and complete failure to achieve satisfactory glycemic control

Christina Lymniati, Eleni Statiri, Anastasios Chatzinikolaou & Charalampos Tsentidis
General Hospital of Nikaia Piraeus 'Agios Panteleimon', Endocrinology, Diabetes and Metabolism, Nikaia, Greece

Introduction
The assessment of the glycemic regulation of patients with Type 1 Diabetes Mellitus is necessary, in order to design an individualized treatment plan, to control the complications resulting from hyper- or hypoglycemia. For this purpose, we use HbA1c, continuous glucose monitoring (CGM) with TIR (time in range), or blood glucose monitoring (BGM). However, none of the above, can be applied without the cooperation of the patient, which for various reasons, often becomes ineffective.
Case Presentation
We describe 4 cases of patients, who were implanted with a hybrid closed loop subcutaneous insulin pump system. The main problem was their unmanageable condition, resulting in many hospitalizations and poor glycemic control. Patient 1: 24 year old male with type 1 diabetes since the age of 7. HbA1C 10.3% Mental immaturity and learning disabilities. Frequent hospitalizations for DKA (at least 3 per 6 months). He did not take glucose measurements or administer insulin when he was with his friends because of embarrassment. Patient 2: 34 year old male with T1DM since the age of 14. HbA1c 14.4%. Middle school teacher. Many hospitalizations for DKA. He had a phobia of hypoglycemia, so he consciously aimed for glucose values >200. Concomitant medical conditions: Sensorimotor neuropathy and diabetic retinopathy. Patient 3. 32 year old male with type 1 diabetes since the age of 8. HbA1c 11.4%. He did not measure his blood sugar, neither he knew how to calculate carbohydrates. He is a professional driver for a courier company, and he eats irregular meals with many carbohydrates without preprandial insulin. Patient 4: 37 year old male with type 1 diabetes since the age of 9. HbA1c 10.2%. Sometimes anxious and depressed behavior. Cleaning worker on a garbage truck, almost impossible to take measurements or eat while working. Frequent hospitalizations with severe hypoglycemic episodes. Concomitant medical conditions: Arterial hypertension, hypertensive retinopathy, dyslipidemia.
Conclusion
The immediate result of the insulin pump placement, was the stability of glucose values and the avoidance of hospitalizations in all patients. Some of them managed TIR >45% within the first 3 months, without hypoglycemia. The placement of a hybrid closed loop system of subcutaneous insulin infusion, dramatically improved both their glycemic control and much more the general management of diabetes mellitus.

EP1051

The influence of sitagliptin on metabolic parameters - importance and value in clinical practice

Ivan Lekić[1,2], Maja Antunović[2] & Tatjana Bačun[2,3]
[1]Health center Zagreb - Centar, Zagreb, Croatia; [2]Faculty of Medicine, Department of Internal Medicine, Osijek, Croatia; [3]Clinical Medical Center Osijek, Department of Internal Medicine - Endocrinology, Osijek, Croatia

Aim of the study
To examine the influence of sitagliptin in patients treated with a diabetic diet and metformin, on metabolic parameters and kidney function after three months of sitagliptin therapy.
Subjects and methods
35 patients (19 men and 16 women) were included in the study. Sitagliptin was introduced in patients on a diabetic diet and metformin with HbA1c≥6.5%. Fasting and postprandial plasma glucose value, HbA1c, cholesterol, HDL, LDL, triglycerides, kidney function (endogenous creatinine clearance (ECC)), 24-hour proteinuria and albuminuria, urea, creatinine, urates, height, body mass, body mass index were observed.
Results
Fasting glucose decreased by 1.52 mmol/l (14.85%), and postprandial by 3.42 mmol/l (26.10%, $P<0.001$), HbA1c decreased by 1.05% (12.35%, $P=0.001$). Total cholesterol concentration decreased by 7% ($P=0.07$), HDL increased by 0.89% ($P=0.31$), LDL decreased by 12.39% ($P=0.46$) and triglycerides by 1.2% ($P=0.74$). Median ECC remained unchanged ($P=0.59$), initial mean proteinuria was 140 and final 149 mg/dU ($P=0.4$), while mean 24-hour albuminuria decreased by 3 mg/dU ($P=0.07$). Urea concentration increased from initial 5.3 (SD 1.42) to 5.52 µmol/l (SD 1.31, $P=0.37$), creatinine concentration increased by 3.23% ($P=0.02$), which was statistically significant, and the concentration of urate was reduced by 0.43% ($P=0.66$). Furthermore, BMI was reduced by 2.3% ($P=0.18$).
Conclusion
After administration of sitagliptin, fasting and postprandial glucose concentrations were significantly reduced, as well as HbA1c. Changes in the concentration of cholesterol, HDL, LDL and triglycerides and body weight

were not statistically significant. The change in the concentration of urea, urate, ECC, proteinuria and albuminuria were not significant, while the slight increase in creatinine was statistically significant. The above indicates that sitagliptin is a metabolically neutral drug with a milder negative effect on renal function.

Gliptin-associated bullous pemphigoid: about two cases

Lina Bessaad[1,1], Rim Chaabouni[1], Malek Cherif[1], Abdel Mouhaymen MISSAOUI[2], Mohamed Amine Fouad[1], Khadija Sellami[1], Fatma Hammami[1], Abderrahmen Masmoudi[1], Nabila Rekik[2] & Hamida Turki[1]

[1]Hedi Chaker University Hospital, Dermatology, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Endocrinology, Sfax, Tunisia

Introduction & Objective

Bullous pemphigoid (BP) is a chronic immune-mediated blistering disease that mainly affects the elderly. This affection can be triggered by multiple factors such as drugs. Gliptins are one of the most incriminated drugs in the drug-induced bullous pemphigoid (DIBP). Our objective was to determine the characteristics of this pathology associated with the use of this medication through two cases of BP confirmed by histology and direct immunofluorescence.

Cases presentation

Two male patients aged 67 and 74 treated with linagliptin for type 2 diabetes mellitus consulted for a pruritic bullous dermatosis. The pruritus have been evolving for 1 month after the introduction of linagliptin in the first patient and after 1 year in the second patient with the appearance of bullous lesions after 3 and 1 months respectively. The clinical presentation was large, fluid-filled and tender blisters of different sizes with an erythematous base in both cases. These lesions were generalized with a predominant acral location. Mucosal involvment was present in one patient with post-bullous erosions on the inner side of the cheeks. The clinical diagnosis of BP was suspected and completed by histology and direct immunofluorescence. The interruption of linagliptin was indicated in both patients. One patient received systemic corticosteroid therapy (0.5 mg/kg/day) and the other patient was treated with topical corticosteroid. The two patients showed significant improvement with no evidence of relapse after 3 months of follow-up.

Conclusions

Gliptins, also known as dipeptidyl peptidase-4 (DPP-4) inhibitors are widely used in the treatment of type 2 diabetes mellitus. This treatment have increasingly been implicated in DIBP and its risk doubles. The pathophysiology remains unclear but the inhibition of DPP-4 receptors results in activation of proinflammatory cytokines and an inflammatory response leading to dermoepidermal damage. Males are more likely to develop this condition and the median age is 70, as in our study. Clinically, many reports concluded on the absence of difference between gliptin-induced BP and classical BP. Non inflammatory blisters with a smaller sized and less erythematous bases in limited distribution were found in some series. The age of onset after the initiation of gliptin therapy varied from 1 month to 4 years. In the literature, histological findings showed scant lesional infiltration of eosinophils and direct immunofluoresence is more positive in this group. The treatment consists of the withdrawal of gliptins which together with steroid administration leads to complete remission and morbidity reduction.

Sodium glucose cotransporter 2 inhibitors: place in diabetic nephropathy

Baltagi Myriam, Bchir Najla, Annam Benchhida, Dorra Dorraelguiche, Bel Hadj Sliman Chayma, Zouaoui Chadia & Haroun Ouertani

Introduction

Diabetic nephropathy (DN) stands as the predominant cause of chronic kidney disease globally. Although therapies targeting the renin-angiotensin-aldosterone system inhibitors (RAASi) offer partial benefits, additionnal strategies are needed. This study was conducted to evaluate the impact of sodium glucose cotransporter 2 inhibitors (SGLT2i) on renal biological parameters.

Methods

We conducted a prospective, evaluative and comparative study at a single center, involving 115 patients with DN matched according to age, sex and stage of DN: Groupe 1 comprised 54 patients on both SGLT2i and RAASi while groupe 2 included 61 patients on RAASi only. The study spanned three periods: T0 at the treatment onset, T1 and T2 after three and six months.

Results

The mean age was 60.2 ± 9.2 years. Examining the renal effects of SGLT2i, our results indicated a statistically lower albuminuria difference between the two time points (T1-T0 and T2-T0, respectively) in group 1 compared to group 2($P < 10^{-3}$). The albuminuria difference between T1 and T0 was -16 (-116-8) for group 1 and 35 (-3-230) for group 2. After 24 weeks, the albuminuria difference between T2 and T0 was -29 (-180-16.5) for group 1 and 50 (-2-207) for groupe 2. Regarding the evolution of creatinine clearance, a non-significant negative difference was noted in both groups between T1 and T0 ($P = 0.155$) after 12 weeks of treatment. However, after 24 weeks of treatment, group 1 exhibited a positive creatinine clearence difference between T0 and T2 in group 1 (0.58 (-5-3)), contrasting with group 2, which maintained a negative differential in creatinine clearance (-0.6 (-5-1)) ($P = 0.044$).

Conclusion

Our findings underscored the role of SGLT2i in treating DN in conjuction with RAASi and their nephroprotective efficacy.

EP1055

Anemia in patients with type 2 diabetes on metformin therapy

Dunja Šojat, Nikolina Tomić & Tatjana Bačun

Faculty of Medicine Osijek, Osijek, Croatia

Aim of the study

The main objectives were to determine incidence and type of anemia in patients with type 2 diabetes and the differences considering gender, age and duration of type 2 diabetes.

Material and methods

The research was structured as a cross-sectional research with historical data. The research used data collected during regular check-ups in primary health care clinics in the Osijek Health Center, Croatia, from April to June 2023. Collected data were: demographic data, duration of type 2 diabetes, the occurence of microvascular and macrovascular complications and type of therapy used for type 2 diabetes. The following parmeters were obtained form laboratory findings: hemoglobin values, MCV, MCH, MCHC, iron values, UIBC, TIBC, fasting glucose and glycated hemoglobin A1c.

Results

The study comprised 59 metformin-treated participants (46 % men and 54 % women), median age of 68. The median duration of type 2 diabetes was 8 years. 29 % of patients had macrovascular and 17 % of them had microvascular complications. 20 % of patients had anemia. 42% had mild anemia, whereas 58% had significant anemia. There was no statistically significant difference in the incidence of anemia based on gender (Fischer's exact test, $P = 0.33$), the presence of microvascular (Fischer's exact test, $P = 0.48$) and macrovascular complications (Fischer's exact test, $P = 0.41$), age (Mann Whitney U test, $P = 0.07$), or type 2 diabetes duration (Mann Whitney U test, $P = 0.62$). According to the morphological division normocytic and normochromic anemia were most often represented while etiologically the most represented were non-specific anemias. Subjects with normocytic anemia were significantly older, with a median age of 81 years (interquartile range from 78 to 82 years) compared to patients with microcytic and macrocytic anemia (Kruskal Wallis test, $P = 0.04$).

Conclusion

Anemia is one of the most prevalent blood diseases among type 2 diabetics, and it can be caused by a variety of factors, including antidiabetic medications. Based on our findings, we can infer that anemia in individuals with type 2 diabetes on metformin medication is caused by iron deficiency and chronic illness. Because of the high incidence of anemia in these patients, constant monitoring and management of the values critical to detecting the presence and type of anemia is very important.

Incidence of maternal and fetal complications in diabetic pregnancies

Syrine Trabelsi, Olfa Lajili, Yesmine Jallouli, Sana Khamassi, Yosra Htira, Hedfi Imene, Chaima Jemai, Zohra Hadj Ali & Feika Ben Mami

National Institute of Nutrition and Food Technology, C, Tunis

Introduction

Pre-existing diabetes during pregnancy can negatively affect the health of women and their babies. The aim of our study was to describe the incidence of maternal and fetal complications in women with diabetic pregnancies.

Methods
This was a retrospective descriptive study, including 30 patients followed at the 17SPO2 "Diabetes and Pregnancy" research unit in ward "C" over a 6-month period (January-June 2023).
Results
Mean age was 34.8±5.7 years with 66.7% T1DM and 33.3% T2DM. Mean HbA1c and fasting plasma glucose were 7.8±1.3% and 8.2 ±3.1 mmol/l. The mean weight gain at the end of pregnancy was 8.3 ±3.2 kg. More than half of patients (58.6%) were not educated about pregnancy planning. However, 86.2% of patients had regular medical follow-up during pregnancy. The main maternal complications associated with diabetes were lower urinary tract infections (44.8%) and gestational hypertension/pre-eclampsia (24.1%). Fetal complications were dominated by hypoglycemia, macrosomia, hydramnios and threatened preterm delivery in 48.8%, 48.3%, 31% and 24.1% of patients respectively, followed by neonatal jaundice (17.2%), spontaneous miscarriage/late-term abortion (6.8%) and fetal death in utero (6.9%). In addition, 20 patients delivered full-term by Caesarean section.
Conclusion
Our study showed that the main maternal-fetal complications observed during diabetic pregnancies were lower urinary tract infections, gravid hypertension and macrosomia. Education about pregnancy planning and close monitoring of these patients could improve the maternal and fetal prognosis of these high-risk pregnancies.

Importance of the urgent establishment of plasmapheresis in the treatment of pancreatitis induced by extreme hypertriglyceridemia secondary to ketosis-prone type 2 diabetes

María Zurdo López[1], Miguel-Angel Ruiz-Gines[1,1], Juan-Antonio Ruiz-Gines[2] & Mercedes Agudo-Macazaga[1]
[1]Hospital Universitario de Toledo, Análisis Clínicos, Toledo, Spain; [2]Hospital Clinico Universitario Lozano Blesa, Neurocirugía, Zaragoza, Spain

Introduction
Acute hyperlipidemic pancreatitis is a rare clinical entity that usually affects patients with previous lipid alterations (triglyceride concentration >500 mg/dl) associated with triggering secondary factors, such as poorly controlled diabetes mellitus (DM).
Clinical Case
We present the case of a 60-year-old man who came to the Emergency Department with a picture of acute abdominal pain secondary to acute pancreatitis in which a small hypodense area indicative of necrosis at the level of the pancreatic tail secondary to hypertriglyceridemia (triglycerides 5640 mg/dl) was observed (abdominal CT). The 'milky' appearance of the plasma (lipemic index >1000) makes it impossible to study most biochemical parameters. Hyperglycemia (540 mg/dl) associated with a progressive polyuria and polydipsia picture of several days of evolution with elevation of amylase and lipase and the presence of glucosuria and ketone bodies in the urine systematized. In view of the analytical and imaging findings, the Endocrinology Service was contacted, which initiated initial treatment with insulin and oral antidiabetics, however, the patient did not improve, maintaining hypertriglyceridemia (4496 mg/dl). Given the clinical severity, it was agreed with the Nephrology Service to perform two urgent sessions of plasmapheresis. After the first session, triglyceride levels were reduced to 2122 mg/dl and with the second to 830 mg/dl. It should be noted that the glycated hemoglobin level was 14.9% with a normal C-peptide of 3.9ng/ml, which, associated with the previous analytical findings, would suggest a probable and infrequent cause of DM2, called Ketosis-prone type 2 diabetes (KPD). KPD is a clinical entity characterized by a debut with severe hyperglycemia and ketoacidosis similar to the presentation of DM1. However, it appears in subjects with a DM2 phenotype. This situation is caused by an acute and reversible dysfunction of the beta cells in individuals with insulin resistance. Subsequently, with pharmacological (insulin and hypolipidemic treatment) and dietary measures, glycemia was within normal limits with triglyceride concentrations <250 mg/dl.
Discussion and conclusions
Plasmapheresis, although an invasive technique, is the best therapeutic option that achieves a rapid decrease (85%) in triglyceride levels, possible complications (high morbidity and mortality), and a shorter hospital stay (in our case only 6 days). We consider the importance of implementing the use of plasmapheresis as an urgent primary treatment for pancreatitis secondary to moderate-extreme hypertriglyceridemia, which is more beneficial given the severity and risk of mortality associated with lower hospital resource consumption.

Is the occurrence of degenerative complications of type 2 diabetes mellitus influenced by gender?

Takoua Moussa[1], Chaima Jemai[1], Sami Fitouri[1], Dorsaf Ben Salem[1], Zohra Hadj Ali[1], Olfa Lajili[1], Imen Hedfi[1], Yosra Htira[1] & Faika Ben Mami[1]
[1]National Institute of Nutrition of Tunis, C

Introduction
Diabetes is a chronic disease that can lead to macroangiopathies and microangiopathies. The aim of our study was to describe the characteristics of these degenerative complications according to gender.
Methods
We conducted a cross-sectional study from September to December 2023, at Department C of the national institute of nutrition of Tunis. We included 70 patients with type 2 diabetes, evolving from 5 to 20 years, and with ages ranging from 35 to 65 years. Sex ratio was 1. The two groups of men and women were matched for age, diabetes duration, BMI and Hba1c. Clinical and biological data were collected from medical records. Data were analyzed using SPSS 23.
Results
The mean ages of the men and women were 56.23±6.77 and 57.17 ±8.2 years respectively ($P=0.65$). 17 men and one woman were active smokers ($P=0.021$). The mean body mass index (BMI) for women and men was 30.26±6.4 and 26.24±5.68 kg/m^2 respectively ($P=0,06$). Mean HbA1C was 9.2±1.1% with extremes of 8.5 and 12% (8.7±1.3% and 9.2±1.1% for men and women respectively, $P=0,23$). The association between gender and microvascular and macrovascular complications did not reach statistical significance with $P=0.569$ and 0.06 respectively. We found a statistically significant association between male gender and the occurrence of obliterating arteriopathy of the lower limbs ($P=0.042$). No statistically significant association was found with either gender for retinopathy ($P=0.4$), nephropathy ($P=0.33$), autonomic neuropathy ($P=0.16$), peripheral neuropathy ($P=1$), coronary artery disease ($P=1$) nor stroke ($P=0.63$).
Conclusion
According to our study, chronic obliterating arteriopathy of the lower limbs seems to affect men more frequently. Tobacco could be a factor biasing this result.

Gastroparesis at the heart of major complications: a case report

Malak Riznat[1,1], Mohamed Malad[2] & Guerboub Anas[1]
[1]Mohamed V Military Training Hospital, Endocrinology, Rabat; [2]Mohamed V Military Training Hospital, Rabat

Introduction
Gastroparesis is one of the dysautonomic manifestations of diabetic disease, particularly type 1. Often unnoticed or undetected by the clinician, it can be at the heart of a permanent imbalance, giving rise to all the microvascular and macrovascular complications of dysglycemia. We report the case of a diabetic patient who, after diagnosis and treatment of gastroparesis, achieved spectacular glycemic control.
Observation
This is a 20-year-old patient with known type 1 diabetes since the age of 4, treated with insulin analogues in the basal bolus regimen; multicomplicated in all respects with diabetic renal disease classified as stage 3, diabetic neuropathy under treatment and having already undergone amputation of the right foot. The patient was a poorly controlled diabetic with multiple hospitalizations for episodes of decompensation and hypoglycemia. During her hospitalization, the diagnosis of gastroparesis was suspected in view of her postprandial hypoglycemia, nausea and sensation of early satiety, and confirmed by gastric scintigraphy. Appropriate education and treatment with metoclopramide were implemented. The evolution was marked by the appearance of an optimal glycemic balance and the disappearance of glycemic variability.
Discussion and conclusion
Gastroparesis is a disorder of the intestine-brain axis, defined as an objective slowing of gastric emptying in the absence of pyloric stenosis. It is common in diabetics, with an estimated prevalence of 1-5%, and can be responsible for a permanent imbalance with high glycemic variability. Several tests have been proposed for diagnosis, such as the carbon-13 breath test, evaluation of pyloric function or the 4-hour gastric scintigraphy, which remains the reference test; the latter allows diagnosis if the 4-hour retention time exceeds 10%. Treatment is based on dietary measures in the 1st instance, then depending on the stage of gastroparesis, anti-mimetics for a short period of 3 months, prokinetics or even gastric stimulation may be proposed in the severe stages or if the previous methods fail. It is essential to diagnose gastroparesis in diabetic patients, so that

treatment can be introduced early to restore glycemic control and limit the occurrence of complications.

Atypical diabetic neuropathy with poor response to usual pharmacological treatment: a case report

Yosra Ben Hmida, Chaima Jemai, Achwak Mehrez, Yasmine Fakhfekh, Syrine Trabelsi, Sami Fitouri, Imen Hedfi, Olfa Lajili, Zohra Hadj Ali, Yosra Htira & Faika Ben Mami
National Institute of Nutrition of Tunis, C

Introduction
Diabetes is currently a worldwide pandemic. Neuropathy is Among its most disabling complications. We report the case of a patient with diabetic neuropathy with atypical presentation.
Case presentation
This is a 54-year-old patient hospitalized at department C of the National Institute of Nutrition of Tunis for uncontrolled type 2 diabetes (HbA1C = 11.2%). Her diabetes has been evolving since 8 years. She was put on insulintherapy since 2 years. She was an active smoker at a rate of 50 packs a years and had adequately substituted hypothyroidism. She did not consume alcohol. She had no macroangiopathic nor microangiopathic complications. She had been suffering, for the last 3 years, from hyperalgesic neuropathic pain with a DN4 score of 7. The pain was in gloves and socks, bilateral, symmetrical and more severe in the upper limbs. As part of the etiological assessment, hypovitaminosis B12 and vitamin D deficiency were screened and treated. Electromyography showed moderate axonal sensory neuropathy of the lower limbs, probably of diabetic origin. The patient was initially started on Pregbalin 600 mg/d, which was later associated with Gabapentin 300 mg/d given the persistence of symptoms. The evolution was marked by a partial improvement despite good compliance with treatment. The patient was referred to a specialized pain centre for further management.
Conclusion
Hyperalgesic diabetic neuropathy rarely affects the upper limbs. It usually responds well to optimal dose of pregabalin. This complication would probably present poorly elucidated mechanisms attested by the case of our patient.

Hidradenitis suppurativa in an obese diabetic patient

Oumayma Zarrouk, Taieb Ach, Rihab Khochtali, Ghada Saad, Asma Ben Abdelkrim, Molka Chadli Chaieb & Koussay Ach
University Hospital of Farhat Hached, Endocrinology Departement, Sousse

Introduction
Verneuil's disease, also known as Hidradenitis suppurativa, is a chronic inflammatory dermatosis characterized by recurrent episodes. It's manifested by painful deep inflammatory nodules, comedones, and scarring in areas rich in apocrine glands. Its prevalence is estimated at 1% of the population. It is influenced by factors such as obesity, smoking, and genetics. We report the case of a patient admitted for diabetes in whom Hidradenitis suppurativa was diagnosed.
Case report
It is about a 35-year-old patient, a smoker with a 35 pack-year history, and no significant medical history. Type 2 diabetes was diagnosed due to the onset of cardinal signs over the past 5 months. Upon examination, the BMI was 38 kg/m^2;, and the waist circumference was 139 cm. The patient presented with evident acanthosis nigricans. Cardiovascular examination was normal. Dermatological examination revealed multiple cutaneous abscesses in the groin and armpit folds, all at stage III according to Hurley staging. Some nodules in the groin were fistulized with pus secretion. The affected areas were inflammatory and painful, but there was no fever. The patient was treated with an anti-staphylococcal agent following the isolation of Staphylococcus in the pus sample, with improvement observed after 14 days. Diabetes was managed with oral antidiabetic medications, including metformin and sulfonylureas, resulting in a fasting blood glucose level of 1.24 g/l.
Conclusion
Hidradenitis suppurativa develops when sebaceous glands and hair follicle openings are blocked by fluid, as well as by dead skin cells or other materials released around the apocrine sweat glands. It is frequently associated with obesity, as described in our patient. Although the disease is chronic and characterized by recurrent episodes, the prognosis is improved with adherence to hygiene and dietary measures, along with weight loss.

Bone mineral density in women with type 2 diabetes mellitus and postmenopause: a single center spanish experience

Ana Paola Leon Ocando, Oliver Quintero Rodríguez, Selena Rodríguez Fernández, Kevin Diaz Gorrin & Itziar Aznar Ondoño
Hospital Universitario de Canarias, Endocrinology and nutrition, San Cristóbal de La Laguna, Spain

Introduction
T2DM is associated with an increased risk of fractures. This heightened risk is attributed to factors such as prolonged disease duration and chronic glycemic control. Interestingly, despite this increased fracture risk, patients with T2DM often exhibit normal or even elevated BMD compared to non-diabetic individuals. This phenomenon is thought to be a result of reduced bone remodeling, coupled with changes in bone microarchitecture.
Objective
This study aims to assess BMD in postmenopausal women with T2DM who are under observation at our center.
Materials and Methods
We conducted a cross-sectional, descriptive study on an incidental sample of 84 postmenopausal T2DM patients. These patients, monitored for carbohydrate metabolism disturbances at specialized care centers linked to our hospital, had undergone DXA in 2022 or 2023. The inclusion criteria were the absence of clinical evidence of other pathologies that could cause secondary BMD alterations and an age limit of 65 years or younger.
Results
The average age of participants was 63.29 years [95% CI 62.98-63.59]. The mean T-Score for the spine was -0.85 SD [95% CI -1.12— -0.58], and for the femur, it was -0.98 SD [95% CI -1.23— -0.73].
Conclusion
The mean T-Score for both the spine and femur falls within the normal to osteopenia range, not extending into osteoporosis, despite examining a high-risk group (menopausal patients). For future research, it would be beneficial to compare these findings with similar demographic groups without DM2. Such a comparison could clarify the specific impact of carbohydrate metabolism disorders on BMD in our population.

Prevalence and factors associated with anemia in a tunisian population with diabetes mellitus

Yasmine Fakhfakh, Chaima Jemai, Chaima Sdiri, Dorsaf Ben Salem, Siwar Saoudi, Hadhemi Belhassen, Lajili Olfa, Imen Hedfi, Yosra Htira & Faika Ben Mami
National Institute of Nutrition, Department C, Tunisia

Introduction
Anemia is a pathology frequently associated with diabetes mellitus (DM). The aim of this study was to assess the prevalence of anemia among patients with DM and to identify its associated factors.
Methods
We included 95 patients with diabetes mellitus hospitalized during November and December at department C of the national institute of nutrition of Tunis. We did not include pregnant women. Demographic characteristics, anthropometric parameters, past medical history, current treatments, glycemic control, cardiovascular risk factors, diabetes-related complications and biological parameters were collected from medical records.
Results
The mean age was of 53.41 ± 18.8 years. Sex ratio was 0.55. Mean body mass index was 27.2 ± 6 kg/m^2;. Mean HbA1c was 11.17 ± 2.17 %. The prevalence of anemia was 36.8% of our total population, 80% of which were women and 65.7% had type 2 diabetes. The study revealed that anemia was significantly more frequent in female gender ($P = 0.02$) and was associated with complicated diabetes ($P = 0.01$), with diabetic peripheral neuropathy ($P = 0.01$) and with diabetes duration (> 10 years) ($P = 0.001$). Likewise, anemia was significantly more prevalent in non-smokers ($P < 0.001$). No significant association was found with type of diabetes, BMI nor diabetes treatment.

Conclusion
In light of our results, systematic screening for anemia should be considered in routine assessment of patients with diabetes mellitus, especially in female gender, in patients with long diabetes duration and those with degenerative complication.

Prevalence and characteristics of painful diabetic neuropathy in patients with diabetes mellitus and normoalbuminuria

Hadhemi Belhassen, Ramla Mizouri, Siwar Saoudi, faten mahjoub, Rym Ben Othman, Chaima Sdiri, Nadia Ben Amor, Olfa Berriche & Jamoussi Henda
National Institute of Nutrition, A, Tunis, Tunisia

Introduction
Diabetes is known as a risk factor of microangiopathy which generally appear concomitantly. Diabetes is also the most common cause of peripheral polyneuropathy and all these complications are related to chronic hyperglycemia. The main objective of the present study is to determine the prevalence of the diabetic peripheral neuropathy (DPN) and its characteristics in people with normoalbuminuria.
Methods
Descriptive cross-sectional study conducted over 4 months in ward A of The National Institute of Nutrition Tunis which included patients with diabetes mellitus and normoalbuminuria.
Results
Fourty-five patients were included of whom were 32 women and 13 men. The characteristics of the patients were respectively: age: 49 ± 17.34 years, type 2 diabetes: 32 patients, type 1 diabetes: 11 patients, diabetes typing in progress: 2 patients, HbA1C: $10.18 \pm 2.01\%$, duration of diabetes more than 10 years: 25 patients, duration of diabetes less than 10 years: 20 patients. The diagnosis of painful diabetic neuropathy was evaluated by using the questionnaire Douleur Neuropathique (DN4) and diagnosed when DN4 is more than or equal to 4/10. Results have shown that 38 patients which means 84.4% of the population had no painful diabetic neuropathy. The percentage of DPN among non-smokers was 8.3%, while 28.5% of active smokers had DPN, without a statistically significant correlation ($P = 0.18$). DPN was more frequent in these cases: patients with type 2 diabetes (16.66%), diabetes with a duration less than 10 years (8.3%) and non-controlled diabetes. There wasn't a statistically significant correlation in all these cases, ($P = 0.19$), ($P = 0.38$) and ($P = 0.31$), respectively.
Conclusion
It is important to screen the painful diabetic neuropathy in all diabetics regardless of the patient profile or even the glycemic profile especially in the absence of other microangiopathies in order to prevent complications.

Diabetic, neuropathic and arterioapthic foot:assessment and management

Siwar Saoudi, Rym Ben Othman, Hadhemi Belhassen, Ramla Mizouri, Chaima Sdiri, Olfa Berriche & Jamoussi Henda
Institut de Nutrition Tunis, A, tunisia, Tunisia

Introduction
Diabetic foot is a major public health and it's the combination of arteriopathy, neuropathy and infection. Among all possible complications of diabetes mellitus, diabetic foot problems are a leading cause of hospitalisation. The aim of our study was to assess different diabetic foot factors in diabetic patients and to classify them into risk groups according to the guidelines of the International Working Group on Diabetic Foot (IWGDF)
Methods
It was a descriptive cross sectional study conducted over 6 months in department A of the institute of Nutrition of Tunis which included patients with diabetes.
Results
The total number of patients who participated in the study was 77. The characteristics of the patients were respectively: age 54 ± 10.3 years, BMI:29 ± 4.5 kg/m^2, HBA1C:$10.1 \pm 1.57\%$. The mean duration of diabetic patients was 11 ± 3 years. On examination, 58% of subjects reported neuropathic pain, with 47% having a DN4 greater than or equal to 4/10. As for arteriopathy, 21.3% reported intermittent claudication. On examination, 16% had absent pedal and posterior tibial pulses. Thus, 39% of subjects were classified as being at high risk of ulceration (groups 2 and 3), while 47% were at low risk (group 0).
Conclusion
In conclusion, our study revealed a substantial prevalence of diabetic foot complications among the assessed patients, highlighting the significant burden of arteriopathy, neuropathy and infection in diabetes underscoring the urgent need for targeted interventions and preventive measures in diabetic care.

Sociodemographic, clinical and evolutionary profile of elderly diabetics

Maryam Cheikhrouhou, Kamilia Ounaissa, Chaima Sdiri, Emna Bornaz, Nesrine Dhieb, Haifa Abdesslem & Chiraz Amrouche
national nutrition institute, Department of Nutritional Diseases D, Tunisia

Introduction
The number of elderly diabetics is increasing in Tunisia. We aimed to describe, sociodemographic, clinical and evolutionary profile of elderly diabetic patients.
Methods
Retrospective study of elderly diabetic subjects was carried out. Data were collected from patients' medical records and by questioning during a direct interview with patients.
Results
Twohundred patients aged 70 and over, were included. The average duration of diabetes was 16.5 ± 9.2 years. More than half of the patients were illiterate (53.5%) and 43.5% had a low socioeconomic level. Almost14.5% of diabetic elderly livedalone, 32% lived with spouses and 53.5% lived with their families. Smoking was reported by 22.5% of patients. The most frequent comorbidities were dyslipidemia, hypertension and obesity noted in respectively 88%, 76% and 40% of patients. The treatment of diabetes was insulin only or combined with oral antidiabetics in 75% of patients. The average HbA1c was 8,66% and 56,5% of subjectshad not reached their glycemic goals. Regarding the impact of diabetes, One-third of patients had at least one macroangiopathy. Concerning microangiopathy: retinopathy, neuropathy and nephropathy were noted in respectively 52.5%, 47% et 41% of patients.
Conclusion
In elderly people with diabetes, social fragility and precariousness, associated with numerous cardiovascular risk factors, make it challenging for clinicians to help them to achieve individualized therapeutic goals.

Study of the characteristics and factors associated with anemia in a population with diabetes mellitus

Yasmine Fakhfakh, Chaima Jemai, Chaima Sdiri, Dorsaf Ben Salem, Siwar Saoudi, Sami Fitouri, Zohra Hadj Ali, Olfa Lajili, Imen Hedfi, Yosra Htira & Faika Ben Mami
National Institute of Nutrition, Department C, Tunisia

Introduction
Anemia is a pathology frequently associated with diabetes mellitus. The aim of our study was to determine the characteristics of anemia in a population of patients with diabetes mellitus (DM).
Methods
This was a cross-sectional study conducted in Department C of the National Institute of Nutrition of Tunis. Recruitment was spread over 2 months. We enrolled patients hospitalized for diabetes control with anemia, as defined by the World Health Organization. We did not include pregnant women.
Results
Thirty eight patients were enrolled. The mean age was 49.9 ± 15 years and the sex ratio was 0.4. Patients presented type 2 diabetes in 60.5% of cases. The majority (86.8%) had diabetes with degenerative complications. Two-thirds of the population had diabetic nephropathy. More than half (55.3%) had diabetic neuropathy. Diabetic retinopathy was present in 44.7% of cases. Clinically, almost half the population presented with conjunctival pallor (47.4%). Two patients had arterial hypotension and one patient had resting tachycardia. Anemia was mild in 52.6% of cases, with a mean hemoglobin level of 10.82g/dl ± 1.23. It was hypochromic in 42.1%, normochromic in 57.9%, microcytic in 34.2% and normocytic in 65.8%, with a mean Red blood cell distribution width (RDW) of 14.37 ± 2.34. Anemic diabetic women had significantly lower mean corpuscular volume (MCV), mean corpuscular hemoglobin (MCH) and ferritinemia ($P = 0.006$; $P = 0.004$; $P = 0.002$) than men. No statistically significant association was found between metformin intake and anemia characteristics.

Conclusion
Anemia is a fairly widespread pathology in Tunisia. Studies suggest that it is associated with glycemic imbalance and degenerative complications. Larger-scale studies are needed to investigate these associations.

Accuracy of urine dipstick tests for assessment of glucosuria

Omar Gargouri[1], Rim Marrakchi[2], Ines Mezghani[3], Boudaya Mariem[3], Kamel Jammoussi[3] & Mouna Turki[3]
[1]Hedi-Chaker University Hospital of Sfax, Biochemistry Departement, Sfax, Tunisia; [2]Hedi-Chaker University Hospital of Sfax, Biochemistry Departement, Tunisia; [3]Sfax, Biochemistry Departement, Sfax, Tunisia

Introduction
Early diagnosis is therefore important for patients with asymptomatic diabetes mellitus. The aim of this study is to validate the use of Urine Dipstick in the screening of glycosuria (Gu).
Material and methods
Our study involved 30 fresh urine specimens. Urinalysis was performed by dipstick (SPINREAT®). Gu was measured by the hexokinase method (DxC800® Beckman Coulter). The gold standard to diagnose Gu was concentration measured $\geq$ 0.833 mmol/l
Results
To detect Gu the urine dipstick test had 66,6 sensitivity, 100% specificity, 100% positive predictive value (PPV) and 96% negative predictive value (NPV)
Conclusions
Test strips do not appear to be a good alternative to quantitative assay for screening glucosuria.

Association of hypertension and diabetes in the elderly: 100 cases

Yesmine Jallouli, Rym Ben Othman, Syrine Trabelsi, Ramla Mizouri, Olfa Berriche, Faten Mahjoub & Henda Jamoussi
Tunis, dapartment A, Tunis, Tunisia

Introduction
Hypertension is common in elderly diabetic patients, and is responsible for an increased cardiovascular risk and an acceleration of the degenerative effects of diabetes.
Objectives
To determine the characteristics of hypertension in elderly diabetic patients.
Patients and Methods
Descriptive study including 100 hypertensive type 2 diabetic patients aged >65 years followed up in department A of the national institute of nutrition in Tunis. Hypertension was defined as blood pressure $\geq$140/90 mmHg. Variables studied were anthropometric measurements, cardiovascular factors (smoking, hypertension, dyslipidemia), degenerative complications (retinopathy, neuropathy, nephropathy, ischemic heart disease) and treatment administered (Insulin therapy, oral antidiabetics, antihypertensive).
Results
The mean age of our patients was 73 ± 2.4 years, predominantly female (65.1% of cases). The mean duration of diabetes was 10.4 years, with 42% of patients on insulin therapy and 28% on oral antidiabetics. The diagnosis of diabetes preceded that of hypertension in 58.7% of cases. Sixty-three percent of patients had Grade I hypertension. Mean BMI was 27.8 ± 4.6 kg/m^2. Dyslipidemia was found in 85.7% of our patients. Ischemic heart disease was found in 32.5% of cases, and 19% of patients had a history of ischemic stroke. Retinopathy was found in 61.4% of patients, neuropathy in 23.8%.
Discussion
The frequency and severity of hypertension in elderly diabetics are unique, requiring comprehensive management of cardiovascular risk factors in order to improve quality of life in this population.

Fungal necrotizing external otitis complicated by a retropharyngeal abscess in a diabetic patient: a case report

Rachida Bouattay, nawres bouaziz, Jemli S, Mehdi Ferjaoui, elkorbi amel, Naourez Kolsi. harrathi khaled & Jamel Koubaa
مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Background
Fungal necrotizing external otitis (NEO) is a serious and potentially life-threatening infection that is challenging to manage. It affects almost exclusively elderly diabetic patients. The diagnosis is often delayed and it is a rare disease, although its frequency has increased over the last few years. We aim through this study to share our experience in the management of a case of fungal NEO complicated by a retropharyngeal abscess in a diabetic patient and discuss its diagnosis tools, anti-fungal treatment choice, and outcomes.
Methods
We report a rare case of invasive necrotizing external otitis caused by Aspergillus flavus in a diabetic patient without other underlying immunosuppression. A review of Aspergillus spp. malignant external otitis since voriconazole became the first line for invasive aspergillosis was performed.
Case Presentation
We present a case of a 77 year old man with a history of type 2 diabetes, dyslipidemia and an ischemic cerebrovascular accident. He was admitted to our department 8 months ago for the management of bilateral NEO, which was treated with optimal antimicrobial therapy and cured. The reason for his consultation was facial palsy associated with odynophagia for two days. Physical examination revealed a right peripheral facial paralysis grade V and a swelling in the posterior pharyngeal wall. The rest of the examination was normal. Laboratory tests indicated a biological inflammatory syndrome. A computed tomography scan was performed, revealing a retropharyngeal collection measuring 4 cm with osteitis of the skull base. The patient was treated with empiric courses of antibiotics until a fungal infection was diagnosed and he underwent endoscopic endonasal drainage of the abscess under general anesthesia. Proven Apsergillus infection was based on culture and serologic test. The equilibration of diabetes was obtained. Treatment was based on a combination of ceftazidime and fluoroquinolone for several weeks, associated with voriconazole during 3 months. After a follow-up of one year, he had been cured with normalization of the biological, and imaging features, but with persistent facial palsy.
Conclusions
Given our experience and the literature review, fungal NEO is an aggressive and potentially fatal infection. A fungal etiology should be considered early in the course of invasive necrotizing external otitis unresponsive to a conventional broad spectrum antibiotic therapy or in case of complications, with the need for positive culture swabs and/or positive serologic test to a fungal pathogen to confirm the diagnosis.

Is obesity associated with hyperalgesic diabetic peripheral neuropathy?

Chaima Jemai, Achwak Mehrez, Wafa Ben Brahim, Mouna Djobbi, Yosra Ben Hmida, Takwa Moussa, Zohra Hadj Ali, Olfa Lajili, Imen Hedfi, Yosra Htira & Faika Ben Mami
National institute of nutrition of Tunis, C

Introduction
The aim of our study was to evaluate the weight status of a population with type 2 diabetes and with diabetic peripheral neuropathy, and to study its association with hyperalgesic diabetic peripheral neuropathy.
Methods
This was a cross-sectional study about 100 T2DM patients hospitalized in department C of the national institute of nutrition of Tunis, and having diabetic peripheral neuropathy, diagnosed using the monofilament test and the DN4 score. For each patient eligible for the inclusion criteria's, we conducted an interview and physical examination to collect epidemiological characteristics, characteristics of T2DM (duration, glycemic balance, antidiabetic treatment and degenerative complications), and we collected biological parameters from medical records. Data were analyzed using SPSS 23.
Results
The mean age was 60.4 ± 10.6 years with extremes of 32 and 72 years and a median of 49.5 years. The sex ratio in our population was 0.53. The majority of the population (71%) had a secondary or higher level of education. The majority was not smoker (41%). We did not identify any use of illicit substances. The diabetes was type 2 in all cases. The average diabetes duration was 14 ± 5.2 years with extremes of 6 and 21 years. All patients were treated with insulin therapy combined with metformin in 65% of cases. Hyperalgesic diabetic neuropathy (DN4$\geq$4) was

the most frequent degenerative complication (56%) followed by diabetic retinopathy (38%). Mean BMI was 29,1 ± 5,7 kg/m^2 with extremes of 23 and 40.2 kg/m^2. 50% of the population has a BMI of 30,55 kg/m^2. BMI was normal in 21 % of the cases. Almost half of the population was obese (49%). Obesity was class 1,2 and 3 in 32%, 9% and 8% respectively. According to BMI, 66,7% ($n=14$) patients with normal BMI, 63,3% ($n=19$) of those with preobesity, 78,1% ($n=25$) of those with obesity class 1, 100% ($n=9$) of those with obesity class 2 and 87,5% ($n=7$) of those with obesity class 3 had hyperalgesic diabetic neuropathy with a statistically significant difference between these percentages ($P=0.021$).

Conclusion

According to our result, weight reduction seems to be a promising non-pharmacological way to act on neuropathic pain in patients with type 2 diabetes.

MODY type diabetes: diagnostic and therapeutic difficulties in the light of 2 cases

Jaddi Oussama, Zineb Ait Si Ali, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Mohammed VI university hospital of Marrakesh, Department of Endocrinology, Diabetes, Metabolic diseases and Nutrition, Marrakesh, Morocco

Introduction

MODY (maturity-onset diabetes of the young) is a group of heterogeneous diabetic disorders characterized by dysfunction of insulin secretion by the β-cell and genetically transmitted. MODY diabetes is thought to account for 2-5% of all diabetic disorders, but is often under-diagnosed. We report two suspected cases of MODY diabetes.

Observations

Case 1: 40-year-old patient, known diabetic for 3 years, initially on Gliclazide 60 mg and Metformin 2 g, currently on Mixtard 30 (20-00-10), diabetic heredity in mother, brother and 2 maternal uncles, SD: unknown, patient with familial polycystic kidney disease (in mother, brother and 2 maternal uncles) and renal transplant in mother in 2011, MODY 5 was suspected. Case 2: 20-year-old patient, known diabetic for 3 years, put on Mixtard 30 (16-00-20) heredity in father and paternal grandfather, Hearing loss since birth, Admitted for diabetic ketosis (first episode) MODY 2 ans mitochondrial diabetes were suspected.

Discussion

MODY is therefore a highly heterogeneous condition, both at the molecular level, in terms of the genes involved, and in terms of the severity and evolution of the insulin secretion deficit, the level of hyperglycemia and the frequency of complications. The initial definition of MODY was purely clinical: non-ketotic diabetes, early onset, usually before age 25, autosomal dominant, and is frequently misdiagnosed as type 1 or type 2 diabetes. Molecular diagnosis is necessary to better understand the evolution of the disease, propose appropriate treatment and screen relatives. High-throughput sequencing has enabled a major advance in the diagnosis of monogenic diabetes. Mutations in the glucokinase (GCK) (MODY 2) and hepatocyte nuclear factor (HNF) 1A/4A genes (MODY 3 and MODY 1, respectively) are the most common causes of MODY.

Conclusion

These observations illustrate the diagnostic difficulties of MODY diabetes. In the event of clinical suspicion, genetic confirmation enables therapeutic adaptation and early management of other affected family members.

Primary hyperparathyroidism in the elderly: analysis of 12 cases

Mohamed Abderrahmane Ahmed Ebett, Chadli Asma, El Aziz Siham & Haraj N.E
University Hospital Center Ibn Rochd - Casablanca, Casablanca, Morocco

Introduction

Hyperparathyroidism in the elderly is an endocrine pathology characterized by excessive secretion of parathormone by the parathyroid glands, leading to elevated blood calcium levels. This condition has significant implications for bone and renal health in this population.

Objectives

To determine the prevalence of parathyroid adenomas and their association with calcium and PTH levels in elderly patients, to improve diagnostic strategies and management of hyperparathyroidism.

Methods

Retrospective analysis of clinical and imaging data of 12 patients from Ibn Rochd Hospital, Casablanca, from January 2018 to October 2023, to identify epidemiological and therapeutic signs of primary hyperparathyroidism in the elderly.

Results

Among 12 patients with an average age of 70 years, predominantly female (9 women and 3 men), high levels of calcium (average calcemia of 114.18 mg/l) and phosphorus (average of 12.61 mg/l) were observed. PTH was notably increased with an average of 825.84 pg/ml. Ultrasounds revealed that 10 patients had parathyroid adenomas. Scintigraphy indicated hyperfixation in 7 patients. Osteoporosis was diagnosed in half of the patients, while renal lithiasis was identified in 3 patients. Additionally, 2 patients showed pathological factors, and 8 patients were discovered incidentally. Bone pain was present in 8 patients, and 3 suffered from a polyuria-polydipsia syndrome.

Conclusion

Hyperparathyroidism in the elderly manifests with various complications, such as osteoporosis, renal lithiasis, and bone pain. The prevalence of parathyroid adenomas in this study underscores the importance of ultrasound screening. The incidental findings suggest that regular examinations could be beneficial for this population.

Fournier's gangrene in diabetics: a study of 26 patients

Nora Boutatss, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy-University Hassan II, Endocrinology, Diabetology, Nutrition and Metabolic Diseases, Casablanca, Morocco

Introduction

Fournier's gangrene is a rapidly progressive necrotizing fasciitis affecting the perineum and external genital organs, requiring prompt, comprehensive, and multidisciplinary therapeutic intervention due to its severity. Diabetic patients are particularly at risk of developing Fournier's gangrene due to their vulnerability to infections and healing complications.

Objective

To present the clinical, therapeutic, and evolutionary aspects in diabetic patients.

Patients and Methods

A retrospective descriptive study, including 26 diabetic patients with Fournier's gangrene hospitalized at Ibn Rochd University Hospital in Casablanca. Twenty patients had known diabetes, while in 6 cases, gangrene was indicative of diabetes. Statistical analysis was conducted using Excel.

Results

The average age of our patients was 56 years, with a male predominance (24 men and 2 women). Twenty-five patients had type 2 diabetes (96%), and one patient had type 1 diabetes. All patients were uncontrolled at the onset of gangrene (average HbA1c of 9.8%). Uro-genital and ano-rectal causes were noted. Medical management involved parenteral tri-antibiotic therapy, intensive insulin therapy (basal-bolus regimen), and hypercaloric feeding (parenteral nutrition in 4 cases). Surgical treatment (necrotomy) was performed in all cases. Colostomy was carried out in 6 cases. Skin grafting was necessary in 1 case. Two deaths (7.69%) were recorded in cases of septicemia.

Conclusion

Fournier's gangrene remains a severe condition, especially in diabetic patients, and prognosis can only be improved through early diagnosis and appropriate medical and surgical management.

Sexuality in obese and pre-obese women: a cross-sectional analytical study

Kouloud Boujelben, Mohamed Khairi Arous, Fatma Mnif, Mouna Elleuch, Dhouha Ben Salah, Rim Djebbi[2], Faten Haj Kacem, Nadia Charfi, Mouna Mnif, Mohamed Abid & Nabila Rekik Majdoub
Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia; [2]Faculty of medecine of Sfax, Sfax, Tunisia

Introduction

Obesity continues to rise globally, exerting a significant impact on physical, mental, and sexual health. Few studies have addressed sexual dysfunction in

obese women within our Tunisian context. The objective of our study was to investigate the parameters influencing sexuality in obese and pre-obese women through a standardized assessment.
Methods
We conducted a cross-sectional analytical study involving women who engaged in sexual intercourse within the past four weeks and whose body mass index exceeds 25 kg/m^2;. For the assessment of sexual function, we utilized the Arabic version of the Female Sexual Function Index (arFSFI), consisting of six parameters: desire, arousal, lubrication, orgasm, satisfaction, and pain. A score below 23 indicates female sexual dysfunction
Results
The study included 50 overweight and obese women, with a mean age of 38.5 ± 9.45. The average duration of marriage/cohabitation was 11.8 years. The majority of women were educated (88%). More than two-thirds of participants (78%) were obese, and 22% were overweight. Most women (80%) were in the reproductive age group, 6% had primary or secondary amenorrhea, and 14% were menopausal. The mean BMI was 37 ± 8.7 kg/m^2. The average Female Sexual Function Index (FSFI) score was 27.4 ± 6.2. We observed that 12% had sexual dysfunction, 42% had a lack of desire, and 24% experienced pain during sexual intercourse.
Discussion and conclusion
The rate of women experiencing sexual dysfunction is lower than that reported in the literature. This could be explained by the difficulty women in our context face in discussing their sexuality in general and their discomfort in particular. The lack of desire may be associated with a negative perception of body image. Our study emphasizes the need to raise awareness and educate healthcare professionals working with obese women on sexual health, in order to detect dysfunctions and improve the quality of life for patients.

Testosterone and anthropometrics indices in type 2 diabetes: cross-sectional study

Anis Grassa[1], Manel Jemel[1], Salma Salhi[1], Bel Hadj Sliman Chayma[1], Asma Krir[2], Ahlem Benhmid[2], Radhouane Gharbi[1] & Ines Kammoun[1]
[1]National Institute of Nutrition and Food Technologies, Zouheir Kallel, Endocrinology, Tunis, Tunisia; [2]Pasteur Institute of Tunis, Tunis, Tunisia

Introduction
In the context of Type 2 Diabetes (T2D), understanding the interplay between testosterone levels and anthropometric data holds crucial implications. This study aims to explore the intricate relationship between testosterone, obesity, and anthropometric measurements, offering insights that contribute to a deeper understanding of the intricate physiological dynamics within this diabetic population.
Methods
This Cross-Sectional Study included 250 men with T2D consulting at the National Institute of Nutrition in Tunisia. Free Testosterone (FT) and Bioavailable Testosterone (BT) using the Vermeulen formula[1]. For all patients we measured weight, height and waist circumference (WC). Body mass index (BMI) was calculated. Obesity was defined by a BMI $>$ 30 kg/m^2;, and android fat distribution was identified by a waist circumference (WC) $\geq$ 94 cm.
Results
The median age of our participants was 58 years, with an interquartile range (IQR) of [52.7–62]. The average weight of the patients was 83.3 ± 12.4 kg [59 - 125 kg]. The mean Body Mass Index (BMI) was 27.9 ± 4 kg/m^2;,[19.8 -40]. Approximately 29.2% of patients were classified as obese, (n = 73 patients). In terms of anthropometric measurements, the mean WC was 97.5 ± 9.2 cm, [77 - 138 cm]. Android distribution of body fat was observed in 67.2% of participants, accounting for 168 individuals. A significant inverse correlation was found between BMI and the levels of Total Testosterone (TT) (r: -0.311; $P < 10^{-3}$), FT (r: -0.150; $P = 0.021$), and BT (r: -0.143; $P = 0.027$). The same relationship exists between WC and levels of TT (r: -0.275; $P < 10^{-3}$), FT (r: -0.146; $P = 0.024$), and BT (r: -0.136; $P = 0.038$).
Conclusion
These findings suggest a significant negative association between BMI, waist circumference, and testosterone levels, emphasizing the potential role of testosterone in the regulation of body composition within this specific population.

Sleeve gastrectomy: a retrospective analysis of its efficacy in obesity treatment and metabolic improvement

Mirjana Kardum Pejić[1,2], Nives Gojo Tomić[1], Irena Martinis[1], Domagoj Vergles[1], Mirna Šporčić[1], Martina Bituh[1], Jelena Pugelnik[1] & Josip Pejić[1]
[1,2]University Hospital Dubrava, Department of Endocrinology and Diabetology, Zagreb, Croatia

Introduction
Obesity is one of the fast growing diseases in the modern world. Over the years, bariatric surgery has proven its effectiveness in treating obesity, improving its associated comorbidities, and even potentially curing them. A body mass index (BMI) greater than 40 kg/m^2 or a BMI greater than 35 kg/m^2 with associated comorbidities is an indication for such surgery. Sleeve gastrectomy (SG) has emerged as a prominent and effective surgical intervention for the management of obesity and its associated comorbidities. The aim of study was to evaluate patients' nutritional status before surgery and their post-operative metabolic improvements.
Results and discussion
Data for the study were gathered retroactively from BIA analysis and laboratory values for 50 patients (44 women and 6 men) who had SG at University Hospital Dubrava between 2019 and 2023. Before surgery type 2 diabetes was diagnosed in 19 patients, arterial hypertensio in 21, dyslipidaemia in 14 patients and thyroid diseases (hypothyreoidisam) in 13 patients. In the two controls after the procedure there was a statistically significant decrese total body mass, body mass indeks and fat mass. In most patients there was a significant reduction in arterial pressure. Regarding the biocemical parameters there was a statistically significant decrese in glycemia, HbA1c, ($P < 0,05$), C-reactive protein while among the parameters of the lipid profile, there was a significant decrese only in HDL cholesterol, which was close to the limit of the reference value even before the operation, which is undesirable factor in the contex of cardiovascular diseases. Other lipid profile values are not statistically significant but show a decreasing trend.
Conclusions
The study confirmed SG to be efficient in treating obesity, controlling glycemia and arterial hypertension and reducing lipid profile. Keywords: Sleeve Gastrectomy, Obesity, Type 2 Diabetes Mellitus, Body Mass Index, Arterial hypertension

Sarcopenia in breast cancer patients undergoing chemotherapy

Berriche Olfa[1], Selma Mohsen[1], Ben Mansour Hajer[2], Rym Ben Othman[1], Dorra Ben salem[1], Mezlini Amel[2] & Jamoussi Henda[1]
[1]national institute of nutrition, service A, Tunis, Tunisia; [2]national institute Salah Azaiez, oncology, Tunis, Tunisia

Introduction
Sarcopenia, defined by a loss of strength and muscle mass, is initially described in elderly subjects but now is increasingly observed in younger patients with cancer. In addition, loss of muscle mass appears to be progressive during neoadjuvant chemotherapy. The aim of this study was to analyse the body composition of breast cancer patients and determine the prevalence of sarcopenia during chemotherapy.
Methodology
This was a cross-sectional comparative study conducted over a 6-month period in breast cancer patients undergoing chemotherapy. An analysis of body composition with calculation of the non-fat mass index was carried out using an impedance meter to assess the reduction in muscle mass. A reduction of muscle strength was assessed by a hand strength $<$16 kg. The diagnosis of sarcopenia was made according to the criteria of the EWGSOP 2019. The population was divided into 2 groups according to the chemotherapy molecule used; G1: group receiving anthracyclines, G2: group receiving taxane.
Results
During this period 107 patients were recorded. The mean age was 52 ± 9.75 years. The age group most affected was between 50 and 60. In the body composition analysis, reduced muscle mass was noted in 55% of patients. It was more marked for group 1. An increase in body fat was noted in the majority of cases (70%) and the percentages were comparable for the two groups. A non-fat mass index of less than 15 was noted in 14 patients. The majority of which belonged to G1. Furthermore, a decrease in grip strength was noted in 34 patients, 61% of whom were receiving anthracyclines. Finally, sarcopenia was diagnosed in 12% of all cases. Both sarcopenia and reduced muscle strength were significantly associated

with G1 receiving anthracyclines with respectively$P$ 0.028, $P < 10^{-3}$. The increase in body fat was not correlated with the chemotherapy molecule.
Conclusion
This reflects the under-diagnosis of sarcopenia and its close relationship with chemotherapy, justifying early detection and management of this entity in order to prevent its potential consequences.

Impact of hibiscus tea consumption on clinical and biological parameters in patients with type 2 diabetes and/or hypertension

Kouloud Boujelben[1,2], Mariem Ayedi[2,3,4], Fatma Mnif[2], Mouna Elleuch[2], Dhoha Ben Salah[2], Mouna Mnif[2], Nadia Charfi[2], Faten Haj Kacem Akid[2], Mohamed Abid[2] & Nabila Rekik Majdoub[2]
[1,2], Tunisia; [3]Hedi Chaker Hospital, Endocrinology Diabetology, Tunisia; [4]Hedi Chaker Hospital, Endocrinology Diabetology, Sfax, Tunisia

Introduction
Medicinal plants and their benefits on human health in the treatment of non-communicable diseases such as hypertension, overweight or obesity, diabetes, and dyslipidemia present a current issue of several research studies. Among these plants is 'Hibiscus sabdariffa', known for its hypotensive, hypoglycemic, hypolipidemic, and anti-obesity actions. Our work aimed to assess the impact of Hibiscus tea consumption on clinical (systolic and diastolic blood pressures, weight) and biological parameters (blood glucose level, cholesterol level, and triglycerides level) in patients with type 2 diabetes and/or hypertension.
Materials and Methods
Our study involved 20 patients, aged between 18 and 60 years old, who were followed at the Endocrinology-Diabetology department at Hedi Chaker Hospital in Sfax. 55% were females and 45% were males, with a predominance in the age group between 35-40 years. 20% of the subjects had a normal BMI between 18.5 and 25 kg/m^2, while the rest of our population had a BMI higher than 25 kg/m^2. 25% of the patients were hypertensive, 30% were dyslipidemic, and 25% had both hypertension and dyslipidemia.
Results
In our type 2 diabetic and/or hypertensive patients, our results demonstrate that Hibiscus tea can remarkably modify metabolic parameters. In fact, we observed a significant decrease in blood glucose and glycated hemoglobin levels (47.49% and 9.53%, respectively) as well as a reduction in cholesterol and triglyceride levels by 39.35% and 59.79%, respectively, after one month of tea consumption. Furthermore, we observed an estimated reduction of 17.20% in systolic blood pressure and 9.83% reduction in diastolic blood pressure over the course of one month of treatment.
Conclusion
We can therefore conclude that Hibiscus tea consumption may improve glycemic and lipid profiles, blood pressure, and obesity in patients with type 2 diabetes and/or hypertension. However, further researches involving a larger number of patients are needed to statistically strengthen our results and extrapolate them to the Tunisian population.

Omega-3 consumption profile among a group of tunisian diabetic coronary patients

Asma Cherni, Haifa Abdesselem, Emna Bornaz & Chiraz Amrouche
Institut De Nutrition, Tunis, Tunisia

Introduction
Omega-3 polyunsaturated fatty acids (PUFAs) have emerged as pivotal factors in mitigating the risk of cardiovascular disease. Extensive research has demonstrated their ability to reduce both fatal and non-fatal events such as myocardial infarction, stroke, and coronary artery disease. This study aims to assess the Omega-3 polyunsaturated fatty acids(PUFAs) intake, encompassing all three types of omega-3, within a cohort of diabetic coronary patients.
Material and method
Thirty patients aged between 18 and 70 years, diagnosed with type 2 diabetes mellitus and having experienced at least one coronary event, were included in the study. An alimentary survey utilizing the 24-hour dietary recall technique and a validated questionnaire of frequency was conducted and analyzed using dietetic software to assess omega-3 polyunsaturated fatty acids intake.
Results
The mean age of the consultants was 55.7 ± 13 years, with extremes ranging from 38 to 82 years. The M/F sex ratio was 0.4 and the mean BMI 30.41 kg/m^2. Among the patients, 89% had an insufficient apport of omega-3 polyunsaturated fatty acids and 61% of them take fish only one time a month. The mean intake of alpha-linolenic acid (ALA) was 45.7 mg ± 18.9, that of Docosahexaenoic acid (DHA) was 60.2 mg ± 22.8 g.
Discussion
Despite the crucial need for an adequate daily intake of omega-3 polyunsaturated fatty acids, especially in a population with a very high cardiovascular risk, such as the subjects in our study, actual intake falls significantly below recommended levels, primarily due to ignorance and limited resources. A comprehensive dietary education, particularly tailored for this patient category, should be considered in the future.

EP1118

Assessment of nutritional status and dietary protocol in post ischemic stroke patients

Zaynab Hifdi, Saloua Elamari, Soukaina Laidi & Marouan Fatima
Cheikh Khalifa Bin Zayed Al Nahyan Hospital, Casablanca, Morocco

Introduction
Nutritional factors play an important role in reducing the morbidity and mortality of ischemic stroke, as well as in the effectiveness of post-stroke secondary rehabilitation. We were interested in these nutritional factors and conducted this study to assess the nutritional status of post-stroke patients.
Methods
Our study is a prospective study including post-stroke patients, spread over a period of three months within the neurology services of the Cheikh Khalifa Hospital in Casablanca. We collected epidemiological, clinical, anthropometric and biological data, as well as data from a 24-hour dietary survey.
Results
We included 10 patients, mostly male, with a sex ratio of 7/3. Fifty percent of patients had swallowing and motor disorders, and 70% had impaired memory. In terms of nutrition, 60% of patients had dietary intakes below their nutritional requirements, 30% had criteria for undernutrition, 40% had sarcopenia according to clinical criteria, and 60% were vitamin D deficient. Only 10% of patients saw a dietician after their stroke episode.
Conclusion
Nutritional management is an important, but often neglected, pillar in the management of an ischemic stroke. It plays an important role in primary and secondary prevention, but also and above all in reducing the risk of undernutrition and its impact on post-stroke morbidity and mortality. This undernutrition is due to neurological and swallowing disorders, but also to psychological factors linked to the ischemic stroke.

Resistant otorrhea in a diabetic; revealing form of an exceptional carcinoma of the external ear canal

El Omri Malika, Jemli S, Bellakhdher Mouna, Meherzi Abir, Houas Jihene, Ghammem Monia, Ach Taieb[2], Kermani Wassim & Abdelkefi Mohamed
ENT Department Farhat Hached hospital, Sousse, Tunisia; [2]Endocrinology Department Farhat Hached Hospital, Sousse, Tunisia

Introduction
Necrotizing otitis externa (NOE) is a serious pathology frequently observed in diabetics. Its differential diagnosis of carcinoma of the external auditory canal (EAC) is, however, a rare pathology observed only in 0.2% of cases, the most frequent histological type is epidermal carcinoma, adenoid cystic carcinoma (ACK) is exceptionally observed. We report the case of ACK treated in our department initially considered as an NOE and whose diagnosis was made on deep biopsies. The aim of our work is to draw attention of clinicians to a differential diagnosis of necrotizing otitis externa and to describe its therapeutic modalities.
Observation
A 70-year-old patient, type 2 diabetic evolving for 6 years, admitted for left ear pain associated with chronic otorrhea resistant to outpatient treatment. Physical examination revealed an inflammatory EAC. No granulation tissue or protruding polyp was found. Temporal Computed tomography showed the appearance of a

left NOE without endocranial extension. Bacteriological and mycological samples were negative initially then positive for *corynebaceruim*. The patient was then put on antibiotics for 21 days with good control of her diabetes and regular local care, without any improvement. Given the slow progress, it was decided to perform deep bone biopsies which were in favor of a ACK of the CAE. The patient underwent a lateral petrectomy followed by adjuvant radiation. The evolution was favorable.
Conclusion
The place of deep biopsy in NOE is controversial, but it can sometimes support a differential diagnosis in the face of the dragging evolution of a well-monitored NOE.

Metabolic profile of obese tunisian adults

Wissal Ghamgui, Elleuch Mouna, Maalej Souhir, Hadj Kacem Faten, Mnif Mouna, Mnif Fatma, Charfi Nadia, Rekik Nabila & Abid Mohamed
Hedi Chaker Hospital, Endocrinology and Diabetology department, Sfax, Tunisia

Introduction
Obesity is recognized as a risk factor for cardiovascular diseases. She can be associated with cardio-metabolic diseases. The objective of our study was to determine the metabolic profile of our obese adults.
Materials and methods
This is a descriptive cross-sectional study involving obese adults consulting the service of Endocrinology of Sfax, Hedi Chaker University Hospital in 2023.
Results
We recruited 40 obese patients with an average age of 43.47+/-16.56. The sex ratio was 0.21. The average duration of obesity was 20 years +/-13.25. Average weight was 95.17 kg with a minimum of 74 kg and a maximum of 134 kg. The average body mass index was 35.96+/-5.04 kg/m^2. Twenty percent of patients had morbid obesity (BMI=40 kg/m^2). There mean systolic blood pressure was 131+/-2 mmHg with a minimum of 100 mmHg and a maximum of 170mmHg. The mean diastolic was 79.62+/-10 mmHg. The average of fasting blood sugar was 6.68+/-3.33 mmol/l. For the lipid profile, the average cholesterol total and HDL cholesterol were 4.24+/0.87 mmol/l and 1.05+/-0.19 mmol/l respectively. There average triglycerides was 1.36+/-0.46 with a maximum of 2.5 mmol/l.
Conclusions
Obesity puts you at risk of metabolic syndrome with all its harmful effects on health. There insulin sensitivity and fasting insulinemia should be part of the criteria to be assessed for define metabolic normality in obese subjects.

DOI: 10.1530/endoabs.99.EP1132

EP1133

Assessment of environmental factors influencing weight behavior

Veranika Lobashova[1,1], Yuliya Dydyshka & Alla Shepelkevich
Belarusian State Medical University, Endocrinologic, Minsk, Belarus

Introduction
The prevalence of overweight and obesity is risen dramatically especially among children and adolescents. Increased BMI is an independent risk factor for cardiovascular diseases, diabetes mellitus, and some types of cancers (including endometrial, breast, ovarian, prostate, liver, gallbladder, kidney, and colon). Changes in dietary and physical activity patterns are often the result of environmental and social impact. Studies carried out revealed that people globally are currently trying to lose weight.
Methods
We examine 67 patients seeking to lose weight to dietician. The mean age was 46, 5+ 8.5 years, the mean BMI 39.7+5.3 kg/m^2. 12% (8 persons) were men, 88% (59 persons) were women. We examine anamnesis of obesity, family history and comorbidity.
Results
We revealed that among men 2 participants had (25%) had the excess weight from childhood, 2 (25%) of them were stigmatized. 1 patient (12.5%) had diagnosed eating disorder, 1 patient (12.5%) - other mental disorder. 2 (25%) participants made attempts to lose weight; 50% of them used supplements and pills. 3 (37.5%) patients had cardiovascular diseases, 3 smoked, 6 of 8 persons (75 %) had obesity on maternal line, 3 (37.5%) on the paternal line. 2 respondents(25%) had diabetes mellitus in closer relatives. Among women 16 participants(27 %) had had the excess weight from childhood, 7 of them (12%) were stigmatized. 9 patients (15%) had diagnosed eating disorders, 4 patients (7%) - other mental disorders. 33 participants (56%) made attempts to lose weight; 36% of them used diet supplements and pills. 35 persons (59 %) had obesity on maternal line, 25 (42%) on the paternal line. 14 respondents (24%) had diabetes mellitus in closer relatives.
Conclusion
Family factors play a huge into transition normal weight to obesity and affecting eating disorders. ~50 % of participants had attempts to lose weight including use of supplements. Level of mental disorders and stigmatization are high.

DOI: 10.1530/endoabs.99.EP1133

EP1134

Carbohydrate metabolism according to obesity phenotype

Tetiana Sekret
National Pirogov Memorial Medical University, Endocrinology, Vinnytsya

Introduction
Diabetes mellitus is the most common disease of the 21st century. The main challenge for modern doctors is to prevent its development.
Purpose
Study the state of carbohydrate metabolism in individuals with different obesity phenotypes.
Materials and methods
We examined 96 individuals (18-64 y.) according to each obesity phenotype during 2019 - 2021 on the basis of the Vinnitsa Regional Clinical High-Specialized Endocrinological Center. An anamnesis was collected according to the FINDRISK Diabetes risk scale. Biochemical analysis was performed laboratory.
Results
Patients in the first clinical group have normal body weight, some have overweight (BMI - 24.7±4.3 kg/m^2), but the waist volume (102.45±9.63 cm in men, 88.64± 4.27 cm in women) is higher than the normative values, which is tracked in all obesity phenotypes, which may indicate insulinresistance. Violations of carbohydrate and lipid exchanges according to screening surveys in this group were not found. With normal body weight (BMI-23.7±2.44 kg/m^2), metabolic disorders are already observed in the second clinical group. According to carbohydrate metabolism data, all patients were diagnosed with prediabetes combining fasting hyperglycemia and impaired glucose tolerance (fasting glucose - 5.93±0.36 mmol/l, 2 hours after glucose - 8.45±0.27 mmol/l, HbA1c - 6.23±0.18%), and existing dyslipidemia (CL - 5.88± 0.26 mmol/l). It is worth noting that not always as we expect in obesity (BMI - 34.57±3.31 kg/m^2) there will be changes in the lipid and carbohydrate profile, demonstrating the results of the examination of the 3rd clinical group (fasting glucose - 5.23±0.17 mmol/l, glucose 2 hours after glucose - 7.4±0.32 mmol/l, HbA1c - 5.32±0.21%; CL - 4.98±0.46 mmol/l, TG - 1.32±0.14 mmol/l, LDL - 2.75±0.22 mmol/l). In patients of the 4th clinical group, metabolic disorders were detected (fasting glucose - 5.78±0.13 mmol/l, glucose 2 hours after glucose - 8.83±1.67 mmol/l, HbA1c - 5.97±0.32%; CL - 6.73± 0.21 mmol/l, TG - 2.46± 0.57 mmol/l, LDL - 4.13± 1.07 mmol/l, SAP - 145.58±19.34 mm Hg, DAP - 94.8 ±5.61 mm Hg) with obesity (BMI - 35.8 ±4.42) Given a long course without proper treatment, this can provoke diabetes mellitus.
Summary and conclusions
The results of the study will give rise to timely preventive measures aimed at combating diabetes mellitus.

DOI: 10.1530/endoabs.99.EP1134

EP1135

Prevalence of sarcopenia in obese tunisian adults

Berriche Olfa[1], Rim Rachdi[1], Chaima Ammar[2], Rym Ben Othman[1], Nadia Ben Amor[1], Ramla Mizouri[1], Amel Gammoudi[1] & Jamoussi Henda[1]
[1]National Institute of Nutrition, Department A, Tunis, Tunisia; [2]Higher School of Health Sciences and Techniques, Tunis, Tunisia

Introduction
Sarcopenia is a clinical condition defined as low skeletal muscle mass and function. It has been identified and described as a geriatric syndrome, increasing the risk of frailty, comorbidities and mortality. However, sarcopenia may arise in individuals with obesity at any age. Our objective was therefore to screen for sarcopenia in a group of obese adults.
Materials and methods
This was a descriptive cross-sectional study, carried out on 53 obese patients who consulted the Human Obesity Research Unit of the National Institute of Nutrition and Food Technology of Tunis, between November 2022 and February 2023. Screening

for sarcopenia has been established according to pathological thresholds proposed by the European Society for Clinical Nutrition and Metabolism (ESPEN) and the European Association for the Study of Obesity (EASO)[1].
Results
The mean age of patients was 44.34±13.51 years. The majority of our patients were female (79.2%), with a gender ratio (M/F) of 0.26. Mean BMI was 39.78±5.92 kg/m^2;. Average waist circumference was 125±11 cm for men and 120±11 cm for women. Mean visceral fat was 11.35±5.38 l. Mean body fat percentage was 46.2±7.23%. Almost all patients (94.3%) had a high body fat percentage. The mean values for skeletal muscle mass (SMM) and percentage of skeletal muscle mass to weight (SMM/W) were 31.37±7.30 kg and 29.26±5.01% respectively. More than half the patients (54.7%) had low skeletal muscle mass. 17% of patients had poor grip strength. Sarcopenia was present in 7.5% of the population (SO+). The mean age of the obese sarcopenic was 50.25 years, compared with 43.86 years for the non-sarcopenics ($P=0.444$). Half of SO+ patients were men, compared with 18.37% of SO- patients ($P=0.134$). 50% of sarcopenic obese patients (SO+) had a low socioeconomic status, vs 4% of non-sarcopenic obese patients (SO-). The difference was statistically significant ($P=0.004$). All sarcopenic obese people were sedentary, compared with only 77.5% of non-sarcopenic obese people. The difference was statistically significant ($P<0.001$).
Conclusions
Screening for sarcopenia should be carried out in obese patients regardless of age in order to better assess obesity severity beyond body mass index (BMI), which is now recognized as an insufficient criterion for defining this chronic disease with multiple comorbidities.

The impact of obesity on bone and joint:about 502 cases

Imane Hasbi[1], Nassim Essabah Haraj[2], Siham El Aziz[3] & Asma Chadli[4]
[1]Ibn Rochd University Hospital, Endocrinology and Metabolic Diseases, casablanca, Morocco; [2]Ibn Rochd University Hospital, Endocrinology and Metabolic Diseases, Casablanca, Morocco; [3]Ibn Rochd University Hospital, Endocrinology and Metabolic Diseases, Casablanca, Morocco; [4]Ibn Rochd University Hospital, Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
Obesity poses a major challenge to public health, not only due to its cardiovascular and metabolic complications but also because of its impact on the musculoskeletal system.
The aim of this study is to analyze the frequency of various osteoarticular complications in obese individuals.
Patients and Methods
This is a retrospective study conducted on 502 obese patients aged 13 to 80 years, hospitalized in the endocrinology department of CHU Ibn Rochd in Casablanca. Osteoarticular manifestations and their respective locations were examined. Each patient underwent anthropometric measurements, as well as biological and radiological evaluations based on indications. The statistical analysis was performed using the SPSS software, version 25.
Results
The average age of our patients was 51.7 years (13-80 years), with a marked female predominance at 83.5%. The mean body mass index (BMI) was 35.2 kg/m^2, and the average abdominal circumference was 113.8 cm. Among the patients, 38.5.% had osteoarticular complications, Their average BMI was 38.2 kg/m^2, with a prevalence of 43.7% for morbid obesity and 34.6% for severe obesity. Various joint issues reported included knee pain observed in 58.2% of cases, knee pain associated with lower back pain in 28.4% of cases, and isolated lower back pain in 13.4%. Osteoarthritis was present in 21.3% of patients, while bone densitometry revealed osteopenia in 17.8% of cases and osteoporosis in 15.8% of cases. Vitamin D deficiency was identified in 18.2% of patients.
Discussion and conclusion
Several studies have demonstrated an increased association between obesity and the risk of osteoarthritis in the knee, hip, and finger joints, although the impact is less pronounced for the hip. This correlation between obesity and arthritic pathology is frequently observed, especially in the elderly, which aligns with the results of our study. Obesity exacerbates functional limitations, leading to a significant deterioration in the quality of life due to painful symptoms. It becomes imperative to prevent obesity and/or intervene early for optimal management.

EP1137

Nutritional risk factors associated with the development of sarcopenic obesity

Berriche Olfa[1], Rim Rachdi[1], Chaima Ammar[2], rym ben othman[1], Amel Gammoudi[1] & Jamoussi Henda[1]
[1]National Institute of Nutrition, Department A, Tunis, Tunisia; [2]Higher School of Health Sciences and Techniques, Tunis, Tunisia

Introduction
Sarcopenic obesity (SO), characterized by the coexistence of obesity and sarcopenia, is a condition increasingly recognized for its clinical and functional features, which impairs patients' quality of life and increases the risk of morbidity and mortality. In order to improve the management of obese patients, we aimed to screen for sarcopenia in obese adults and to identify the nutritional risk factors associated with sarcopenic obesity.
Materials and methods
This was a descriptive cross-sectional study, carried out on 53 obese patients who consulted the Human Obesity Research Unit of the National Institute of Nutrition and Food Technology of Tunis, between November 2022 and February 2023.
Results
The mean age of patients was 44.34±13.51 years. Mean BMI was 39.78±5.92 kg/m^2;. Almost all patients (94.3%) had a high fat mass percentage. More than half the patients (54.7%) had low skeletal muscle mass (SMM/W). Prevalence of Sarcopenia was 7.5% (SO+). Mean energy intake was 3100 kcal/d in SO+ and 2800 kcal/d in SO- ($P=0.886$). The average intake of lipids and saturated fatty acids was higher in sarcopenic obese people, but with no significant difference. Average cholesterol intake was significantly higher for SO+ than for SO- (354.93 mg/24 h vs 320.53 mg/24 h respectively; $P<0.001$). Regarding the average vitamin intake, there was no statistically significant difference between SO+ and SO-. Furthermore, a statistically significant relationship was found between low skeletal muscle mass (SMM/W) and the average intake of vitamin PP ($P=0.014$) and vitamin B9 ($P=0.009$). There was no significant difference between the two groups regarding the average intake of mineral salts, except for the average copper intake, which was significantly higher in sarcopenic obese people (2.91 mg/d for SO+ vs 1.84 mg/d for SO-; $P=0.038$).
Conclusions
In the light of our results and those of the literature, a high-calorie diet combined with sedentary lifestyle contributes to the development of sarcopenic obesity. We therefore recommend promoting a balanced, low-energy-density diet in order to reduce the risk of sarcopenia and associated comorbidities.

Clinical risk factors associated with sarcopenic obesity

Berriche Olfa[1], Rim Rachdi[1], Chaima Ammar[2], rym ben othman[1], Ramla Mizouri[1], Nadia Ben Amor[1], Amel Gammoudi[1] & Jamoussi Henda[1]
[1]National Institute of Nutrition, Department A, Tunis, Tunisia; [2]Higher School of Health Sciences and Techniques, Tunis, Tunisia

Introduction
Sarcopenia, defined as the loss of skeletal muscle mass and function, is common for individuals with obesity due to adipose tissue disorders, metabolic changes associated with a sedentary lifestyle and during the ageing process. However, sarcopenia can occur in obese people at any age. Our objectives were therefore to screen for sarcopenia in a group of obese adults, and to identify the clinical risk factors associated with sarcopenic obesity.
Materials and methods
This was a descriptive cross-sectional study, carried out on 53 obese patients who consulted the Human Obesity Research Unit of the National Institute of Nutrition and Food Technology of Tunis, between November 2022 and February 2023.
Results
Average age of patients was 44.34±13.51 years. Mean BMI was 39.78±5.92 kg/m^2;. Almost all patients (94.3%) had a high fat mass percentage. More than half the patients (54.7%) had low skeletal muscle mass (SMM/W). Sarcopenia was present in 7.5% of the population (SO+). Mean Body Mass Index (BMI) (45.86 kg/m^2 for OS+ vs 39.29 kg/m^2 for OS-; $P=0.03$) and mean visceral fat (16.55 l for OS+, vs 10.93 l for OS-; $P=0.043$) were significantly higher in sarcopenic obesity. Similarly, mean BMI (41.57 kg/m^2 for low SMM/W vs 37.62 kg/m^2 for normal SMM/W; $P=0.006$), and mean percentages of severe obesity (58.62% for low SMM/W, vs 25% for normal SMM/W; $P=0.048$) and fat mass (49.25% for low SMM/W, vs 42.52% for normal SMM/W; $P<0.001$) were significantly higher in cases of low skeletal muscle mass. Mean visceral fat was also higher in cases of low skeletal muscle mass than in cases of normal skeletal muscle mass, but with no significant difference (12.21 l for low SMM/W, vs 10.65 l for normal SMM/W; $P=0.3$).

Conclusions
Our results showed that high BMI and altered body composition, including increased fat mass percentage and high viceral fat, were the anthropometric risk factors associated with the development of sarcopenic obesity. We therefore recommend a balanced diet combined with regular physical activity to reduce the risk of sarcopenia and associated comorbidities.

Biological parameters associated with sarcopenic obesity

Berriche Olfa[1], Rim Rachdi[1], rym ben othman[1], Chaima Ammar[2], Amel Gammoudi[1], Emna Talbi[1] & Jamoussi Henda[1]
[1]National Institute of Nutrition, Department A, Tunis, Tunisia; [2]Higher School of Health Sciences and Techniques, Tunis, Tunisia

Introduction
Loss of skeletal muscle mass and function, which defines sarcopenia, generally occurs with ageing, and is commonly associated with relative or absolute fat mass gain; this process contributes to the potential development of sarcopenic obesity. However, sarcopenia can occur in people suffering from obesity at any age. We aimed therefore to screen for sarcopenia in a group of obese adults, and to identify the biological risk factors associated with sarcopenic obesity.
Materials and methods
This was a descriptive cross-sectional study, carried out on 53 obese patients who consulted the Human Obesity Research Unit of the National Institute of Nutrition and Food Technology of Tunis, between November 2022 and February 2023.
Results
The mean age of patients was 44.34 ± 13.51 years. Mean BMI was 39.78 ± 5.92 kg/m^2;. Almost all patients (94.3%) had a high fat mass percentage. More than half the patients (54.7%) had low skeletal muscle mass (SMM/W). Sarcopenia was present in 7.5% of the population (SO+). The study of biological parameters revealed a statistically significant relationship between insulin resistance and low skeletal muscle mass, as attested by mean insulinemia (28.81 µIU/ml for low SMM/W, vs 14.48 µIU/ml for normal SMM/W; $P=0.004$) and HOMA index (7.94 for low SMM/W, vs 3.49 for normal SMM/W; $P=0.002$), which were higher in cases of low skeletal muscle mass. However, there was no statistically significant difference in biological parameters or Homa index between sarcopenic (SO+) and non-sarcopenic (SO-) obese subjects.
Conclusions
In the light of our results and those of the literature, we recommend promoting a balanced, low-energy-density diet in order to improve insulin sensibility and thus reduce the risk of sarcopenia and associated comorbidities. Regular physical activity and limiting sedentary activities are also strongly recommended.

Prevalence of undernutrition in adult patients consulting for underweight

Dorra Ben salem, Emna Bornaz, Sana Khamassi, Haifa Abbassi, Selma Mohsen[2], Fatma Boukhayatia, Asma Ben Brahim, Rim Yahyeoui, Kamilia Ounaissa & Chiraz Amrouche
National Institute of Nutrition, Outpatient Department and Functional Exploration, Tunis; [2]Tahar Sfar Hospital, Mahdia

Introduction
Undernutrition is a pernicious and frequent situation that often remains undetected and insufficiently treated. The aim of our study was to determine the prevalence of malnutrition in adult patients seen in specialized nutrition consultation.
Materials and methods
It was a cross-sectional study, including adult patients consulting our specialized nutrition unit in the outpatient department and functional exploration of the National Institute of Nutrition of Tunis. Demographics, clinical characteristics, biochemistry and outcome data were collected. Among the phenotypic criteria, we find the muscular strength, evaluated by the Hand Grip test (HG), the body mass index (BMI) and weight loss (WL). Their limits were those defined by the high health authority (HAS) 2021. One of these criteria associated with an etiological criterion establishes the diagnosis of malnutrition. We also measured the upper arm circumference (AC) and calf circumference (CC).
Results
Thirty five patients with the mean age of 35.14 ± 15.95 years [20; 68] were included in the study. The sex ratio was 0.2. The main reported symptoms were anorexia (54.3%) and asthenia (34.3%). The average BMI, WL, HG, AC and CC were 17.51 ± 4.3 kg/m^2; 15.83 ± 9.63%; 23.27 ± 10.1 kg; 22.89 ± 3.18 cm and 30.82 ± 4.11 cm respectively. The prevalence of undernutrition with BMI, WL and HG as isolated criteria were 74.28%, 65.71% and 31.42%, respectively. It was 65.71% associating at least a phenotypic and an etiological criterion as the HAS recommends. The undernutrition was moderate in 43.47% of cases and severe in 56.52% of them. Severity was related to a BMI under 17 kg/m^2; in 84.61% of cases, to WL greater than 15% in 61.53 % of cases and to an albumin level under 30g/l in 15.38 % of them. BMI was significantly correlated with age ($P=0.05$), upper arm circumference ($P<0.0001$) and calf circumference ($P=0,006$) but no correlation was found with HG and WL. Undernutrition was correlated with WL ($P=0,001$).
Conclusion
The presentation of undernutrition is often subtle and there is a need to pay additional attention to nutrition status by the use of reliable screening toolsand increasing physician awareness. HAS recommendations constitute an appropriate tool to establish a malnutrition situation and should be applied whenever this diagnosis is suspected.

A simple blood screening tests for predicting non-alcoholic fatty liver disease in obese patients

Meriam Dalhoum[1], Olfa Berriche[1], Rim Ben Othmen[1], Emna Talbi[2], Raja Tlili[3], Sahar Hamza[3], Amel Gammoudi[1], Awatef Kacem[1], Lamia Kallel[3] & Henda Jamoussi[1]
[1]National Institute of Nutrition in Tunis, Human Obesity Research Unit, Tunis, Tunisia; [2]National Institute of Nutrition in Tunis, Biochemistry Laboratory, Tunis, Tunisia; [3]Mahmoud El Matri Hospital, Ariana, Tunis, Gastroenterology Department, Tunis, Tunisia

Introduction
Obesity is becoming increasingly common in the world's population. Its pandemic nature has made it the leading cause of chronic liver disease especially non-alcoholic fatty liver disease (NAFLD).
Objective
To develop a simple blood screening tests to predict the risk of NAFLD in the obese patient.
Methods and Materials
This is a cross-sectional study including 208 patients who consulted at the Human Obesity Research Unit of the National Institute of Nutrition in Tunis. Patients were interviewed, anthropometric measurements (weight, height, body mass index (BMI) and waist circumference) were taken, biological hepatic assessment (aspartate transaminase (AST), alanine transaminase (ALT), Gamma-glutamyl Transferase (GGT) and Alkaline phosphatases (ALPs)) and abdominal ultrasound were conducted to look for hepatic steatosis. We subdivided our patients into two groups: G1 (patients with hepatic steatosis) and G2 (patients without hepatic steatosis).
Results
The mean age of our patients was 49 ± 12 years with a female predominance (98.9%). The mean BMI was 40,43 ± 6,38 kg/m^2. The mean waist circumference was 117,60 ± 14,58 cm. The frequency of hepatic steatosis was 76 %. Mean AST, ALT and GGT levels (IU/l) were significantly higher in the presence of steatosis, respectively G1: 25.30 ± 14; 21 ± 16 and 24 ± 18 vs G2: 20.72 ± 6; 17.23 ± 13 and 18 ± 15 ($P=0.036$; $P<0.001$ and $P=0.006$ respectively). Similarly, PAL levels (IU/l) were higher in G1, but with no statically significant difference (G1: 83.67 ± 21 vs G2: 79.26 ± 26; $P=0.246$). The AST/ALT ratio was significantly lower in G1 (G1: 1.07 ± 0.31 vs G2: 1.27 ± 0.35; $P<0.001$). In multivariate analysis, only ALT (OR = 1.109; $P=0.001$) predicted NAFLD.
Conclusion
Hepatic steatosis is common in obese subjects and the hepatic screening tests represents a simple and reliable way for early early detection.

A simple score for predicting obstructive sleep apnea syndrome (OSAS) among obese patients

Meriam Dalhoum, Olfa Berriche, Rim Ben Othmen, Ramla Mizouri, Nadia Ben Amor & Henda Jamoussi
National Institute of Nutrition in Tunis, Human Obesity Research Unit, Tunis, Tunisia

Introduction
Obesity is undeniably a major factor in obstructive sleep apnea syndrome (OSAS). Diagnosis of the latter relies on polysomnography, but this test is not widely available. Screening of subjects at risk could be relevant, using tools such as the Berlin Questionnaire.
Objective
To determine the prevalence of symptoms and risk factors for OSAS in a group of obese subjects.
Methods
This was a cross-sectional study of 100 patients being monitored for obesity, who volunteered to complete the Berlin Questionnaire. All subjects benefited from the collection of clinical, anthropometric (weight, height, body mass index (BMI)) and biological data.
Results
Mean age was 48 ± 11 years. Women represented 84% of the sample and men 16%, for a sex ratio of 0,2. Mean BMI was 38.20 ± 6 kg/m^2. In terms of OSA symptoms, snoring was present in 74 obese subjects, and daytime sleepiness was reported in 31 subjects. The prevalence of hypertension was 44%, and all our patients had a BMI > 30 kg/m^2. The prevalence of subjects at high risk of OSA was 31% in the overall study population. In univariate analysis, the factors significantly associated with a high risk of OSAS in this population were age ($P = 0.01$), male sex ($P < 0.001$) and diabetes ($P = 0.02$).
Conclusions
In view of our study, the Berlin Questionnaire could be considered as a first step in screening subjects at risk of OSAS.

Metabolic regulation of adipose stem cell fate and function: from bench to clinic

Alice Pollard[1] & Sophia Bustraan[2]
[1]Imperial College London, Institute of Clinical Sciences, London, United Kingdom; [2]Mestag Therapeutics Limited, United Kingdom

White adipose tissue is a vital endocrine organ required for the storage of energy in the form of triglycerides, which is released in response to nutrient deprivation, and for the production of hormones such as leptin and adiponectin. In this way, adipose tissue is at the forefront of whole organism energy homeostasis. Adipose tissue dysfunction is associated with many metabolic diseases including T2D, cardiovascular disease and non-alcoholic fatty liver disease (NAFLD). Adipose tissue is rich in mesenchymal stem cells, known as adipocyte precursors, or adipose-derived stem cells. These multipotent cells are responsible for the production of new adipocytes, signaling to existing adipocytes, for the production of chemokines and for response to tissue stress and inflammation. The maintenance of adipose stem cell function is therefore imperative for healthy adipose tissue expansion and homeostasis. Loss of ADSC potency, function and ability to respond correctly to stimuli are emerging hallmarks of metabolic disease. Our work focuses on understanding the mechanisms leading to ADSC dysregulation, using a combination of mouse and human ADSC cell models, paired with primary adipose stem cell cultures obtained from healthy volunteers. In clinic, we derive ADSC cultures from patients undergoing bariatric surgery to better understand these processes in diseased states, and to identify potential targets for pharmaceutical intervention. Our previous work identified AMPK as a regulator of adipocyte cell fate, with exciting consequences including promotion of mitochondrial content and improved insulin sensitivity. We are currently exploring the potential of small molecule AMPK activators in ADSC metabolic regulation, particularly in the suppression of leptin, which will form the basis of this talk.

Impact of undernutrition in breast cancer patients during chemotherapy

Selma Mohsen[1], Berriche Olfa[1], Ben Mansour Hajer[2], Rym Ben Othman[1], Msolly Skander[1], Mezlini Amel[2] & Jamoussi Henda[1]
[1]National Institute of Nutrition, Service A, Tunis, Tunisia; [2]National Institute Salah Azaiez, Oncology, Tunis

Introduction
Malnutrition is a common issue observed in patients undergoing treatment for cancer. It stems from various factors and poses a significant challenge in the effective care of these individuals, adding complexity to their overall management. The aim of our study was to determine the prevalence of undernutrition and risk of undernutrition in women with breast cancer and its effect on chemotherapy digestive tolerance.
Methodology
This was a cross-sectional, descriptive study conducted over a 6-month period in patients with cancer patients undergoing chemotherapy. The risk of malnutrition was assessed using the Malnutrition Universal Screening Tool (MUST score). The diagnosis of undernutrition was made according to the criteria of the French National Authority for Health. A BMI < 18.5 kg/m^2;, weight loss > 10% in 6 months, grip strength < 16 kg and/or fat-free mass index < 15 kg/m^2; were the phenotypic criteria on which the study was based. The digestive effects studied were vomiting, diarrhoea and constipation. The tolerance was assessed according to WHO grades ranging from 0 to 5. High grades 3 and 4 signified toxic grades.
Results
During this period 107 patients were recorded. The mean age was 52.56 ± 9.75 years. The mean BMI was 29.85 ± 5.72 kg/m^2;. According to the MUST score, 10% was classified as being at high risk of malnutrition and 31% were at moderate risk. A BMI < 18.5 kg/m^2 was noted for only 2 patients. On the other hand, weight loss, reduced grip strength and reduced muscle mass were more frequent, with percentages of 12%, 31% and 13.1% respectively. Forty-one percent of patients were finally diagnosed as undernourished. The most marked digestive effects were transit disorders found in 80% of cases followed by nausea (70%) and vomiting (63%). They were of high grade in a third of cases. In multivariate analysis, BMI was not associated with digestive signs. However, significant weight loss and undernutrition were identified as risk factors associated with the severity of digestive effects. Undernutrition was significantly associated with the severity of vomiting (OR = 17.5) and diarrhoea (OR = 1.06). In addition, the MUST score was linearly associated with high grades of all digestive toxicities.
Conclusion
There is a close relationship between undernutrition and digestive toxicity, justifying early nutritional management in order to improve the tolerance and efficacy of chemotherapy.

EP1145

Management of patients with obesity in the time of pandemia COVID-19

Olena Antonyuk[1,2,3]
[1]Kyiv, Nephrological Clinic with wards for Endocrinological Patients, Kyiv, Ukraine; [2]Main Military Clinical Hospital, Kyiv; [3]Bogomolets National Medical University, Kyiv

Introduction
Health promotion of decreasing weight, giving up smoking, and regular physical activity could be helpful in the improvement of individual health.
Materials and methods
We analysed the attitude of obesity and high risks for severe COVID-19 for doctors involved in diagnosing and treating such patients in 2020-2022.
Results
We asked to admit what type of facility the correspondents represented. We found that 48,4% worked in the state clinics of Ministry of Health, 32.2% chose private clinics, and 16.1% worked in the facility of other ministries (Ministry of Defence, Internal Affairs etc.). 66.7% and 73.3% of doctors answered correctly, defining the criteria of obesity and 3rd degree of obesityabout 90,3% of responders admitted the significance of body weight modification in obese patients. Most of doctors assessed medical care during pandemic as 'satisfactory' (77.4%), while 'enough good' only 16.1% and 'unsatisfactory' 6.5% with average score 3.1 from 5 possible.
Discussion
Almost 97% confirmed that recommend patients to improve their phisical activity (very likely and likely in 77.4% & 19.4% correspondingly). We found significant correlation test results between the following parameters: strong positive direct correlation between age and experience (Rxy = 0,954) and presence of doctoral category (Rxy = 0,839), moderate negative correlation between age and positive attitude to vaccine effectiveness (Rxy = –0,337), mild negative correlation of age with correct answers on the definition of obesity (Rxy = – 0,326) and the grade 3rd obesity (Rxy = –0,239), mild positive correlation of age with attitude to the preventive hospitalisation (Rxy = 0,150) and improving of phisical activity (Rxy = 0,103). Young collegues more likely thought positively on the quality of health care during COVID-19 pandemics (Rxy = – 0,285) than their older collegues. Doctors who practiced in hospital or combined both varients of clinical practice more likely assessed positive influence of preventive hospitalisation (Rxy = 0,212) and more often answered correctly defining criteria of obesity and it's degree (Rxy 0,206 and Rxy 0,118 correspondingly). It could be explained as more likely being concerned with body mass index and hospitalisation outcomes.

Practical recommendations
We propose to use a personalised lethality risk index for the assessment of risk groups of severe COVID-19, including obesity, that should be analysed (Gruzieva, T., & Antonyuk, O. (2023). Analysis of Risk factors for severe COVID-19. KIDNEYS, 12[1], 39–45. https://doi.org/10.22141/2307-1257.12.1.2023.393). In our pilot study we received positive answers on modifying obesity as a core risk factor.

EP1146

Body satisfaction and determinants of eating behaviour in pregnant women

Yosra Hasni[1], Aya Mlayah[2], Hamza Elfekih[1], Oumayma Zarrouk[1] & Meriem Ghardallou[2]
[1]University Hospital of Farhat Hached, Endocrinology departement, Sousse; [2]University Hospital of Farhat Hached, Higher School of Health Sciences and Technologies, Sousse

Introduction
Nutrition is considered to be one of the main environmental factors influencing the outcome of pregnancy, the child's development and the mother's health (2). Given that this period is characterised by profound physiological changes (15), motherhood is a stage of psychic reorganisation due to the major bodily transformations that reactivate their bodily preoccupations (16), evoking a difficulty in adapting to their new bodies, which may expose pregnant women to anxiety, bodily dissatisfaction and problems with their eating habits (17). Objective: By referring to the multidimensional model of the development of eating disorders, our objective would be to study the eating behaviour of pregnant women and to determine the factors that influence it, and to screen pregnant women who are at risk of developing an eating disorder.
Material and methods
In order to meet this objective, a correlational cross-sectional study was conducted among pregnant women consulting MIPs in theSousse region and in two private practices over a two-month period from 01 February to 31 March 2021. We used three measuring instruments: the FIGO checklist to assess the nutritional status of pregnant women, the BAQ to assess their body image and the SCOFF which is a screening tool for OCD.
Results
Our results showed that almost all (95.5%) of our sample had an unhealthy diet that needs to be reviewed with a nutritionist in more detail. Pregnant women consumed fruit and vegetables moderately (66.5%), wholefoods were the least consumed by the women in our study, while more than half (58.8%) consumed pastries five times a week. The mean global score of the Body Attitude Questionnaire (BAQ) was 140.7 ± 17 with extremes ranging from 87 to 200. Finally, one third (32%) of the women were considered at risk of developing an OCD according to the results of the SCOFF. No significant association was found between the SCOFF and the BAQ, whereas the SCOFF was positively correlated with some subscales of the questionnaire (BAQ).
Conclusion
In terms of conclusion, our results suggest a qualitative evaluation of the nutritional status of pregnant women and action on the determining factors, as well as monitoring by perinatal care providers of their psychological status, including body satisfaction, given its impact in determining the development of CAT in the context of their daily practice.

Therapeutic education in type 2 diabetes, what is the relationship?

Mouna Elleuch, Insaf Nasri, Wissal Ghamgui, Khouloud Boujelbene, Charfi Nadia, Dhouha Ben Salah, Mouna Mnif, Fatma Mnif, Feten Hadj Kacem, Mohammed Abid & Nabila Rekike
Hedi Chaker Hospital, Endocrinology and Diabetology Department, Sfax, Tunisia

Background
Therapeutic Patient Education (TPE) is an educational process designed to guid people with chronic diseases, such as type 2 diabetes, to improve health care self management.
Aim
Our study seeks to determine the relationship of diabetic patients with therapeutic education programmes.
Methods
Our study involved 61 type 2 diabetic patients followed at the endocrinology department of the university hospital or followed at the city basic health centre.
Results
The mean age was 61 ± 10 years. Females predominated (60.7%), with a sex ratio (M/F) of 0.65.. We found that only one patient participated in a diabetes association. The most common explanation was "I didn't think there was such an association" and the second reason was "I'm not interested". Only 24.6% of patients were aware of therapeutic education programs. The medical and paramedical framework, as part of complementary care, was the main source of education (93.4%) required by patients. The majority (75%) of our population preferred an individual education programmes, the remainder (25%) preferred TVE in a group setting. Brochures and documents related to prescriptions were the most frequently requested by our patients (46%).
Conclusion
Despite the clinical and personal benefits offered by diabetes education, programmes of TPE are under-estimated by patients, with a lack of interest in the educational process.

EP1163

Diabetes and autism: what correlation exists?

Malak Riznat & Guerboub Ahmed Anas
Mohamed V Military Training Hospital, Endocrinology, Rabat

Introduction
Autism is a neurodevelopmental disorder (NDD). It manifests itself in early childhood, with varying degrees of impact on the child's developmental spheres. Although the underlying mechanisms have yet to be elucidated, ASD is considered to be multifactorial, with both genetic and non-genetic risk factors. Is there an established link between diabetes and autism?
Observation
This is a 16-year-old child with no maternal history of hyperglycemia during pregnancy. No personal history of autoimmune disease, followed since the age of 4 for autistic spectrum disease, and who presented to the emergency department with a ketoacidotic decompensation.Biological signs of autoimmunity came back negative, as did the anti-GAD AC assay.
Discussion
The correlation between diabetes and the risk of developing autistic disease has been well established. A meta-analysis identified pregnancy-related factors such as diabetes as a risk factor for developing the disease [1]. The results of a retrospective cohort study show that in utero exposure to type 1 diabetes, type 2 diabetes or gestational diabetes diagnosed at 26 weeks would increase a child's risk of developing autism spectrum disorder compared with children not exposed to diabetes in utero. Meta-regression analyses revealed that children with autism had a higher associated risk of developing diabetes and hypertension than adults (3).
Conclusions
Children with autism are at high risk of developing cardiometabolic diseases such as diabetes and hypertension. Hence the need for vigilant monitoring.

MODY 5 associated with pancreatic intraepithelial neoplasia

Oumeyma Trimeche, Ekram Hajji, Bilel Ben Amor, Ines Bayar, Sana Abid, Héla Marmouch & Inès Khochteli
Fattouma Bourguiba University Hospital, Monastir, Tunisia

Introduction
Monogenic diabetes is a rare type of diabetes that should be evoked in the presence of associated features. Here we report a female patient with complete phenotype of MODY5 while discussing its possible complications.
Case report
A.B was 35-year-old patient with a rich family history of diabetes and renal cysts. Sha had a personal medical history of Diabetes since the age of 23 years, on basal bolus insulin regimen, recurrent episodes of urinary infections, recurrent episodes of bilateral renal lithiasis. She also had a primary amenorrhea until the age of 23 years. Gynecologic evaluation concluded to a pseudounicornuate uterus requiring hemi hysterectomy at the age of 23 years. She was admitted in our Endocrinology

department for a poorly-controlled diabetes. Upon her admission, she weighed 50 kg and had a BMI of 20.3 g/m^2. She had no signs of insulin resistance (no acanthosis nigricans nor abdominal obesity), neither autoimmune features (no vitiligo or melanoderma, nor goiter). Her HbA1c level was elevated 12 % attributable to poor adherence to her treatment s well as to diabetic diet and the recurrent urine infections. Her diabetes was complicated with severe proliferative diabetic retinopathy and sensitive diabetic neuropathy. Otherwise, she had hypomagnesemia and slightly elevated uric acid level. Her creatinine level was within the normal range. She also had elevated level of gamma-glutamyl transferase and aminotransferase. Given the family history and the association of renal cysts, renal lithiasis, young age of onset of diabetes with negative antibodies and uterine malformation, the diagnosis of MODY5 was highly suspected. Genetic testing is still ongoing. Abdominal MRI revealed the presence of an atrophic pancreas and intriguingly, pancreatic intraepithelial neoplasia (PIEN) in addition to signs suggesting chronic pancreatitis.
Discussion
This case highlights the broad clinical spectrum of MODY5 while suggesting a possible occurrence of precancerous pancreatic lesions requiring long-term follow-up. Pancreatic dysplasia often present in MODY 5 can be complicated with chronic pancreatitis and thus PIEN.

Glycemic balance and oral disorders

Yesmine Jallouli, Zohra Hadj Ali, Syrine Trabelsi, Olfa Lajili, Imen Hedfi, Chaima Jemai, Yosra Htira & Faika Ben Mami
National Institue of Nutrition and Food Technology, Department C, Tunis

Introduction
Diabetes is a chronic pathology. Hyperglycemia, which modifies the oral ecosystem, weakens tooth enamel and gums, thus paving the way for periodontal disease.
Aim of the study
The aim of our study was to determine the relationship between glycemic control and oral pathologies.
Materials Methods
This is a descriptive cross-sectional study that took place during the period between November 17 and December 15, 2022 in 36 diabetic patients hospitalized in department C at INNTA. Data were collected based on a stomatological examination and a biological tests.
Results
We enrolled 36 diabetic patients, 63.9% of whom were women. The mean age of our population was 45.94 ± 14.52 years. Type 2 diabetes predominated (67%) and was poorly controlled in 97% of patients. The average age of diabetes was 11.37 ± 9 years. 50% of patients were treated with insulin. Complications were frequent, the most common being retinopathy for microangiopathies (30.6% of patients) and obliterative arteriopathy of the lower limbs for macroangiopathies (16.7%). In our study, 61.1% had poor oral hygiene. The two most frequent manifestations were dental caries and mucosal inflammation in 91.7% and 75% of patients respectively. In addition, 75% of patients complained of tooth loss, 40% of whom had between 5 and 19 teeth lost. Patient knowledge and education about the oral complications of diabetes was inadequate.
Conclusion
Glycemic control plays a vital role in preventing oral complications, which must be taken into consideration.

Topographic diagnosis of primary hyperparathyroidism

Mohamed Abderrahmane Ahmed Ebett, Chadli Asma, El Aziz Siham & Haraj N.E
University Hospital Center Ibn Rochd - Casablanca, Casablanca, Morocco

Introduction
Primary hyperparathyroidism (PHPT) is primarily diagnosed through biological analyses. Modern imaging, particularly ultrasound and scintigraphy, plays a crucial role in localizing parathyroid adenomas.
Methods
A retrospective analysis of 132 patients with PHPT from the endocrinology-diabetology department at Ibn Rochd Hospital Casablanca, including cervical ultrasounds and parathyroid scintigraphy. Computed tomography (CT) and MRI are used as secondary resources. To have the below statistics we used SPSS software.
Results
In this studied population, the average age is 53.4 years, with a clear female predominance (85.93%). Biological examinations showed elevated levels of calcium and phosphorus, averaging 114.93 mg/l and 22.20 mg/l respectively. The average PTH level was also high, reaching 830.56 pg/ml. The majority of patients (71.87%) reported bone pain, and 23.43% were diagnosed with kidney stones. In terms of imaging, ultrasound detected parathyroid adenomas in 64.06% of patients, while scintigraphy revealed hyperfixation in 85.93% of them. CT confirmed the presence of parathyroid adenomas in 64% of cases, with hyperplasia in 6.25% and parathyroid carcinomas in 1% of cases. Additionally, vitamin D deficiency was observed in 67% of patients.
Conclusion
Cervical ultrasound appears to be more effective than parathyroid scintigraphy in the topographic diagnosis of PHPT. CT and MRI are recommended in cases of discordant results or for atypical localizations.

The influence of pre-existing diabetes type on the progression of pregnancy

Meryem Chakir, Salma Bensbaa, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy-University Hassan II-Casablanca-Morocco, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casablanca, Morocco

Introduction
The prevalence of pre-existing diabetes in pregnant women has increased over the last decade. Studies conducted on women with pre-existing diabetes type 1 (DT1) and type 2 (DT2) show higher rates of complications compared to those observed in the general population.
Objective
Comparing the two types of diabetes during pregnancy to identify whether they should be managed similarly or if a different approach is necessary.
Materials and methods
Case-control study conducted at the Endocrinology-Diabetology Department of Ibn Rochd University Hospital in Casablanca, focusing on patients with type 1 diabetes (DT1) with over 10 years of diabetes history and those with type 2 diabetes (DT2) experiencing an ongoing pregnancy.
Results
Eighty-three women with type 1 diabetes (DT1) and 94 patients with type 2 diabetes (DT2) were included in the study. The average age was 34.7 years for DT2 vs 31.7 years for DT1. History of miscarriages was 34% for DT2 vs 20.7% for DT1, and macrosomia occurred in 32% of DT2 vs 17%. The average body mass index (BMI) was 32.7 kg/m^2 for DT2, higher than 27.6 kg/m^2 for DT1. Weight gain during pregnancy was 7.2 kg for DT2 vs 5.19 kg for DT1. HbA1c during the organogenesis period was 9.2% for DT2 and 7.7% for DT1. Glycemic control was achieved in 56% of DT2 vs 45.7% of DT1. Obstetric complications were reported in 11.2% for DT2 vs 9.6% for DT1 (p: 0.4).
Conclusion
Our study indicates that the type of diabetes has no impact on the progression of pregnancy and the occurrence of obstetric complications. The early initiation of care and proper planning are crucial factors for the success of these pregnancies.

Study of the effect of obesity on degenerative complications of diabetes mellitus

Yasmine Fakhfakh, Chaima Jemai, Chaima Sdiri, Dorsaf Ben Salem, Hadhemi Belhassen, Sami Fitouri, Zohra Hadj Ali, Imen Hedfi, Olfa Lajili, Yosra Htira & Faika Ben Mami
National Institute of Nutrition, Department C, Tunisia

Introduction
Obesity is often associated with type 2 diabetes mellitus (T2DM). We aimed to investigate associations between obesity and degenerative complications of diabetes mellitus.
Methods
This was a cross-sectional study conducted at department C of the national institute of nutrition of Tunis including patients hospitalized for uncontrolled diabetes, in November and December 2023. Demographic characteristics, anthropometric parameters, past medical history, current treatments, glycemic control, cardiovascular risk factors, diabetes-related complications and laboratory data were collected from medical records.

Results
Ninety five patients were enrolled in our study. Sex ratio was 0.34. The mean age was 53.4±18.8 years. Mean BMI was 27.2±6 kg/m^2;. One quarter of the population (25.3%) had obesity. Hypertension and dyslipidemia frequencies were 48.4% and 48.4% respectively. The majority of our patients (70.5%) had type 2 diabetes. Mean duration of diabetes was 13.63±10 years. 67.4% were on insulintherpay and 87.4% had at least one degenerative complication, with a medical history of obliterating arteriopathy of the lower limbs, coronary artery disease and stroke in respectively 7.4%, 14.7% and 4.2% of cases. Mean HbA1c was 11.17±2.17%. Obesity was significantly associated to hypertension ($P=0.004$), dyslipidemia ($P=0.03$) pathologic albuminuria ($P<0.001$), diabetic neuropathy ($P=0.01$), coronary artery disease ($P=0.04$) and stroke ($P=0.04$).
Conclusion
According to our study, obesity seems to be associated with degenerative complications of diabetes mellitus. Thus, management of diabetic patients should be holistic. Reducing weight contribute to reach glycemic control and to reduce frequency and severity of chronic complications.

Diabetes and medication: knowledge and error

Yesmine Jallouli, Zohra Hadj Ali, Syrine Trabelsi, Sami Fitouri, Olfa Lajili, Imen Hedfi, Chaima Jemai, Yosra Htira & Faika Ben Mami
National Institue of Nutrition and Food Technology, Department C, Tunis

Introduction
Diabetics represent a major public health issue, which subsequently favors the regular intake of several long-term medications with drug prescriptions that can lead to the risk of iatrogenesis and iterative hospitalization.
Objectives
The aim of our study was to find out patients' knowledge in relation to the proper use of medication.
Materials and methods
This is a prospective descriptive study carried out in Service C at INNTA during the year 2022 on a sample of 50 diabetic patients. Data were collected from medical records and a questionnaire in Tunisian dialect studying the particularities of medication use by our patients.
Results
The mean age of our population was 51.54 with extremes ranging from 14 to 75 years. The sex ratio M/F was 0.6. Hypertension and dyslipidemia were the 2 most frequent comorbidities in 68% and 72% of cases respectively. Diabetes was poorly controlled in 90% of cases. A third of our patients were polymedicated, but only 56% knew their treatment by name. Most of them stored their insulin in the refrigerator (84%), but 50% did not know the shelf life of the insulin vial after opening. When it came to storing insulin on the move, 60% used a plastic bag and 36% an isothermal bag. Proper use of insulin was significantly correlated with female gender.
Conclusion
The association of several co-morbidities has a negative impact on the attitude of our patients towards taking their medication carefully, so good education is essential to limit the risk of errors, which are a source of morbidity and mortality.

Cognitive disorders in T2DM patients: case reports of 152 patients

Benzineb Sara[1], Saloua Elamari[2], Soukaina Laidi[2] & Marouan Fatima[2]
[1]Cheikh Khalifa Bin Zayd Al Nahyan Hospital-University Mohamed VI of Health Sciences, Endocrinology, Casablanca; [2]Cheikh Khalifa Bin Zayd Al Nahyan Hospital-University Mohamed VI of Health Sciences, Endocrinology, Casablanca, Morocco

Introduction
Cognitive decline is recognized as an important comorbidity of diabetes. The aim of this study was to determine the prevalence and predictive factors of cognitive decline in patients with type 2 diabetic patients.
Materials and methods
This was a prospective study including all elderly patients with type 2 diabetes aged between 45 and 75 years with a diabetes duration of more than five years, admitted to the endocrinology department Sheikh Khalifa University Hospital in Casablanca, between February and December 2022, we collected the clinical and metabolic characteristics. Cognitive decline was assessed by the Mini mental state examination and was retained if the score was less than 27.
Results
We included 152 patients. The median age was 64 years, median duration of diabetes was 15 years, 48.68% of patients had cognitive decline. In multivariate analysis, cognitive decline was significantly associated with the presence of diabetic retinopathy OR 0.00 (CI 4.85-0.09), elevated creatinine OR1.29 (CI 1.01-1.64) and the presence of dyslipidemia OR10.87 (CI 69-70.00).
Discussion
It is necessary to consider cognitive decline in diabetic patients because of its impact on disease progression and treatment compliance.

Charcot neuroarthropathy-still an unsolvable issue?

Snezana Vujosevic & Sanja Borozan
Clinical Centre of Montenegro, Department of Endocrinology, Montenegro

Charcot's neuroarthropathy (CN) is a destructive disease of the bone and joints in patients with neuropathy, often found in people with diabetes. Despite being recognized for over 150 years, the early detection and therapeutic approach remain a challenge for physicians. We present a 40-years old women, non-smoker, who was referred to endocrinologist for poorly-controlled type 2 diabetes mellitus (T2DM) and swollen left ankle and foot with sharp, stabbing pain when standing or walking. She denied any local injury. Swelling and redness developed suddenly, with increased local warmth, pain and reduced sensation; she was treated with antibiotics, local antiseptic and anticoagulant therapy for 2 weeks but without any improvement. In past medical history, she had diabetic polyneuropathy for 6 years, proliferative retinopathy, hypertension and dyslipidemia. On hospital admission, the collapse of the midfoot arch (rocker bottom foot) was noted, together with intact skin surface and slightly more diminished pulse in left dorsalis pedis artery. Plain radiograph, CT scan and NMR of the left foot were performed and joint destruction and defragmentation with multiple bone fragments (debris-loose bodies), calcifications in soft tissue around navicular bone and calcaneus, dislocation and altered structure of navicular bone and old calcaneal fracture with irregularly formed callus pointed out to CN. The condition was further managed together with orthopedic doctor using conservative, non-surgical treatment (non-weightbearing) and protective orthosis. Since the first description of CN, the pursuit for the appropriate treatment continues. Anti-resorptive treatment with bisphosphonates (mostly zolendronic acid), calcitonin, recombinant parathyroid hormone (rhPTH) showed some improvement but there is no definitive evidence of better clinical outcomes. Although the sample sizes in studies were small, the published data regarding the use of denosumab are encouraging.

Chronic complications of type 2 diabetes: time from diagnosis to the appearance of complications and the influence of glucoregulation on complications

Tatjana Bačun[1,2], Dunja Šojat[3], Domagoj Šimić[1], Marko Pirić[3] & Ivan Lekić[1,4]
[1]Medicinski fakultet, Department of Internal medicine, Osijek, Croatia; [2]Clinical Medical Center Osijek, Department of Internal Medicine - Endocrinology, Osijek, Croatia; [3]Osijek Health Center, Osijek, Croatia; [4]Dom zdravlja Zagreb - Centar, Zagreb, Croatia

Research objective
To examine the frequency of chronic complications of type 2 diabetes with regard to age, sex, duration of diabetes and glucoregulation.
Subjects and methods
The research included 78 subjects of both sexes with a diagnosis of type 2 diabetes treated in the Health Center of the Osijek-Baranja County. The following data were collected: gender, age, duration of diabetes, type of diabetes therapy and HbA1c, and complications of diabetes.
Results
The research was conducted on 78 patients with type 2 diabetes (T2DM), of which 34 (43.6%) were men and 44 (56.4%) were women. The median age of the subjects is 71 years, and the median duration of T2DM is 8 years. 39.7% had microvascular complications, and 26.9% had macrovascular complications. The most common microvascular complication is diabetic retinopathy (26.9%), followed by diabetic neuropathy (16.7%) and diabetic nephropathy (9%). Cerebrovascular disease (10.3%) is the most common macrovascular complication, followed by cardiovascular disease (5.1%) and peripheral vascular disease (5.1%). No complications were diagnosed in 33.3% of patients. Nephropathy was diagnosed 3 years after T2DM diagnosis,

neuropathy, retinopathy, and coronary artery disease after 5 years, cerebrovascular insult after 6 years, and peripheral vascular disease after 8 years. Patients whose HbA1c values are higher than 7.5% have retinopathy ($P=0.002$), neuropathy ($P=0.03$) and ischemic heart disease ($P=0.02$) more often. In women, the incidence of neuropathy is statistically significantly more frequent than in men ($P=0.004$). Subjects with microvascular complications were significantly older ($P=0.04$), median age 74 years, compared to those without microvascular complications.
Conclusion
Chronic complications in patients with T2DM occur most often in older patients with a longer duration of the disease and poorer regulation of diabetes. A third of the patients had microvascular complications, a quarter of the subjects had macrovascular complications. The most common microvascular complication is diabetic retinopathy, followed by diabetic neuropathy and diabetic nephropathy. Of the macrovascular complications, cerebrovascular disease is the most common, followed by cardiovascular and peripheral vascular disease. Diabetic nephropathy, diabetic retinopathy, diabetic neuropathy and coronary disease were diagnosed in the first 5 years after the diagnosis of diabetes, and cerebrovascular disease and peripheral vascular disease in the second 5 years. Patients with elevated HbA1c more often have retinopathy, neuropathy and ischemic heart disease.
Key words: Type 2 diabetes, Chronic complications, Diabetic retinopathy, Diabetic neuropathy, Diabetic nephropathy

Anemia and diabetic retinopathy in type 2 diabetes mellitus

Hadhemi Belhassen[1,1], Ramla Mizouri, Siwar Saoudi, Rym Ben Othman, Chaima Sdiri, Nadia Ben Amor, Olfa Berriche & Jamoussi Henda
National Institute of Nutrition, A, Tunis, Tunisia

Introduction
Anemia, known as a common complication in diabetic type 2 population, was observed to be an independent risk factor for the development of high-risk proliferative diabetic retinopathy. The aim of our study is to estimate the prevalence of anemia in persons with type 2 diabetes mellitus and its role as a risk factor in the presence and the severity of diabetic retinopathy, in a population based study.
Methods
Descriptive cross-sectional study conducted over 3 months in ward A of The National Institute of Nutrition Tunis which included patients with type 2 diabetes mellitus.
Results
Fourty-four patients were included of whom 27 were women and 17 men. The characteristics of the patients were respectively: age: 57 ± 11.2 years, Body Mass Index: 28 ± 6.5 kg/m^2, HbA1C: 10.39 ± 1.66%. The prevalence of anemia (Hb <12 g/dl in women, and <13 g/dl in men) was 18.2%. The prevalence of diabetic retinopathy which diagnosis is based on the modified Klein classification was 36.4%. In patients with a diabetic retinopathy, 33.33% were diagnosed with an anemia and 66.67% had a normal rate of Hemoglobin. In patients without diabetic retinopathy, 7.69% were diagnosed with anemia. There was no statistically significant correlation between anemia and the risk of development of diabetic retinopathy ($P=0.117$) neither the severity of diabetic retinopathy ($P=0.632$) if diagnosed.
Conclusion
Anemia is important to diagnose in patients with type 2 diabetes mellitus. However, its presence doesn't predispose neither to a high risk of diabetic retinopathy nor to a severe diabetic retinopathy if established.

EP1208

Using hot water for heating in neuropathic diabetics: beware of disasters

Ahmed Boukhalfa, hanane boualam, Sana Rafi, Ghizlane El Mghari & Nawal El Ansari
Mohamed VI University Hospital Center, Marrakech, Morocco, Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakesh, Morocco

Introduction
Diabetic 'neuropathies are a heterogeneous group of disorders with diverse clinical manifestations. Up to 50% of diabetic peripheral neuropathy may be asymptomatic. Glycemic control can effectively prevent diabetic peripheral neuropathy (DPN) in type 1 diabetes (T1D) (1,2) and may modestly slow their progression in type 2 diabetes (3). We report the case of a patient who presented leg burns with no healing making treatment extremely difficult.
Clinical Case
Eighty one years-old patient, diabetic since 34 years treated with insulin, admitted for complicated thermal (contact) burns to the right leg following the use of hot water contained in an unsuitable plastic bottle. Clinically, patient was hemodynamically and respiratorily stable. Examination of the right leg: deep ulceration of the anterior face of the lower third, approx. $10\times6\times1$ cm, with exposed tendons and fibrin deposits with warm red swelling of the homolateral forefoot. Biological tests: capillary glycemia: 5;29 g/l without ketosis, WBC: 11600, CRP: 290 mg/l. A dressing protocol provided by the plastic surgeons was instituted with antibiotic therapy, with no clear improvement and no scarring after 2 months of follow-up. The patient was hospitalized for skin grafting.
Discussion
Symptoms of DPN vary according to the class of sensory fibers involved. The most common early symptoms are induced by the involvement of small fibers and include pain and dysesthesia. The involvement of large fibers may cause numbness and loss of protective sensation (LOPS) and it is a risk factor for diabetic foot ulceration. Near-normal glycemic control, implemented early in the course of diabetes, has been shown to effectively delay or prevent the development of DPN mainly in T1D. Dyslipidemia is a key factor in the development of neuropathy in people with type 2 (4,5). Positive effects of physical activity, weight loss, and bariatric surgery have been reported in individuals with DPN, but use of conventional lipid-lowering pharmacotherapy (such as statins or fenofibrates) does not appear to be effective in treating or preventing DPN development (6). Our patient's long-standing diabetes and inability to feel the high temperature when using hot water, testify to the absence of the sensation of protection and confirm the advanced damage to the essentially large sensory fibers. The absence of healing is evidence of associated vascular damage.
Conclusion
Foot ulcerations and amputations are common complications associated with diabetes especially when there is a triggering mechanism such as burns.
Keywords: DPN, burn, glycemic balance, healing.

Carob powder-enhanced bread: a promoting alternative for the gluten-free diet

Kouloud Boujelben[1], Mohamed Khairi Arous[1], Fatma Mnif[1], Dhoha Ben Salah[1], mouna elleuch[1], Faten Haj Kacem Akid[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Introduction
The gluten-free diet is a challenge not only for the patient and their treating physician but also for specialists in the agro-food industry. Gluten-free breads, especially those made from corn, are reputed to be of lower quality than wheat bread. In this context, we conducted a study to test gluten-free cornbread enriched with carob (GFCEC) in terms of flavor, acceptability, and glycemic index
Methods
This is a prospective study involving a group of healthy Tunisians. Our study included 7 healthy volunteers to investigate the glycemic response. We tested 3 foods: white bread, gluten-free cornbread (GFC) and GFCEC. Each tested food contains 50 g of carbohydrates, which are present in 100 g of white bread, 87 g of GFC, and 60 g of GFCEC. A rating test was employed to assess the tasted products based on a 5-point increasing hedonic scale (1 = extremely unpleasant, 5 = very pleasant) and involved 30 participants. All participants filled out an evaluation form focusing on taste, smell, aftertaste, and overall appreciation. At the end, participants selected their preferred product among the three options.
Results
The average age was 25 ± 10.18 years, and the average Body Mass Index (BMI) was 23.63 ± 5.17 kg/m^2. All 7 volunteers for the glycemic response study were females (100%). The glycemic index of GFC was 61.04%, while that of GFCEC was 40.13%, compared to the reference white bread. GFCEC had the highest percentage of taste preference (85%). The smell of GFCEC was significantly more appreciated ($P<0.001$). The aftertaste of GFCEC was the favorite among the majority of tasters (85%). Overall appreciation of GFCEC was the highest among tasters (85%). GFCEC was preferred by 90% of the participants.
Conclusion
Carob, thanks to its polyphenol-rich fiber content, possesses beneficial metabolic effects, particularly acting as a hypocholesterolemic, anti-hyperglycemic, and antioxidant agent. Its incorporation into GFC could provide both health and hedonic benefits. GFCEC could be a preferred alternative, especially for diabetic patients with celiac disease, for whom dietary management remains a perpetual challenge.

Psychological effects of gpp-1 agonists in the treatment of young overweight patients with type 2 diabetes mellitus (clinical case)

Liana Jashi[1], Tamar Peshkova[2], Tamar Sharashenidze[3], Ketevan Dundua[4], tamar shervashidze[4] & Sophio Beridze[1]
[1]Avicena-Batumi Medical University, Georgia, Medicine, Batumi, Georgia; [2]Batumi Shota Rustaveli state University, Medicine, Batumi, Georgia; [3]Sulkhan-Saba Orbeliani University, Medicine, T'bilisi, Georgia; [4]David Aghmashenebeli University Of Georgia, Medicine, T'bilisi, Georgia

Background
Patient: male, 34 years old, height 32.4 cm (height 182 cm, weight 118 kg), heredity not severe, history of cholecystectomy, depressive background, takes Solian and Lemonex. Bad habits - smokes tobacco, does not drink alcohol. Covid 19 in 2021, vaccinated with 2 doses of Pfizer-BioNTech vaccine. 2023 In May, he was hospitalized with hyperglycemia, where insulin therapy was started: Apidra - 9^{00} - 16IU 14^{00} – 14IU 19^{00} - 12 IU, Lantus 22^{00} - 28 IU, but the glycemic profile ranged from 160 mg% to 270 mg%.
Method
He went to our clinic in September 2023. The main complaints were glycemic variability, weight gain, burning and pain in the extremities, and numbness. Based on the conducted examinations: HbA1c - 8.2% Vitamin D3 - 13.2 ng/ml (> 30ng/ml) Complete blood and urine count Cardioechoscopy with abdominal ultrasound: liver enlarged, thyroid v = 20 ml, echogenicity normal, no nodes present—astigmatism of the eye. Hepatitis is negative, and liver function and lipid metabolism are normal. Free testosterone 7.76 ng/dl (3.03-14.8 ng/dl), GSPG-18,94 mmol/l (17.30-65.80 mmol/l, Cortisol 10.95 μg/dl (4.3-22.4 μg/dl), Creatinine 77.18 μmol/l (62.0) -115.00 μmol/l), SCF-116 ml/min (75-128.00 ml/min), Anti-GAD-antibodies 0.61 U/ml (< 5.0 U/ml), Urea 31.12 mg/dl (15.00-38.50 mg/dl), C-peptide 0.32 nmol/l (0.2-0.8 nmol/l);
Results
Diagnosis: uncontrolled T2DM (A1C >8.2%), obesity (BMI 32.4 kg/m^2), D3 vitamin deficiency. The treatment regimen/lifestyle was changed. Previously, the patient received no dietary recommendations; he was currently obese. The patient realized that excessive carbohydrate intake influenced his glucose control and agreed to improve his eating habits and walk 15–20 minutes twice daily. The treatment regimen changed and was prescribed: Ozempic 0.25 1 time a week (1 month), 0.5 1 time a week (1 month) at 1 mg... titration of the dose by months, simultaneously began to reduce the insulin dose with strict glucose control. In the evening, the patient was added metformin XR 1000 mg. Also, vitamin D3 used 5000 IU per day. A month later, the patient was completely canceled from insulin, he lost 8 kg. Motivation increased, and antidepressants decreased. After 3 months, weight decreased by 32 kg, HbA1c - 6.2%, glycemic profile adjusted, antidepressants discontinued, and the last dose of Ozempic - 1.5 mg. Treatment is ongoing.
Conclusion
Therefore, the proper management of a young patient with diabetes is of great importance; the use of GLP 1 inhibitors in relation to this patient not only reduced weight but also significantly changed his psycho-emotional state.

A rapid action plan to improve diagnosis and management of lipodystrophy

Lindsay Fourman[1], Josivan Lima[2], Vinaya Simha[3], Marco Cappa[4], Saif Alyaarubi[5], Renan Montenegro Jr[6], Baris Akinci[7] & Ferruccio Santini[8]
[1]Massachusetts General Hospital and Harvard Medical School, Metabolism Unit, Boston, MA, United States; [2]Hospital Universitário Onofre Lopes, Universidade Federal do Rio Grande do Norte, Departamento de Clinica Medica, Natal-RN, Brazil; [3]Mayo Clinic, Division of Endocrinology, Rochester, MN, United States; [4]Bambino Gesù Children's Hospital, IRCCS, Research Area for Innovative Therapies in Endocrinology, Rome, Italy; [5]Oman Medical Specialty Board, Pediatric Endocrinology, Muscat, Oman; [6]Federal University of Ceará, Department of Clinical Medicine, Fortaleza, Brazil; [7]DEPARK & Izmir Biomedicine and Genome Center, Izmir, Turkey; [8]University Hospital of Pisa, Obesity and Lipodystrophy Center, Endocrinology Unit, Pisa, Italy

Introduction
Lipodystrophy is a rare disease that can present with a broad range of symptoms. Delays in diagnosis are common, which in turn, may predispose to the development of severe metabolic complications and end-organ damage. Many patients with lipodystrophy are only diagnosed after significant metabolic abnormalities arise.
Aim
Prompt action by clinical teams may improve disease outcomes in lipodystrophy. The aim of the Rapid Action Plan is to serve as a set of recommendations from experts that can support clinicians with limited experience in lipodystrophy.
Methods
The Rapid Action Plan was developed using insights gathered through a series of advisory meetings with clinical experts in lipodystrophy. A skeleton template was used to facilitate interviews. A consensus document was developed, reviewed, and approved by all experts.
Results
Lipodystrophy is a clinical diagnosis. The Rapid Action Plan discusses tools that can help diagnose lipodystrophy. The roles of clinical and family history, physical exam, patient and family member photos, routine blood tests, leptin levels, skinfold measurements, imaging studies, and genetic testing are explored. Additional topics such as communicating the diagnosis to the patients/families and patient referrals are covered. A set of recommendations regarding screening and monitoring for metabolic diseases and end-organ abnormalities is presented. Finally, the treatment of lipodystrophy is reviewed.
Discussion
The Rapid Action Plan may assist clinical teams with the prompt diagnosis and holistic work-up and management of patients with lipodystrophy, which may improve outcomes for patients with this rare disease.

Cardiac insufficiency in morbid obesity

Ifigenia Kostoglou-Athanassiou[1], Lambros Athanassiou[2], Sofia Nikolakopoulou[3], Alexandra Konstantinou[3], Charilaos Samaras[3] & Panagiotis Athanassiou[4]
[1]Asclepeion Hospital, Voula, Department of Endocrinology; [2]Asclepeion Hospital, Voula, Department of Rheumatology; [3]Asclepeion Hospital, Voula, 1st Department of Medicine; [4]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece

Morbid obesity is accompanied by multiple comorbidities and may be associated with a high mortality risk. Cardiac manifestations accompany morbid obesity and may account for the increased morbidity and mortality risk which accompanies the disorder. However, cardiac insufficiency as the first cardiovascular manifestation in morbid obesity is a less recognized comorbidity. The aim was to describe cardiac insufficiency as the first cardiovascular disease manifestation in morbid obesity. A cohort of 10 morbidly obese patients (3 female and 7 male) aged 43.8 ± 6.9 years (mean ± SD) is described. Patients had a MBI of 51.3 ± 3.8 kg/m^2. None of the patients had a history of cardiac disease. Patients presented for evaluation with multiple symptoms, mainly inability to exercise and peripheral edema. They were metabolically evaluated. Mild diabetes mellitus was diagnosed. Cardiological evaluation revealed the presence of cardiac insufficiency. Morbid obesity severely affects quality of life. The disease is difficult to treat and persists. Patients although they may try to lose weight, either they cannot attain their goal, or they may gain weight again. Cardiac insufficiency as the first symptom of cardiovascular involvement in morbid obesity severely affects quality of life and may lead to early mortality. In other studies obesity accompanied by malnutrition has been associated with adverse cardiac remodeling. Patients with morbid obesity should be counseled appropriately on the possible adverse effects of morbid obesity on cardiovascular health and the possibility of early and severe cardiovascular involvement.

Comparison of changes in body anthropometric measurements with medical nutrition treatment of turkish and arab individuals with obesity

Ferhan Mantar[1,1], Rabia Oner Kiliç[1] & Nurseli Gürsoy[1]
[1]Bahçeşehir University, Health Science Faculty, Nutrition and Dietetics, Istanbul, Turkey

Differences in individuals' eating habits affect adherence to diets and the weight management process. Identifying factors that influence the prevalence of obesity is crucial for addressing obesity-related health issues and implementing necessary preventive measures. This study aims to compare the changes in body composition resulting from medical nutrition therapy applied to individuals of Arab and Turkish origin seeking weight loss at a specialized clinic. Additionally, it explores the impact of demographic and sociocultural characteristics, as well as dietary habits, on these changes. In this context, adults aged 20-64 with a BMI > 30 who sought weight loss at a specialized clinic were individually consulted with medical nutrition therapy. The consultations occurred at the initial meeting, followed by sessions with a one-month interval, totaling three months. Weight losses and anthropometric measurements were repeated. The Mann-Whitney U test was used to determine the source of differences in anthropometric measurements at the end of the third month. According to the test results, the differences in measurements between the first and third months were statistically significant for Turkish participants compared to Arab participants, based on mean rank values ($P<0.05$). In conclusion, personalized medical nutrition therapy within the same timeframe yielded better results for Turkish participants compared to Arab participants. The dietary habits and cultural norms of the Arab community had a more adverse impact on the diet process.

Machine Learning-based Online Survival Prediction Tool for Adrenocortical Carcinoma

Emre Sedar Saygili[1], Yasir S Elhassan[2], Alessandro Prete[2], Juliane Lippert[3], Barbara Altieri[4] & Cristina L Ronchi[2]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Faculty of Medicine, Canakkale Onsekiz Mart University, Çanakkale, Turkey; [2]Institute of Metabolism and Systems Research, University of Birmingham, United Kingdom; [3]Institute of Human Genetics, University of Wuerzburg, Germany; [4]Division of Endocrinology and Diabetes, University Hospital of Wuerzburg, Germany

Background
Adrenocortical carcinoma (ACC) is a rare endocrine cancer. We aimed to develop machine learning (ML) models for predicting clinical outcomes of patients with ACC and deploy them as a web-based decision support tool.
Methods
The S-GRAS dataset[1] was used as a training cohort ($n=942$), while the COMBI dataset[2] and new patients were used as a validation cohort ($n=220$). We used S-GRAS parameters previously described[1] for ML models. The PyCaret 3.1.0 ML library in Python was used to create models. The F1 score is calculated as the harmonic mean of sensitivity and precision. We compared sixteen ML models and chose the best by F1 score. Clinical outcomes were defined as 5-year overall mortality (OM), 1-year disease progression (DP), and 3-year DP, respectively.
Results
The study has 579, 968, and 858 patients' data for clinical outcomes, respectively. The study's 5-year OM, 1-year DP, and 3-year DP rates were 55.1%, 39.7%, and 67.6%, respectively (training + validation cohorts). Quadratic Discriminant Analysis (QDA), Light Gradient Boosting Machine (LGBM), and AdaBoost Classifier (ABC) were the best models for predicting clinical outcomes. The F1 scores of the best ML models for the training cohort were 0.79 for OM, 0.63 for 1-year DP, and 0.83 for 3-year DP; while for the validation cohort were 0.72, 0.60, and 0.83, respectively. Sensitivity and specificity for 5-year OM were 77% and 77% in the training cohort and 65%, and 81% in the validation cohort, respectively. Streamlit in Python is used for deploying the models as a website (https://acc-survival.streamlit.app).
Conclusion
We could demonstrate that S-GRAS parameters can predict OM and disease progression with an AUC range of 0.74-0.87. To the best of our knowledge, this is the first ML-based online survival tool for ACC. This app instantly gives the probability of outcomes for patients with ACC based on S-GRAS parameters after resection. Medical professionals could use it in clinical practice to drive personalised management decisions.

Pediatric adrenocortical tumors (pACTs) represent a group of rare entities arising from the cortex of the adrenal gland. The mean patient age at diagnosis is 4,8 years. pACTs are divided into highly malignant pediatric adrenocortical carcinomas (pACCs) and the more benign pediatric adrenocortical adenomas (pACAs), although the exact identification of patients at high risk and the accurate pathological differentiation between pACCs and pACAs remain difficult. Most patients show signs of virilization, Cushing syndrome, or both, and germline variants of *TP53* are common. Complete tumor resection is required to achieve cure, which is particularly difficult in children with advanced disease. In our study, we analyzed DNA methylation data of pACTs from 149 patients and identified four distinct methylation subgroups of clinical relevance: One of which confered a significantly poorer prognosis than the other subgroups, with a 5-year overall survival (OS) of only 27%, while OS in the other subgroups ranged between 81%-95%. Importantly, the high-risk subgroup also contained tumors previously considered as pACA. In addition, we performed single nuclei RNA sequencing (snRNA-Seq) to reveal the biological heterogeneity underlying this disease. The methylation-derived subgroups differed in the composition of regulatory modules (so called meta-signatures), with the high-risk subgroup being enriched for proliferation-related programs (with an upregulation of e.g. *PLK1*, a pharmacologically targetable protein kinase, and *CCNE2*). Other regulatory modules which were enriched in the standard risk ACC groups displayed genes involved in steroidogenesis (such as *SULT2A1*), but also in the detoxification of xenobiotics (such as *CYP2E1*), which may contribute to chemotherapy resistance in these tumors. Performing trajectory analyses, we found that the single cell distribution of pediatric ACC recapitulates the centripetal differentiation of the adrenocortex from Zona glomerulosa to Zona reticularis - with the high-risk tumors displaying more glomerulosa-like transcriptional profiles. In accordance with this, we detected strongly upregulated WNT signaling (mainly through *WNT4*) in these high-risk tumors when performing receptor-ligand analyses. Overall, our study not only sheds light on the intertumoral and intratumoral heterogeneity of pACTs but provides means for improved risk stratification by establishing four distinct subgroups. Moreover, the single cell dissection of these tumors highlights novel drug targets, thus potentially opening new avenues for targeted therapy.

[1]Jan Kochanowski University, Collegium Medicum, Kielce, Poland; [2]Holycross Cancer Center, Endocrinology Clinic, Kielce, Poland; [3]Holycross Cancer Center, Department of Molecular Diagnostics, Kielce, Poland; [4]Jan Kochanowski University, Division of Medical Biology, Institute of Biology, Kielce, Poland; [5]Holycross Cancer Center, Department of Epidemiology and Cancer Control, Kielce, Poland; [6]Holycross Cancer Center, Surgical Pathology, Kielce, Poland; [7]Holycross Cancer Center, Genetic Clinic, Kielce, Poland; [8]Holycross Cancer Center, Clinical Oncology, Kielce, Poland; [9]Kielce, Endocrinology Clinic, Kielce, Poland

Introduction
The *CHEK2* gene is involved in DNA repair. Germline mutations in the *CHEK2* gene impair this mechanism, increasing the risk of various cancers, including papillary thyroid cancer (PTC). There are four different mutation variants in the *CHEK2* gene in the Polish population: three truncating mutations (1100delC, IVS2+1G>A and del53950) and one missense mutation (I157T).
Material
The study included 1,547 PTC patients (1,358 women and 189 men) treated in single center, median age 50 years (range 15-85).
Method
DNA samples from peripheral blood and *CHEK2* mutation genotyping was performed using TaqMan PCR (I157T) or allele-specific PCR and chip electrophoresis (IVS2 + 1G > A del5395, and 1100delC). Detected mutations (I157T, IVS2 + 1G > A, and 1100delC) were confirmed by Sanger sequencing. The patient's age, *CHEK2* mutation type and co-occurrence of other cancers were assessed.
Results
A mutation in the *CHEK2* gene was found in 240 (15.5%). The dominant mutation in the *CHEK2* gene was the missense mutation I157T, found in 189 (12.3%), while the truncating mutation (IVS2+1G>A, del5395, 1100delC) was found in 44 (2.8%). The co-occurrence of two mutations was found in 7 (0.4%) patients. No mutations in the *CHEK2* gene were detected in 1,307 (84.5%) patients. The age of patients with a *CHEK2* mutation at the time of diagnosis ranged from 18 to 76 (mean age 51 years), compared to the age of patients without the mutation - 15 to 85 (mean age 50 years). Other cancers were found in 33/240 (13.8%) patients with *CHEK2* mutations compared to 158/1307 (12.1%) patients without *CHEK2* mutations. The difference was not statistically significant ($P=0.4721$) The most common malignant tumor in women was breast cancer ($n=49$, 30.8%), including 36 (27.9%) without the *CHEK2* mutation, 10 (40.0%) with the I157T missense mutation and 3 (60.0%) with truncating mutation. There was a significant difference ($P=0.0416$) in the incidence of breast cancer in patients with and without the *CHEK2* (any) mutation. The proportion of women with breast cancer with a *CHEK2* mutation (any) was almost twice as high 13 (6.0%) compared to women with breast cancer without a *CHEK2* mutation 36 (3.2%).
Conclusions
1. Mutations in the *CHEK2* gene occur in 15.5% of PTC patients. 2. The occurrence of mutations in the *CHEK2* gene in PTC patients is associated with a higher risk of breast cancer in women, especially in the case of truncating mutation (60%), the most common in the case of del5395.

"Deciphering the genomic complexity of thyroid cancers: an in-depth exploration through pan-exomic analysis using whole exome next-generation sequencing"

Ramesh Bangaraiahgari[1], Rajesh Bangaraiahgari[1], Ramakanth Bhargav Panchangam[2], Udaya Kumar[3], Banala Rajkiran Reddy Banala[4] & Chakrapani Bangaraiahgari[5]
[1]TRR Institute of Medical Sciences, Hyderabad, India; [2]Bhargav Endocare Hospital, Endocrine and Metabolic Surgery, Andhra pradesh, India; [3]Arundathi Institute of Medical Sciences, Pediatrics, Hyderabad, India; [4]Sunshine Hospital, CRL, Hyderabad, India; [5]Chakri Neuro Hospital, Neurology, Nizamabad, India

Background
Thyroid cancers represent a diverse group of malignancies characterized by intricate genomic landscapes, necessitating advanced molecular investigations for a comprehensive understanding of their underlying genetic alterations. This study harnesses the power of Whole Exome Next-Generation Sequencing (WES) to unravel pan-exomic mutations in thyroid cancer samples. The primary objectives include correlating genomic changes with clinicopathologic features and unravelling the intricate mechanisms steering disease onset and progression.
Methods
Raw sequencing data derived from both normal and cancerous thyroid tissues underwent a meticulous analytical pipeline. Leveraging tools such as the NGS QC Toolkit, Burrows-Wheeler Aligner, and GATK, the study commenced with a thorough assessment of read quality. Subsequent steps involved alignment of sequences to the human reference genome (hg19), recalibration of base quality, and calculation of coverage metrics. Somatic variations were identified using MuTect for single nucleotide variations (SNVs) and VarScan for small insertions and deletions (indels). ANNOVAR facilitated comprehensive annotation of the identified variants. Stringent filtering criteria excluded common single nucleotide polymorphisms (SNPs), noncoding variants, and those residing within repetitive genomic regions. Manual validation using the Integrated Genomics Viewer ensured the accuracy of the identified mutations.
Results
The study unveiled significant mutations predominantly in BRAF, CDKN2A, HRAS, NRAS, PI3KCA, RET, RAS, and TP53 genes. Noteworthy common mutations included RET (M918T), NRAS (Q61R), BRAF (V600E), HRAS (Q61R), and a missense mutation in TP53 (c.217 – c.1178). Additionally, a mutation in the KMT2D gene was identified in one patient sample, introducing an intriguing aspect to the genomic landscape.
Conclusion
This research significantly contributes to the evolving field of thyroid cancer genomics. By identifying prevalent mutations and indicating the need for ongoing efforts to detect rare mutations, our findings underscore the complexity of these cancers. The discerned genomic landscape not only advances scientific understanding but also lays the groundwork for the potential integration of precision medicine into thyroid cancer diagnosis and treatment strategies. The structured approach offers a comprehensive overview of the research methodology, key findings, and their broader implications.

Paraneoplastic hypoglycemia

Mouna Elleuch[1], Yassmine Abdelkafi[1,1], Khouloud Boujelben[1], Faten Hadjkacem[1], Rihab Khochtali[1], Souhir Maalej[1], Nadia Charfi[1], Fatma Mnif[1], Mouna Mnif[1], Dhoha Ben Salah[1], Mohamed Abid[1] & Nabila Rekik[1]
[1]CHU Hedi Chaker, Endocrinology, Tunisia

Introduction
Non-Islet Cell Tumor Hypoglycemia (NICTH) is a rare but serious condition. We report a case of NICTH in a patient with a gastrointestinal stromal tumor.
Observation
The patient was a 56-year-old with a history of metastatic gastrointestinal stromal tumor (GIST), diagnosed and operated on in 2016. He received tyrosine kinase inhibitors: Imatinib for 5 years, followed by sunitinib with two courses, and was later declared in palliative care due to tumor progression. He was admitted to the endocrinology department for exploration of recent severe hypoglycemic episodes occurring unexpectedly at any time of the day, with a capillary blood glucose level of 0.15 g/l at admission. Iatrogenic causes were ruled out through questioning, and general pathologies were eliminated based on normal test results. Hormone counter-regulation deficiencies were also excluded. Endogenous hyperinsulinism was refuted with insulin levels at 1 mIU/l, a collapsed C-peptide level at 0.04 ug/l, and a concurrent venous blood glucose level of 2 mmol/l. IGFII level was normal at 444 ng/ml, while IGFI level was suppressed at 30.5 ng/ml. NICTH was confirmed with an IGFII/IGFI ratio > 10. The patient was treated with corticosteroids at a dose of 80 mg/day in four divided doses (20 mg× 4/day). The course of the disease showed a decrease in the frequency and severity of hypoglycemic episodes. However, the patient succumbed to the progression of his illness one month later.
Discussion
NICTH is attributed to the secretion of an abnormal IGFII molecule, mainly by malignant tumors such as mesenchymal tumors. This molecule, called BIG IGFII immature, has a threefold stronger effect than mature IGFII. It binds to the insulin receptor, leading to its hypoglycemic effect. Diagnosis is established with an IGFII/IGFI ratio greater than 10. Treatment involves tumor excision, dietary measures to increase caloric intake and the number of snacks, along with

corticosteroid therapy at the minimum effective dose. Combining with rhGH (recombinant human growth hormone) may assist in minimizing the doses and side effects of each treatment.

Insulin autoimmune syndrome due to alpha lipoic acid: a case report

Safiye Kızışar Yılmaz[1], Bilge Dibeklioğlu[1], Kübra Durmuş Demirel[1], Neslihan Çuhacı Seyrek[2], Oya Topaloğlu[2], Reyhan Ersoy[2] & Bekir Çakır[2]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Turkey; [2]Ankara Yıldırım Beyazıt University, Endocrinology and Metabolism

Insulin autoimmune syndrome is a condition characterized by production of autoantibodies against insulin. Drugs are one of the ethiological factors, especially when they contain the sulfydryl group such as methimazole and alpha lipoic acid. Herein we present a case report of insulin autoimmune syndrome due to alpha lipoic acid. A 77 year-old female patient presented to emergency department with syncope because of hypoglycemia. She was diagnosed with type 2 diabetes mellitus a year ago. Metformin and gliclazide was prescribed. During her follow-up, she had complaints of neuropathy, so alpha lipoic acid was added to her treatment. She also had autoimmune thyroid disease but didnot need for levothyroxine replacement. When she was questioned it was learned that she hadnot been taking metformin and gliclazide aproximately for 2 weeks, but she continued to take alpha lipoic acid. During a hypoglycemic episode insulin and c-peptide levels were examined and was compatible with hyperinsulinemic hypoglycemia. Anti-insulin antibody titer was high. She was considered to have insulin autoimmune syndrome due to alpha lipoic acid. Alpha lipoic acid was stopped, afterwards hypoglycemia was ceased, anti-insulin antibody titer decreased accordingly. There are several case reports of insulin autoimmune syndrome presented in literature due to intake of alpha lipoic acid. All of the cases had autoantibodies against insulin at presentation, cessation of hypoglycemia and deacrease of anti-insulin antibody titer after discontinuation of alpha lipoic acid. There are certain HLA allels which causes predisposition to this syndrome. Also these patients have higher incidance of other autoimmune diseases. If a patient who takes a drug containing sulfydryl group and has any of the autoimmune diseases presents with hyperinsulinemic hypoglycemia, insulin autoimmune syndrome must be considered.

"Quantitative RT-PCR profiling reveals the regulatory landscape of miRNAs (miRNA-149-5p, miRNA-548c-3p, miRNA-3619-3p) in anaplastic thyroid cancer: implications for progression and metastasis"

Ramesh Bangaraiahgari[1], Rajesh Bangaraiahgari[1], Ramakanth Bhargav Panchangam[2], Udaya Kumar[3], Rajkiran Reddy Banala[4] & Chakrapani Bangaraiahgari[5]
[1]TRR Institute of Medical Sciences, Hyderabad, India; [2]Bhargav Endocare Hospital, Endocrine and Metabolic Surgery, Andhra pradesh; [3]Arundathi Institute of Medical Sciences, Pediatrics, Hyderabad; [4]Sunshine Hospital, CRL, Hyderabad, India; [5]Chakri Neuro Hospital, Neurology, Nizamabad, India

Objective
Anaplastic Thyroid Cancer (ATC) represents a formidable challenge in oncology due to its aggressive nature and high metastatic potential. This study delves into the quantitative assessment of microRNAs (miRNAs), specifically miRNA-149-5p, miRNA-548c-3p, and miRNA-3619-3p, to elucidate their roles in ATC progression and metastasis. Employing the robust technique of quantitative Reverse Transcription Polymerase Chain Reaction (RT-PCR), we meticulously examine the expression profiles of these miRNAs in ATC tissues, juxtaposed against adjacent normal thyroid tissues. Our findings reveal distinct and quantifiable alterations in the expression levels of miRNA-149-5p, miRNA-548c-3p, and miRNA-3619-3p in ATC, providing valuable insights into their potential as diagnostic and prognostic markers. Furthermore, the study employs RT-PCR to quantitatively assess the impact of these miRNAs on key cellular processes integral to cancer progression, such as proliferation, invasion, and metastasis.
Material and Methods
miRNA-149-5p, miRNA-548c-3p, miRNA-3619-3p expression was analyzed in ATC tissue and whole blood by Real-Time Quantitative Polymerase Chain Reaction.
Results
The investigation extends to delineating the regulatory influence of the selected miRNAs on target genes associated with ATC pathogenesis. Through quantitative analyses, we unravel the intricate molecular mechanisms underlying the suppressive effects of miRNA-149-5p on cell proliferation, as well as the regulatory roles of miRNA-548c-3p and miRNA-3619-3p in modulating cellular migration and invasion. The quantitative RT-PCR data presented herein not only contribute to a comprehensive understanding of miRNA involvement in ATC but also lay the foundation for potential therapeutic interventions. The precise quantification of miRNA expression provides a basis for developing targeted therapeutic strategies aimed at modulating these molecular regulators, thereby offering new avenues for personalized treatment approaches in the pursuit of mitigating ATC aggressiveness.
Conclusion
This study, leveraging the quantitative power of RT-PCR, advances our understanding of miRNA-mediated mechanisms in ATC, presenting a promising framework for future research and therapeutic exploration in the field of precision medicine.

Introduction
Recently, the incidence of thyroid carcinoma (TC) has been increasing rapidly worldwide and caused with significant increase in detection of papillary thyroid microcarcinomas (PTMC), especially among young women. Most authors associate the high incidence of microcarcinomas with improved quality of diagnosis and medical supervision of population. The clinical course of microcarcinomas can be different, which gives rise to many controversies regarding their diagnosis and treatment.
Objective
The aim of the study was to assess the experience of diagnosis and management of patients with PTMC in Republican Clinical Oncological Dispensary (RCOD) of the Ministry of Health of the Republic of Tatarstan (Kazan, Russia) in the period from 2020 to 2022.
Materials and Methods
42 patients with PTMC, treated in RCOD between 2020 and 2022, were included in this study. This accounted for 4.35% of total number of patients, operated for TC over these years (966 people).
Results
There were 36 women (85.7%), aged from 21 to 83 years and 6 men (14.3%), aged from 28 to 67 years. Patients aged 45 and older accounted for 57.1% (24), fertile-age female patients - for 41.7% (15). PTMC was an accidental finding during thyroid ultrasound in most cases with EU-TI-RADS 4 and 5 in 78.6% of patients. Thyroid cytopathology reported Bethesda V and VI in 75.5% of patients. 15 patients (33.3%) underwent hemithyroidectomy with isthmusectomy, including one with central lymph node dissection (LND). Thyroidectomy was performed in 27 patients (66.7%), including 15 patients with LND (55.5%): 13 -

with central, 2 - with central and lateral. Papillary thyroid cancer was verified histologically in 100% of cases, including follicular variant in 3 patients (7.4%). Capsular invasion was found in 15 patients (35.7%), regional metastases – in 8 (19%). Combination of capsular invasion with regional lymph node metastases was diagnosed in 5 of 8 patients (62.5%). No distant metastases were detected. Tumor size up to 0.5 cm was detected in 4.7% (2), from 0.6 cm to 1 cm – in 95.3% (40) of cases. Multifocal tumor growth occurred in 6 patients (14.3%). In two of them (33.3%), multifocal microcarcinoma growth was combined with regional lymph node metastases. 12 patients (28.6%) underwent radioiodine therapy. All patients are alive without disease recurrence.
Conclusion
PTMC often affects fertile-age women (41.7%). 19% of patients had regional lymph node metastases, 35.7% - capsular invasion, 14.3% - multifocal tumor growth. Papillary microcarcinoma requires timely diagnosis and radical treatment.

Introduction
Immune checkpoint inhibitors (ICIs), are widely used as therapeutic option in oncological patients. However, ICIs treatment is often complicated by endocrinological adverse events, such as hypophysitis. Although diagnostical approach of hypophysitis is standardized, imaging features have not been characterized yet.
Methods
Pituitary gland magnetic resonance imaging (MRI) findings were retrospectively recorded in 59 oncological patients with ICI-induced hypophysitis. Patients with cerebral or pituitary metastases were excluded. 59% of patients were treated with PD-1/PDL-1, 8% with CTLA-4, and 33% with combined PDL-1/PD-1 and CTLA-4 therapy.
Results
First MRI assessment was performed at a median time of 12 months from ICI initiation. Pituitary MRI abnormalities were described in 29 (49%) patients. Abnormal MRI findings included microadenoma ($n=8/59$, 14%), increased dimensions with heterogeneous enhancement of the pituitary gland ($n=7/59$, 12%), partially empty sellar ($n=8/59$, 14%), cyst at the adeno-neuropituitary border ($n=2/59$, 3%), reduced size of the pituitary gland ($n=1/29$, 2%), slight deviation of the pituitary peduncle with submergence in the sellar ($n=1/59$, 2%), thickening of the lower peduncle of the pituitary gland ($n=1/59$, 2%) and pathological tissue in sellar (possibly inflammation) ($n=1/59$,2%). Seven patients had a second MRI performed at a 17 months median time from the first MRI. Four patients presented with stable MRI findings. From the remaining patients, one with a microadenoma showed a partially empty sellar turcica, another one with a normal initial MRI also had a partially empty sellar turcica, and the last one with thickening of the pedicle, showed increased dimensions of the gland. Twenty patients out of 29 with an abnormal MRI presented an affected corticotrophin axis. 69% ($n=6/19$) of them represented mostly pituitary microadenomas. Five patients out of 29 presented with corticotropin and thyrotrophic axis deficiency and the last 4 patients had 3 axis insufficiency (corticotrophin, thyrotropin and gonadotrope). Although hypophysitis was biochemically reversible in 6 out of 59 patients, MRI pathological findings persisted in 5 of them even after pituitary-axes restoration after a median follow-up 37 months.
Conclusion
An abnormal MRI was found in 49 % (29/59) of patients with ICI-induced hypophysitis. Microadenoma and empty sella were the commonest findings (28% of the cases). In some cases, MRI abnormalities persisted even after restoration of the pituitary axes.

Tumor behaviour in neuroendocrine tumors (NETs) of unknown primary versus known primary site location

Calin Cristiana[1,2], Ramona Dobre[1,2], Iulia Florentina Burcea[1,2], teodor constantin[1] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders Department, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Endocrinology Department, Bucureşti, Romania

Introduction
While most of neuroendocrine tumors (NETs) primary sites are discovered, NETs of unknown primary are not entirely uncommon in the clinical setting. The primary site is a significant factor in terms of overall prognosis. The aim is to determine whether NETs of unknown primary site location (NET-USs) have more aggressive behavior than those with a known primary location.
Matherials and Methods
We retrospectively studied 50 consecutive patients with NETs, who presented in our clinic between 2018 and 2023: 9 patients with NET-USs and 41 patients with well-differentiated, gastroenteropancreatic neuroendocrine tumors (GEP-NETs, 16 patients with pancreatic NETs).
Results
The incidence of NET-USs was 18% ($n=9$). The median age at diagnosis and duration of disease in the NET-USs patients were 55 $\pm$15.9 years, respectively 4.5$\pm$3.8 years, compared to 62$\pm$11.2 years, respectively 5$\pm$5.6 years in GEP-NETs patients. At the time of diagnosis, 66.7% of NET-USs patients presented with distant metastases (mainly hepatic - 88%), versus 31.7% of patients with known primary. Majority of NET-USs patients underwent 68Ga-DOTATATE PET/CT or 99mTc-Octreotide SPECT/CT, with no origin discovered, only high uptake in hepatic metastases. Incidence of multiple organ metastases was 11.1% in NET-USs patients, respectively 31.7% in the known primary group. All patients with NET-USs received treatment with somatostatin analogues (SSAs), and one underwent hepatic metastases removal, while patients with known primary received, in addition to SSAs, more aggressive regimens, systemic therapy (chemotherapy, Everolimus, Sunitinib) and liver metastases-targeted therapies (PRRT, chemoembolization). Median progression free survival was 38 months in NET-USs patients compared to 30 months in GEP-NETs patients. At the last evaluation, 33.3% of NET-USs patients and 36.6% of patients with known primary presented progressive disease, according to RECIST criteria. No death was registered in NET-USs subgroup, while 5 deaths occurred in the GEP-NETs patients, with an overall survival of 60 months.
Conclusions
Althought the majority of studies in the literature postulated that patients with unknown primary site exhibit markedly poor prognosis, we showed similar outcomes in both subgroups. In fact, in our serie, NETs with known primary site showed a greater tendancy for multiple organ involvement, respectively more agressive regimens were needed to acquire disease control, nevertheless expressed a poorer progression free survival compared with NET-USs, most likely due to a higher tumor burden.

A rare case of functioning adrenocortical carcinoma: attaining the balance between deep vein thrombosis, pulmonary embolism and post-operative hemorrhage

Ada Teo[1], Pei Chia Eng[1], Rajeev Parameswaran[2], Michelle Poon[3], Run Ting Chin[1], Chin Meng Khoo[1] & Doddabele Deepak[1]
[1]Division of Endocrinology, Department of Medicine, National University Hospital, National University Health Systems, Singapore; [2]Division of Endocrine Surgery, Department of Surgery, National University Hospital, National University Health Systems, Singapore; [3]Department of Hematology-Oncology, National University Hospital, National University Health Systems, Singapore

Background
Adrenocortical carcinomas (ACC) are rare aggressive tumors occurring at a rate of less than two per million per year. Uncommonly, there can be intravascular extension into renal veins and inferior vena cava (IVC), with resultant poorer prognosis.
Clinical Case
A 26-year-old woman was referred for investigation of a two-month history of persistent left-sided abdominal pain - Computed tomography (CT) revealed a heterogeneous 12 cm left adrenal mass with thrombosis of left renal vein and IVC. On suspicion of ACC, biochemical tests showed combined hypercortisolism and

hyperandrogenism (unsuppressed 1 mg dexamethasone overnight test 546 nmol/l [$n<50$], midnight salivary cortisol 364 ng/dl [$n<100$], DHEA 50.59 µmol/l [$n<13.9$], testosterone 12.4 nmol/l [$n<1.9$], ACTH <0.7 pmol/l [1.6-13.9]). Further imaging by ^{18}F-FDG-PET-CT showed no distant metastasis. As the imaged thrombus was heterogeneous with high FDG avidity (Standard uptake volume SUV_{max} 19.6, compared to tumor SUV_{max} 23.1), it was determined as tumor thrombus instead of bland thrombus. Therefore, only prophylactic dose subcutaneous enoxaparin 40 mg daily was administered. Whilst awaiting curative resection, she developed lower limb deep vein thrombosis over the left common, internal and external iliac veins. Doppler ultrasound features suggested bland thrombus this time, with repeat CT revealing new pulmonary embolism. Anticoagulation was then escalated to therapeutic dose enoxaparin 1 mg/kg twice-daily until the day before surgery. The patient underwent enbloc left adrenalectomy, left nephrectomy, caval thrombus resection with mechanical thrombectomy of IVC and iliac thrombus. Intra-operatively, embolic protection discs were also deployed into the suprahepatic segment of IVC. Histopathology was consistent with ACC, with Ki67 index of 25%. The post-operative process was complicated by anterior abdominal wall hematoma. In view of ongoing need for anticoagulation, prophylactic embolisation of inferior epigastric and iliac arteries was carried out. 48h post-embolisation, therapeutic dose enoxaparin was restarted. However, 2 months later, she experienced hemorrhagic shock with hemoglobin level of 5.4 g/dl ($n>11.5$g/dl). Abdominopelvic CT then showed a large 14.5 cm hematoma, but with concomitant thrombosis of right renal vein, adjacent IVC, splenic infarct and spinal cord infarct.

Conclusion

This interesting case highlights the importance of recognising ACC as a hypercoagulable state-due to direct tumor invasion, tumor thrombi or secondary to hypercortisolism. Clinicians should be aware of this unique sequence of progression and associated complications. Recognition of venous invasion has clinical significance and management implications, highlighting the value of radiological modalities in differentiating tumor thrombus from bland thrombus. Timely implementation of anticoagulation is crucial and should be a tailored regimen considering individual risk factors and surgical plans.

EP158

A new kind of hypophysitis: adverse effect of ICPIs

Belvis Torres Arroyo[1], Ana Martinez[1], Carolina Suarez[1], Gonzalo Maldonado[1], Jose Gomez[2], Miguel Angel Valero[1], Ivan Quiroga[1] & Benito Blanco[1]

[1]Hospital General Universitario Nuestra Señora del Prado, Endocrinology, Talavera de la Reina, Spain; [2]Hospital General Universitario Nuestra Señora del Prado, Oncology, Talavera de la Reina, Spain

Introduction

Hypophysitis is a rare disease. Lately, it is more frequent due to the use of Inmune Check Point Inhibitor (ICPIs). Ipilimumab or combo Ipilimumab + Nivolumab are the main cause. Agree with literature, 17-18% of the patients with these drugs suffer from. By contrast, with Idiopatic Autoimmune Hypophysitis and Lymphocytic Hypophysitis, this type of hypophysitis occurs in sixties men. Autoinmunity mechanism is known, but precise pathophysiology is unclear

Case

A seventy-four years old man diagnosed renal carcinoma (T3NxMx) seven years ago. In 2023, a progression lymphatic nodal mediastinal and lung micrometastasis were confirmed. Consequently, he received first line treatment with Ipilumab-Nivolumab. Twelve weeks later, previous to filth cycle, he had a syncopal crisis with hypotension and bradycardia. Moreover, the patient referred to feel cold, mental slowing, constipation and visual disturbances one month ago. Also, sickness and weakness two weeks ago. Urgently stress dose of Hydrocortisone was started. Finally, analytics confirmed the diagnosis: 0,1 mg/dl cortisol, Na 133,4 mmol/l, K 3,51 mmol/l. TSH 0,06 mcUI/ml, T4L 0,93 ng/dl, T3L 4,54 ng/dl. Rest of pituitary hormones are regular. So, Levotiroxina was started too. Magnetic Resonance showed pituitary enlargement. One month later, the patient refers visual deficit had corrected. Overall status of the patient is better and blood pressure is normal. In the analytics, hypocortisolism and hypothyroidism are with replacement treatment correctly. Three months later, Magnetic Resonance showed pituitary smaller and partial empty sella. On the other hand, lung micrometastasis disappeared and lymphatic nodal mediastinal were stabled. So, the patient received fifth cycle of Ipilimumab-Nivolumab

Conclusion

- Nowadays, hypophysitis is more frequent in Oncology Patients.
- The main immune-related adverse effects (IrAE) produced by CTLA-4 inhibitor (Ipilumumab) is hypophysitis
- According to literature, Hypophysitis secondary to Ipilimumab-associated is a clinical entity distinct from anti-PD-1 hypophysitis (Nivolumab, Pembrolizumab)
- In our case the diagnosis did when four treatment cycles were received, according to literature.
- Hormonal deficiency more frequent is ACTH, followed to TSH and FSH/lH
- IrAE due to Ipilimumab-Nivolumab need hormonal treatment by long term, permanently in most cases.
- Recognition and timely diagnosis of these patients avoid unnecessary potential effects on morbidity and mortality from untreated adrenal insufficiency and stopping ICPIs

Clinical and pathological predictors of death for adrenocortical carcinoma

Eduardo Pato[1], Victor Srougi[1], Claudia Zerbini[2], Felipe Ledesma[3], Fabio Tanno[1], Madson Almeida[4], William Nahas[1], Ana Claudia Latronico[4], Berenice Mendonca[4], Jose Chambô[1] & Maria Candida Fragoso[4]

[1]Hospital das Clínicas, University of São Paulo School of Medicine, Division of Urology, São Paulo, Brazil; [2]Hospital das Clínicas, University of São Paulo School of Medicine, Division of Pathology, São Paulo, Brazil; [3]Hospital das Clínicas, University of São Paulo School of Medicine, Division of Pathology, São Paulo, Brazil; [4]Hospital das Clínicas, University of São Paulo School of Medicine, Division of Endocrinology, São Paulo, Brazil

Adrenocortical Carcinoma (ACC) is a rare and lethal disease with a poor prognosis. This study aims to share our 41-year experience as a referral center, focusing on identifying risk factors associated with ACC mortality. Our retrospective analysis included a cohort of 150 adult patients with ACC in all stage categories, treated between 1981 and 2022. Tumor hormonal hypersecretion was observed in 78.6% of the patients, and the median age of diagnosis was 40 years. The majority presented as ENSAT III or IV (22.9% and 31.2%, respectively), and the overall mortality rate was 54.6%. Independent predictors of death were elevated secretion of cortisol (HR = 2.0), androstenedione (HR = 2.2), estradiol (HR = 2.8), 17-OH progesterone (HR = 2.0), and 11-deoxycortisol (HR = 5.1), higher Weiss (HR = 4.3), modified Weiss (HR = 4.4), and Helsinki scores (HR = 12.0), advanced ENSAT stage (HR = 27.1), larger tumor size (HR = 2.7), higher Ki-67% (HR = 2.3), and incomplete surgical resection (HR = 2.5). Mitosis >5/50HPF (HR = 5.6), atypical mitosis (HR = 2.3), confluent necrosis (HR = 15.4), venous invasion (HR = 2.8), and capsular invasion (HR = 2.4), were also identified as independent predictors of death. Knowing the risk factors for ACC's mortality may help determine the best treatment option.

Translaryngeal ultrasound (TLUS) as a novel method of vocal folds evaluation in patients undergoing neck surgery

Sylwia Wolff[1], Adam Gałązka[1] & Marek Dedecjus[2]

[1]National Oncology Institute of Maria Sklodowska-Curie – National Research Institute, Department of Endocrine Oncology and Nuclear Medicine, Warsaw, Poland; [2]National Oncology Institute of Maria Sklodowska-Curie – National Research Institute, Department of Head and Neck Cancers, Warsaw, Poland

Introduction

One of the most serious complications after thyroid surgery is dysfunction of the recurrent laryngeal nerve (RLN). RLN damage leads to disorders of the vocal folds (VFs). The "gold standard" method in VFs assessment is laryngoscopy, which causes significant discomfort to patients, requires consultation with an ENT specialist and additional equipment.

Purpose

The aim of the study was to prospectively evaluate translaryngeal ultrasound (TLUS) in the assessment of VFs function in patients after thyroid, parathyroid and neck lymph node surgeries. An additional goal was to identify preoperative and intraoperative factors that increase the risk of RLN damage.

Methods

The prospective study included a total of 219 patients who underwent 230 surgical operations. Patients' vocal folds were analyzed independently by both TLUS and laryngoscopy before and after surgery. Additional variables obtained during TLUS were assessed, such as vocal fold displacement velocity (VFDV), arytenoids symmetry and more. In addition, a questionnaire was conducted to assess the discomfort experienced by patients during the examination with both

methods. A multivariate analysis of prognostic factors for the occurrence of RLN dysfunction was performed.
Results
Thyroid cancer surgeries constituted 85% of all procedures. The incidence of RLN injury was 10.4% in all patients and 11.7% in the oncological subgroup. There were 1.7% transient and 8.7% permanent RLN injuries. The accuracy of TLUS compared to laryngoscopy was 98.3%, sensitivity 98.1%, specificity 100%. Laryngoscopy caused significantly more discomfort than TLUS. Detection of VFs in the whole group using TLUS was 94%. VFs were visualized in more women (99.0%) than men (76%). VFs visibility was lower among males, smokers, patients with higher BMI, multifocal cancer, higher left thyroid lobe volume. VFDV was lower for the vowels "a" and "e" on the right and "e" on the left side after RLN injury. Among patients with RLN damage TLUS more often showed VFs and arytenoids asymmetry and crescendo-decrescendo Doppler wave pattern. Factors contributing to RLN dysfunction included: lateral nodes metastases and theirs dissection, lymph nodes involvement and RLN entrapment to the tumour.
Conclusions
TLUS in a majority of cases can adequately assess whether the function of the VFs is intact or paresis/paralysis has occurred. It is non-invasive and rapid. It adds no extra cost and can be a part of the preoperative examination of the thyroid gland. TLUS in VFs assessment before and after thyroid surgery is a highly accurate tool and in most patients was not inferior to laryngoscopy.

Proteins and peptides from granin family in patients with adrenal incidentalomas and PPGLs

Alicja Szatko[1,2], Dorota Leszczynska[1], Nadia Sawicka-Gutaj[3], Barbara Bromińska[3], Urszula Ambroziak[4], Lucyna Papierska[1], Marta Araujo Castro[5,6], Henrik Falhammar[7,8], Wojciech Zgliczyński[1] & Piotr Glinicki[1,2]
[1]Department of Endocrinology, Centre of Postgraduate Medical Education, Warsaw, Poland; [2]EndoLab Laboratory, Centre of Postgraduate Medical Education, Warsaw, Poland; [3]Department of Endocrinology, Metabolism and Internal Medicine, Poznań University of Medical Sciences, Poznań, Poland; [4]Department of Internal Medicine and Endocrinology, Medical University of Warsaw, Warsaw, Poland; [5]Endocrinology & Nutrition Department, Hospital Universitario Ramón y Cajal & Instituto de Investigación Biomédica Ramón y Cajal (IRYCIS), Madrid, Spain; [6]University of Alcalá, Madrid, Spain; [7]Department of Endocrinology, Karolinska University Hospital, Stockholm, Sweden; [8]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

Introduction
Adrenal incidentalomas are tumors incidentally discovered on imaging tests. Regarding functionality, although 75% of adrenal incidentalomas are non-functioning cortical adenomas (NFAA), there is a subset of adrenal incidentalomas associated with important clinical consequences: adrenocortical cancer (ACC), pheochromocytoma (PHEO, together with paraganglioma (PGL) referred as PPGL), primary aldosteronism (PA), mild-autonomous cortisol secretion (MACS) and Cushing syndrome (CS). The granin family consists of numerous proteins and derived peptides. The aim of this project was to evaluate the clinical usefulness of various proteins/peptides from the granin family in the diagnostics of patients with adrenal incidentalomas and PGLs.
Materials and methods
80 patients with various adrenal tumors (PHEO, PA, ACC, MACS, CS, NFAA) and PGL were enrolled in the study. Plasma/serum concentrations of selected proteins/peptides were determined in all patients: Chromogranin A and derived peptides: Pancreastatin, Serpinin, WE-14, Catestatin, Vasostatin-2, and Chromogranin B, Secretogranin II and Secretoneurin. The concentration of the tested proteins and peptides in serum/plasma were determined by the ELISA/EIA method.
Results
The following results of tested biomarkers differentiating individual syndromes (PHEO, PGL, PA, ACC, MACS, CS) against patients with NFAA were obtained: PHEO vs NFAA: CgA ($P=0.005$), Vasostatin-2 ($P=0.019$), Secretoneurin ($P=0.002$), and SgII ($P=0.001$). PA vs NFAA: Pancreastatin ($P=0.039$). PGL vs NFAA: Secretoneurin ($P=0.021$), and SgII ($P=0.002$). ACC vs NFAA: Serpinin ($P=0.044$). CS vs NFAA: Serpinin ($P=0.011$), Pancreastatin ($P=0.045$), Secretoneurin ($P=0.039$), and SgII ($P<0.001$). MACS vs NFAA: SgII ($P=0.011$). Usefulness of the biomarkers tested in differentiating between the two groups of patients with hypercortisolemia, was not demonstrated.
Conclusions
The obtained results showed different usefulness of the tested proteins and peptides from granin family: CgA (PPGLs), Secretoneurin (PPGLs, CS, PA), SgII (PPGLs, CS), Pancreastatin (PA, CS), Vasostatin-2 (PPGLs) and Serpinin (ACC).

EP199

A rare case of encapsulated medullary thyroid cancer

Emin Mammadov[1], Ionut Bogdan Sandu[1], Dana Terzea[2] & Mihai Ciprian Stoicea[1]
[1]Regina Maria Private Healthcare Network, Bucureşti, Romania; [2]Onco Team Diagnostic, Bucureşti, Romania

Background
Medullary thyroid carcinoma (MTC) is a rare thyroid tumor (around 2% of thyroid cancers). Its prognosis is generally worse than for differentiated thyroid cancers. A very rare subset of MTC is described as encapsulated MTCs. To date, a limited number of case reports and case series have been published, and this type of tumor presents with no evidence of metastases even in case of very high levels of serum calcitonin.
Case
A 33-year old pregnant woman, diagnosed incidentally with a suspicious nodule in the right thyroid lobe (taller-than-wide, hypoechoic, well-defined, regular border). She also had slightly elevated serum calcitonin 20 pg/ml, which increased to 27 pg/ml in 4 weeks, along with slightly increased CEA 5.08 ng/ml, and FNAB was performed. The cytological result was benign (Bethesda II). She returned to our clinic at 3 months post-partum with a calcitonin level of 36 pg/ml and increased anxiety, her thyroid nodule had less suspicious appearance (wider-than-tall, more anechoic zones). She underwent a core-needle biopsy with a result suggesting a Hürthle-cell neoplasm (KTA-CNB IVc). The next step was a diagnostic right hemithyroidectomy with a pathology report suggesting a benign follicular lesion with some atypia. Hence, the IHC (immunohistochemistry) was performed and revealed a low-grade encapsulated MTC, follicular variant with Ki-67 1%, CK-19 and CD-56 positive, Thyroglobulin and Galectin-3 negative, Calcitonin, CEA, Chromogranin-A positive. Postoperatively, the patient had undetectable calcitonin, normal CEA (1.26 ng/ml), no pathological findings on neck ultrasound (no nodular lesions in her left thyroid lobe, no suspicious lymph nodes in central or lateral neck) . The endocrinologist's advice was to test for hereditary RET mutations, as well as somatic mutations and to follow up with neck ultrasound and calcitonin measurements. The surgeon advised her to opt for total thyroidectomy and the patient's decision was to avoid any risk and undertake surgery. A contralateral lobectomy with ipsilateral lymph node dissection were performed to minimize any risk and better stage the disease. Postoperative pathology did not reveal any foci of thyroid cancer in the left lobe and no lymph node metastases.
Conclusion
This case reflects the importance of the multidisciplinary team discussion. Logistic and financial difficulties in genetic testing also contributed to patient's decision to choose the second surgery. We probably need more data on these tumors to be able to classify them as benign (adenoma?) or very low-risk tumors which could reduce anxiety of the patients and doctors.

Chromogranin A (CgA) in patients with pheochromocytomas and paragangliomas (PPGLs)

Piotr Glinicki[1,2], Alicja Szatko[1,2], Jan Calissendorff[3,4] & Henrik Falhammar[3,4]
[1]Department of Endocrinology, Centre of Postgraduate Medical Education, Warsaw, Poland; [2]EndoLab Laboratory, Centre of Postgraduate Medical Education, Warsaw, Poland; [3]Department of Endocrinology, Karolinska University Hospital, Stockholm, Sweden; [4]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden

Introduction
Pheochromocytomas (PHEO) and paragangliomas (PGL) - (PPGLs) are neuroendocrine tumors derived from chromaffin cells of the adrenal medulla or extraadrenal nonchromaffinic tissue, respectively. PPGLs occur in 0.05% to 0.1% of patients with secondary hypertension. Chromogranin A (CgA) is the main non-specific biomarker of neuroendocrine tumors. It is produced and secreted into the blood by endo- and neuroendocrine cells of various organs (e.g., adrenal glands). The sensitivity of the determination of this biomarker in the diagnosis of pheochromocytoma exceeds 80%-90%. Current immunoassays for the determination of CgA concentrations in the blood differ from each other, e.g. they recognize different fragments of CgA, are calibrated differently, and use different antibodies (monoclonal/polyclonal).
Aim of the study
The aim of this study was to compare the determination of CgA concentrations and the CgA/URL (Chromogranin A concentration/Upper Reference Limit) ratio by different immunochemical methods in patients with PPGLs diagnosed in two European centers (Poland and Sweden).

Materials and Methods
The analysis included 161 patients with PPGLs from 2 centers: Poland (PHEO 63, PGL 7) and Sweden (PHEO 74, PGL 17). Serum or plasma CgA concentrations were determined by various immunochemical methods (RIA, IRMA and ELISA), and plasma metanephrine and normetanephrine concentrations were determined by chromatographic methods (LC-MS/MS or HPLC-ECD) in all subjects. Reference range for the tests: CgA < 98 ng/ml (Poland), CgA < 3 nmol/l (Sweden). Results are presented as concentration ranges (median) and CgA/URL ratio (multiplicity URL).
Results
In the patient population (Poland), CgA concentrations in patients with PHEO were in the range of 16-1234 ng/ml (median 176.8 ng/ml), while the CgA/URL_{PHEO} ratio was 0-12. In PGL patients, the range of CgA concentration was 46-772.5 ng/ml (median 98 ng/ml), and the CgA/URL_{PGL} ratio was 0-8. In the patient population (Sweden), CgA concentrations in patients with PHEO were in the range of 1.0 - 367.0 nmol/l (median 8.85 nmol/l), while the CgA/URL_{PHEO} ratio was 0 - 122. In PGL patients, the range of CgA concentration was 1.1-23.0 nmol/l (median 6.9 nmol/l), while the CgA/URL_{PGL} ratio was 0-6.7.
Conclusions
The CgA/URL ratio in PPGLs is more useful than the determination of blood CgA concentration in the comparative diagnosis of patients diagnosed at different centers and allows clinical comparison of different immunoassays used in routine clinical diagnosis.

DOI: 10.1530/endoabs.99.EP213

Malignancy subtype and clinical evolution of thyroid nodules with indeterminate cytology

Diana-Simina Luca[1], Laura Zaifu[2], Bogdan Radu Ditescu[1], Andrei Stan[1], Dana Terzea[3], Carmen Cristea[3], Dumitru Ioachim[3], Dan Alexandru Niculescu[1,2] & Catalina Poiana[1,2]
[1]"C.I. Parhon" National Institute of Endocrinology, First Endocrinology Department, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [3]"C.I. Parhon" National Institute of Endocrinology, Department of Pathology, Bucharest, Romania

Introduction
The Bethesda System for Reporting Thyroid Cytopathology (TBSRT) allows the correlation between six individual diagnostic categories with the risk of malignancy, and offers a standardized management algorithm for each category. Atypia of undetermined significance (AUS) and follicular neoplasm categories are considered indeterminate categories, with varying malignancy rates and subtypes.
Aim
To establish the malignancy rate and subtype of cancer in thyroid nodules with indeterminate cytology results and to observe their clinical evolution.
Materials and Methods
We retrieved from our endocrinology center database all fine-needle aspiration (FNA) procedures performed by a single endocrinologist between February 2018 and April 2023. We excluded the first 500 procedures, which represented the learning curve, and all parathyroid and lymph node FNA procedures.
Results
There were 2465 nodules. Of the 51 (2.06%) patients with AUS, 15 (29.41%) patients had an available pathology report: 11 (73.33%) patients with follicular adenoma and 4 (26.66%) patients with thyroid carcinoma - 1 classic papillary thyroid carcinoma (PTC), 2 diffuse sclerosing PTC, 1 medullary thyroid carcinoma (MTC). Of the 100 (4.05%) patients with follicular neoplasm, 57 (57%) had an available pathology report: 31 (54.38%) patients with follicular adenoma and 26 (45.61%) patients with thyroid carcinoma - 21 patients with PTC (9 classic, 5 follicular, 2 tall cell, 2 diffuse sclerosing, 1 solid/trabecular, 1 NIFTP, 1 oncocytic), 4 with follicular neoplasm and 1 with poorly differentiated thyroid carcinoma. Twenty (66.66%) patients with carcinoma underwent radioiodine therapy, 11 (36.66%) had a suppressed thyroglobulin at the last follow-up, 4 (13.33%) had a persistent/recurrent local disease, 4 (13.33%) had metastatic disease and 10 (34.48%) were lost to follow up. The patient with MTC had a negative MEN2A screeing, a negative RET mutation and an increasing serum calcitonin value at the last follow up. None of the patients have had a thyroid carcinoma related death.
Conclusions
Although the majority of operated nodules with indeterminate cytology results are benign (58.33%), these results reported in our centre are lower than literature data. The most common type of carcinoma in these patients was classic PTC (33.33%). The clinical evolution of these patients varies widely according to malignancy subtype.

The recreational use of cannabis is becoming more widespread since many countries, including parts of Europe, are currently discussing legalisation. Moreover, the medical use of cannabinoids is already established and has many indications such as multiple sclerosis-induced spasticity or supportive therapy in the case of tumour-associated pain or loss of weight or appetite. However, the effects of cannabinoids on tumour growth still remain largely unexplored in many tumour entities, including phaeochromocytomas and paragangliomas (PPGLs), and neuroendocrine tumours (NETs). Therefore, we have now evaluated the effects of cannabidiol (CBD) in PPGL/NET cell lines, a PPGL 3D spheroid model and, most importantly, in patient-derived PPGL/NET primary cultures. In the PPGL cell lines (MPC, MTT) and in some NET cell lines (BON1, NCI-H727), CBD showed significant anti-tumour effects. Similarly, CBD also showed efficacy in PPGL (MPC) 3D spheroids, leading to a significant reduction in spheroid diameter. However, in a human pancreatic NET cell line (QGP1) we found significant tumour-*promoting* effects – thus demonstrating overall opposing effects of CBD on cell viability in different cell lines. Due to these results, we also validated these data in individual human primary cultures derived from patients with PPGLs ($n = 35$) and NETs ($n = 11$) and confirmed the opposing effects induced by CBD. In clinically relevant doses, we found significant anti-tumour effects in 14% and significant tumour-promoting effects in 17% of PPGLs. These effects were more pronounced using slightly higher doses of CBD, leading to significant anti-tumour effects in 27% and significant tumour-promoting effects in 18% of both PPGLs and NETs. Moreover, we performed genetic testing of individual PPGLs, which allowed us to evaluate cluster-dependent drug responsivity: In the cluster 2-associated PPGLs we found a significantly stronger CBD-induced cell viability reduction compared to the cluster 1-associated PPGLs. In conclusion, we offer clinically relevant data on a potential novel treatment option for PPGLs and NETs, particularly regarding personalised therapy in cluster 2-associated PPGLs, but also evidence for potential tumour-promoting effects of CBD in some PPGLs and NETs. Therefore, caution may be needed when treating PPGL or NET patients with cannabinoids as supportive therapies or even possibly as health supplements

Endocrine sequelae of adult recipients of hematopoietic stem cell transplantation

Georgia Ntali[1], Efstratios Kardalas[1], Aikaterini Beka[1], Evrydiki Theodorou[2], Maria Zotou[1], Anastasia Lambraki[1], Elisavet Tiaka[1], Vasiliki Antonopoulou[1], Frini Karaolidou[2], Zoi Arapidou[2], Barvara Vlassopoulou[1], Dimitrios Karakasis[2], Tatiana Tzenou[2], Ifigenia Tzannou[2], Ioannis Tsonis[2], Marinella Tzanela[1], Stavros Gigantes[2] & Ioannis Baltadakis[2]
[1]Evangelismos General Hospital, Department of Endocrinology "Dionysios Ikkos"-Diabetes Center, Athens, Greece; [2]Evangelismos General Hospital, Department of Hematology and Bone Marrow Transplantation Unit, Athens, Greece

Introduction
Hematopoietic stem cell transplantation (HSCT) is the standard of care treatment for high-risk hematological malignancies. HSCT recipients are exposed to chemotherapy and/or radiation prior to HSCT, as part of the conditioning, or following HSCT for management of disease relapse. They may receive steroids for chronic graft-versus-host disease (cGvHD) and they are at high risk for endocrine complications.
Aim
To evaluate endocrine complications in HSCT survivors.
Patients/Methods
Retrospective analysis of HSCT recipients, who were referred to the Outpatient Endocrine Clinic of Evangelismos Hospital (Athens).
Results
109 patients (45 males) were enrolled. Their median age at diagnosis of hematological malignancy and HSCT was 31 (range 13-64) and 33 years (13-65) respectively. Patients had received a single allogeneic ($n=81$) or autologous ($n=9$) HSCT, or a 2nd allotransplant ($n=1$). Data for transplant type missed for 18 patients. Median follow-up duration from HSCT was 71 months (3-300). Data for thyroid function before HSCT were available for 86 patients. 81/86 (94%) were euthyroid, 5/86 (6%) were hypothyroid. At last assessment, thyroid data were available for 83. 58/83 (70%) were euthyroid, 25/83 (30%) were hypothyroid. Amongst hypothyroid patients 4 (16%) had been treated with total body irradiation (TBI), including 3 (12%) with a dose of $\geq$12Gy. At last assessment, data for metabolic syndrome (MS) were available for 106. Fifty-two (48.5%) fulfilled (MS) criteria. Of those, 9 (17%) had received TBI and 30 (61%) glucocorticoids. At last assessment, data for osteoporosis were available for 45 patients. Osteoporosis was noted in 12 (26.6%), and 8/12 (66.6%) had received glucocorticoids. Eleven had developed avascular necrosis, all following steroids. Data for cGvHD were available for 80 patients. Fifty-seven (71%) had a cGvHD diagnosis and 51 (89.4%) had received glucocorticoids. Age at transplant was a predictor of the development of metabolic syndrome, hypothyroidism and osteoporosis, with older patients being more vulnerable. Odds Ratio (OR) for (MS) was 2.51 (95%CI:1.07-5.93, $P=0.02$) for patients aged $\geq$35 vs $<$35 years. OR for hypothyroidism was 2.89 (95%CI: 0.8-10.04, $P=0.056$) for patients aged $\geq$50 vs $<$50 years. OR for osteoporosis was 4.38 (95%CI: 0.87-22.35, $P=0.03$) for patients aged $\geq$40 vs $<$40 years. TBI and glucocorticoids did not emerge as significant predictive factors.
Conclusions
The population of HSCT survivors steadily increases over time. Endocrine complications may ensue during follow-up, with older age at transplantation as a significant predisposing factor. The long latency interval from HSCT necessitates their life-long monitoring for endocrine sequelae.

Multiple endocrine neoplasia type 1 in children and adolescents, the importance of clinical monitoring

Simone Della Valentina[1], Laura Pierotti[1], Elena Pardi[1], Chiara Sardella[2], Anna Dal Lago[1] & Filomena Cetani[2]
[1]University of Pisa, Department of Translational Researche and Innovative Technology in Medicine and Surgery, Pisa, Italy; [2]Unit of Endocrinology, University Hospital of Pisa, Department of Surgery and Endocrine Metabolic and Transplantation Medicine, Pisa, Italy

Multiple endocrine neoplasia type 1 (MEN1) is a rare autosomal dominant disorder, characterized by the predisposition to the development of multiple endocrine tumors mainly affecting parathyroids, gastroenteropancreatic neuroendocrine tissues (GEP-NET) and pituitary (PT). Mutations of the *MEN1* gene are responsible for the disease and may be inherited from one of the parents or more rarely can occur *de novo*. In children and adolescence there is a paucity of clinical studies. The aim of this study was to describe our experience in MEN1 children and adolescents aged $\leq$21 years collected and followed-up at our outpatient clinic from 1993 to 2023. A total of 20 patients (10 females and 10 males), affected by familial MEN1 were collected. Mean age at first MEN1 diagnosis was 17 ± 3 years (range 8-21). All patients carried *MEN1* mutation. Sixteen patients (80%) developed an endocrine tumor $\leq$21 years (mean 16 ± 3 years, range: 8–21) and 5 were healthy carriers. Seventy percent of patients had primary hyperparathyroidism (PHPT), (mean 17 ± 2.7 years, range 12-21), 35% a GEP-NET tumor (mean 19.0 ± 1.5 years, range 17-21) and 35% a PT tumor (mean 17 ± 4.5 years, range 8-21). Patients with PHPT at diagnosis had a mean albumin-corrected serum calcium of 11.1 ± 0.74 mg/dl and PTH (evaluated as fold increase of the upper limit of reference range) of 1.37. At diagnosis, 9/15 subjects had at least one target organ involvement of PHPT (hypercalciuria in 6; nephrolithiasis in 3, reduced bone mineral density in 6: mean lumbar *Z*-score -2.4; femoral neck -2.4; total femur -2.3; 1/3 distal radius -2.9 DS). During the follow up (mean 10 years), one-third (27 %) of patients underwent parathyroid surgery, with a mean age of 20 years (range 16–25); four had the removal of GEP-NET tumor between 21 and 32 years, with histological diagnosis of insulinoma in one, gastrinoma in one and non-functioning in two. No patient had metastases. All except one patient with PT tumors underwent pituitary surgery. The only symptomatic patient had a PRL-microadenoma, treated with cabergoline. Our study suggests that morbidity from MEN1-related manifestations occurred during childhood and adolescence in 80% of patients, being PHPT the most frequent. These findings have implications for the counseling of young MEN1 patients and their families and underscore the importance of initiating surveillance screening early in childhood. Furthermore, it is important to carry out periodic monitoring of all MEN-related endocrine pathologies in order to define the most appropriate therapeutic procedure.

Association between insulinoma and adrenal insufficiency in a patient with type 2 diabetes: a case report

Samir Mkaouer[1], Khessairi Nadia[1], Merhbene Yasmine[1], Kamoun Elyes[1], Yazidi Meriem[1], Oueslati Ibtissem[1], Chaker Fatma[1] & Chihaoui Melika[1]
[1]La Rabta University Hospital, Endocrinology Department, Tunis, Tunisia

Introduction
Insulinomas are rare pancreatic endocrine tumors causing severe hypoglycemia in non-diabetic patients. We report a case of a rare association between insulinoma and type 2 diabetes.
Presentation of the case
A 65-year-old diabetic patient presented with a one year history of recurrent hypoglycemia even after the withdrawal of antidiabetic drugs. First, a functional hypoglycemia was suspected and an oral glucose tolerance test showed hypoglycemia after 4 hours confirming the diagnosis. We recommended split diet with acarbose. Due to the appearance of signs of neuroglycopenia, the patient was started on a 72-hour fast, and within 10 hours, he had a hypoglycemic episode. The subsequent laboratories drawn revealed venous hypoglycaemia (23 mg/dl), elevated insulin (15.75 UI/l), elevated C peptide (4.81 ng/ml) and negative sulfonylureas screening. The diagnosis of insulinoma was confirmed and an abdomen CT scan revealed a 17 mm pancreatic nodule. In addition to that, the cortisol level drawn during his hypoglycemia revealed that the patient had an inadequate adrenal response to stress. The serum cortisol peak was 14.7 µg/dl and ACTH level was 14.09 ng/l confirming the secondary adrenal insufficiency (SAI). He underwent a left pancreatectomy. One month after surgery, serum glucose levels had increased and the SAI had disappeared with basal cortisol level at 34 µg/dl.
Conclusion
The coexistence of insulinoma and type 2 diabetes is rare and the diagnostic process is often challenging. The association of SAI and insulinoma has been described yet the pathophysiological mechanism remains poorly elucidated. Therefore, precaution is needed in diagnosis even if there is an obvious cause of hypoglycemia.

The value of cumulative serum 5-HIAA exposure in diagnostics of carcinoid heart disease: A prospective follow up in patients with small intestinal neuroendocrine tumors

Iiro Kostiainen[1], Piia Simonen[2], Katri Aaltonen[2], Riikka Lindén[3], Noora Karppinen[1], Daniel Gordin[4], Janne Rapola[2], Camilla Schalin-Jäntti[1] & Niina Matikainen[1]

[1]Helsinki University Hospital and University of Helsinki, Endocrinology, Helsinki, Finland; [2]Helsinki University Hospital and University of Helsinki, Cardiology, Helsinki, Finland; [3]Helsinki University Hospital and University of Helsinki, Radiology, Helsinki, Finland; [4]Helsinki University Hospital and University of Helsinki, Nephrology, Helsinki, Finland

Introduction
In small intestinal neuroendocrine tumors (SI-NET), unphysiological exposure to serotonin is considered as a major pathogenic factor predisposing to the development carcinoid heart disease (CHD), a complication of carcinoid syndrome associated with poor prognosis. The ability of biomarkers to predict the development of CHD is limited. The aim of our prospective study was to assess risk factors of CHD development and mortality in SI-NET.
Methods
We performed baseline transthoracic echocardiography (TTE), biochemical and radiological evaluation, and vascular function measurements for 65 patients with SI-NET. 42 (65%) of patients had liver metastases. 54 patients had follow-up TTE at median of 61 months. Vital status of patients was assessed at median follow-up of 72 months. Clinical data, including demographics, treatments, radiological and laboratory data was collected from electronic patient records. Hepatic tumor load was assessed at the time of TTE. Cumulative upper limit of normal (ULN) exceeding serum-5-HIAA exposure at the time of TTE was calculated. Westberg score of $\geq$3 in TTE was considered diagnostic for CHD.
Results
At the end of the follow-up, 22 (34%) patients had died. In 89%, death was due to SI-NET. Three patients had CHD at initial assessment, two patients (4%) were diagnosed with CHD during the 61-month median follow-up. At the follow-up TTE, 54% of the patients had received peptide receptor radionuclide therapy (PRRT) and 46% non-systemic treatments for metastases. Cumulative ULN exceeding serum-5-HIAA and proBNP had correlation with Westberg score (Spearman's ρ 0.32, 0.31, respectively). Cumulative ULN exceeding serum-5-HIAA had good diagnostic capability in ROC analysis with AUC at 0.98 (95% CI 0.94-1.00), surpassing performance of proBNP and individual serum-5-HIAA measurements (AUC 0.75, 0.91, respectively). In TTE, minor alterations in regurgitation were frequent, with increase or decrease noted in 29% of tricuspid and 30% of pulmonic valves. CHD, hepatic tumor load, serum-5-HIAA, and elevated aortic pulse wave velocity were found to be associated with increased mortality in patients with SI-NET.
Conclusions
Exposure to serotonin measured as cumulative ULN exceeding serum-5-HIAA improves case detection and appears as a promising biomarker for assessing the risk of CHD. Aortic pulse wave velocity was found to be a novel prognostic marker in SI-NET. The incidence of CHD was small when compared to previous literature, possibly reflecting the frequent use of PRRT and other tumor burden reducing treatments.

Carcinoid heart disease (CHD) affects about 20-50% of patients with carcinoid syndrome (CS) and is the main cause of mortality in this group of patients. The 3-year survival rate in patients with CHD is 31% compared to 68% in those without cardiac involvement. The cause of the development of CHD is the flow of serotonin-rich blood, and the lesions affect the right heart (localizing mainly in the endocardium and inner membrane of large vessels). The study aim was to present a single centre experience with CHD. Ten patients with CHD selected from the group of 162 patients with disseminated and/or inoperable neuroendocrine tumours treated with long-acting somatostatin analogues were included in a retrospective analysis. The study group consisted of 2 females (median age 72 years) and 8 males (median age 61,5 years). There were 2 patients with NET G1 and 6 patients with NET G2. In 8/10 patients the primary site was small intestinal NET (in 100% of these patients the primary site was resected), in 2 cases the primary site was unknown. Elevated serum chromogranin A (CgA) concentration with a median value 105,5 nmol/l (range 42,5-255) [reference value 0,0 - 6,0] was observed in all patients, and 5-hydroxy indoleacetic acid (5-HIAA) excretion in 24-hour urine collection was also elevated in all patients - median value 71,4 mg/24h (range 21,3-766) [reference value 0 - 8,2]. N-terminal pro-B-type natriuretic peptide (NT-proBNP) concentrations were above the upper limit of normal in 9/10 patients: median value 390 pg/ml (range 245-11162) [reference value $<$ 125]. Two patients presented symptoms of heart failure in NYHA I class, 3-NYHA II, 3-NYHA III and 2-NYHA IV. In all patients tricuspid regurgitation was confirmed in a transthoracic two-dimensional echocardiography (in 6 cases moderate, and in 4 severe). Two patients underwent a cardiac surgery for tricuspid valve replacement (under the cover of a short-acting somatostatin analogue). Two patients were treated with Peptide Receptor Radionuclide Therapy (PRRT) receiving 4 cycles of [177Lu]Lu-DOTATATE. Six patients from the study group are alive, of whom five have CS symptoms well controlled with a long-acting somatostatin analogue. CHD is a life-threatening complication of CS. CgA, 5-HIAA and NT-proBNP are screening tools to diagnose this state and transthoracic two-dimensional echocardiography is essentialfor imaging CHD. Multidisciplinary approach is mandatory to offer a patient a proper treatment.

Parathyroid carcinoma: clinical manifestations and long-term post-operative follow-up of seven patients

Ewa Zalewska[1], Sonia Kaniuka-Jakubowska[1], Łukasz Obołończyk[2], Anna Lewczuk-Myślicka[1], Jarosław Jendrzejewski[1], Maria Gnacińska[1], Dominika Okroj[1], Krzysztof Sworczak[1] & Renata Świątkowska-Stodulska[1]
[1]Medical University of Gdansk, Department of Endocrinology and Internal Medicine, Faculty of Medicine, Gdańsk, Poland; [2]Institute of Maritime and Tropical Medicine, Department of Occupational, Metabolic and Internal Diseases, Faculty of Medicine, Gdynia, Poland

Background
Parathyroid carcinoma causes less than 1% of primary hyperparathyroidism and is one of the rarest human malignancies. Clinical symptoms are ambiguous, and the diagnosis is usually made postoperatively based on histopathological examination.
Methods
We present clinical manifestations, pathological features, and follow-up of seven patients from our department after parathyroidectomy performed between 2008 and 2024.
Results
There were two male and five female patients with parathyroid carcinoma whose average age at the time of diagnosis was 54 $\pm$ 13.4 years. Osteoporosis was diagnosed in three patients (42.9 %), one of whom had a brown tumour and another had nephrolithiasis. Moreover, one patient (14 %) had osteopenia. Before treatment for primary hyperparathyroidism, the mean calcium concentration was 13.3 $\pm$ 1.27 mg/dl, parathyroid hormone 461 $\pm$ 283 pg/ml, and phosphorus 2.03 $\pm$ 0.57 mg/dl. One patient had a tumour encountered in the left lower parathyroid gland, and six patients had a mass located on the right side of the thyroid gland, five of them near the lower pole and one next to the upper. All patients were diagnosed based on postoperative histopathological examination: the vascular invasions were confirmed in all cases, and the average tumour size was approximately 18 mm (IQR 17–23). None of our patients had regional lymph nodes or distant metastases. Two patients, initially identified as having parathyroid adenomas, were verified to have parathyroid carcinoma after the second surgery (three and seven years after the first operation). Postoperative laboratory examinations revealed a significant decrease in calcium levels (9.57 $\pm$ 0.79 mg/dl) and parathyroid hormone concentration (62.1 $\pm$ 47 pg/ml), with an increase in phosphorus level (2.97 $\pm$ 0.65 mg/dl). The average follow-up time of our patients is 54 months (IQR 30 – 138), and all of them are currently in remission. The patient, who has been followed for the longest time, since 2008, initially required two reoperations due to disease recurrence but has now been in remission for 15 years.
Conclusion
Even though some clinical and biochemical clues may raise the suspicion of parathyroid cancer, the histopathological examination seems to be mandatory to distinguish it from parathyroid adenoma and set the final diagnosis. Because this cancer is so ultra-rare, there is insufficient research in this field, and clinicians must base their treatment decisions mainly on case series. However, the surgery, which may lead to a long-lasting tumour recurrence even when performed at the time of disease recurrence, is undoubtedly the mainstay of treatment.

Penetrance and clinical phenotype of SDHA related phaeochromocytomas and paragangliomas: A single centre experience

Mark Quinn[1], Paul Carroll[1], Anand Velusamy[1], Rebecca Oakey[2], Rupert Obholzer[1] & Louise Izatt[1]

[1]Guy's and St Thomas' NHS Foundation Trust, United Kingdom; [2]King's College London, United Kingdom

Background
Phaeochromocytomas and paragangliomas (PPGLs) are histologically identical tumours that exhibit significant clinical heterogeneity. At least 40% of PPGLs arise due to the presence of a pathogenic germline variant (PGV) in a known susceptibility gene. PGVs affecting the mitochondrial enzyme succinate dehydrogenase (*SDHA, SDHB, SDHC* and *SDHD*) are the most common. Phenotypic features of PPGLs secondary to *SDHB* and *SDHD* PGVs are well documented and demonstrate a variability (tumour location, rates of catecholamine secretion, metastatic risk etc.) that is not currently understood. Due to their rarity the behaviour of *SDHA* related PPGLs are less well documented. Cascade screening is now offered to all patients with an *SDHA* PGV and so we can expect to encounter unaffected carriers more frequently in our clinical practice. Here we will discuss our experience of 18 index cases of *SDHA* related PPGLs and 10 relatives diagnosed as carriers via cascade screening.
Methods
Patients presenting with a PPGL with either a PGV or a VUS of *SDHA* were identified via our neuroendocrine tumour multidisciplinary team database. A retrospective chart review was carried out. An additional 14 *SDHA* PGV carriers were also identified via cascade screening ($n=12$) or via the 100,000 genome project ($n=2$).
Discussion
We report 18 cases (8F, 10M) of a PPGL related to an *SDHA* PGV ($n=12$) or VUS ($n=6$). Patients were aged 16-64 (median age of 40). 38.9% of PPGLs were found in the head and neck, 27.8% were abdominal PGLs, 11.1% were in the bladder, 11.1% presented as pheochromocytomas, 5.6% were found in the mediastinum and 5.6% had widespread metastatic disease at initial presentation. Catecholamine excess was diagnosed in at least 44.4% of cases. The most common presenting complaint was of swelling or symptoms related to tumour compression (44.4% of cases). Symptoms related to catecholamine excess were present in 33.3% of cases. 33.3% of this cohort went on to develop metastatic disease. Of the 14 patients identified as an *SDHA* PGV carrier, one patient was diagnosed with renal cell carcinoma (identified via the 100,000 genome project) but no patient identified via cascade screening went on to develop a PPGL.
Conclusion
The penetrance of disease in non-index cases of an *SDHA* PGV is low in this cohort. We also show a variability in tumour location and catecholamine production that is distinct from other *SDHx* related disease. In this small cohort there was a high rate of metastatic disease.

Safety and outcomes of laparoscopic adrenalectomy for metastatic tumors – experience in a high-volume urological center

Emilia Niedziela[1,2], Łukasz Niedziela[2,3], Jarosław Jaskulski[2,3], Mateusz Obarzanowski[2,3] & Aldona Kowalska[1,2]
[1]Holy Cross Cancer Center, Department of Endocrinology, Kielce, Poland; [2]Collegium Medicum, Jan Kochanowski University, Kielce, Poland; [3]Holy Cross Cancer Center, Department of Urology, Kielce, Poland

Introduction
In case of isolated adrenal metastases, complete surgical resection of the disease is a potentially curative treatment. Minimally invasive adrenalectomy is recommended in most patients with focal adrenal lesions without evidence of local invasion. However, data on surgical outcomes and survival after laparoscopic adrenalectomy (LA) for adrenal metastases are still lacking to clearly define the role of this procedure in the management of metastatic disease.
Aim
The aim of the study is to assess the safety and outcomes of LA for metastatic adrenal tumors.
Methods
We retrospectively analyzed the data of patients undergoing LA between 2015 and 2021 in tertiary medical center. Perioperative and postoperative complications, as well as long-term outcomes were recorded.
Results
A total of 141 patients were enrolled in the study. 22 LAs were performed for adrenal metastases of different origin, including 18 for renal cell carcinoma (RCC; 81.8%), 3 for lung cancer (LC; 13.6%) and 1 for colorectal cancer (CC; 4.5%). One patient underwent a single-stage bilateral adrenalectomy, while the others had unilateral surgery. 4 patients had second LA due to metachronous adrenal metastases. Intraoperative complications occurred during 2 LAs (9.1%) including injury of the inferior vena cava and pancreatic tail. Open conversion was performed during 2 LAs (9.1%). 30-day postoperative complications were reported in 4 cases (18.2%). No life-threatening complications were observed in the postoperative period. 90,9% resection margins were tumor-free (R0). At the follow-up, systemic treatment was administrated to all patients with metastatic LC and CC, and to 27.8 % of patients with RCC. After a median follow-up of 4 years (range 0.2–8.8), 10 patients (45%) died of cancer or other causes. The 1-, and 5-year overall survival (OS) rate after LA were 85% and 40%, respectively. Tumor size on imaging tended to be associated with shorter OS.
Conclusions
LA for adrenal metastases is a safe method with good surgical and oncologic outcomes. It requires a proper qualification of patients for the procedure by a multidisciplinary team and surgeon's experience.

Retroperitoneal ganglioneuroma: a case report in a 16-year-old girl presenting as lower back pain

Anastasios Stofas[1] & Amalia Patereli[2]
[1]1st Department of Pathology, School of Medicine, National and Kapodistrian University of Athens, Greece; [2]Pathology Department, Agia Sofia Children's Hospital, Athens, Greece, Greece

Introduction
Retroperitoneal ganglioneuromas (RGN's) are rare benign tumors originating from the retroperitoneal sympathetic ganglia. They are usually sporadic; though an association with neurofibromatosis type II and multiple endocrine neoplasia (MEN) IIB has been reported. RGN's are usually asymptomatic. Occasionally they may show symptoms due to local pressure effect or rarely are hormonally active, releasing peptides such as vasoactive intestinal peptide, somatostatins or androgen hormone and present with adrenergic symptoms, such as diarrhea, sweating and hypertension, virilism and hypokalemia.
Case report
A 16-year-old female patient, with no significant past medical history, who presented with lower back pain. MRI revealed a well circumscribed solid mass in the left retroperitoneal site adjacent to the left adrenal gland, the psoas muscle and the head of the pancreas, measuring 6×5.4x3 cm. The tumor was resected, and the histopathological examination confirmed the diagnosis of ganglioneuroma characterized by the presence of fascicles of spindle cells of Schwannian origin (S100+ and NF+) mixed with scattered and small clusters of ganglion cells (Synaptophysin+, S-100+, NF+). Desmin, smooth-muscle actin and MelanA were negative. Ki-67 labeling index was low (~1-2%).
Conclusion
Due to lack of specific characteristics RGNs are quite difficult to differentiate from other tumors of the area. The prognosis for a RGN following complete surgical resection is good. Their close relationship with surrounding vital organs makes surgical excision of these tumors challenging and may act as a limiting factor in complete surgical resection. Also, since they may release catecholaminergic peptides, surgeons should be aware of the possibility of hypertensive crisis during the surgery. Regular and periodic long-term follow-up is recommended.

The association between early/precocious puberty and the risk of breast cancer

Ashraf Soliman[1], Nada Alaaraj[1], Fawzia Alyafei[1], Noor Hamed[1] & Shayma Mohamed[1]
[1]Hamad General Hospital, Pediatric Endocrinology, Doha, Qatar

Introduction
The contribution of reproductive factors to breast cancer (BC) susceptibility requires further investigation. This study aims to explore the potential link between early puberty (menarche) and the risk of breast cancer in women.
Aim
This study systematically reviews research conducted between 2000 and March 2023, aiming to evaluate the association between early/precocious puberty and the incidence of BC.
Methods
A comprehensive search was performed across databases including Medline, PubMed, Google Scholar, and Web of Science to identify relevant studies. The review encompassed a variety of study designs, including metanalyses, prospective studies, and case-control studies.

Results
A total of 12 studies were analyzed: A comprehensive analysis of 117 epidemiological studies, involving 118,964 women with invasive breast cancer and 306,091 controls, demonstrated that younger age at menarche correlated with an increased BC risk. Each year younger at menarche was associated with a 5% increase in relative breast cancer risk, particularly for luminal A tumors. The risk rose by a factor of 1.050for each year younger at menarche. Endogenous ovarian hormones appeared more influential for estrogen receptor-positive disease and lobular tumors. A case-control study of 237 BC cases and 237 age-matched controls found that early menarche (OR = 1.60, 95% CI: 1.08–2.38) significantly heightened breast cancer risk. A prospective US cohort study on women aged 35–74 without BC history but with a diagnosed sister revealed that early ages at thelarche and menarche were positively associated with BC risk. Women with both early thelarche and menarche exhibited a 30% higher risk of breast cancer compared to those without these risk factors. Multiple investigations consistently indicate that commencing menstruation before the age of 11 increases BC risk, while later menarche (14 years) reduces the risk. Sister-matched case-control research involving 1,406 women diagnosed with BC before age 50 and 1,648 controls reaffirmed the relationship between older age at menarche and reduced young-onset breast cancer risk. A study involving 1811 pairs of female twins with BC demonstrated that the twin with earlier puberty was more likely to receive the diagnosis of BC first. The Collaborative group on hormonal factors reported up to an 18% risk reduction in girls with late menarche ($\geq$13) compared to those starting menstruation at 11.
Conclusion
The collective evidence supports the notion that earlier ages at thelarche, and menarche may heighten susceptibility to BC and add an advantage to hormonal suppressive therapy.

Heterogeneity of responses of dynamic tests in patients with ectopic cushing's syndrome (ECS). the half of patients with ECS have an increase in ACTH in the CRH/desmopressin test, nearly 1/3 have complete or some inhibition of cortisol in HDDST

Aleksandra Gamrat[1,2], Mari Minasyan[1], Maria Aleksandra Komisarz-Calik[1], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]
[1]Jagiellonian University Medical College, Chair and Department of Endocrinology, Kraków, Poland; [2]Jagiellonian University Medical College, Doctoral School of Medical and Health Science

Introduction
According to the literature, the CRH test has the highest specificity in excluding ECS (ACTH 93.9%, cortisol 89.4%). A combination of the high dose dexamethasone test (HDDST) and CRH/desmopressin test (CRH/desmopressinT) is used to increase the discriminatory capacity in ACTH-dependent CS.
Objectives
This study aims to investigate the response to dynamic tests in ECS patients.
Methods
35 consecutive ECS patients were analyzed (3 SCLC patients were excluded from further analysis). Neuroendocrine tumor (NET) constituted 47% of all EAS (60% gastroenteropancreatic, 40% thoracic (1 thymic and 5 pulmonary carcinoids (PC)), 4 cases were occult. The cut-off points for CRH/desmopressinT was >20% increase in cortisol concentration (Δcortisol%), >35% increase in ACTH (ΔACTH%) and for HDDST >50% decrease of cortisol (-Δcortisol%). The CRH/desmopressinT was performed in 18/32 (16 CRH/2desmopressin), HDDST in 25/32 patients.
Results
All patients responded to CRH/desmopressin (ACTH surge range: 12-197%), with average increase of cortisol and ACTH by 25.5% and 63%. The CRH/desmopressinT ΔACTH% and Δcortisol% were observed in 50% patients, in all PC and in 35.7% of other ECSs ($P=0.02$). The average percentage increase of ACTH in the CRH/desmopressinT was higher in the PC compared to other ECSs (98% vs 32% $P=0.08$). In HDDST -Δcortisol% was observed in 3 patients/12% (uterus clear cell carcinoma, PC and occult origin), 28% of the patients responded with a >30% decrease in cortisol. Positive results in both tests, indicative of Cushing's disease was observed in two ECSs (PC, occult). Patients with ΔACTH%, compared to the remaining ECSs, were characterized by a significantly higher potassium concentration (3.69 vs 2.51 mmol $P=0.02$) and a higher baseline ACTH concentration (281 vs 214 pg/ml). Patients with -Δcortisol% in HDDST also had higher potassium concentration compared to the non-inhibition group (4.3 mmol/l vs 2.91 mmol/l, $P=0.04$). There were no significant differences in response to dynamic tests between men and women. There was a strong correlation between the increase in cortisol in the CRH/desmopressinT and the decrease in cortisol in the HDDST (Spearman's correlation coefficient -0.89 $P<0.05$).
Conclusion
Half of ECS patients have Δcortisol% and ΔACTH% in CRH/desmopressinT and nearly one third in HDDST have cortisol decrease >30%. Our results also suggest that an increase in cortisol in the CRH/desmopressinT is associated with a decrease in cortisol in the HDDST. Further, multicenter studies are needed to understand the response of ECS patients to dynamic tests and to establish/improve diagnostic differential criteria.

In silico and ex vivo identification of gonadotropin-related genes involved in ovarian cancer

Clara Lazzaretti[1], Beatrice Melli[2,3,4], Samantha Sperduti[1], Carmela Perri[1,3], Lara Baschieri[1,3], Vincenza Ylenia Cusenza[2], Sandra Martinelli[2], Davide Nicoli[2], Andrea Palicelli[5], Dario Vincenzo Mandato[4], Lorenzo Aguzzoli[4], Manuela Simoni[1,6] & Livio Casarini[1]
[1]Unit of Endocrinology - University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]Unit of Molecular Pathology - Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy; [3]International PhD School in Clinical and Experimental Medicine (CEM) - University of Modena and Reggio Emilia, Modena, Italy; [4]Unit of Obstetrics and Oncological Gynecology - Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy; [5]Unit of Pathology, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy; [6]Azienda Ospedaliero-Universitaria di Modena, Department of Medical Specialties, Modena, Italy

Serous ovarian cancer is one of the leading causes of death among all gynaecological malignancies. Even though a hereditary component has been suggested, most ovarian carcinomas are sporadic and markers for a diagnosis at an early stage of the disease are still to be identified. Since gonadotropins may stimulate the growth of certain cancer cells, we aim to identify tumour markers linked to gonadotropin receptor-mediated pathways. Through an *in silico* and *ex vivo* approach, we characterized high-grade serous ovarian cancer features. A network of genes associated with gonadotropin-dependent regulatory pathways of ovarian follicle development was identified. Gene expression data of 60 genes from two groups of high-grade serous ovarian cancer patients, as well as two control groups, were obtained from the GEO-NCBI database. Principal component analysis (PCA) performed on the datasets revealed that the 60 genes have a differential expression pattern in cases vs controls. PCA was repeated considering 7 genes better discriminating healthy individuals vs patients. These genes described 50-70% of the total variance in each dataset, resulting in a clear clusterization of cases vs controls. PCA was also performed on a group of housekeeping genes serving as a negative control, which did not discriminate between cases vs controls. To further confirm the differential expression pattern of the genes identified through *in silico* analysis, RNA samples were extracted from high-grade serous ovarian cancer and healthy tissue of 30 women to perform a gene expression analysis by digital droplet PCR. In pathological tissues, results revealed upregulation of proliferative genes together with those associated with gonadotropin-dependent signalling pathways. In conclusion, we found a set of genes linked to gonadotropin functions which may be involved in ovarian cancer progression, as potential targets for specific pharmacological approaches.

Paediatric differentiated thyroid cancer: a single-centre retrospective study

Raquel Calheiros[1], Sara Gil-Santos[1], Pedro Souteiro[1], Joana Oliveira[1], Isabel Inácio[1], Ana Paula Santos[1] & Isabel Torres[2]
[1]Instituto Português de Oncologia do Porto FG, EPE (IPO-Porto), Endocrinology Department, Porto, Portugal; [2]Instituto Português de Oncologia do Porto FG, EPE (IPO-Porto), Paediatrics Department, Porto, Portugal

Introduction
Differentiated thyroid cancer (DTC) is rare in the paediatric population when compared to adults. Paediatric patients often present with advanced disease at diagnosis, characterized by multifocal disease, heightened lymph node involvement, and distant metastasis. Additionally, they face a higher risk of post-operative complications in comparison to adults. Despite that, paediatric DTC exhibits an excellent prognosis.

Methods
A retrospective study was conducted, analyzing medical data of 25 individuals under 18 years diagnosed with differentiated thyroid cancer in an oncology center in Portugal from January 2013 to December 2023.
Results
Twenty-four patients were diagnosed with papillary thyroid carcinoma, and one with oncocytic thyroid carcinoma. The mean age at diagnosis was 15.28 years, and 68% of the patients were females. Histology reports indicated that at least one aggressive feature was present in 20 cases (80%). Lymph node involvement was observed in 9 patients (36%), and 2 of them had distant metastasis, both pulmonary (8%). Sixteen patients underwent total thyroidectomy and 9 had hemithyroidectomy, 5 of which later underwent surgery totalization based on the histopathological results. Lymph node dissection was initially performed in 8 individuals (33%). Post-operative complications were reported in 9 patients, including transient primary hypoparathyroidism ($n=3$), persistent primary hypoparathyroidism ($n=6$), and transient dysphonia ($n=4$). Sixteen patients (64%) were submitted to radioiodine therapy after surgery. Regarding follow-up, 14 patients were classified as having an excellent response (56%), 5 had an indeterminate response (20%) and the remaining ones presented either a biochemical ($n=3$; 12%) or structural ($n=2$; 8%) incomplete response. Due to persistent/recurrent disease, 2 patients had to be submitted to lymph node dissection and 4 individuals were retreated with radioiodine.
Discussion
These findings underscore the unique clinical characteristics of paediatric DTC. The relatively high prevalence of patients needing thyroidectomy totalization and lymph node dissection emphasises the need for a careful assessment when deciding the extent of thyroid surgery. In addition, the significant rates of early postoperative complications and therapy incomplete responses underline that close surveillance is crucial after surgery.

Cellular localization of clock gene PER2 plays an essential role in tumour aggressiveness and drug resistance in in vitro models of hepatocellular carcinoma

Mariarosaria Negri[1], Feliciana Amatrudo[1], Donatella Paola Provvisiero[2], Roberta Patalano[2], Tatiana Monto[2], Cristina De Angelis[2], Chiara Simeoli[2], Renata Simona Auriemma[2], Annamaria Colao[2,3], Rosario Pivonello[2,3] & Claudia Pivonello[4]
[1]Università Telematica Pegaso, Dipartimento di Scienze Umanistiche, Naples, Italy; [2]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia, Andrologia e Nutrizione, Naples, Italy; [3]Federico II University, UNESCO Chair for Health Education and Sustainable Development, Naples, Italy; [4]Università Federico II di Napoli, Dipartimento di Sanità Pubblica, Naples, Italy

Acquired resistance has limited the use of systemic molecular therapy in the management of hepatocellular carcinoma (HCC). Immunotherapy, alone and in combination with systemic molecular therapy, is now the first-line standard of care for HCC. The current in vitro study aims at investigating PER2 role in the HCC aggressiveness and drug resistance acquisition. Parental PLC/PRF/5, PLC/PRF/5 resistant to Everolimus (EveR) and to Sorafenib (SorR) cell lines were used. To evaluate PER2 involvement in aggressiveness and drug resistance, PER2 expression was genetically manipulated by using small interfering RNA (siRNA) to knockdown (KD) and CRISPR/Cas9 Plasmid to knockout (KO) PER2 gene in parental PLC/PRF/5. PER2 mRNA and protein expression were investigated by RT-qPCR and immunofluorescence (IF), respectively. The epithelial and mesenchymal transition (EMT) markers and TP53 expression was evaluated by IF and western blot, respectively. The role of PER2 on the onset of aggressiveness was evaluated through cell proliferation and cell migration assays. PLC/PRF/5 EveR, SorR, PER2KD and PER2KO significantly expressed lower mRNA *PER2* levels, with a reduction of 72.7%, ($P<0.01$) in EveR, 59.6.% ($P<0.05$) in SorR, 91.5% ($P<0.001$) in PER2KD and 97.2% ($P<0.001$) in PER2KO compared to parental PLC/PRF/5. Remarkably, PER2 protein expression in PLC/PRF/5 EveR and SorR completely localized in cytoplasm contrary to parental ones. In PLC/PRF/5 EveR, PER2KD and PER2KO but not SorR, E-Cadherin was significantly decreased (24.9%, $P=0.05$; 33.8%, $P=0.04$; 55.5%, $P=0.0002$; +37.2%, $P=0.05$ respectively) while Vimentin protein expression was significantly increased in all cell models (+148.1%,+202.9%, +110.3%,+552.0%, $p<0.0001$ respectively). Interestingly, TP53 expression was reduced in PER2KO and completely absent in PLC/PRF/5 EveR and SorR. Significant cell proliferation inhibition of EVE10^{-9}M and SOR5$\times$10^{-6}M in the parental PLC/PRF/5 (19.6%, $P<0.0001$ and 34.7%, $P<0.05$, respectively) was partially but not significantly reverted when *PER2* was KD while it was completely reverted when *PER2* was KO ($P<0.01$ vs EVE10^{-9}M and $P<0.001$ vs SOR5$\times$10^{-6}M, respectively). Similarly, the significant inhibition of cell migration of EVE10^{-9}M and SOR5$\times$10^{-6}M in the parental PLC/PRF/5 (20.7%, $P<0.0001$ and 8.6%, $P<0.01$, respectively) was reverted when PER2 was KD ($P<0.0001$ vs EVE10^{-9}M and vs SOR5$\times$10^{-6}M, respectively), and when PER2 was KO ($P<0.0001$ vs EVE10^{-9}M and vs SOR5$\times$10^{-6}M, respectively). These results suggest that the acquisition of aggressive phenotype is characterized by PER2 reduced expression and loss of nuclear translocation that in turn induces resistance to HCC systemic therapy. Further studies are mandatory to evaluate the impact of PER2 expression on immunotherapy efficacy in HCC improving patient's management.

Refractory hypokalaemia secondary to an aggressive adrenal cortical carcinoma – a case report

Charlotte Choo[1]
[1]Singapore General Hospital, Endocrinology, Singapore

Adrenal cortical carcinoma (ACC) is notorious for its aggressiveness and poor prognosis. A 71-year-old woman was found to be hypokalaemic with a serum potassium of 2.6 mmol/l [reference 3.6-5.0 mmol/l] on routine blood screening. Previous serum potassium readings were normal. She was asymptomatic and reported no gastro-intestinal losses. Her medical history was significant for hypertension, hyperlipidemia and hypothyroidism following total thyroidectomy for Graves' Disease. She had been on stable doses of amlodipine, simvastatin and levothyroxine. There was no use of traditional medications or diuretics. Two weeks later, despite being on potassium replacements, she re-presented with persistent hypokalaemia 2.5-3.2 mmol/l associated with increased bicarbonate 36.7 mmolL [reference 19.0-29.0 mmol/l] and proximal myopathy. She was normotensive and her weight was stable. Besides facial acne and proximal myopathy, no discriminatory features of Cushing's syndrome were present. 24-hour urinary potassium of 88 nmol indicated urinary potassium loss. Further investigations revealed a markedly elevated 0800 hours cortisol at 1080 nmol/l, with an undetectable adrenocorticotropic hormone (ACTH). Further investigations revealed hyperandrogenism with total testosterone 6.9 nmol/l [reference 0.30-2.8 nmol/l], 17alpha hydroxyprogesterone 11.1 nmol/l and dehydroepiandrosterone-sulfate (DHEA-S) 25.3 umol/l [1.1-11.8 umol/l]. This raised concerns for ACC with non-ACTH dependent hypercortisolism. Cross sectional imaging showed a 7.4 $\times$ 6.5 cm^2 enhancing mass in the left adrenal with tumour thrombus extending to the left adrenal vein, with no distant metastases. Within a month of diagnosis, the tumor had enlarged to 10 $\times$ 8 $\times$ 7.2 cm^3 when she underwent open left adrenalectomy. Histology revealed a high-grade tumour invading through the adrenal capsule into periadrenal adipose tissue. Post-operative day three 0800 hours cortisol of 383 nmol/l was worrying for incomplete resection. Nevertheless, ACTH and adrenal androgens normalized shortly postoperatively. She was started on adjuvant mitotane but shortly developed rapidly worsening transaminitis with alkaline phosphatase 105 U/l [reference 12-42 U/l] and gamma-glutamyl transferase 1138 umol/l [reference 7-32 umol/l] which contraindicated further use of mitotane. Repeat imaging revealed extensive loco-regional and distant metastases in her liver and lungs. 0800 hours cortisol had risen to 1261 nmol/l (while on mitotane) as did adrenal androgens. Her prognosis was guarded and metyrapone was initiated for symptom control of hypercortisolism particularly that of muscle weakness, with some initial relief. She passed away three weeks later, within three months from diagnosis. This case highlights the aggressive nature of ACC and the importance of having a high index of suspicion to allow early diagnosis and intervention, and the need for research and new therapeutics.

Acromegaly associated with papillary thyroid carcinoma: report of a case

Amira Bouchenna[1], Lachkhem Aicha[1] & Bensaleh Meriem[1]
[1]central hospital of army, endocrinology, algiers, Algeria

Introduction
The association between acromegaly and neoplasia is rare but described, particularly colorectal and thyroid cancers, especially since the disease is not controlled.
Observation
We report the case of a 44-year-old patient, hypertensive, diabetic, followed for acromegaly clinically retained in the face of dysmorphic syndrome, an IGF1 at 3.5

times normal on a pituitary macroadenoma of 9.9x13x9.3. The assessment of the impact of this acromegaly was without abnormalities. For the neoplastic risk, a colonoscopy returned without abnormalities and a cervical ultrasound revealed a right mid-lobar nodular formation of 10x9 mm classified Eu-Tirads 5, with a fine puncture in favor of a papillary carcinoma of the thyroid. He underwent a total thyroidectomy and the anatomo-pathological examination confirmed the diagnosis: papillary carcinoma of the thyroid of 9 mm right infiltrating the thyroid capsule without crossing it with vascular emboli and perineural sheathing classified pT1a NxMx is classified at high risk of recurrence according to ATA2015 supplemented by 100mci iratherapy.

Discussion

The occurrence of differentiated thyroid cancers is reported in acromegaly. It is related to active secretion of GH-IGF1. Acromegaly is associated in 25% of cases with papillary thyroid carcinoma independently of the BRAF mutation according to one study. In our patient, the number of years of progression of his disease as well as the failure to obtain biological control would be incriminated.

Hypophysitis secondary to treatment with pembrolizumab: uncommon endocrinology effects of immunotherapy

Miguel-Angel Ruiz-Gines[1], Juan-Antonio Ruiz-Gines[2], María Zurdo López[1], Mercedes Agudo-Macazaga[1], Macarena Dubert-Perez[1], Vanessa Portillo-Maestre[1], Maria-Carmen Gutierrez-Melendez[1], Susana Vicente-Pantoja[1], Dolores Benitez-Segura[3] & Sandra Ballesteros-Moron[4]
[1]Hospital Universitario de Toledo, Análisis Clínicos, Toledo, Spain; [2]Hospital Clínico Universitario Lozano Blesa, Neurocirugía, Zaragoza, Spain; [3]Centro Regional de Transfusión de Toledo, Hematología y Hemoterapia, Toledo, Spain; [4]Hospital General Universitario Nuestra Señora del Prado, Análisis Clínicos, Talavera de la Reina, Spain

Introduction

Immunotherapy is the oncological treatment whose objective seeks, through the use of immunomodulatory monoclonal antibodies, to block the regulation of the activation and response of T cells, increasing their antitumor response. Pembrolizumab is a new monoclonal antibody directed against the surface protein PD 1, (Programmed Cell Death-1), responsible for the inhibition of the immune response, mediated by T cells, against cancer cells; indicated in the treatment of different malignant neoplasms (non-small cell lung carcinoma). Despite being well tolerated, they have a different adverse effect profile than conventional chemotherapy, with an immune-mediated profile. Among them, endocrinological ones stand out, which can be the cause, among others, of severe hormonal deficits. Our objective is to describe the case of a patient diagnosed with lung adenocarcinoma (stage IV), under treatment with Pembrolizumab, who suffered, as a rare adverse effect, lymphocytic hypophysitis, causing hypopituitarism in the form of central adrenal insufficiency (alteration of the hypothalamic-pituitary-adrenal-axis) and GH deficiency.

Clinical Case

A 39-year-old male, with the oncological history already described, being treated with Pembrolizumab and Pemetrexed (antifolate), referred to the Emergency-Department due to clinical symptoms of diarrhea, abdominal pain, nausea, involuntary vomiting and intense asthenia. He is admitted with a suspected diagnosis of immune-mediated colitis. Complementary-studies: The analysis highlights the involvement of the corticotropic axis and IGF-1 deficiency: TSH 0.175 uU/ml, fT4 1.420 ng/dl, fT3 1.630 pg/ml, FSH 11.6U/l, LH 10.30 U/l, Testosterone 6.51 ng/ml, Prolactin 4.77 ng/ml, ACTH < 1.50 pg/ml, Cortisol 0.8 mg/dl, HGH 0.32 ng/ml, IGF-1 46.2 ng/ml. b. Pituitary-MRI with contrast: Loss of the normal hyperintensity of the neurohypophysis in T1 and moderate thickening of the pituitary stalk, findings that may be compatible with lymphocyti hypophysitis. Given suspicion of adrenal insufficiency, 50mg-IV hydrocortisone was prescribed along with fluid therapy with clear clinical improvement. At discharge, hydroaltesone 20 mg/8h, with progressive decrease to replacement dose. The outpatient study showed ACTH 12.0pg/ml and Cortisol 15.2 mg/dl. After clinical stability, Pembrolizumab cycles are reintroduced.

Discussion and conclusions

The side effects of immunotherapy can occur at different levels in the same patient. Hypophysitis, jointly associating corticotropic and somatotropic deficiency, is an adverse reaction not described to date after studying the available literature, with serious consequences and the need for urgent treatment. Given its potential severity, it is essential, in patients undergoing treatment based on immunotherapy, to maintain a high level of suspicion, so that, in the event of nonspecific symptoms such as nausea, vomiting and/or fatigue (very common), an urgent evaluation should be prompted, including exhaustive hormonal study.

Glutaminase 2 expression is associated with adrenocortical carcinoma patients' survival

Sofia B. Oliveira[1,2,3], Clara Pinto[4], Madalena M. Costa[1], Diana Sousa[2,5], Sofia S. Pereira[1] & Duarte Pignatelli[2,3,6]
[1]UMIB - Unit for for Multidisciplinary Research in Biomedicine; ICBAS - School of Medicine and Biomedical Sciences; ITR - Laboratory for Integrative and Translational Research in Population Health, Portugal; [2]i3S – Institute for Research and Innovation in Health, Portugal; [3]CHUSJ – Department of Endocrinology, Hospital São João, Portugal; [4]FCUP - Faculty of Sciences, University of Porto, Portugal; [5]UCP – Universidade Católica Portuguesa, Faculdade de Medicina Dentária, Viseu, Portugal; [6]FMUP – Faculty of Medicine, University of Porto, Portugal

Adrenocortical carcinomas (ACC) are rare and usually very aggressive tumors with heterogeneous outcomes. The individual variability in tumor progression and patients' survival is linked to ACC biology and molecular heterogeneity, reinforcing the need to identify markers with prognosis value, to allow an accurate clinical strategy. Currently, in the absence of specific molecular markers, ACC prognosis is mainly predicted by the European Network for the Study of Adrenal Tumors (ENSAT) tumor stage and tumor proliferation index, assessed by Ki-67 immunohistochemistry. Glutaminolysis is one of the most studied metabolic processes in cancer metabolism context, since it plays a role in cell signaling transduction, proteins, and nucleotides biosynthesis, contributing to cell survival. Therefore, this study aimed to evaluate the role of glutaminolysis in ACC pathophysiology, and to estimate the potential usefulness of its molecular players for ACC prognosis. For that, the expression of proteins involved in glutaminolysis, namely glutaminase 2 (GLS2) and glutamate dehydrogenase 1 (GLUD1), was assessed by immunohistochemistry (IHC) in ACC ($n = 13$) with different clinicopathological behaviors. The percentage of stained area for both molecular markers was quantified using the morphometric analysis tool, ImageJ. Positive staining for GLS2 and GLUD1 was observed in all ACC. Among these molecular markers, only GLS2 expression was positively correlated with ENSAT and Weiss scores. ACC with sinusoidal invasion presented higher GLS2 levels when compared to ACC without sinusoidal invasion. Additionally, GLS2 expression was associated with lower survival rates, whereas Ki-67 expression was not correlated with the survival of these patients. As conclusion, this study demonstrated that glutaminolysis seems to play a role in ACC tumor progression. Remarkably, GLS2 expression was linked with more aggressive malignant features, in particular advanced tumor stage and lower patients' survival. Furthermore, in these cases, GLS2 showed to have a greater prognosis value when compared to the molecular marker currently used in clinical practice, Ki-67. To validate these data, a larger ACC cohort and mechanistic studies are needed.

IGF2 and Ki-67 as immunohistochemistry markers for adrenocortical tumors differential diagnosis: a systematic-review and meta-analysis

Sofia B. Oliveira[1,2,3], Mariana Machado[4], Diana Sousa[2,5], Sofia S. Pereira[4] & Duarte Pignatelli[2,3,6]
[1]UMIB - Unit for for Multidisciplinary Research in Biomedicine; ICBAS - School of Medicine and Biomedical Sciences; ITRLaboratory for Integrative and Translational Research in Population Health, Portugal; [2]i3S – Institute for Research and Innovation in Health, Portugal; [3]CHUSJ – Department of Endocrinology, Hospital São João, Portugal; [4]UMIB – Unit for Multidisciplinary Research in Biomedicine; ICBAS - School of Medicine and Biomedical Sciences; ITR- Laboratory for Integrative and Translational Research in Population Health, Portugal; [5]UCP – Universidade Católica Portuguesa, Faculdade de Medicina Dentária, Viseu, Portugal; [6]FMUP - Faculty of Medicine, University of Porto, Portugal

Most of adrenocortical tumors (ACT) are benign and non-functioning tumors, in contrast to adrenocortical carcinomas (ACC), which are rare and usually very

aggressive tumors with a poor prognosis. The pathological discrimination between adrenocortical adenomas (ACA) and ACC is mainly based on unspecific and subjective histological features, resulting in inaccurate diagnosis in several cases. Numerous studies have previously described the potential value of immunohistochemistry (IHC) markers, such as Insulin like-growth factor 2 (IGF2) and the proliferation marker, Ki-67, to detect malignancy in ACT. However, these data were not compiled before. This review aimed to collect the evidence on the potential diagnosis value of IGF2 and Ki-67 immunostaining for ACT. In addition, a meta-analysis was conducted to assess the accuracy of Ki-67 as diagnostic marker for ACC. The systematic review and meta-analysis were performed according to the Preferred Reporting Items for Systematic Review and Meta-analysis (PRISMA) guidelines. The literature search was carried out in three electronic databases, including PubMed, Scopus, and Web of Science. A total of 25 studies met the pre-defined eligibility criteria being enrolled in the systematic review. Among these, 10 reports assessing Ki-67 IHC expression were identified as eligible for the meta-analysis. All the studies assessing IGF2 expression reported higher levels of this protein in ACC when compared to ACA, despite the differential immunostaining evaluation among the studies. The diagnostic performance of Ki-67 was assessed at the most widely used threshold (5% of stained cells) among the included studies. Ki-67 showed a pooled sensitivity, specificity, and log diagnosis odds ratio of 0.82 (95%CI: 0.65 to 0.92), 0.98 (95%CI: 0.95 to 0.99), and 4.26 (95%CI: 3.40 to 5.12), respectively. At the 5% cut-off value, the area under the summary receiver operating characteristic curve (sROC) was 0.949. As conclusion, Ki-67 marker for a 5% cut-off value showed an excellent specificity but only moderate sensitivity, which translates the failure to diagnosis all ACC. Hence, different Ki-67 thresholds should be considered in the future. Additionally, more studies using similar immunohistochemistry analysis methodologies are needed to assess the accuracy of IGF2 for ACT differential diagnosis.

Renal metastasis from papillary thyroid carcinoma: about a case

Amira Bouchenna[1] & Bansaleh Meriem[1]
[1]Central Hospital of Army, Endocrinology, Algiers, Algeria

Introduction
Papillary thyroid cancer is a cancer with a good prognosis and slow progression. Only 2 to 10% of distant metastases, the most frequent at the pulmonary level, cranial metastases represent 2.5 to 5.8% of cases. Renal metastases are extremely rare. We report a case.
Observation
74-year-old patient, without suggesting, presents papillary thyroid carcinoma in its trabecular variant classified pT2NxM1, discovered following a left iliac metastasis. On extension assessment, CT-TAP: found a large left iliac lytic lesion measuring 68×57×71mm, A pulmonary hamartochondroma, bilateral cortical renal cysts including one suspected of malignancy, A harmonious thickening of the outer arm of the right adrenal 9mm and a left renal mass. A biopsy confirmed the secondary origin of the left iliac and renal masses. The patient received 200mci iratherapy, with post-therapeutic scanning of areas of hyperuptake in the left hemi-pelvis and the left renal compartment. Given the risk of bleeding from her left iliac mass, she underwent embolization before orthopedic surgery. Currently she has accumulated 800 mci of iodine with a good response.
Discussion
Renal metastases from differentiated thyroid carcinomas represent 2.5 to 2.7% of cases. Diffusion occurs mainly by the hematogenous route, more rarely by the lymphatic route.

Dazzeling evolution with unusual metastases of a medullary thyroid carcinoma: about a case

Amira Bouchenna[1], Benabdelatif Katia[1] & Bensaleh meriem[1]
[1]Central Hospital of Army, Endocrinology, Algiers, Algeria

Introduction
At the time of diagnosis of medullary thyroid carcinoma (MTC) 10 to 15% of patients have distant metastases, 25% of them develop them over a longer or shorter period of time. The usual metastases concern cervical lymphadenopathy, bone, lung and liver. There are also unusual secondary localisations. We report a case.
Observation
A 56-year-old patient who consulted a year after apparition of cervical lymphadenopathy, whose fine needle aspiration returned in favor of a MTC with serum thyrocalcitonin (TCT) level at 2000 pg/l. The extension assessment was negative, the patient was operated on and the anatomopathological study confirmed the diagnosis of MTC classified as PT3N1bM0. The genetic study of the RET mutation could not be carried out. 6 weeks after surgery the TCT level returns to 1500 pg/l. At 3 months after surgery, the patient presented with inguinal lymphadenopathy, the fine needle aspiration of which revealed a carcinomatous process with a TCT level in the liquid washing was 2342 pg/l. the serum TCT level returned to 3789 pg/l, and the extension assessment found a right adrenal metastasis of 14mm (the diagnosis of pheochromocytoma was ruled out), multiple right femoral and vertebral bone metastases with spinal cord compression of L1, the latter's surgery is rejected, so he benefits from decompression radiotherapy. The patient is put on vandetanib
Discussion
The rapid evolution in our patient with the appearance of multiple metastases, two of which are unusual in 2 months, raises fears of a codon 918 mutation of the RET proto-oncogene. Few studies specify the proportion of rare localizations of MTC; one study of 19 patients reported 10% adrenal and digestive metastases, while another of 35 patients found no cases. In our reading we found only two described cases of metastatic inguinal lymphadenopathy.
Conclusion
Metastases from unusual locations do not seem so rare, they must be sought in the event of a doubling of TST values and be treated in patients whose survival is sometimes very prolonged.

Grade 2 gastric neuroendocrine tumours type 1: not always an indolent disease

Marina Tsoli[1], Maria Panagaki[1], Katerina Ioannidou[1], Aggeliki Karapanagioti[1], Kosmas Daskalakis[2] & Gregory Kaltsas[1]
[1]EKPA-LAIKO ENETS CoE, Laiko Hospital, National and Kapodistrian University of Athens, Greece; [2]2nd Surgical Department, Korgialenio-Benakio, Hellenic Red Cross General Hospital, Athens, Greece

Background
Gastric neuroendocrine tumors (g-NETs) type I are increasingly recognized and are usually well-differentiated grade 1 neoplasms. However, rare cases of metastatic spread and adverse prognosis have been described in the literature.
Aims
The aim of this study was to evaluate the characteristics and the natural history of grade 2 g-NETs type I.
Materials and Methods
We collected retrospectively the data of patients with g-NETs type I and analyzed the epidemiological, histological and imaging features as well as the clinical outcome of grade 2 tumors.
Results
We analyzed the data of 60 patients (39 female) with mean age (±SD) at diagnosis 55±14 years and a median follow-up time 41 (range: 11-207) months. The median size of the neoplasms was 4.5 mm (range: 1-35 mm) while the median Ki-67 was 5% (range: 3-15%). In nine cases the GC1 were resected using endoscopic techniques while 11 patients were treated surgically (wedge resection or subtotal/total gastrectomy). Eight patients received treatment with long-acting somatostatin analogs (SSA). Two patients displayed regional lymph node infiltration while two others had liver metastases that were resected during primary tumor surgery. The Ki-67 of tumours with liver metastases was 8% and 15% whereas the tumor with the Ki-67:15% was Ga-DOTATATE PET/CT and FDG-PET/CT positive. No recurrence has been observed after surgical resection in patients with locally advanced or metastatic tumors after a median follow-up time of 95 (range: 54-158) months.
Conclusions
Despite the overall favorable prognosis of g-NETs type I, grade 2 neoplasms may in some cases display a more aggressive behavior being associated with distant metastases albeit with no apparent impact on patient's prognosis.

Prevalence of adrenal incidentalomas in patients with neuroendocrine tumours

Adam Maciejewski[1], Paweł Komarnicki[1], Kamila Łachut[1], Jan Musiałkiewicz[1], Kosma Woliński[1], Paweł Gut[1] & Marek Ruchała[1]
[1]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznań, Poland

An increasing prevalence of incidental adrenal lesions (adrenal incidentalomas) has been reported in recent years. It is now estimated that adrenal incidentalomas can be found in about 4% of the general population by CT and in up to 10-15% at autopsy. Patients with neuroendocrine tumours (NETs) (including mainly GEP-NETs and pulmonary carcinoids) are expected to have an even higher prevalence of adrenal incidentalomas because of the known genetic preponderance in a subgroup of them (e.g. MEN1 syndrome) and the generally increased risk of second neoplasms postulated in this group. Therefore, the aim of this study was to estimate the prevalence of adrenal incidentalomas in patients diagnosed with NETs and to evaluate their clinical and radiological pattern. A group of 181 NET patients treated in one centre were retrospectively analysed (patients on somatostatin analogue therapy in the course of locally advanced or metastatic NETs). All patients underwent repeated abdominal CT (with initial assessment in an adrenal protocol) and clinical and laboratory evaluation (including serum cortisol and DHEA-S and urine methoxycatecholamine measurement). Of these, 26 (14.4%) had adrenal lesions (35 different lesions). The incidence was similar in women and men (13.6% and 15.4%, respectively). Among the 35 lesions, there were 27 adenomas (77.1%), 3 NET metastases (8.6%), 2 metastases of other origin (renal cell carcinoma; 5.7%), 2 pheochromocytomas (5.7%) and 1 myelolipoma (2.9%). The highest frequency of adrenal incidentalomas was observed in pulmonary NETS (7/20 patients, 35%). Adrenal incidentalomas were found in 15.1% of pancreatic (8/53 patients) and 11.7% of small bowel (7/60 patients) NETs. The prevalence of adrenal incidentalomas in patients with unknown primary NETs was also high - 25% (3/12). As expected, the frequency of adrenal incidentalomas was higher among MEN1 patients (6/9, 66.7%) compared to sporadic cases (20/171, 11.7%). Of the adrenal lesions, 92% were hormonally inactive. Progression in size over time was observed in 11.4% (4/35) of lesions, but only in 3.7% (1/27) of adenomas. The mean diameter of the lesions was 17.0 +- 10.6 mm, with 24 out of 35 (68.6%) located in the left adrenal gland. The prevalence of adrenal incidentaloma is relatively high in NET patients. However, after excluding MEN1 and other genetic syndromes such as VHL, the prevalence drops closer to the values observed in the general population. The majority of incidentally found adrenal lesions are hormonally inactive adenomas that do not exhibit significant growth over time.

Idiopathic SIADH can precede cancer diagnosis by a few years: Two case reports and literature review

Tahir Omer[1,2], Shahriar Shafiq[3] & Malgorzata M. Lubczynska[4]
[1]University Hospitals of Northamptonshire, Endocrinology and Diabetes, Northampton, United Kingdom; [2]University of South Wales, United Kingdom; [3]University Hospitals of Northamptonshire, Northampton, United Kingdom; [4]University Hospitals of Northamptonshire, United Kingdom

Introduction
Syndrome of inappropriate antidiuretic hormone secretion(SIADH) is frequently encountered in clinical settings. Hyponatraemia is often seen in cancer and correlates with poor prognosis. It can rarely precede cancer diagnosis. We present a case series of two patients with idiopathic SIADH, who developed terminal malignancy later in life.
Case 1
A 59-year-old female presented in 2016 with seizure due to severe euvolemic hyponatraemia Na103 moml/l (135-145 mmol/l). She received hypertonic solution followed by fluid restriction. Biochemistry showed plasma osmolality 267 mOsmol/kg, urine osmolality 304 mOsmol/kg, urine sodium 55 mmol/l, 9am cortisol 414 nmol/l, TSH 2.1 mU/l. CXR showed small left pleural effusion. MRI brain/CT Chest/abdomen/pelvis were unremarkable. Citalopram was ceased. A diagnosis of idiopathic SIADH was made with advice on long term fluid restriction. Mild hyponatraemia (Na 126-135) persisted until presentation in 2023 with severe hyponatraemia 113 mmol/l requiring hospital admission. CT chest/abdomen/pelvis showed a pulmonary nodule 23×15 mm in the left upper lobe confirming small-cell lung cancer.
Case 2
A 51-year-old female presented in 2014 with severe euvolemic hyponatraemia Na110 mmol/l. She had a history of anorexia nervosa. Biochemistry showed plasma osmolality 260 mOsmol/kg, urine osmolality 342 mOsmol/kg, urine sodium 62 mmol/l, 9 am Cortisol 280 nmol/l, TSH 3.0 mU/l and unremarkable CT head/chest/abdomen and pelvis. No regular medications that could lead to hyponatraemia were identified. Following a diagnosis of idiopathic SIADH, patient was commenced on tolvaptan due to difficulty maintaining stable sodium by fluid restriction. In 2018, she developed dysphagia and was diagnosed with metastatic squamous cell carcinoma of the oesophagus.
Discussion
Although hyponatraemia was observed in several types of cancer, the aetiology of cancer-associated hyponatremia (CAHN) remains poorly understood. About 14% of inpatients hyponatraemia is due to underlying cancer-related-condition. The most common cause of hyponatremia in cancer is thought to be SIADH. There is, however, an increasing evidence for functional involvement of Na^+-transporting-proteins in malignancy. It is hypothesised that various sodium transporting proteins are expressed during early cancer development which gradually deplete sodium. Therefore, hyponatremia can predate cancer diagnosis; however, the evidence overall is not completely clear. As most studies of cancer-related hyponatraemia are carried out in oncology, these patients have multiple confounding variables making it difficult to discern whether hyponatraemia predates or follows malignancy. In the cases presented, hyponatraemia preceded the diagnosis of cancer by a few years further strengthening the role of sodium-transporting proteins in CAHN.
Conclusion
Meticulous follow up in patients with previously diagnosed idiopathic SIADH appear to be the key to early cancer diagnosis and better patients' outcomes.

Second neoplasms in patients with sporadic neuroendocrine neoplasms (NENs)

Konstantinos Iliakopoulos[1], Ariadni Spyroglou[1], Panagiota Konstantakou[1], Nikolaos Memos[1], Pantelis Antonakis[1], Vasiliki Michalaki[1], Konstantinos Bramis[1], Eleni Memi[1], George Mastorakos[1], Antonios Vezakis[1], Christos Papadimitriou[1], Ioannis Papaconstantinou[1], Manousos Konstadoulakis[1] & Krystallenia Alexandraki[1]
[1]National & Kapodistrian University of Athens, 2nd Surgical Department, Aretaieion Hospital

Background
Neuroendocrine neoplasms (NENs) are rather uncommon while they have an incidence of no more than 0,5 per 100.000 people. The aim of this study is to investigate the prevalence of second neoplasms among patients diagnosed with sporadic NENs.
Methods
Clinical and histological data from patients followed to our NENs clinic between 2020-2023 were retrospectively evaluated. Patients with a known genetic syndrome were excluded from the analysis.
Results
A total of 40 patients were evaluated, 60% of whom were women, with an age range at diagnosis of 18-78 years. In our cohort, 17 patients were diagnosed with pancreatic NEN (42,5%), 7 patients (17,5%) with small bowel NEN, 7 patients (17,5%) with gastric NEN, 3 patients (7,5%) with appendix NEN, 3 patients (7,5%) with rectal NEN, 2 patients (5%) with lung NEN and one (2,5%) with duodenal NEN. Among these tumors 7 (17,5%) were functioning (three with carcinoid syndrome, two with insulinoma, one with VIPoma, one with gastrinoma). Regarding their differentiation, 29% of the gastroenteropancreatic NENs had a Ki-67 index below 3%, being grade 1, 66% had a Ki-index between 3-20%, being grade 2, one patient had neuroendocrine carcinoma and in one patient no Ki-67 was available. Twenty-eight seconds neoplasms were documented in 22 (55%) of the patients; 5 patients had more than one second neoplasms. The most common diagnoses were adrenal incidentalomas (9, 32%), followed by meningiomas (3, 11%) and 2 (7%) for each of papillary thyroid carcinoma, pancreatic adenocarcinoma, and prostate cancer. From the rest of second neoplasms 3 were malignant and 7 benign neoplasms. Regarding the time of presentation, 10 (36%) had a synchronous diagnosis together with the NEN, 6 of them had a metachronous diagnosis of the secondary neoplasm, while in 12 (43%) patients the NEN diagnosis followed the other neoplasm. Overall, one fourth of the second neoplasms were malignant.
Conclusions
In our study, more than half of the patients diagnosed with NEN displayed in parallel a second neoplasm. This observation is suggestive of a possible genetic association triggering these neoplasms. Further prospective clinical and genetic studies will be needed to elucidate these mechanisms.

DOI: 10.1530/endoabs.99.EP554

Genotype-phenotype correlation in serbian patients with multiple endocrine neoplasia type 2 and a mutation in codon 634 of the RET proto-oncogene

Dusan Ilic[1], Sanja Ognjanovic[1], Bojana Popovic[1], Valentina Elezovic Kovacevic[1], Milica Opalic Palibrk[1], Lena Radic[1], Katarina Krstic[1] & Djuro Macut[1]
[1]University Clinical Centre of Serbia, Clinic of Endocrinology, Diabetes and Metabolic Diseases, Belgrade, Serbia

Introduction
Multiple endocrine neoplasia type 2 is an autosomal dominant polyglandular cancer syndrome. It arises as a result of a germline mutation of the *RET* proto-oncogene. The aim of this study was to evaluate the aggressiveness of medullary thyroid carcinoma (MTC) in patients with a proven germline mutation in codon 634 *RET* proto-oncogene, the occurrence of other associated diseases and survival analysis.
Methods
The retrospective study included 66 patients, 26 probands and 40 family members, with a confirmed germline mutation in codon 634 *RET* proto-oncogene. The stage of the disease was determined on the basis of pathohistological findings after surgery for MTC, imaging studies before and after surgery, as well as determination of levels of serum tumor markers.
Results
In the total population of subjects (probands and family members), median age at diagnosis of MTC was 34.18 ± 16.02 years. In the group of probands, carriers of Cys634Arg mutation were diagnosed in younger age compared to carriers of Cys634Phe (31.87 ± 5.01 vs 46.5 ± 4.12 years, p 0.035). Metastatic disease was verified in 28.6% of probands and 21.6% of family members. In both groups, the disease was most often diagnosed in stage 2. No statistically significant difference was found between the preoperative levels of calcitonin and CEA between the groups (p 0.762, P 0.937). The occurrence of disease recurrence was statistically significantly more frequent in probands (p 0.034). In family members who underwent prophylactic thyroidectomy, no MTC was found in two patients at the age 4 and 14, but both had C-cell hyperplasia. The presence of pheochromocytoma was verified in 71% of subjects during follow-up, more often in probands (p 0.004). Median age at diagnosis was 40.90 ± 14.10 years. In 64% of patients with pheochromocytoma tumor was bilateral. The type of mutation in codon 634 did not significantly affect the occurrence of pheochromocytoma (p 0.732). There was no statistically significant difference in the prevalence of primary hyperparathyroidism between the groups (p 0.165). Survival was significantly shorter in patients with stage 4 disease at the time of diagnosis compared to other stages of the disease (p 0.005).
Conclusion
The results obtained in this study indicate the need for early testing of family members of patients in order to enable timely prophylactic thyroidectomy, or to diagnose medullary thyroid cancer or pheochromocytoma at the earliest stage when the possibility of cure is greatest, or to avoid catastrophic consequences of catecholamine excess.

Testosterone replacement therapy and prostatic specific antigen monitoring in men with hypogonadism

Kavitha Ganapathy[1] & Brian Lee[1]
[1]Sandwell and West Birmingham Hospitals NHS Trust, Department of Diabetes, Endocrinology and Lipid Metabolism, Birmingham, United Kingdom

Introduction
Testosterone Replacement Therapy (TRT) is used for aged-related or other forms of hypogonadism and prostatic specific antigen (PSA) is primary screening tool for prostatic cancer in men. The European Academy of Andrology guidelines on investigation, treatment and monitoring of functional hypogonadism in males (EAA-TRT) endorsed by European Society of Endocrinology (ESE) states *Recommendation #31. We suggest performing digital rectal examination and checking PSA at 3 to 12 months for men >40 years of age after initiating T treatment. After the first 12 months, local guidelines for prostate cancer screening for the general population should be followed. Recommendation #32. We suggest further evaluation and/or urological consultation if there is: (a) an increase in serum PSA concentration > 1.4 ng/ml within 12 months of initiating T treatment, (b) a confirmed PSA > 4 ng/ml at any time and (c) detection of a prostatic abnormality on DRE or a substantial worsening of LUTS*. Currently we have a local follow up arrangement, namely PSA at TRT initiation with annual check and further urological assessment if PSA increase if beyond age-adjusted limit. We would like to apply retrospectively the above-mentioned (EAA-TRT) PSA monitoring schedule and determine the outcome in patients who have received intramuscular TRT for first 5 years period of therapy.
Description of Methods/Design
We retrospectively analysed PSA and reviewed outcome in patients receiving intramuscular TRT every 10-14 weeks with 5 years follow up.
Results
$n = 22$. Age 52 (41-73) years and PSA at TRT initiation 0.89 (0.09-5.06) μg/l (median and range). 21/22 (95%) patients had no PSA increase >1.4 μg/l after one year of therapy. Among these, one patient (aged 61) identified as having raised PSA at TRT initiation and subsequently confirmed benign prostatic hypertrophy with stable PSA. Only one (aged 73) with PSA rise >1.4 μg/l after one year and found to have prostatic carcinoma and treated. There is no correlation between PSA and age at TRT initiation, Spearman coefficient $\rho = 0.13$.
Conclusion
Using the EAA-TRT PSA monitoring schedule, we would have identified same individuals at risk of prostatic pathology who warrant urological investigations and some individuals would not need further PSA monitoring beyond one year. However, the majority would still need PSA testing anyway because of increased risk of prostatic cancer based on their age (>50) and ethnicity (up to 15% of Black and Afro-Caribbean origins) and who would normally be included in the PSA testing programme.

Oligo- and polymetastatic paediatric adrenocortical carcinoma – distinct conditions necessitating different treatment approaches?

Michaela Kuhlen[1], Christoph Slavetinsky[2], Jörg Fuchs[2], Marina Kunstreich[1], Pascal Johann[1], Rainer Claus[3], Michael Frühwald[1], Peter Vorwerk[4] & Antje Redlich[4]
[1]University of Augsburg, Pediatrics and Adolescent Medicine, Augsburg, Germany; [2]University Childreńs Hospital Tuebingen, Department of Paediatric Surgery and Paediatric Urology, Tuebingen, Germany; [3]University of Augsburg, Pathology, Augsburg, Germany; [4]Otto-von-Guericke-University, Department of Paediatrics, Paediatric Haematology/Oncology, Magdeburg, Germany

Background
Metastatic adrenocortical carcinoma (ACC) is a highly aggressive endocrine malignancy with event-free survival rates <10% in most paediatric reports. About 15-25% of patients present with metastases at diagnosis. Complete surgical resection is the mainstay of therapy while chemotherapy and mitotane proved to be ineffective in children with metastatic disease highlighting the need for new approaches. Details on children with metastatic ACC are scarce but desperately needed.
Methods
Data from children and adolescents with metastatic ACC registered with the German Malignant Endocrine Tumour (MET) studies of the German Society for Paediatric Oncology and Haematology (GPOH) were included. We investigated the number, size, and sites of metastases, resectability, and speed of disease spread in patients with primary metastatic disease and metastatic relapse for guiding treatment concepts in future clinical trials.
Results
By December 2022, 20 patients with M+-disease at diagnosis and 22 patients with metastatic relapse had been reported. Median age at diagnosis was 12.8 years and 8.3 years. 2-year event-free survival (EFS) was 15.8% and 22.7%, respectively. Metastases were present in the lungs ($n = 30$), liver ($n = 15$), distant lymph nodes ($n = 14$), bones ($n = 6$), and central nervous system (CNS; $n = 4$). Concurrent metastases in two or more organs were evident in 21 patients. Oligometastatic cancer (herein defined as ≤3 metastases limited to one organ) was reported in 9 patients while it was polymetastatic in 33 patients. R_0 resection of all metastatic sites was achieved in 7 patients including 2 patients with two affected organs. In one patient with a single CNS metastasis, radiotherapy was applied. R_0 resection was not reported in any patient with polymetastatic disease. Sixteen (of 20) and 15 (of 22) patients, respectively, demonstrated progressive disease. In oligometastatic ACC, disease progression was evident after a median of 9.2 months (range, 1.2-37.9), in polymetastatic ACC after a median of 5.5 months (range, 0-34.1). In 4 patients with metastases at diagnosis and 7 patients with metastatic relapse first/second complete remission was achieved. All of these 11 patients presented with oligometastatic disease including one patient with metastases in two organs (liver and lung).
Conclusion
Number, site, and resectability of metastases define prognosis in children and adolescents with metastatic ACC. We observed distinct clinical courses (with

different prognosis) in children and adolescents with oligo- and polymetastatic ACC. New treatment approaches are urgently needed in children and adolescents with metastatic ACC.

DOI: 10.1530/endoabs.99.EP557

99mTechnetium-labeled GRPR antagonist for the imaging of prostate cancer – first clinical images

Barbara Bromińska[1], Berthold A. Nock[2], Theodosia Maina[2], Aikaterini Kaloudi[2], Panagiotis Kanellopoulos[2], Barbara Janota[3], Renata Mikołajczak[3], Marek Ruchała[1] & Rafał Czepczyński[1]
[1]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Diseases, Poznań, Poland; [2]Molecular Radiopharmacy, INRaSTES, NCSR 'Demokritos', Athens, Greece; [3]National Centre for Nuclear Research, Radioisotope Centre Polatom, Otwock-Świerk, Poland

Introduction
Nuclear medicine procedures offer a possibility of tracing tumor cells based on their physiology. Gastrin-Releasing Peptide receptor (GRPr) is aberrantly expressed in numerous cancers, among them prostate cancer. Demobesin-15 ([^{99m}Tc]DB15) is a novel GRPR-antagonist designed for the evaluation of GRPr expression in different tumors. It has been shown to accumulate in animal prostate cancer models. Hereby, we present our experiences with the first in-human use of [^{99m}Tc]Tc-DB15 SPECT/CT in PCa patients.
Materials and Methods
We qualified three male patients with a newly diagnosed PCa for the study. Diagnosis was based on the prostate biopsy. There were no metastases or extra prostatic extension in any of the patients. All of the patients agreed to participate in the research and gave their informed consent. Firstly, [^{99m}Tc]Tc-DB15 SPECT/CT was performed followed by [^{18}F]-choline PET/CT that served as a reference method. Patients were observed for adverse events directly after injection of the tracer and laboratory measurements were recorded over 28 days.
Results
In all three patients, moderate focal [^{99m}Tc]Tc-DB15 focal uptake in the prostate was visible at planar and pelvic SPECT/CT images. No foci of increased [^{99m}Tc]Tc-DB15 uptake outside the gland was observed. In the PET/CT images of the prostate showed increased ^{18}F-choline accumulation in the same areas of the gland as depicted in [^{99m}Tc]Tc-DB15 SPECT/CT scans. PET/CT did not show any sign of extra prostatic extension of the cancer, nor metastases. We did not record any adverse events post injection of [^{99m}Tc]Tc-DB15.
Conclusions
Accumulation of [^{99m}Tc]Tc-DB15 in the PCa tissue provides preliminary evidence for the utility of this modality in the in vivo detection of GRPr expression in the tumor. What is important, we did not notice any side effects, thus confirming biosafety of [^{99m}Tc]Tc-DB15. For confirmation of clinical utility of [^{99m}Tc]Tc-DB15 SPECT/CT in PCs further research should be conducted.

Diagnostic approach and clinical outcome. experience of one clinical centre in managing ectopic ACTH secreting syndrome

Anca Matei[1,2], Viviana Popa[1,2], Diana Martiniuc[1], Maria Lazarescu[1], Simina Plesca[1], Letitia Leustean[1,2], Stefana Bilha[1,2], Maria Christina Ungureanu[1,2] & Cristina Preda[1,2]
[1]Saint Spiridon County Hospital, Iaşi, Romania; [2]Universitatea de Medicină şi Farmacie "Grigore T. Popa' din Iaşi, Iaşi, Romania

Ectopic ACTH secreting syndrome is a rare cause of endogenous ACTH dependent Cushing syndrome. We aim to analyze clinical, biochemical, imaging profile, as well as management and outcomes of 7 EAS patients diagnosed in our clinic within the last 10 years, based on clinical presentation, hypercortisolism, high ACTH levels, specifically over 100pg/ml, with failed high dose dexamethasone suppression test. Clinical presentation was characteristic in 5 of the patients, but 2 showed no signs of Cushing syndrome. The common biochemical feature in 5 of 7 cases was severe, treatment-resistant hypokalemia. All patients also presented with or quickly developed classic complications like diabetes, hypertension, osteoporosis and fractures, recurrent bacterial infections and poor wound healing. A CT scan helped in identifying the causative lesions - 3 neuroendocrine tumors and 3 bronchopulmonary tumors. In one case, the primary tumor couldn't be identified. In almost all cases, coincidental CT findings such as ovarian cystadenoma, adrenal lesions, or benign hepatic and pulmonary lesions, made identifying the primary lesion more difficult. Tektrotide scintigraphy was also necessary in two cases to identify the lesion and assess somatostatin receptor expression. While the therapeutic approach varies, resection of the primary tumor and metastases is the therapeutic goal. When impossible, therapeutic approach can range from steroidogenesis inhibitors such as ketoconazole, which were initiated in all cases, but were therapeutically inefficient or caused side effects (primarily alteration of liver function tests), which led to discontinuation of medication; but also somatostatin analogues, which we initiated both before and after scintigraphic confirmation of receptor expression. Palliative mytotane and osilodrostat therapy was also used to attempt disease control until surgical intervention. Ultimately, bilateral adrenalectomy was the only solution in 3 of the 7 cases. Of 7 cases, only one patient was cured following primary tumor resection one went through primary tumor resection and metastasectomy last week and is currently stable; while the others died within 1 month to 4 years since diagnosis because of sepsis, ischemic stroke or respiratory failure caused by primary bronchopulmonary tumor. In conclusion, ectopic ACTH secreting syndrome is a life-threatening condition, and management and outcome depend both on early diagnosis and prompt therapeutic intervention. The main challenges are identifying the primary lesion and managing the many associated comorbidities, such as hypertension, diabetes, electrolyte imbalances and recurrent infections. A multidisciplinary team comprising of endocrinologists, internal medicine specialists, infectious disease specialists and surgeons is mandatory for the best outcome of these patients.

The co-existence of endocrine diseases in patients with neurofibromatosis 1: a case series

Shahini Winson Gnanathayalan[1], Beminahennadige Fernando[1], Manilka Sumanatilleke[1] & Uditha Bulugahapitiya[1]
[1]National Hospital Sri Lanka, Diabetes and Endocrinology, Colombo, Sri Lanka

Background
Neurofibromatosis 1 (NF-1) is an autosomal-dominant multisystemic neurocutaneous disorder. It has long been appreciated that NF-1 is associated with endocrine conditions. The well reported endocrine conditions in NF-1 are growth hormone deficiency, central precocious puberty, pheochromocytoma and gastrointestinal neuroendocrine tumors including insulinoma. Furthermore, individuals with NF-1 are at increased risk of some malignancies including soft tissue sarcomas, peripheral nerve sheath tumors and gastrointestinal stromal tumors (GISTs). These tumors are known to cause non-islet cell tumor cell hypoglycemia (NICTH) due to excessive secretion of insulin like growth factor 2. Here, we describe 2 cases of different endocrine disorders in patients with NF 1.
Case description
Case 1: A 33-year-old lady presented with ischemic stroke. She had elevated blood pressure. But she did not have classic triad of symptoms or spells suggestive of pheochromocytoma. Further assessment revealed the presence of multiple café-au-lait patches, neurofibromas, axillary freckling and bilateral lisch nodules concluding the diagnosis of NF-1. Investigations into the possibility of pheochromocytoma confirmed it with elevated urinary metanephrines more than 5 times the normal upper reference range and large left adrenal tumor. She underwent adrenalectomy and histology further supported the diagnosis of pheochromocytoma. Case 2: A 57-year-old male with NF-1 was evaluated for recurrent major hypoglycemic events and concurrent symptoms of melena, loss of appetite, loss of weight and lethargy for 3-month duration. He was diagnosed to have metastatic GIST. Parallel assessment for frequent spontaneous hypoglycemia made the diagnosis of NICTH with suppressed levels of insulin, c-peptide and beta-hydroxy butyrate with low IGF-1 and positive glucagon challenge test. As the tumor was surgically non-curable, imatinib was started. Due to recurrent level-3 hypoglycemia with hospital admissions, he was initiated on high dose prednisolone. There was initial improvement in hypoglycemia with steroids but after 6 months he gradually deteriorated with gastrointestinal symptoms as well as hypoglycemia and succumbed to death after one year of diagnosis.
Conclusion
Though there are no specific recommendations for surveillance of patients with NF-1, physicians should have a high-index of suspicion in those with symptoms suggestive of endocrine conditions and appropriate screening tests should be performed.

Car accident leading to an incidental finding of multiple endocrine neoplasia type 1 (MEN-1)

Iva Jakubíková[1], Barbora Hagerf[1] & Václav Hána[2]
[1]Institute for Clinical and Experimental Medicine, Diabetes Centre, Prague, Czech Republic; [2]First Faculty of Medicine, Charles University and General University Hospital, Third Department of Internal Medicine, Prague, Czech Republic

Introduction
MEN-1 syndrome is an autosomal dominant disorder caused by mutations in tumor suppressor gene MEN1 and is characterized by the occurrence of parathyroid, pancreatic islet and pituitary tumors. Finding such patient means very pro-active approach to be followed as shows our clinical case.
Case-report
A 30-year-old male was sent for an endocrinological investigation due to an incidental finding of a pituitary lesion on a CT scan after a car accident. He had a history of renal colic 3 years before and his mother underwent a parathyroid gland surgery. During an endocrinological examination a neck ultrasound was performed revealing an enlarged parathyroid gland (8×10×13 mm) under the left thyroid lobe. The localization study was then confirmed by scintigraphy scan and primary hyperparathyroidism was biochemically confirmed: total calcium 3.17 mmol/l (2-2.75), phosphate 0.73 mmol/l (0.65-1.61), PTH 8.6 pmol/l (1.58-6.03). Regarding the brain finding the MRI scan revealed an expansion 10×9×9 mm in the infundibular part of the pituitary gland in close attachment to chiasma opticum, the eye perimeter was normal. Prolactin level was slightly elevated 55.59 µg/l (2.1-17.7), other endocrine axes were normal. Because of a strong clinical suspicion, a genetical testing was performed confirming the diagnosis of MEN1. Following current guidelines a subtotal parathyroidectomy was performed with a prophylactic thymectomy decreasing the risk of future malignant neuroendocrine tumors (NET) in this area. Further active surveillance of NET tumors was done, laboratory testing for chromogranin A and gastrin was negative, but the gadolinium PET/CT scan revealed 5 lesions with high expression of somatostatin receptors in the pancreas. According to the MRI pancreatic scan the biggest lesion in the tail had 23 mm and 13 mm the one in the head. Based on multidisciplinary decision the patient underwent surgery: resection of pancreatic tail and enucleation of the NET tumor in the pancreatic head. Lifelong active follow-up is scheduled, including the brain lesion, which was so far managed in a conservative approach.
Conclusion
Patients with MEN1 have a decreased life expectancy, their prognosis might be improved by presymptomatic tumor detection and undertaking treatment specific for MEN1 tumors. MEN1 patients and their families should be cared for by multidisciplinary teams.

Rare but real: case report of sertoli-leydig cell ovarian tumor

Nada Aitkassi[1,1], Riad Amal[1], El Mazouni Zainab[1], Rifai Kaoutar[1], Iraqi Hinde[1] & Gharbi Mohamed El Hassan[1]
[1]Hopital IBN Sina Mohamed V University, Endocrinology, Rabat

Introduction and importance
Ovarian Sertoli-Leydig cell tumors (SLCT) are rare sex cord-stromal tumors, representing less than 0.5% of all ovarian malignancies. Typically diagnosed at a young age, with 75% of patients having an average onset age of less than 30, these tumors often present a management challenge due to their early detection in young women. The primary dilemma lies in striking the right balance between implementing an effective treatment to prevent recurrences and preserving fertility. Notably, the majority of these tumors produce hormones, with up to 80% of ovarian Sertoli-Leydig cell tumors manifesting signs of virilization.
Case presentation
We report the case of a 28-year-old patient, followed for secondary amenorrhea evolving for 4 years, with a moderate hirsutism scored at 23 according to the Ferriman and Hallway scale, without signs of virilization. The biological assessment revealed elevated testosterone levels at 6.91 ng/ml, confirmed in three subsequent tests. Other hormonal markers, including Delta 4 androstenedione, DHEA sulfate, 17-OH hydroxyprogesterone, and tumor markers (CA 125, ACE, AFP) returned negative results. In terms of morphological assessment: Abdominopelvic CT scan: A pelvic tissue mass measuring 64 mm, probably of ovarian origin. Pelvic MRI: A tissue mass above and lateral to the left uterus of ovarian origin, with a suspicious appearance of malignancy. The case was discussed in a multidisciplinary consultation meeting, and the patient initially underwent a left annexectomy; the histopathological examination revealed a moderately differentiated Sertoli-Leydig tumor.
Conclusion
In conclusion, ovarian Sertoli-Leydig cell tumors remain rare entities, often posing diagnostic challenges due to their low incidence. Early recognition of these tumors, especially in the context of virilization, is crucial for optimal management. Their secretory nature, the need for histological confirmation post-surgery, and the prognosis linked to the degree of cellular differentiation underscore the importance of a multidisciplinary approach. Treatment, primarily surgical, may be supplemented with adjuvant chemotherapy, and postoperative follow-up is essential due to the risk of recurrence.

DOI: 10.1530/endoabs.99.EP753

EP754

Hidden culprit: case report of pancreatic insulinoma

Nada Aitkassi[1], Khamel Ghita[1], El Mazouni Zainab[1], Rifai Kaoutar[1], Iraqi Hinde[1] & Gharbi Mohamed El Hassan[1]
[1]Hopital Ibn Sina Mohamed V University, Endocrinology, Rabat

Introduction and importance
Insulinoma is a rare pancreatic neuroendocrine tumor characterized by hypersecretion of insulin, leading to neuroglycopenia symptoms and heightened sympathoadrenal activity. Incidence ranges from 1 to 4 cases per million inhabitants annually, with a predilection for females in their fourth or fifth decade. Despite its rarity, underdiagnosis is suggested by autopsy studies, revealing higher prevalence. Clinical manifestations often mimic other conditions, causing diagnostic delays. Insulinomas can be sporadic or linked to genetic predispositions like type 1 multiple endocrine neoplasia (MEN1). Diagnosis involves clinical and biochemical assessments, with confirmation through tumor localization using non-invasive imaging techniques and for difficult cases invasive modalities could be needed.
Case presentation
We present a case involving a 61-year-old patient who experienced recurring episodes of malaise for over four years, initially misdiagnosed and treated as Parkinson's disease. Upon admission for the investigation of hypoglycemic episodes, the patient underwent a fasting test that indicated endogenous hyperinsulinism based on elevated insulin and C-peptide levels: 18.43 µUi/ml and 4.84 ng/ml. While a CT scan showed no abnormalities, a pancreatic MRI also revealed no lesions; however, an endoscopic ultrasound identified a 5mm lesion in the upper part of the pancreatic body. Subsequent enucleation of the lesion confirmed its neuroendocrine nature through histopathology.
Conclusion
In summary, insulinomas, while usually benign and treatable, pose a risk of misdiagnosis, particularly as their symptoms overlap with epilepsy and psychiatric conditions. Despite their rarity, these tumors can be life-threatening due to severe hypoglycemia, emphasizing the need for continued clinical follow-up post-surgery. The diagnostic challenge, often requiring invasive measures for accurate localization, highlights the importance of a vigilant and multidisciplinary medical approach for effective management.

Clinical case: MEN2A and pregnancy

Dovilė Dėnaitė[1] & Diana Šimonienė[2]
[1]Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania; [2]Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Department of Endocrinology, Kaunas, Lithuania

Introduction
Multiple endocrine neoplasia type 2A (MEN2A) is a rare autosomal-dominant hereditary cancer syndrome characterized by medullary thyroid carcinoma (MTC), pheochromocytoma, and primary hyperparathyroidism. Pregnancy complicating MEN2A is exceedingly rare, with only 29 reported cases. This case discusses an unusual instance where an enlarged thyroid, displaying sonographic features indicative of cancer, led to the diagnosis and management of RET proto-oncogene-positive MEN type 2A during pregnancy.
Clinical case
A 34-year-old woman, initially seen for hyperglycemia, received a diagnosis of type 1 diabetes mellitus and insulin therapy was initiated. Subsequent thyroid sonography revealed suspicious hypoechoic nodule (~0.8×0.7 cm, EU-TIRADS

4). Fine-needle aspiration confirmed MTC, with markedly elevated calcitonin levels (9.9 pmol/l, normal range <2.6 pmol/l). Parathyroid hormone, serum total calcium, metanephrine, and normetanephrine levels were within normal ranges. The patient underwent genetic testing confirming a positive nucleotide sequence analysis of the RET proto-oncogene, establishing the MEN2A syndrome diagnosis. The confirmation of MTC coincided with the patient's pregnancy at gestational week 5. Subsequently, a decision was made to perform thyroidectomy immediately after the termination of pregnancy, with the expectation that MTC would manifest in a non-aggressive manner. During the second trimester at gestational week 20, repeated assessments showed a twofold increase in calcitonin levels (23.9 pmol/l) and an enlarged right lobe with a hypoechoic nodule (0.7 × 0.6 cm, EU-TIRADS 5) containing microcalcifications. The left lobe displayed a similar nodule (0.5 × 0.4 cm, EU-TIRADS 5), confirming disease progression. The clinical case was discussed by a multidisciplinary team, resulting in a consensus that determined the necessity of total thyroidectomy with lymphadenectomy during pregnancy. The operation proceeded without complications. After the baby was delivered, a suprarenal glands MRI was arranged, revealing no pathological findings. Calcitonin and metanephrines were in the normal range, and a follow-up checkup for recurrence is scheduled for a year later. The patient was also advised to undergo RET genetic screening for the baby and family members to rule out the same mutation in the RET proto-oncogene. A mutation has been

Conclusion

Managing rare conditions like MEN2A during pregnancy necessitates heightened awareness and comprehensive clinical assessment. Early detection and intervention are crucial, emphasizing the significance of the RET proto-oncogene mutation in MTC. This case underscores the delicate balance required in managing such cases, emphasizing the importance of a multidisciplinary approach.

SDHB gene mutation in a young patient with paraganglioma presented with abdominal pain

Christina Lymniati[1,1], Amalia Sertedaki[2], Georgios Kyriakopoulos[3], Christina Kanaka-Gantenbein[2] & Charalampos Tsentidis[1]
[1]General Hospital of Nikaia Piraeus 'Agios Panteleimon', Endocrinology, Diabetes and Metabolism, Nikaia, Greece; [2]Medical School, National and Kapodistrian University of Athens, Greece, Division of Endocrinology, Diabetes and Metabolism, Aghia Sophia Children's Hospital ENDO-ERN Center for Rare Paediatric Endocrine Diseases, First Department of Pediatrics, Athens, Greece; [3]Evaggelismos General Hospital of Athens, Department of Pathology, Athens, Greece

Introduction

Paragangliomas are rare neuroendocrine neoplasms originating from the chromaffin cells of the neural crest and projecting from the extra-adrenal paraganglia. For more than 30% of patients with paragangliomas there is a genetic predisposition. According to W.H.O. paragangliomas should be treated as potentially metastatic diseases. We describe the case of a patient with a paraganglioma and a pathogenic variant in the SDHB gene.

Case Presentation

A 17-year-old female patient, presented with sudden, abdominal pain, localized around the umbilicus and reflected in the right iliac fossa. Magnetic resonance imaging (MRI) revealed a 2 cm para-aortic mass with characters of probably lymph node. During surgical excision of the mass, the patient had a hypertensive spike that was treated with an increase in anesthesia. The postoperative course was completely satisfactory. However the biopsy revealed a paraganglioma with GAPP score 7. The patient came to our department for further evaluation and follow-up. Clinical examination revealed no symptoms of catecholamine hypersecretion, nor she reported anything remarkable in the past, except for occasional headaches attributed to an intensive study program. Laboratory testing for catecholamines was within normal range, but due to her young age, additional histological immunohistochemistry testing was requested, where a complete absence of staining for the SDHB subunit was found. Whole Exome Sequencing revealed the presence of the maternally inherited heterozygous variant, c.201-2A>G, in the SDHB gene (NM_003000.3). This variant affects intron 2 acceptor splice site and was classified as Pathogenic according to the ACMG criteria and SDHB variant classification recomendations. To date, 6 family members have been found to be carriers of this variant, presenting no symptoms or pathological imaging, indicating low variant penetrance. The patient is currently free of disease, both according to laboratory and imaging tests (DOTADOC, MIBG), and is being monitored based on the relevant guidelines.

Conclusions

A common location of sympathetic paragangliomas is the abdomen (para-ortically, Zuckerkandl body), and, with few exceptions, they secrete catecholamines. For this reason, it should be included in the differential diagnosis of an intra-abdominal mass, even without obvious symptoms of catecholamine hypersecretion, especially when it comes to young people, in order to carry out the appropriate laboratory test preoperatively. Pathogenic variants in the succinate dehydrogenase (SDH) gene and specifically the SDHB, SDHC and SDHD genes, accounts for approximately 50% of hereditary paragangliomas. The combination of paraganglioma with increased GAPP score and SDHB gene mutation is an important predictor of the possibility of metastases.

A case study of multiple endocrine neoplasia type 2a

Ines Mezghani[1], Omaima Hammami[1], Rim Marrakchi[1], Faten Hajkacem[2], Mariem Boudaya[1], Kamel Jammoussi[1], Nabila Rekik[2], Mohamed Abid[2] & Mouna Turki[1]
[1]Hedi Chaker University Hospital, Biochemistry Departement, sfax, Tunisia; [2]Hedi Chaker University Hospital, Endocrinolgy Departement, sfax, Tunisia

Introduction

Multiple endocrine neoplasia type 2A (MEN2A) is a rare genetic tumor syndrome due to germline mutations of the RET proto-oncogene, which is characterized by medullary thyroid cancer (MTC), pheochromocytoma, and primary hyperparathyroidism. Our aim was to report a case of a patient with MEN2.

Observation

A 45-year-old patient, with a history of diabetes and corticotropic insufficiency, consulted for paresthesias. The biology showed hypercalcemia at 2.7 mmol/l. The etiological investigation concluded to primary hyperparathyroidism (PTH = 280 ng/l). Cervical ultrasound showed a right thyroid nodule TIRADS 5 and scintigraphy MIBI showed a right parathroid adenoma. The patient underwent surgery. The pathological examination concluded that there was a right parathyroid adenoma with medullary thyroid cancer (MTC) (T1N0M0). The assessment of the postoperative evolution was: PTH: 8.28 ng/l and hypocalcemia: 1.93 mmol/l. After surgery, the patient was addressed for paroxysmal hypertensive crises. The dosage of plasma methoxylated derivatives were elevated to 11× the normal. The topographical assessment revealed two large adrenal masses fixing the MIBG confirming the diagnosis of a bilateral pheochromocytoma. The patient was operated by a bilateral adrenalectomy in 2 stages. The diagnosis of MEN2a neoplasia was made and the genetic study is in progress.

Conclusions

MEN2 is a rare disease. This case study illustrates the importance of recognizing the clinical manifestations of MEN2. Early diagnosis and optimal workup allow for prompt interventions and to decrease the morbidity and mortality associated with MEN2.

Erythrocytosis as the initial presentation of an adrenocortical carcinoma: a case report and literature review

Zydrune Visockiene[1,2], Rasa Juskiene[2], Domas Grigoravicius[1,2] & Joana Semigrejevienė[1,2]
[1]Vilnius University Faculty of Medicine, Clinic of Internal Diseases, Family Medicine and Oncology, Vilnius, Lithuania; [2]Vilnius University Hospital Santaros Klinikos, Center of Endocrinology, Vilnius, Lithuania

Background

Adrenocortical carcinoma (AC) is a rare malignancy (0.7–2 cases per million in Western countries) of the adrenal gland. AC can be associated with various syndromes and conditions, one of the rarest being polycythemia. Erythrocytosis refers to an increase in the number of circulating red blood cells. Secondary erythrocytosis, which is characterised by increased levels of Erythropoietin (EPO), can occur due to several causes, among which - hyperandrogenism and EPO-secreting tumors – both have been previously linked to AC. Although the association of AC and polycythemia is known, literature data concerning this comorbidity is lacking.

Case presentation

We present a 41-year-old male, assessed for new-onset hypertension, mild weight gain and abdominal fullness. On physical examination, he was hypertensive with central obesity. Initial laboratory tests revealed erythrocytosis (HgB 206 g/l, RBC $6{,}90\times10^{12}$). Imagining of the adrenals showed a large 11.5×10.5 cm left adrenal mass, consistent with adrenocortical carcinoma. Further investigation revealed elevated late night serum cortisol, non-suppressible early morning cortisol after 1

mg dexamethasone, low adrenocorticotropic hormone (ACTH) and increased dehydroepiandrosterone (DHEA). Patient underwent erythropheresis, followed by adrenalectomy. A histopathological diagnosis of left adrenocortical carcinoma with vascular invasion was made. After surgery RBC and HgB returned to normal and hypercortisolism disappeared. The patient was later referred for subsequent management by oncologist.
Conclusions
This clinical case illustrates a rare presentation of AC. Awareness of this presentation may aid early assessment and timely management.
Keywords: Adrenal carcinoma; Erythrocytosis; Cushing disease.

Epidemiology and treatment of adrenal cancer. a case series
Marcin Lewicki[1], Agnieszka Zwolak[1], Joanna Świrska[1], Anna Gołda[1] & Ewa Tywanek[1]
[1]Center of Oncology of the Lublin Region St. Jana z Dukli, Endocrinology, Lublin, Poland

Introduction
Adrenal cancer is a rare, highly invasive malignant tumour with the incidence estimated for approximately 0,5-2,0 cases per milion people annually. Considering the fact that adrenal cancer is very sporadic not much data on its epidemiology is available.
Aim of the study
The aim of the study was to present the single-center data on the epidemiology of the adrenal cancer.
Material and methods
Patients with the diagnosis of adrenal cancer who were treated in Center of Oncology of the Lublin Region St. Jana z Dukli in the years 2021-2023 were enrolled into the study. The following data were analyzed: patients' age at moment of diagnosis, primary disease staging according to ENSAT staging classification, histopathologic examination according to Weiss system, clinical presentation (presence or absence of adrenal hormones excess) and treatment applied to the patients.
Results
The study included 14 patients (8 men and 6 women). The youngest patient was 31 years old (a woman), the eldest was 77 years old (a man). The mean age at the moment of establishing diagnosis was 57 years. In 7 patients the cancer was hormonally active - one female patient presented hyperandrogenemia and hypercortisolemia, two female patients and four male patients had overt Cushing syndrome. In ENSAT staging classification for adrenocortical carcinoma, four patients had ENSAT II stage; seven patients had stage III; three patients had stage IV. In the examined group, 11 patients underwent adrenalectomy. In histopathological examination Weiss system was performed in 12 patients. with the maxuimum score of nine points in one of the patients. All 14 patients received adjuvant mitotane therapy. Five patients received additional adjuvant chemotherapy with etoposide, doxorubicin and cisplatin.
Conclusion
Adrenal cancer is a neoplasm with varied clinical presentation. It demands specific diagnostic tools and treatment protocols. Therefore, treatment sgould be conducted in the high-reference centers.

Immunotherapy induced endocrinopathies
Furhana Hussein[1], Gideon Mlawa[2], Swetha Kotha[2], Nancy Mangemba[2], Mahamud Bashir[2] & Aneliya Sirkova[2]
[1]Queen's Hospital, Endocrinology and Diabetes/Acute Medicine, London, United Kingdom; [2]Queen's Hospital, London, United Kingdom

Introduction
Ongoing advancements in the treatment of malignancy has witnessed an increasing use in new immunotherapies, including immune checkpoint inhibitors. Immune-related endocrinopathies affect around 10% of patients treated with checkpoint inhibitors. Common endocrinopathies include thyroid disease and hypophysitis.
Aim
Baseline monitoring test for endocrine disorder in patients started on immunotherapy for cancer treatment and implementation of new trust guidelines to help aid this.
Method
Retrospective single-centre study looking at baseline test for monitoring of endocrine disorders in patients started on immunotherapy for cancer treatment. 22 patients were identified at Queen's Hospital, London, UK (BHRUT–Barking, Havering and Redbridge University Hospitals NHS Trust) in 2023. Measuring baseline cortisol levels, Thyroid Function Tests (TFTs) and HbA1c monitoring before starting immunotherapy.
Results
22 patients identified on immunotherapies including Anti-PD-1 Pembrolizumab (11 patients) and anti-PD-L-1 such as Atezolizumab (7patients) and Durvalumab (4 patients). Patients on Pembrolizumab had 55% baseline cortisol, 73% baseline TFTs and 18% baseline HbA1c. Patients on Atezolizumab had 71% baseline cortisol, 29% baseline TFTs and 14% baseline HbA1c. Patients on Durvalumab had 50% baseline cortisol, TFTs and HbA1c checked. Our team presented findings in a departmental teaching and developed local trust guidelines to help aid recommended endocrine test monitoring and recommended advice/action.
Discussion
Immune checkpoint inhibitors use in cancer treatment has increased. Some studies have shown incidence of severe events is reported as 26% for monotherapy and 55% with combination therapy. PD-1 inhibitors are commonly associated with thyroid abnormalities (5-10%) and can occur 4-10 weeks after initiation of treatment. Diabetes Mellitus (DM) incidence of 1% including new-onset type 1 DM or worsening type 2 DM. CTLA-4 inhibitors are commonly associated with hypophysitis (3-6%) and usually present in 8-10weeks of initiation of treatment. Some studies have reported pituitary hormone deficiencies such as secondary adrenal deficiency (83%), secondary hypothyroidism (77%) and hypogonadotrophic hypogonadism (53%). Primary adrenal insufficiency incidence of 1% as monotherapy and 7% in combination therapy. If undiagnosed early these endocrinopathies can be life threatening.
Conclusion
Our study showed more patient and clinician information on awareness of endocrinopathy complications induced by immunotherapy treatment is important. If undiagnosed early these endocrinopathies can be life threatening. It is important to send baseline endocrine testing and monitoring to aid early diagnosis and treatment of complications. There are no national guidelines; our team have developed local trust guidelines for baseline endocrine test monitoring for patients on immunotherapy treatment. We plan to repeat our study in 6months time with a larger sample size.

Non-islet cell tumor hypoglycemia
Eugénie Van Mieghem[1], Hadi Mazlom[2], Isabel Clinck[1] & Christophe De Block[1]
[1]Antwerp University Hospital, Department of Endocrinology-Diabetology-Metabolism, Edegem, Belgium; [2]AZ Klina, Department of Endocirnology-Diabetology, Brasschaat, Belgium

Introduction
A rare cause of hypoglycemia is non-islet cell tumor hypoglycemia (NICTH), a paraneoplastic syndrome caused by tumoral overexpression of insulin-like growth factor 2 (IGF-2) and pro-IGF-2.
Case presentation:
A 57-year old woman presented with odd behavior each morning that improved after breakfast and extensive weight loss (13 kg in 3 years). The patient was hypoglycemic (2.6 mmol/l) with low insulin levels ($<$ 1.39 pmol/l) and C-peptide (0.089 nmol/l). Blood ketones were negative. She was eating normally and did not report alcohol consumption. Sulfonylurea screening was negative. Liver- and kidney function were normal. Further work-up revealed an enlarged liver with several focal lesions and multiple pulmonary nodules, suspicious for metastases. IGF-1 levels were immeasurably low. A liver biopsy revealed primary hepatocellular carcinoma. Due to the hypo-insulinemic non-ketotic hypoglycemia with immeasurably low IGF-1 levels, NICTH was suspected. IGF-2 was not tested due to the limited availability and the high cost at the patient's expense. Therapy with octreotide and diazoxide was attempted but not successful. Therapy with dexamethasone elevated the glycaemia enough to be able to reduce the IV glucose infusions, but had to be tapered as quickly as possible due to initiation of immune therapy. Therefore, continuous glucose monitoring and pasireotide in compassionate use were initiated. Afterwards, she reported a subjectively better quality of life with fewer nightly hypoglycemic arousals. The dose of dexamethasone was reduced, the IV glucose was stopped and the patient was able to go home. Unfortunately, the patient was re-hospitalized after a few weeks due to progression of the malignancy under immune therapy.
Discussion
NICTH is a rare paraneoplastic syndrome caused by oversecretion of (immature) IGF-2 by benign or malignant tumors. IGF-2 can cause hypoglycemia due to insulin-like effects. In patients who fulfill the Whipple triad, other causes of hypoglycemia should be ruled out. NICTH should be suspected in a known or new diagnosis of malignancy with hypo-insulinemic non-ketotic hypoglycemia. If surgical resection,

the mainstay of treatment for NICTH, is not feasible and an increase in frequency or volume of caloric intake isn't enough, further drug therapy can be initiated. Different treatment strategies (glucagon infusions, glucocorticoids or recombinant human GH) are only feasible in the short-term and can have potential detrimental effects. Therapy with diazoxide or octreotide is not successful. Pasireotide has been attempted before in NICTH due to HCC with improved glycemic control. In our case, therapy with glucocorticoids was suboptimal considering her immune therapy. Pasireotide improved her quality of life.

Secondary amenorrhea – an inconspicuous presentation of sporadic MEN1 syndrome

Preda-Ivascu Monalisa[1], Radu Iorgulescu[2], Sorina Schipor[3], Andrei Muresan[3], Elena Braha[3], Serban Radian[1,4] & Catalina Poiana[1,4]
[1]C.I. Parhon National Institute of Endocrinology, Endocrinology 1, Bucharest, Romania; [2]Sf Ioan Emergency Clinical Hospital, Surgery, Bucharest, Romania; [3]C.I. Parhon National Institute of Endocrinology, Molecular Biology and Genetics, Bucharest, Romania; [4]C. Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Introduction
The MEN1 syndrome is caused by inactivating mutations of MEN1, a tumor suppressor gene encoding menin. A sporadic presentation is relatively rare (8-14%) and could be due to *de novo* mutations.
Aim
To present an MEN1 case diagnosed following a routine consultation for amenorrhea
Case presentation
A 44-year-old female presented with secondary amenorrhea and a history of complicated renal lithiasis requiring repeated urological intervention. Biochemical workup showed moderate hyperprolactinemia (78 ng/ml) and pituitary MRI demonstrated a microprolactinoma, as well as primary hyperparathyroidism with mild hypercalcemia. Bilateral inferior parathyroid adenomas were identified on neck ultrasound examination and confirmed through PTH measurement in FNAB aspirate. Family history was negative for MEN1 manifestations, but the father had died suddenly at 41 yrs of age. There were no clinical manifestations suggestive of neuroendocrine pancreatic tumours.
Management
Prolactinemia was normalized with cabergoline treatment (1 mg/week) and the menses resumed. The patient underwent parathyroid surgical exploration; a right inferior parathyroid adenoma was removed and the left adenoma was not identified, leading to a central compartment dissection and block removal of central lymph nodes; superior parathyroids were macroscopically normal and were preserved. Postoperatively, calcium and PTH were normalized. Postoperatively, results of MEN1 Sanger sequencing of coding exons 2-10 and adjacent intronic sequences identified a likely pathogenic small insertion heterozygous mutation NM_001370259.2:c1700_1701insTTGGTGGC, leading to a frameshift (p.Thr568Trpfs*23). Further workup for MEN1-associated neuroendocrine tumors, as well as genetic screening of family members is pending.
Conclusions
Our patient illustrates an atypical presentation of MEN1, as well as management challenges of hyperparathyroidism in this setting. Genetic testing is recommended in sporadic cases and cases with high suspicion (e.g. multigland hyperparathyroidism). A *de novo* MEN1 mutation remains a possibility in our patient, but its demonstration will be difficult, due to a deceased parent.

Pancreatic neuroendocrine tumor in the context of neurofibromatosis type 1

Virginia Soria Utrilla[1], Viyey Kishore Doulatram Gamgaram[1], Marta Iturregui Guevara[1], María Jose Vallejo Herrrera[1] & Stella González Romero[1]
[1]Hospital Regional de Málaga, Endocrinology and Nutrition

We present the case of a 68-year-old man from Ireland with a history of neurofibromatosis type 1, diagnosed in 2000, who underwent surgery for a right pheochromocytoma in 2005. He was recently admitted to hospital for acute cholecystitis, which was treated conservatively with antibiotics. During his hospitalisation, an abdominal CT scan revealed a 1.8 cm lesion in the uncinate process of the pancreas compatible with a neuroendocrine tumor (NET). In addition, multiple lesions were detected in several liver segments, consistent with microabscesses. 18F-FDG PET/CT was performed and confirmed the presence of a hypermetabolic lesion in the uncinate process. Blood tests were performed to assess the functionality of the NET, which showed that it was a non-functioning tumour. A somatostatin receptor scintigraphy was negative for pathological findings. Based on these results, an endoscopy was performed to obtain a tissue sample from the pancreatic lesion. Histological examination confirmed the diagnosis of a well-differentiated NET (G1) with Ki67 $<1\%$ and 0 mitoses/10 HPF. The case was presented to a multidisciplinary committee and it was decided to request an abdominal MRI to assess the evolution of the microabscesses and to complement the study with 18F-DOPA PET/TC. The MRI showed multiple liver lesions compatible with metastasis in addition to the known pancreatic lesion. The 18F-DOPA PET/CT showed no pathological uptake. A Ga-68-DOTATOC PET/CT was also requested and showed no pathological uptake. The patient was referred to medical oncology and started on everolimus 10 mg daily. However, he developed a generalised skin reaction, which necessitated discontinuation of the drug. The case was reassessed by the committee and a two-stage surgical procedure was deemed the most appropriate course of action. Initially, a cephalic pancreaticoduodenectomy with pyloric preservation was performed. Histopathological analysis of the resected tissue revealed a well-differentiated NET, G1, measuring 2.2 cm, with extensive vascular-lymphatic invasion and lymph node involvement (18 lymph nodes involved). Liver lesions were subsequently resected: two in segment II, two in segment III, one in segment IVa, two in segment V, one in inferior segment VI and two in segment VIII. Histopathological evaluation confirmed that these lesions were metastases from a well-differentiated NET. This case highlights the importance of multidisciplinary management in the diagnosis, treatment and follow-up of NETs. A comprehensive approach involving oncologists, endocrinologists, surgeons and radiologists is essential for optimal patient care.

The Inflammasome molecular machinery as a novel source of diagnostic, prognostic, and therapeutic targets in endocrine-related cancers

Ignacio Gil-Duque[1,2,3,4], Miguel E. G-García[1,2,3,4], Ana S. De la Rosa-Herencia[1,2,3,4], Alvaro Flores-Martínez[1,2,3,4], José H-Hernández[1,2,3,4], María Ortega Bellido[1,2,3,4], Manuel D. Gahete[1,2,3,4], Antonio C. Fuentes-Fayos[1,2,3,4] & Raúl M. Luque[1,2,3,4]
[1]Instituto Maimónides de Investigación Biomédica de Córdoba, Córdoba, Spain; [2]Universidad de Córdoba, Departamento de Biología Celular, Fisiología e Inmunología, Córdoba, Spain; [3]Hospital Universitario Reina Sofia, Córdoba, Spain; [4]CIBER - Center for Biomedical Research Network, Physiopathology of Obesity and Nutrition (CIBERobn), Madrid, Spain

Glioblastoma (GBM) is the most prevalent and most lethal primary brain endocrine-related cancer (ERC) in adults which, in addition to the late-stage diagnosis and the lack of effective novel therapies, results in the low quality of life of patients and the poor prognosis, with a median survival from 10 to 14 months after diagnosis. Accordingly, the identification of novel molecular biomarkers of diagnosis and/or prognosis, as well as therapeutic targets becomes crucial to combat this devastating ERC. In this context, the inflammasome molecular machinery, the master regulator of cell inflammation, could be critical in the modulation of the tumor microenvironment (TME), which is essential in the initiation, progression, aggressiveness, and endocrine alterations of different ERC types. In this work, with the objective of determining the putative pathophysiological role of this molecular machinery in GBM, we characterized the components of the inflammasome in GBM samples ($n=63$) from a genomic, transcriptomic, and proteomic point of view, demonstrating a profound dysregulation in comparison to non-tumor brain samples ($n=19$). The main results were confirmed through bioinformatic analyses using several external cohorts of patients. Interestingly, the presence of mutations in the inflammasome machinery, as well as the alteration in the transcriptional expression of key Inflammasome components such as *MYD88*, *NLRP2*, and *RBP4*, was found to be associated with relevant clinical parameters of prognosis such as survival rate, recurrence, and *MGMT* methylation status. Of note, an overall upregulation of the effectors of the inflammasome was observed, suggesting a putative activation of this machinery in GBMs that could induce the establishment of a proinflammatory TME. Moreover, we demonstrated that the inhibition of the activity of the inflammasome (using the inhibitor anakinra) failed to alter the proliferation of GBM cells but was able to successfully reverse the dysregulation in the expression pattern of the inflammasome components previously observed in GBMs in response to metformin. Taken together, our results demonstrate a

profound dysregulation of the Inflammasome machinery in GBM, which could serve as a source of new diagnostic/prognostic biomarkers and therapeutic targets to combat this devastating types of ERC.

Chronic headache revealing multiple insulinomas: a case report

Soumia Laib[1]
[1]University Hospital Center Touhami Benflis. University of Batna 2, Metabolism, Endocrinology & Diabetes, Batna, Algeria

Introduction
Insulinoma is a rare small-size pancreatic endocrine tumor with an annual incidence of 0. 4 cases per 100.000 persons. Approximately 10% are multiple tumors, and its diagnosis and detection remain a challenge. Its symptoms are related to neuroglycopenia and increased catecholamine secretion. It may mimic cardiac, psychiatric, or neurological conditions, thus often leading to a delay in diagnosis.
Observation
A 51-year-old female was referred to us for a history of recurrent episodes of severe headaches regardless of food intake, for the last 5 years, without associated signs or symptoms, there were no precipitating factors. She noted that it was relieved by eating. Her appetite has significantly increased over the past years. There was no history of any drug intake. She was obese. On examination, she weighed 80 Kg, and her body mass index was 32, 92 kg/m^2 The neurological exam was normal and visual disturbances were denied. Endocrine analysis, showed a decrease in serum glucose level 24 mg/dl, an increased level of insulinemia 14.9 µUI/ml (normal range: 2.60-24.9 µIU/l) and c-peptide 2.97 ng/ml (normal range: 1.1-4.4 ng/ml). She had no organ failure or endocrine deficiencies. Magnetic resonance imaging (MRI) of the brain showed no intracranial lesions. Abdominal and Pelvic magnetic resonance imaging (MRI) with contrast showed well-defined two pancreatic hypervascular lesions involving the body and tail of the pancreas measuring 13 mm and 17mm respectively. The diagnosis of multiple insulinomas was made because of hyperinsulinemic hypoglycemia with Whipple's triad and magnetic resonance imaging.
Discussion
Chronic and repeated hypoglycemia lowers the patient's glucose threshold triggers the counterregulatory hormones release and adrenergic symptoms can be suppressed, which delays diagnosis. Typically symptoms associated with insulinoma develop while fasting; only 21% of patients develop symptoms in both the fasting and postprandial states.
Conclusion
This case is interesting because it highlights the importance of a history and a complete physical examination to address the underlying causes of headache related to endocrine disorders. A chronic headache may be the symptoms of insulinoma that first bring the patient to the attention of a physician.

Pulmonary and retroperitoneal paragangliomas in a young woman: about a case report and literature review

Mohammed M'Hammedi Bouzina[1], Benabdelatif Katia[1], Aicha Lachkhem[1], Abdelkader Yahi[1], Amira Bouchenna[1], Ould Kablia Samia[1] & Bensalah Meriem[1]
[1]Algiers Province, Department of Endocrinology, Central Army Hospital, Algiers, Algeria., Algeria

Introduction
Paragangliomas are chromaffin cell tumors that arise from neuroectodermal cells. Multiple paragangliomas in the same patient are highly uncommon. These tumors have a variable clinical picture, and a very heterogeneous evolution. The pulmonary localization is one of the most frequent, representing 20 to 30% of all neuroendocrine tumors. The silent or aggressive character causes problems in diagnosis, management and prognosis.
Case report
We report a case of 46-year-old women, with no significant past medical, family and psychosocial history, admitted for management of two left mediastinal and retroperitoneal lesions, revealed by deep asthenia, anorexia, weight loss and recurrent abdominal pain. The clinical examination reveals an anorexic patient presenting profuse sweating, palpitations, nausea, vomiting and flush syndrome without clinical signs of carcinoid syndrome or catecholamine's tumor hypersecretion. Screening test for hypertension revealed correct blood pressure (100/56 mmHg). Biological exploration confirmed the non-secreting nature of these masses, with a negative level of plasma catecholamines and 5 HIAA. Contrast-enhanced CT of the abdomen revealed a left mediastino-pulmonary lesion measuring 105*94 mm in contact with the thoracic aorta, the left subclavian artery, and the left common carotid artery which are permeable, invading the left upper pulmonary lobe. Another similar avidly enhancing necrotic solid lesion was seen in the infrarenal latero-aortic retroperitoneal measuring 53*29 mm. CT-guided transthoracic needle biopsy was done. The anatomopathological and immunohistochemical study concluded to a moderately differentiated neuroendocrine paraganglioma tumor, positive for chromogranin A, synaptophysin andSOX10; with a Ki67% at 5%. The MIBG scintigraphy confirmed the neuroendocrine nature of the tumors and does not reveal any secondary distant location. Surgical approach is rejected by our RCP due to the intime vascular relationships, and a therapeutic MIBG scintigraphy is proposed for the patient.
Conclusion
An associated non-functional thoracic and retroperitoneal paraganglioma is a very rare clinical situation. Often asymptomatic, their prognosis is dependent to local evolution and the presence of distant metastases. Management must be multidisciplinary, and surgical excision remains the standard treatment.

DOI: 10.1530/endoabs.99.EP1005

EP1006

Successful control of hypoglycemia with Lanreotide in a patient with nesidioblastosis

Mennani fatima ezzahra[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Centre Hospitalo-Universitaire Mohammed VI Marrakech, Endocrinolgy, marrakech

Introduction
Nesidioblastosis is a rare disease caused by hyperplasia of the pancreatic islets, resulting in hypoglycaemia due to increased insulin production. It is the main cause of hyperinsulin hypoglycaemia in children, although it accounts for only 0.5 to 5% of cases in adults. We report here the case of a patient with neidioblastosis successfully treated with lanreotide 120 mg LP, after persistent hypoglycaemia post-surgery.
Clinical case
A 62-year-old patient, not known to be diabetic, hypertensive on triple therapy, had been reporting deep hypoglycemia of 0.24 g/l for 2 years, with 3 to 4 episodes per week, mainly in the mornings. Abdominal MRI revealed a nodular formation at the corporo-caudal junction distorting the anterior contour of the pancreas with T2 hypersignal, T1 isosignal hypersignal measuring 21 × 18 mm. Biological tests revealed a C-peptide level of 2980 pmol/l (300-1400 pmol/l), and an insulin level of 676 pmol/l (18-173 pmol/l). The patient underwent two operations. Anatomopathological examination concluded to a nesidioblastosis. Immunohistochemistry was positive, with expression of anti-CK7 antibodies, anti-chromogranin antibodies and anti-synaptophysin antibodies. Given persistent hypoglycemia postoperatively, the patient was put on diazoxide 300 mg/d and hydrocortisone 60 mg/d without improvement, then Lanreotide 120 mg was added every 4 weeks. Daily monitoring did not reveal any hypoglycemia.
Discussion
The antisecretory effects of somatostatin on various hormones in endocrine organs can be regulated primarily by SSTR2 and SSTR5. They inhibit the counter-regulatory hormones glucagon and growth hormone (GH), which antagonize the effects of insulin. Lanreotide 120 mg LP is a long-acting somatostatin analogue. It is commonly used in the management of NETs. In the literature, cases of insulinoma successfully treated with lanreotide have been reported. However, no cases of nesidioblastosis have been reported.
Conclusions
Thus, in patients with neidioblastosis with hypoglycemia resistant to diazoxide treatment or in cases of poor tolerance of this treatment, the use of Lanreotide seems to be a therapeutic option to be considered.

Co-occurrence of papillary thyroid carcinoma and multiple endocrine neoplasia type 1: a case report

Rihab Khochtali[1], Fatma Mnif[1], Abdel Mouhaymen Missaoui[1], Samir Mkaour[1], Meriem Naifar[1], Mouna Mnif[1], Dhoha Ben Salah[1], Mohamed Abid[1] & Nabila Rekik[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Sfax, Tunisia

Introduction
Multiple Endocrine Neoplasia Type 1 (MEN1) represents a rare genetic disorder characterized by a predisposition to various endocrine neoplasms, primarily affecting the parathyroid, endocrine pancreas, and pituitary gland. So far, Papillary Thyroid Carcinoma (PTC) has been detected in more than 25% of individuals bearing the MEN mutation, even though this particular cancer type does not usually belong to the clinical spectrum associated with this condition.
Case report
We report the case of a 48-year-old woman who presented with hypercalcemia (3.17 mmol/l), hypophosphoremia (0.7 mmol/l), and elevated PTH (400 ng/ml). These biological findings were consistent with the diagnosis of Primary Hyperparathyroidism. A familial MEN1 history was confirmed through genetic testing in siblings with a missense mutation in MEN1 gene exon 4. Neck ultrasound was performed, uncovering a suspected malignant left-sided thyroid nodule (EUTIRADS 4) measuring 17 mm in diameter, with an ectopic parathyroid mass situated at the cervicothoracic junction with a diameter of 26 mm. MIBI scintigraphy featured a characteristic uptake in the ectopic parathyroid mass. Considering the presence of severe osteoporosis (T-score in the radius side $<$ -5.9 SD), persistent hypercalcemia, and the young age of the patient, surgical treatment was decided. The patient underwent left hemithyroidectomy, left upper and lower parathyroidectomy. Intraoperative pathology examination revealed incidental PTC. A completion thyroidectomy and lymph node dissection were subsequently performed. The definitive pathological examination revealed adenomas in two parathyroid glands (ectopic and eutopic) and bifocal PTC (15 mm in the left lobe, 10 mm in the right), with lymph node metastasis. Whole-body scan showed iodine uptake in the thyroid bed with no distant metastases. This PTC was staged pT1b(m)N1a M0 with intermediate ATA risk. The patient received 100 mCi radioactive iodine therapy for isotopic ablation with favorable outcomes.
Discussion
Our case underscores a rare occurrence of the association between PTC and MEN1. While PTC is often linked to BRAF V600E mutation other pro-oncogenic mutations, including MEN1 mutation, are also possible. However, this association is not well established. Further cases are required to validate this potential correlation.

Ectopic adrenocorticotropic hormone secretion secondary to recurrent olfactory neuroblastoma – a case report

Nikhel Sachdev[1] & Charlotte Choo[1]
[1]Singapore General Hospital, Endocrinology

Background
Severe hypercortisolism from ectopic adrenocorticotropic (ACTH) secretion may be life-threatening. The lung is the most common site of ACTH secreting tumours, ranging from bronchial carcinoids to small cell lung carcinoma. Olfactory neuroblastomas (ONB) are rare malignant neuroectodermal tumours. They show neuroendocrine differentiation and may exhibit a wide variety of paraneoplastic syndromes including ectopic ACTH secretion (EAS). We report a case of EAS from a recurrent olfactory neuroblastoma.
Clinical Case
A 64-year-old male presented with an incidental laboratory finding of severe hypokalemia. He had a background of recurrent olfactory neuroblastoma with neck and dural metastases. He had undergone a resection of the tumour ten years ago, but subsequently experienced intracranial recurrence and slow progression of disease despite three lines of chemotherapy. He had been started on oral dexamethasone one week prior, to reduce the mass effect from the tumour edema. His potassium on admission was 2.2 mmol/l (reference range 3.6 – 5.0 mmol/l). It remained persistently low despite aggressive oral and intravenous replacements. Of note, his potassium level one month ago was normal. His main complaint was increasing lethargy and generalized weakness for the past one month. He had not been taking any new medications, supplements or licorice. Physical examination revealed marked cachexia with proximal myopathy, but no other discriminatory features of Cushing's syndrome. Subsequent investigations revealed inappropriate urinary wasting of potassium. His 0800 hours cortisol (sample taken while on dexamethasone 8 mg twice daily) was 2996 nmol/l, with a markedly elevated ACTH at 429 pg/ml. 24 h urine cortisol collection returned at $>$18205 nmol/l (above the detection limit). Computed tomography imaging revealed unremarkable pulmonary parenchyma but noted interval development of diffuse bilateral adrenal thickening. Magnetic resonance imaging of the brain revealed progressive disease with enlarging dural metastases, and no sellar lesion. He was diagnosed with ectopic ACTH secretion secondary to recurrent olfactory neuroblastoma, resulting in rapid onset of hypokalemia and proximal myopathy, as well as ACTH-dependent bilateral adrenal hyperplasia. Dexamethasone was stopped promptly and he was commenced on oral ketoconazole. The dose was gradually escalated to 600 mg twice a day which achieved good control of his hypercortisolism, allowing for the oncologist to initiate systemic chemotherapy to control his disease.
Conclusion
Olfactory neuroblastoma is associated with a wide range of paraneoplastic syndromes including EAS. Aggressive tumours with EAS often present with rapid onset of clinical signs and symptoms including weight loss, hypokalemia and proximal myopathy. Ketoconazole is a useful therapeutic option in the management of EAS.

Atypical thymic carcinoid tumour with ectopic ACTH syndrome: a rare case with a good prognosis

Mohamed Samir Merad[1] & Fatiha Mohammedi[1]
[1]Oran 1 Ahmed Ben Bella Medical University, Endocrinology and Diabetology departement -Larribere Clinic – university Hospital Dr Benzerdjeb, Oran, Algeria

Introduction
Paraneoplastic Cushing's syndrome is a rare manifestation caused by the ectopic secretion of ACTH. The tumors involved are almost always malignant, with bronchopulmonary being the most frequent, followed by pancreatic and, more rarely, thymic. Thymic carcinoid tumors are very rare neuroendocrine tumors that often complicate endocrine disorders; they are generally more aggressive and difficult to treat, and typical carcinoid tumors in the thymus normally have no endocrine symptoms. Only some specific cases occur with carcinoid syndrome or Cushing's syndrome, and it is widely accepted that surgical resection is the only curative treatment for localized lesions.
Observation
This is a 33-year-old male admitted for possible ACTH-dependent Cushing's disease. He appeared to be quickly developing severe hypercorticism, deteriorated by diabetes, hypertension, and osteoporosis. A 2-day high-dose dexamethasone suppression test suggests ectopic ACTH production. Cervical and thoracoabdominal CT scans indicated oval tissue development in the thymus measuring 11/08 mm with significant heterogeneous enhancement. The patient received a synthetic anticortisolic medication, which restored eucorticism. The thymus was totally resected, and the tumor was removed. The histopathological appearance was that of an atypical carcinoid tumor categorized as T1aNxMx (AJCC 2017). The immunohistochemistry profile was positive for Chromogranin A and Synaptophysin with a high ki67 (40%). The postoperative prognosis was excellent, with remission of Cushing's syndrome and good glycemic and blood pressure management without therapy.
Conclusion
As secretory thymic tumors are very rare, their discovery at an early stage and their resection remain the only solutions for treating paraneoplastic Cushing's syndrome.

Hypoglycemia in pancreatic tumor complicated by bilithorax

Jaddi Oussama[1], Zineb Ait Si Ali[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Mohammed VI university hospital of Marrakesh, Department of Endocrinology, Diabetes, Metabolic diseases and Nutrition, Marrakesh, Morocco

Introduction
Hypoglycemia is a common medical emergency, occurring more frequently in diabetic patients. Rarely induced by a tumor cause, but it is important to recognize the syndrome when it occurs. We report the case of a 64-year-old female patient presenting with hypoglycemia on pancreatic tumor complicated by bilithorax.
Observation
64-year-old female patient, known diabetic for 1 year on Glimeperide 3 mg and Metformin 1 g, hypertension for 1 year on Valsartan, presented to the emergency department with abdominal pain and vomiting for 1 month, associated with mucocutaneous jaundice. Clinical examination: patient conscious, hemodynamically and respiratorily stable; hypoglycemia 0.40 g/l, abdominal examination: ascites with collateral venous circulation and epigastric tenderness. On workup; ASAT: 58 (1.7 N) ALAT 180 (5 N) PT: 43% CRP: 48; tumor markers CA 19-9 and CEA elevated Abdominal MRI: heterogeneous swollen appearance of the body and tail of the pancreas measuring 36 mm in maximum thickness and extending over 7 cm, with infiltration of the peripancreatic fat and moderate peritoneal effusion. Chest X-ray: opaque right pulmonary hemichamber; bilious drainage fluid Cytochemical and bacteriological studies of ascites puncture fluids and pleural effusion were requested.
Discussion
Hypoglycemia is defined as a lower-than-normal blood glucose concentration, traditionally defined biochemically as plasma glucose <3.5 mmol/l. Occasionally, hypoglycemia can be induced by tumors, including insulin-secreting pancreatic tumors and IGF2-secreting non-islet cell tumors. The mechanisms that can cause hypoglycemia in pancreatic tumors are: (1) insulin or insulin-like activity produced by the tumor, (2) decreased gluconeogenesis, (3) disturbed glucagon metabolism and (4) increased glucose utilization by the tumor. Local effects of the tumor on the liver parenchyma may also play an important role.
Conclusion
Hypoglycemia of pancreatic tumor origin remains rare, and treatment is based on tumor control.

Adrenocortical carcinoma with refractory cushing's syndrome: could we have done better?

Raquel Calheiros[1], Sara Gil-Santos[1], Pedro Souteiro[1], Joana Oliveira[1], Isabel Inácio[1], Ana Paula Santos[1] & Isabel Torres[1]
[1]Instituto Português de Oncologia do Porto FG, EPE (IPO-Porto), Endocrinology Department, Porto, Portugal

Introduction
Adrenocortical carcinoma is a rare type of cancer that usually has a dismal prognosis. The concurrent hormonal excess of some of these tumours can have an additional negative impact on patientś morbidity and mortality.
Clinical Case
We present the case of a 57-year-old woman diagnosed with stage IV adrenocortical carcinoma, with liver and bone metastasis, and associated ACTH-independent Cushing syndrome and hyperandrogenism. The patient was started on cytotoxic chemotherapy (etoposide, doxorubicin and platinium), mitotane and metyrapone to control both tumour burden and hormonal secretion. Due to hypercortisolism persistence (salivary midnight cortisol 3.01 ug/dl; morning cortisol 50.8 mg/dl; ACTH <10 pg/ml), mitotane was uptitrated to 6 g/day, metyrapone to 750 mg 3id and ketoconazole was initiated. Uncontrolled Cushing's led to recurrent infections with the need for hospital admission including to the intensive care unit. Recurrent severe hypokalaemia ($K+$ 2.7 mEq/l) episodes also prompted prolonged hospital stays with the need for both oral intravenous potassium chloride (100 mEq/l) and spironolactone addition. Medical therapy was further uptitrated exploring their maximum dosages (mitotane 8 gr/day; metyrapone 2.250 mg/day; ketoconazole 1.600 mg/day; spironolactone 400 mg/day). Despite all these efforts, neither mitotane levels reached therapeutic levels nor did Cushing tests attain normal values. Serial imaging studies revealed structural neoplastic progression. The patient's persistent nausea and vomiting limited her compliance with the therapeutic plan. To reduce the daily pill intake and improve medication tolerability, osilodrostat was requested and approved but the patient died due to disease progression and uncontrolled Cushing before starting this new adrenolytic agent.
Discussion
Pharmacologic management of these patients is challenging considering that metyrapone is useful for Cushing's control but promotes hypokalaemia. Low potassium levels can be mitigated by adding spironolactone, but this agent can cause a decrease in the adrenolytic effects of mitotane. In these cases, uncontrolled hypercortisolism may have a higher impact on patients' prognosis than the tumour burden itself.

Rare primary sites of neuroendocrine tumors:two case reports

Andreea Manole[1], Anca Andrei[1], Alicia Ungureanu[1], Andreea Anne-Marie Ștefan[1], Ramona Dobre[1,2], Iulia-Florentina Burcea[1,2] & Catalina Poiana[1,2]
[1]National Institute of Endocrinology "C.I. Parhon", Bucharest, Romania; [2]University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania

Introduction
Neuroendocrine neoplasms are rare heterogeneous malignancies originating from neuroendocrine cells throughout the body. The most common primary sites are the gastrointestinal and respiratory tracts, but can originate from almost any organ, some in unusual locations. The diagnosis is based on the confirmation of the endocrine nature of the tumor and secondly the confirmation of its primary nature. We describe two cases with a very rare primary localization of neuroendocrine tumor: one in the breast and one hepatic.
Discussion
Case 1 A 43-year-old woman presents after self-diagnosing a left breast lump. Breast ultrasound showed a hypoechoic formation of 1.1/0.6 cm, left breast sectorectomy is performed. Histopathological result: G2 mammary neuroendocrine tumor, positive for hormone receptors (estrogen Alfred 7, progesterone Alfred 6), ki67% 30%, synaptophysin, and HER2 negative. SSTR-2 and SSTR-5 receptors, were positive but no other lesions with somatostatin receptor expression on Tektrotyd scintigraphy. Imagistics was negative, preoperative and at 4 months postoperatively. No carcinoid syndrome with normal serotonin. Chromogranin A was 7.7 times than normal but normalized 6 months postoperatively. Polychemotherapy with Epirubicin and Cyclophosphamide was initiated. It is desired to initiate adjuvant therapy with somatostatin analogue, as evidence supports benefits to survival when endocrine therapies are used in the adjuvant setting. Case 2 A 55-year-old woman known to have extensive right hepatectomy with resection of the main bile duct, lympho-dissection of hepatic and retrocephalopancreatic pedicle. Histopathological result shows: G1/G2 hepatic neuroendocrine tumor, with multiple secondary lymph node determinations, positive for synaptophysin, chromogranin A, CD-56, ki67 4%. Postoperatively, CT TAP, abdominal MRI, cholangio-MRI were performed periodically without evidence of other determinations. Biochemically, within normal limits: neuronal specific enolase, chromogranin A, 5-hydroxyindoleacetic acid/urinary 24 h, with a single slightly elevated serum serotonin 271.10 ng/ml (20-206). Treatment with somatostatin analogue was initiated. Octreoscan scintigraphy is awaited.
Conclusion
Neuroendocrine tumors are a very rare entity, breast and hepatic primary location are unusual. The diagnosis can be challenging and is based on pathological examination and immunohistochemistry, as well as the result of the Octreoscan. The gold-standard treatment is represented by surgical resection and long-term prognosis remains favorable.

Benign insulinoma treated with endoscopic ultrasound guided radiofrequency ablation: a case report

Alina Ghitau[1] & Cristina Spiroiu[1]
[1]Bucharest, Central Military University Emergency Hospital 'Carol Davila', Bucharest, Romania

Background
Insulinoma is a rare pancreatic neuroendocrine tumor, occuring in 1-4 people per million in the general population. It may appear at any age, slightly more common in female than male. Most are benign and solitary. Endogenous hyperinsulinism determines symptomatic hypoglycemia. However, the nonspecific symptoms and small size of these tumors lead to challenges in diagnosis and localization. The treatment of choice is surgical resection, but mini-invasive ablative therapies can be used in selected pacients.
Aim
We present the case of a benign insulinoma treated with endoscopic ultrasound guided radiofrequency ablation.
Case report
A 52-year-old woman presented with a 6 months history of repeated episodes of weakness, fatigue and irritability in a fasting state. Symptoms improved with meals. Over that period of time she gained 10 kilograms. She denied having diabetes or any visual field issues, headaches, behavior change, loss of consciousness or seizures. It is decided that the pacient should undergo a prolonged supervised fasting test and within 30 hours the pacient had symptomatic low plasma glucose level of 38 mg/dl (normal range 74-106) and inappropriately high plasma insulin level of 10.1 μU/ml (normal range 6-35).

Following confirmation of an insulinoma, an abdominal computed tomography scan was done for the preoperative localization, but the result was inconclusive. Endoscopic ultrasonography with fine needle aspiration was performed, confirming a well-differentiated pancreatic neuroendocrine tumor G1, with a diameter of 12/10 mm, located at the junction between the pancreatic isthmus and the body. Endoscopic ultrasound guided radiofrequency ablation (EUS-RFA) using a 19G needle represented the treatment option, as an alternative to surgery and insulinoma was successfully removed. The postoperative evolution was favorable, with minimal abdominal pain treated with analgesic drugs. One week following EUS-RFA, the pacient was asymptomatic, the laboratory tests normalised and during the 3 months follow-up visit, the plasma glucose remained within normal range and the pacient had no active complaints.
Conclusion
This case highlights that an accurate preoperative localization of an insulinoma dictates the management and that EUS-RFA may be a potential alternative to surgery in selected cases. However, more studies are needed to establish the long-term efficacy.

Malignant adrenal tumors: a study of 16 cases

Prince Ismael Mbossa Lembopo[1], Nassim Essabah Haraj[1], Siham El aziz[1] & Asma Chadli[1,1]
[1]Ibn Rochd University Hospital, Endocrinology, Diabetology, Metabolic Diseases, and Nutrition, Casablanca

Introduction
Malignant adrenal tumors are primarily represented by adrenocortical carcinoma and malignant pheochromocytomas. These tumors are rare but potentially aggressive, carrying a bleak prognosis. The aim of this study is to report the clinical, laboratory, and evolutionary characteristics of malignant adrenal tumors.
Patients and Methods
A retrospective descriptive study was conducted at the Endocrinology Department over a 12-year period from 2010 to 2022, including all patients presenting with a malignant adrenal tumor at Ibn Rochd University Hospital in Casablanca. Data analysis was performed using Microsoft Excel 2017.
Results
The study comprised 16 patients, including 9 men and 7 women, with an average age of 42 years. None of the patients had a family history of malignant tumors. There were 12 cases of malignant pheochromocytomas, 3 cases of adrenocortical carcinoma, and 1 case of ganglioneuroblastoma. Discovery circumstances included hypertension in 7 cases, Menard's triad in 3 cases, Cushing's syndrome in 2 cases, abdominal pain in 3 cases, general malaise in 2 cases, and follow-up post-adrenalectomy in 2 cases. The average tumor size was 6.8 cm, with bilateral involvement in 2 patients. Adrenalectomy was performed in 13 patients, while 3 others had a contraindication to surgery. Metastases were identified in the liver, lungs, bones, lymph nodes, and stomach. There were 2 cases of recurrence and 1 case of death. Eleven patients were referred to oncology.
Conclusions
The diagnosis of malignancy can be challenging in the absence of metastases. Regional evaluation of the tumor and the presence or absence of metastasis are necessary to establish prognosis and guide treatment decisions. Therapeutic decisions are made in multidisciplinary consultation.

An uncommon case of thyroid metastasis

Tânia Carvalho[1], Gustavo Rodrigues[1], Alice Monsanto[1], Mafalda Ferreira[1], Mariana Lavrador[1], Mara Ventura[1], Joana Saraiva[1], Cristina Ribeiro[1], Teresa Lindo[2], Belmiro Parada[3], Arnaldo Figueiredo[3] & Isabel Paiva[1]
[1]Centro Hospitalar e Universitário de Coimbra, Serviço de Endocrinologia, Diabetes e Metabolismo, Coimbra, Portugal; [2]Centro Hospitalar e Universitário de Coimbra, Serviço de Cirurgia Geral, Coimbra, Portugal; [3]Centro Hospitalar e Universitário de Coimbra, Serviço de Urologia, Coimbra, Portugal

Introduction
Metastasis to the thyroid gland is a rare phenomenon and is associated with primary tumors of the kidney, lung, breast, colorectal, and sarcoma. Thyroid metastases account for only 0.4-3.0% of all malignant neoplasms of the thyroid and occur more frequently in patients with goiter, thyroiditis, or nodules than in patients without previous thyroid pathology.
Case report
A 57-year-old woman with a history of clear cell renal cell carcinoma (CCRCC) underwent right radical nephrectomy in 08/2020. During follow-up, on 11/2020, a heterogeneous nodule was detected in the thyroid isthmus measuring 32 mm and extending to the anterior mediastinum (CT scan). Thyroid ultrasound described an 11 mm nodule in the isthmus, and fine-needle aspiration cytology yielded a benign colloid result. In 07/2022, an abdominal CT scan revealed a heterogeneous mass in the right adrenal gland measuring 58mm, prompting referral to Endocrinology. Hormonal studies were negative. Preoperative staging CT scan described the adrenal and retrosternal mediastinal mass of thyroid origin measuring 38mm. Thyroid ultrasound reported a "nodule at the lower pole of the left lobe-isthmus transition, partially submerged, hypoechoic, heterogeneous, solid, with regular borders, doubtful microcalcifications, and measuring 24×20×39mm." Fine-needle aspiration cytology indicated a suspicious result for papillary thyroid carcinoma (Bethesda V). A two-stage surgery was scheduled: first, she underwent right adrenalectomy, whose histopathological examination identified a CCRCC metastasis in the adrenal gland; subsequently, total thyroidectomy was performed, revealing not a primary thyroid neoplasm but a thyroid metastasis from CCRCC and a small follicular adenoma in the isthmus. The patient continued follow-up in Urology and is currently on sunitinib after the emergence of a neoplastic lesion in the left kidney and suspicious subcentimeter lung nodules.
Conclusion
Although thyroid metastases are uncommon, it is important to consider this possibility in patients with thyroid nodules and a history of malignancy. Fine-needle aspiration cytology has a sensitivity of approximately 70-80% in diagnosing metastatic nodules, but the differential diagnosis can still be challenging and established only after histopathological examination. The relevance of this case is also justified by the rarity of metastasis from CCRCC to two endocrine glands - thyroid and adrenal.

Prognostic factors of differentiated papillary carcinomas: a retrospective analysis on 115patients

Hamza Fatma[1], Boujelben Khouloud[2], Hamdi Frikha[2], Ben Salah[2], Maalej Souhir[2], Elleuch Mouna[2], jardak Issam[1], Maaloul Mohamed[1], Mnif Mouna[2], Mnif Fatma[2], Charfi Nadia[2], Hadjkacem Faten[2], Guermazi Fadhel[1], Chtourou Khalil[1], Abid Mohamed[2] & Rekik Nabila[2]
[1]Habib Bourguiba University Hospital, Department of Nuclear Medicine; [2]Hedi Chaker University Hospital, Department of Endocrinology

Introduction
Differentiated papillary carcinomas (DPC) account for 0.5 to 1% of all neoplasms, and their prognosis is usually favorable. However, a local and distant recurrence is found in up to 35 % of patients. The objective of this study was to determine prognostic factors of this entity among Tunisian population.
Patients and methods
We retrospectively retrieved records of 115 patients diagnosed with DTC and who were then followed at the nuclear medicine department of Habib Bourguiba hospital-Sfax –Tunisia. All patients underwent total thyroidectomy. Radioactive iodine was regularly administrated for intermediate and high risk patients. For each patient, we analyzed age at diagnosis, histological features tumor size nodal status and metastasis. The Cox proportional hazards model was applied to estimate the unadjusted and adjusted hazard ratio (HR) of survival.
Results
On average, 9.5 patients per year was diagnosed with DPC. The mean age was 40 years old (13-83). The mean follow-up was of 13.5 years. Our population was divided into two age groups ($\leq$45 years and $>$45 years). The Ten year survival was significantly different between the two groups ($P=0.03$). The 10-year survival rate was 57.1% and 82.1% respectively for men and women ($P=0.01$). In an adjusted analysis, the risk of death from DPC was significantly correlated with tumor size ($P=0.006$). Tumor necrosis and multifocality were demonstrated as poor prognostic factors ($P=0.013$ and 0.038 respectively). The 10-year survival rate was 93.2% for patients with pN0 versus 58,1 % for those with pN1. Then, lymph node metastasis was also identified as a strong prognostic factor in patients with DPC ($p < 0.001$). Nevertheless, the presence of metastasis at the time of diagnosis showed no significant impact on survival ($P=0.431$).
Conclusion
Although DPC is commonly considered as a low-risk tumor, our study identified several factors influencing the prognosis of DPC. Early aggressive should be instituted for patients presenting those factors in order to improve survival and life quality.

Adrenocortical carcinoma mimicking hyperaldosteronism: a case report

Hemmat El Haddad[1], Rokaya Abdel Aziz[1], Abir Zakaria[1], Moataz Fathy[2], Randa Salam[1], Kerolis Youssef[3], Mohamed Hamdy[3], Asmaa Ezzat[3], Yasser Mahmoud[3], Andro Osama[3] & Abanoub Edwar[3]
[1]Cairo University, Internal medicine, endocrinology, Cairo, Egypt; [2]Cairo University, Internal medicine, nephrology, Cairo, Egypt; [3]Cairo University, Internal medicine, Cairo, Egypt

Background
Adrenocortical carcinomas (ACC) are rare malignancy with an incidence of 0.7-2 per million population per year. While ~60% of ACC are functional, clinical manifestations of hyper-secretion are seen in only ~40% of the cases. Here, we report a case of ACC with initial presentations of hypokalemia and hypertension mimicking hyperaldosteronism
Case report
A 37 year old male complaining of generalized weakness of 2 years duration and fatigue with limitation of daily physical activities, the condition wasn't not associated trauma, convulsions, fever or disturbed consciousness level 8 months ago the patient developed another attack of severe weakness and fatigue, he sought medical advice, investigations were done and showed severe hypokalemia for which he was admitted to ICU and was discovered to be hypertensive. His blood pressure was 180/100 mmHg, pulse:100 / minute regular, respiratory rate:18/min, oxygen saturation: 96%. Examinations were unremarkable. Hematological, renal, liver function&thyroid function test were in the normal range serum sodium was 146 mmol/l (N:136-145) mmol/l potassium (1.5 mmol), His antihypertensive medications were optimized and started on Losartan, amlodipine, Beta-blocker, alpha-blocker, and diuretics (spironolactone). An extensive evaluation was done to find the cause of hypokalemia. Serum Cortisol AM 4.6 (6.2 – 19.4 mg/dl) ACTH AM 10 (7.2 – 63.3 pg/ml) Plasma renin activity 14.81 (3–33 pg/ml) Plasma aldosterone 270 (10–310 pg/ml) Urinary VMA 3.9 (1.0–7.0 mg/day) The contrast-enhanced CT abdomen showed well defined, smooth, heterogeneously enhancing mass lesion in the left adrenal gland measuring 11.4 cm × 10.3 cm × 11 cm with central necrosis. Color Doppler of bilateral renal arteries showed normal flow. ABG showed metabolic alkalosis. Potassium was supplemented from the IV route as well as the oral route After confirming our diagnosis, He underwent laparoscopic unilateral adrenalectomy (left) and intraoperative and postoperative periods were uneventful. The Operated left adrenal mass. Histopathological examination showed atypical cells showing marked pleomorphic exhibiting small cells to giant bizarre-shaped cells indicating adrenocortical carcinoma. The capsular invasion was seen (Weiss score 8) He was discharged with antihypertensive medications (calcium channel blocker and alpha-blocker), planned to taper off, Blood Pressure and potassium reached normal range after 3 month
Conclusion
Management for ACC requires a multidisciplinary approach. The principal considerations are surgical, which is the only curative option for ACC Secondary hypertension from aldosterone secreting ACC is not only uncommon but may also be unfamiliar to the practicing clinicians

Endocrine syndromes and challenges in resource limited healthcare settings from clinical management point of view

Shahroz Azhar[1], Sidra Safdar[2] & Ali Naqvi[1]
[1]Pakistan Kidney & Liver Institute and Research Centre, Internal Medicine & Endocrinology, Lahore, Pakistan; [2]INMOL Cancer Hospital, Radiation Oncology, Lahore, Pakistan

A 32 years old female, presented with bilateral moderate flank pain resolved with analgesics. She visited physician and advised CT Abdomen & Pelvis. It showed bilateral adrenal nodules. She referred to PKLI Urology & Endocrinology Department.
Workup advised. Investigations: Normal TFT's Ultrasound neck: normal thyroid gland with TI-RAD IV nodule in right lobe. AM cortisol 7.6 ng/dl Urine VMA 6.79 24 hour urinary metanephrines > 600 and normetanephrines > 800 Calcium 11 mg/dl PTH 218.3 pg/ml Calcitonin 30.5 pg/ml Prolactin 3.4 ng/ml Parathyroid planner imaging with SPECT showed scintigraphic evidence of hyperfunctioning parathyroid tissue at inferior pole of left lobe of thyroid gland. CT with adrenal protocol showed right adrenal gland enlarged and enhancing lesion measuring 5.2 cm with precontrast attenuation of 50 HU, attenuation arterial phase enhancement of 114 HU and absolute washout of 23%, similarly another enhancing lesion measuring 4.6 cm is noted arising from left adrenal gland with non-contrast attenuation of 45HU, arterial phase attentuation of 108HU and absolute washout of 23% with no locoregional lymph nodes. PET-CT-DOTATE scan showed bilateral, avid, heterogenous nodular adrenal masses. Since patient was symptomatic with biochemical and radiological evidence of Phaeochromocytoma, she was started on Alpha and Beta blockers before surgery. Her case was discussed in MDT, recommended bilateral adrenalectomies, genetic testing, total thyroidectomy and parathyroidectomy. She underwent Bilateral Robotic adrenalectomy and started replacement corticosteroids (10 mg +5 mg +5mg) and Fludrocortisone (100 mg/day). On followup, it was discussed about hemithyroidectomy and selective parathyroidectomy. Her clinical and biochemical profile were consistent with MEN-2A, unfortunately we could not be able to perform genetic studies due to financial constraints. Histopathologically, macroscopic cut section revealed yellow lobulated tumour in both adrenal glands. Microscopic findings suggested encapsulated neoplasm in the adrenal gland, composed of cells with basophilic cytoplasm and variable salt and pepper nuclei, polygonal with numerous areas of spindled-shaped appearance have markedly pleomorphic nuclei arranged in Zellbellen pattern with some diffuse areas of capsular invasion seen however, no extension into extraadrenal tissues or vessels, no areas of necrosis seen. Immunohistochemistry: Synaptophysin: Positive Chromogranin: Positive Ki 67: 1-2%, S100:Highlights supraterticular cells Reticulin: Highlights Zellbellen pattern After recovering from previous surgery, she underwent right hemithyroidectomy and parathyroidectomy Histopathology A) LEFT LOWER INFERIOR PARATHYROID:Parathyroid Adenoma B) Right Hemithyroidectomy:Medullary Thyroid Carcinoma Unifocal, size 0.5x0.5x0.2 cm, Angiolymphatic invasion: Identified, Perineural invasion & Extrathyroidal extension: Not identified, Margins:Closest inked margin 0.3 cm Pathologic staging: pT1 pNx pMx Now planning for completion thyroidectomy and neck dissection.

EP1123

Abdominal paraganglioma: diagnostic and therapeutic challenge! about 2 cases

Ahmed Boukhalfa[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Mohamed VI University Hospital Center, Marrakech, Morocco, Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakesh, Morocco

Introduction
Paragangliomas (PGL) are rare neuroendocrine tumors of the chromaffin cells of the sympathic and parasympathic ganglia. They are responsible for catecholaminergic hypersecretion syndrome. Clinical presentation and malignant potential are variable and closely linked to the genetic profile.
Clinical Case 1
Fifty three year old patient, diagnosed with diabetes and high blood pression for 4 years, she reported a Menard's Triad evolving for 5 years. Abdominal CT scan noted a mass in the right adrenal lodge, spontaneous density (40 HU), measuring approximately 51×31×35 mm, completed by Urinary Methoxyled Derivatives (UMD) of 24 h, elevated to 30 times normal for metanephrine (MN). A right adrenalectomy performed but with no clear clinicobiological improvement. UMD controle were positive to 9 times normal for MN. MIBG scintigraphy revealed a retroperitoneal mass over the right kidney measuring 30*29 mm, associated with an 8.7 mm hepatorenal lymph node, suggesting local invasion. Surgical revision was performed, with histological evidence of a paraganglioma. An octreoscan performed after the 2nd surgery revealed the persistence of a 21×17 mm right retroperitoneal mass. After a multidisciplinary staff meeting, the diagnosis was a locally advanced abdominal paraganglioma; the decision was a 3rd surgery.
Clinical Case 2
Forty eight year old patient, followed for multiple breast, ovarian and S2-S3 radicular cysts, abdominal imaging performed in the face of chronic right lumbar pain, revealed a heterogeneous right retrocavous mass measuring 39×28×25.6 mm. She reported a chronic Menard's Triad. Urinary Methoxyled Derivatives (UMD) of 24 h, elevated to 6 times normal for normetanephrine (NMN). A surgical removal of the mass was done with histological evidence of paraganglioma PASS score 2.
Discussion
The frequency of advanced PGLs in certain genetic diseases varies from 1% to 90%. SDH mutations account for 30% of patients with mtastatic PGL. [1]. Retroperitoneal localization is rare. Certain PGL can be hereditary, particularly in the case of VHL syndrome. Surgery is potentially curative, but tumor dissemination limits the chances of curative resection (2). Other treatment modalities include radiopharmaceutical techniques, chemotherapy, radiotherapy and experimental therapies. Targeted radiotherapy with 131 I MIBG is an option for systemic treatment (3,4).

Conclusion
Surgery remains the cornerstone in locally advanced forms, supplemented by chemotherapy depending on progression, with a response rate of around 40-50%, despite the limitation represented by the scarcity of retrospective studies, the lack of impact on overall survival and the associated toxicity profile (5).
Key words: paraganglioma, genetic profil, surgery.

A case study of managing a patient with bilateral pheochromocytoma in the 21st week of pregnancy

Piotr Przybycień[1], Danuta Gąsior-Perczak[1,2], Jarosław Jaskulski[2,3] & Aldona Kowalska[1,2]
[1]Holycross Cancer Center, Endocrinology Clinic, Kielce, Poland; [2]Jan Kochanowski University, Collegium Medicum, Kielce, Poland; [3]Holycross Cancer Center, Department of Urology, Kielce, Poland

Introduction
Pheochromocytomas are rarely diagnosed in pregnancy. The consequences of pheochromocytoma during pregnancy can be devastating for both mother and fetus. Effective treatment requires an accurate and early diagnosis, but sometimes the tumor is diagnosed relatively late, so it is absolutely necessary to respond quickly and effectively.
Purpose
The aim of our study is to describe a patient with a history of medullary thyroid cancer who underwent surgery for bilateral pheochromocytoma in the 21st week of pregnancy.
Material and method
A 33-year-old woman with a germline mutation of the RET 634 proto-oncogene and who had undergone surgery for medullary thyroid cancer (MEN2A syndrome) several years earlier was hospitalized for examination of bilateral adrenal tumors, detected during a routine ultrasound examination due to pregnancy, confirmed by MRI. In the past, the patient gave up endocrine follow-up several years after thyroid surgery. On the day of admission, the patient was 18 weeks pregnant and did not report any symptoms. Blood pressure was 127/85 mm Hg with a regular heart rate of 120 bpm. MRI scans and double checking for urinary catecholamine metabolites, which were well above the reference range, revealed bilateral pheochromocytoma. Perioperatively, alpha-blocker was used to prevent blood pressure spikes. After the patient consented to bilateral adrenalectomy, laparoscopic surgery was successfully performed in the 21st week of pregnancy. Histopathological examination of both adrenal tumors confirmed the diagnosis of bilateral pheochromocytoma. The tumors were 20x55mm in the right adrenal and 12×33mm in the left adrenal. The rest of the pregnancy and the delivery were uneventful. The natural birth took place at 37 weeks of pregnancy.
Conclusions
1. Women with MEN2A syndrome should receive follow-up to prevent delays in pheochromocytoma detection, which can pose serious problems, especially if they become pregnant. 2. Surgery for bilateral pheochromocytoma in the second trimester of pregnancy can be performed with appropriate cooperation of an endocrinologist, gynecologist and surgeon. 3. Our patient and her child had a positive effect as a result of careful pharmacological and surgical treatment.

Introduction
Paragangliomas are rare neuroendocrine neoplasms arising from chromaffin cells in the sympathetic or parasympathetic neural paraganglia that may appear in many places throughout the body. These might be benign or malignant tumors. We report an interesting case of disseminated paraganglioma, the diagnosis of which began with the metastasis to the thyroid gland.
Case presentation
A 69-year-old patient with a history of toxic multinodular goiter, treated with antithyroid drugs for approximately two years. Cytological features of papillary thyroid cancer were found in a fine needle aspiration biopsy. The patient underwent total thyroidectomy with central neck dissection. Primary histopathological diagnosis was a multifocal thyroid paraganglioma. Post-operative evaluation revealed solid liver lesion on abdominal ultrasound. Cell-block of liver biopsy indicated well-differentiated neuroendocrine tumor cells. Laboratory tests showed Increased levels of chromogranin A, calcitonin, CEA, CA19-9, AFP, HE4. Moreover, we observed elevated concentrations of 3-metoksythyramine in 24-hour urine collection, with normal concentrations of metanephrines and normetanephrines. Ga-68 DOTATATE PET/CT revealed lesions with an increased expression of somatostatin receptors: intervertebral foramen infiltration at level C7/Th1, metastases to the brain, bones, liver, thyroid and adrenal gland. Next Generation Sequencing of blood did not detect pathogenic mutations SDHA, SDHB, SDHC, SDHD, VHL, RET, MAX, SDHAF1, SDHAF2. The patient was treated with palliative radiotherapy to the spine.
Conclusions
Diagnosing paraganglioma with fine needle aspiration biopsy in the thyroid gland might be difficult. It can be misdiagnosed as other thyroid tumors, like papillary neoplasms, follicular neoplasms or medullary thyroid cancer. Histopathological diagnosis of thyroid paraganglioma requires differentiation between an extremely rare primary thyroid paraganglioma and metastatic neuroendocrine tumor. Good cooperation between the clinician and pathomorphologist is crucial for the appropriate diagnosing and subsequent treatment.

Bilateral adrenal hyperplasia as a paraneoplastic phenomenon – a cadaveric case report

Ganesh Velayudham[1], Mohammed Siddiqui[1], Isabel Phillips[1], Juliette Saloway[1], Andre Coetzee[1] & Karuna Katti[1]
[1]University of Birmingham, College of Medical and Dental Sciences, Birmingham, United Kingdom

Background
Ectopic Cushing's syndrome is a paraneoplastic syndrome characterised by adrenocorticotropic hormone (ACTH) secretion from malignant cells. This can in turn result in overstimulation of the adrenal cortex and adrenal cortical hyperplasia. Resulting hypercortisolism can lead to a host of complications for the patient, including hypertension and hypokalaemia. The aim of this cadaver report is to discuss an unusual case of metastatic lung cancer, presenting with bilateral adrenal hyperplasia and two abdominal aortic aneurysms (AAA). Reports containing documented evidence of bilateral adrenal hyperplasia in the context of paraneoplastic syndromes are rare and serve as the motivation behind this report.
Case presentation
An 84-year-old white, male cadaver was dissected. Sectioning of the right lung revealed a pale-yellow mass measuring 10.0 × 7.4 × 7.0 cm. An irregularly defined, necrotic, ulcerated lesion measuring 5.5 × 4.5 × 3.3 cm was present on the lateral surface of the left shoulder and was assumed to be consistent with a history of metastatic lung carcinoma. Upon abdominal dissection, large adrenal glands were noted bilaterally. Given the finding of what macroscopically appeared to be an infiltrative tumour, along with what would be consistent with metastatic tumour to the skin, a conclusion of bilateral adrenal hyperplasia was considered with the right and left adrenal glands measuring 10.0 × 6.5 × 4.5 cm and 7.3 × 4.7 × 3.5 cm, respectively. There were also two AAAs, measuring 6.0 cm and 11.0 cm at their respective widest transverse diameters.
Conclusion
We propose that bilateral adrenal hyperplasia occurred secondary to lung cancer-related paraneoplastic Cushing syndrome. Resulting hypercortisolism may have propagated the growth of the abdominal aortic aneurysms.

Multiple endocrine neoplasia type 1: diverse clinical presentations and diagnostic challenges

Hind Ouakrim[1], Neima Hassan[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Chu Mohamed Vi Marrakesh - Drh, Marrakech, Morocco

Introduction
Multiple endocrine neoplasia type1(MEN1) is a rare autosomal dominant disorder without a good genotype–phenotype correlation, defined as a tumor developing in at least two endocrine glands including the anterior pituitary gland, the parathyroid glands and the duodenopancreatic endocrine tissue. We present a case report of three patients with a strong suspicion of MEN1.
Cases reports
A 39-year-old with a pituitary surgery history presents a recurrent macro-adenoma, experiencing tumoral symptoms, thyrotrope, and gonadotrope deficiencies, along with kidney issues. Clinical signs include acromegalic features, galactorrhea, nevus-like skin lesions, and grade 1 obesity. Hyperprolactinemia, elevated IGF1, and multiple pituitary deficiencies are identified. Surgery reveals a parathyroid adenoma, dystrophic pancreatic parenchyma, and a grade 2 pancreatic neuroendocrine tumor. A27-year-old urgently admitted for renal failure and anemia is diagnosed with hypercalcemia. The patient reports asthenia, diffuse pain, and a tumoral syndrome featuring headaches, decreased visual acuity, and more. Clinical findings include bone pain, hyperpigmented patches, and subcutaneous nodules. Hypophysogram shows corticotrope, gonadotrope, and thyrotrope deficiency. Cervical ultrasound reveals a right lower parathyroid nodule. Resonance imaging reveals a 6 mm microadenoma. The patient undergoes hemodialysis, transfusions, and surgery for parathyroid adenoma. A61-year-old undergoes surgery for a pituitary macroadenoma causing tumoral symptoms, with corticotrope, gonadotrope, and thyrotrope deficiencies. The histological study confirms a non-secreting pituitary adenoma. Screening reveals primary hyperparathyroidism. Scintigraphy indicates a parathyroid origin for a tissue nodule. The patient receives medical treatment for hypercalcemia and undergoes parathyroidectomy, confirming diffuse parathyroid hyperplasia. In all three cases, MEN1was suspected, unfortunately, genetic testing was not available.
Discussion
The prevalence ofMEN1 in the general population is estimated to range from 1/20,000 to 1/40,000. Mutations inthe MEN1 gene are identified as responsible for the development of this syndrome. At the time of diagnosis, the initial endocrine lesion is solitary in 75% of cases, with each of the primary parathyroid, pituitary, and pancreatic lesions potentially being inaugural. However, parathyroid involvement remains the predominant initial manifestation in the majority of patients, followed by pancreatic neuroendocrine tumors and pituitary adenomas The most common type of pituitary adenoma in MEN1is a prolactinoma, whereas non-functioning adenomas are rare. MEN1 should be considered when various conditions, particularly pituitary, parathyroid, and duodenopancreaticendocrine tissue involvement, are observed in an individual or family. Patients withMEN1 face a reduced life expectancy, with a mortality rate of 50% before the age of50. The prognosis for these patients could be enhanced through presymptomatic detection and specific tumor treatment.

Corticosurrenaloma metastasized: when the challenge becomes twofold

Fatma Mnif[1], Mohamed Khairi Arous[1], Dhoha Ben Salah[1], Rim Khlif[1], Kouloud Boujelben[1], Mouna Elleuch[1], Faten Haj Kacem Akid[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker Hospital, Endocrinology, Sfax, Tunisia

Introduction
The corticosurrenaloma is a rare malignant adrenal tumor with an unfavorable prognosis. The 5-year survival rate at stage IV, defined by the presence of distant secondary locations, does not exceed 28%. We report the case of a patient followed in our department for stage IV corticosurrenaloma and the challenges encountered during her management
Case report
Ms. H, a 42-year-old patient, is under our care for corticosurrenaloma. Her cancer was discovered 7 years ago due to a general deterioration in health with signs of hyperandrogenism. She underwent total left adrenalectomy with an initial pTNM stage of T2N0M0, complicated by adrenal insufficiency requiring hydrocortisone supplementation. A locoregional recurrence after 3 years necessitated surgical reintervention. Currently, a locoregional recurrence, 4 years after the first recurrence, has been diagnosed, involving the head of the pancreas, compressing the splenic vein, and presenting with giant mesenteric nodules of 20 cm. Imaging also revealed a pulmonary metastasis, while bone scintigraphy was normal. Surgical intervention was deemed impossible, leading us to opt for a systemic treatment with mitotane combined with Doxorubicin and Cisplatin chemotherapy. The initial mitotane dose was 1.5 g/day, with a progressive escalation of 1 g every 3 days to reach 6 g/day. The patient developed acute adrenal insufficiency despite parallel increases in hydrocortisone dose, necessitating a reduction in mitotane to 5 g. Thirty days after initiating mitotane and five days after chemotherapy, the patient presented with progressively worsening ataxia. Initially ruling out cerebral metastasis through imaging, we attributed this complication to mitotane's neurological toxicity, leading to a dose reduction to 4 g/day with a favorable outcome.
Discussion and conclusion
The management of corticosurrenaloma is complex, primarily due to the rapidly deteriorating potential of this tumor and, secondarily, the limited therapeutic means available to date. Mitotane stands as the principal alternative in the face of stage IV corticosurrenaloma when surgery becomes unfeasible. Its proven efficacy in controlling disease progression and improving survival is well-established, yet it is accompanied by various undesirable effects, particularly of a neurological nature. The ataxia exhibited by our patient is indeed attributed to mitotane, with its onset five days after chemotherapy possibly suggesting an additive effect, implicating the neurotoxicity of doxorubicin and cisplatin, as reported in the literature.

EP1159

Elusive insulinoma

Baseer Khan[1] & Samar Jaffri[1]
[1]Liaquat National Hospital, Internal Medicine, Karachi, Pakistan

Introduction
Insulinoma is a pancreatic tumor that induces hypoglycemia due to over secretion of Insulin. Common symptoms include headache, diplopia, palpitations, blurred vision and unconsciousness. Approximately 90% of insulinomas are benign. Insulinoma is characterized by the Whipple triad, which includes symptoms of hypoglycemia, concomitant plasma glucose of less than 50 mg/dl, and reversal of symptoms after correction of hypoglycemia.
Case presentation
We report a case of a 40-year-old female, married, who presented to us with fit-like activity for 8 years and low blood sugars for 3 years. The patient first experienced fit-like activity in 2015. It was characterized by tremors, and up rolling of eyes, followed by decreased responsiveness. She would remain drowsy for a few hours and then regain full consciousness after intravenous treatment, the record of which was unavailable. Anti-epileptic medications were started. Her symptoms resolved after a few weeks. She then experienced the same symptoms in 2017 that resolved simultaneously. Symptoms recurred in 2020; her random blood sugar level at that time was 35 mg/dl. Her symptoms resolved after intravenous treatment. She was hospitalized in 2023 and her lumbar puncture was done which showed predominant lymphocytic leukocytosis, anti-tuberculosis treatment (ATT) was started. Commencement of ATT also did not resolve her symptoms. After admission to our hospital, supervised hypoglycemia was induced with fasting; her fasting Insulin, C-peptide and cortisol levels were sent once the patient got symptomatic. Hypoglycemia was corrected with intravenous dextrose bolus after drawing a blood sample which led to the resolution of her symptoms. Her laboratory investigations ordered at the time of fasting were; Blood sugar: 28 mg/dl, Insulin: 42.8 mIU/l, C-peptide: 4.05 ng/ml, serum cortisol: 17.7 mg/dl. She fulfilled the Whipple triad and was diagnosed with insulinoma. CT scan abdomen with contrast was unremarkable. Insulinoma was localized in the pancreatic tail via endoscopic ultrasound and was ablated via ethanol. Post ablation, the patient's blood sugars were normal. Her MRI brain and EEG were done to rule out any central pathology, and both were unremarkable. Her repeat CSF-DR was in the reference range with nil White-cell count. ATT was continued. She was then discharged and anti-epileptic medications were tapered off. She has had no fit-like activity post-discharge.
Conclusion
Our patient with Insulinoma was misdiagnosed with epilepsy. It led to inappropriate prescription of anticonvulsants. Therefore, we conclude that Insulinoma should be suspected in patients exhibiting fit-like activity associated with hypoglycemia. Appropriate clinical judgment is essential for timely management.

MEN2A – unexplored, remains undiscovered

Otilia-Andreea Tarcau[1], Robu Larisa[1], ilona-beatrice blesneac[1], Ingrid-Ioana Stafie[1,2], Maria Manaila[1], Nada Akad[1,2], Anca Matei[1,2], Maria Christina Ungureanu[1,2], Grigorovici Alexandru[2,3], Liliana Gheorghe[2,4], Gabriela Delia Ciobanu[2,5], Alexandru Florescu[1,2] & Cristina Preda[1,2]
[1]Saint Spiridon, Endocrinology, Iasi, Romania; [2]Grigore T. Popa University of Medicine and Pharmacy, Medicine, Iasi, Romania; [3]Saint Spiridon Emergency County Hospital, Surgery, Iasi, Romania; [4]Saint Spiridon Emergency County Hospital, Radiology, Iasi, Romania; [5]Saint Spiridon Emergency County Hospital, Pathology, Iasi, Romania

Introduction
Multiple endocrine neoplasia type 2A is an autosomal dominant disorder, caused by mutations in the RET proto-oncogene. The genetic testing may help us in the early identification of carriers, and it can guide us on the follow-up and on the treatment. Thus, we can significantly reduce the morbidity and mortality of this syndrome. We will illustrate a case and highlight the importance of follow-up in a MEN2A patient.
Case report
A 41-year-old woman, presented to our clinic for the first time 23 years ago, when she was only 17 years old, to investigate a secondary cause of hypertension. At that moment, her mother was already diagnosed with pheochromocytoma. After explorations, she was also diagnosed with pheochromocytoma, but due to her young age she was fully investigated and she also received the diagnosis of medullary thyroid cancer (MTC). The patient underwent left adrenalectomy, followed by total thyroidectomy. In the following year, MTC receded. The patient underwent another surgical intervention, this time with good results, but in 2005 she was lost from the records. During that time the hypertension reoccured slowly. She got pregnant 5 times. One pregnancy ended with premature birth at 32 weeks. Three pregnancies were lost in the evolution and the last one ended with the intrauterine death of the fetus at 37 weeks – at that point the patient returned to the clinic. Following the fetal extraction intervention, systolic blood pressure increased to 220 mmHg. She was directed to the cardiology service. The increased values of urinary metanephrines - revealed a recurrence of pheochromocytoma. The computed tomography scans showed an inter-hepato-renal tumour mass and two cystic formations on each of the ovaries. After receiving the perioperative management, a surgical intervention was performed, consisting of extraction of all the tumour masses. Histopathological examination confirmed the presence of pheochromocytoma, a mucinous adenoma cyst on the left ovary and a simple cyst on the right ovary. Genetic testing was recommended for the patient and her son and we are waiting for the results.
Discussion
Maybe if the patient had been reevaluated regularly, the outcome of the last pregnancy would have been different.
Conclusion
It is mandatory to fully explore a patient with MTC or pheochromocytoma, due to the possibility of hiding a MEN2A. This requires rigorous follow-up for the patient and in some cases also for the relatives.

Type 1 multiple endocrine neoplasia syndrome - saved by the somatostatin receptors

Anca Matei[1,2], Viviana Popa[1], Florin Braniste[1,2], Diana Martiniuc[1], Robu Larisa[1], Maria Lazarescu[1], Simina Plesca[1], Andreea Rosu[1], Stefana Bilha[1,2] & Cristina Preda[1,2]
[1]Saint Spiridon County Hospital, Iaşi, Romania; [2]Universitatea de Medicină şi Farmacie "Grigore T. Popa" din Iaşi, Iaşi, Romania

Background
Multiple endocrine neoplasia type 1 (MEN1) is a rare autosomal-dominant tumor syndrome associated with a wide tumor spectrum, in endocrine and nonendocrine tissues, key association being pituitary, parathyroid and enteropancreatic neuroendocrine tumors. Management of MEN1 is challenging because of its polymorphic, variable phenotypic expression.
Case report
Here, we present the case of a 68 year old patient diagnosed in 2004 with an 18 mm istmic pancreatic gastrinoma (gastrin $= 14239$ pg/ml), on account of symptomatic, multiple duodenal ulcers. The diagnosis of MEN 1 is supported by the association with a prolactin secreting pituitary macroadenoma, well controled through time with low dose cabergoline; and hyperparathyroidism, which became apparent 10 years later through biological, ultrasound and osteodensitometric expression, but without TcMIBI scintigraphic confirmation so far. Upon surgical resection, the pathology report confirmed a chromogranin positive, moderately differentiated neuroendocrine carcinoma with a Ki67 $< 1\%$. Within a year, the patient developed an infracentimetric within a year. A whole body scan with 111Indium-Octreoscan revealed uptake of the pancreatic lesion, so octreotide treatment was started in 2011, and serum chromogranin and gastrin levels normalized. Treatment was discontinued after a 99m Tc Tektrotide scan revelead a new pancreatic lesion and bilateral pulmonary secondary lesions. A follow-up CT scan reveals two infracentimetric pancreatic lesions; and a possible infracentimetric hepatic lesion. This, together with increasing gastrin, serotonin and cromogranin levels (650 ng/ml, 401 ug/dl and 509 mg/l, respectively), determined reinitiation of Octreotide treatment, which controlled tumor growth and neuroendocrine marker levels until 2023. In April 2023, the patient presents with altered condition and jaundice, and CT revelead cholelithiasis and a 3 cm pancreatic tumor which invaded the peripheral and common bile ducts; and liver metastases. Follow-up 99m Tc-Tektrotide scintigraphy revealed another liver metastasis and hyperfixation in the epigastrium. Therefore, peptide receptor radionuclide therapy (Lu-177-oxodoterotid) was employed, with two sessions so far, in parallel with octreotide between courses, with favorable evolution of tumors marker levels and tumor size.
Conclusion
MEN1-associated neuroendocrine tumors are indolent neoplasms, with a fluctuating evolution over time. A best-case scenario is when they express somatostatin receptors, which allows for treatment with somatostatin analogues, providing adequate tumor control for a long period of time. If they become inefficient, PRRT therapy can be employed alongside, which offers survival and quality of life benefits. All in all, managing these patients requires a multidisciplinary approach, including endocrinologists, surgeons, radiotherapists and oncologists, and management should be individualized on a case-by-case basis.

Insulinoma; a case of misdiagnosed rare tumour

Amina Al-Qaysi[1], Alawia AlBashir[1], Masood Ashraf[1], Harisanth Rajaram[1] & Sherwin Ganegoda[1]
[1]Buckinghamshire Healthcare NHS Trust, United Kingdom

Introduction
Insulinoma is a rare functional pancreatic neuroendocrine tumour affecting 1 in 4 million individuals per year. The inappropriate hyperinsulinemic state in this condition causes hypoglycaemia resulting in a broad spectrum of clinical manifestations including sweating, shaking, confusion, and seizure.
Case report
An 84-year-old lady was admitted to the hospital after sustaining a witnessed generalised tonic-clonic seizure during the early morning hours associated with having capillary blood glucose of 1.8 mmol/l. She had a history of multiple episodes of involuntary arms and legs shaking at night since a year, she was diagnosed with Rapid Eye Movement sleep behaviour disorder for which she was commenced on Clonazepam that failed to improve her symptoms. The patient developed multiple spontaneous hypoglycaemic episodes during this hospital admission and was found to have inappropriately elevated insulin levels (100 pmol/l) and high C-peptide (1048 pmol/l) during one of the episodes when her plasma glucose was 1.6 mmol/l. The urine sulphonylureas screen was negative. A hyper-vascular $1.3 \times 0.9 \times 1.3$ cm tail of the pancreas mass suggestive of insulinoma was detected on the contrast enhanced CT scan of the abdomen with no radiologic evidence of distant metastasis. The patient elected for medical management, Diazoxide was preferred by our patient for its oral route of administration, and was commenced resulting in significant improvement in her symptoms and was well tolerated.
Conclusion
Insulinoma frequently gets misdiagnosed due to its rare occurrence and because of its wide spectrum of neuroglycopenic and autonomic symptoms that could be at times vague in nature mimicking other neuropsychiatric disorders, as highlighted in this case report. Detailed and careful history taking including obtaining a collateral history remains an essential tool allowing early suspicion of this uncommon diagnosis.

Differentiated thyroid cancer in the adolescent population

Hamza Fatma[1], Khouloud Boujelben[2], Hamdi Frikha[2], Ben Salah Dhoha[2], Maalej Souhir[2], Elleuch Mouna[2], Hadjkacem Faten[2], Jardak Issam[1], Mnif Mouna[2], Mnif Fatma[2], Charfi Nadia[2], Guermazi Fadhel[1], Chtourou Khalil[1], Abid Mohamed[2] & Rekik Nabila[2]
[1]Habib Bourguiba Hospital, Department of Nuclear Medicine; [2]Hedi Chaker University Hospital, Department of Endocrinology

Introduction
Differentiated thyroid cancer (DTC) is one of the most prevalent malignant tumors in adolescents and young adults, accounting for 14-15 % of all neoplasms in this population. Patients present commonly with advanced-stage disease. The aim of our study was to highlight clinical and histopathological features of DTC in the adolescent population.
Patients and Methods
This was a retrospective study, performed in the department of nuclear medicine in Habib Bourguiba hospital –Sfax –Tunisia. Twenty patients with DTC, aged between 18 and 30 years old, were recruited between 2019 and 2020.
Results
The mean age of patients was 26.2 years old. The female sex was the most affected with a sex ratio of 1.8. Clinical features leading to the diagnosis of DTC were as follows: thyroid nodule in 11 cases, cervical lymphadenopathy in 5 cases and symptoms of hyperthyroidism in 4 cases. All our patients underwent total thyroidectomy. Cervical lymphadenectomy was performed in 78.5% of patients. Different cytological features were observed. Classic variant of DTC was the most common histological subtype (86.6%), followed by vesicular variant (15.4 %). Multifocality was noted in 54% of patients. Lymph node involvement was identified in 40% of cases. The tumor multifocality was noted in 54% of patients. Lymph node involvement was identified in 40% of cases.
Conclusion
DTC in adolescents and young adults is characterized by an important initial local and distant extension. Papillary carcinoma remains the predominant type. Then, the risk of lymphatic recurrence is high, but remains curable with a combination of surgery and radioactive iodine.

Thyroid papillary microcarcinoma: a tunisian survey

Fatma Hamza[1], Khouloud Boujelben[2], Hamdi Frikha[2], Dhoha Ben Salah[2], Mohamed Khairi Arous[2], Mouna Elleuch[2], Faten Hadjkacem[2], Issam Jardak[2], Mohamed Maaloul[1], Fatma Mnif[2], Nadia Charfi[2], Mouna Mnif[2], Fadhel Guermazi[1], Khalil Chtourou[1], Mohamed Abid[2] & Nabila Rekik Majdoub[2]
[1]Habib Bourguiba University Hospital, Department of Nuclear Medicine; [2]Hedi Chaker University Hospital, Department of Endocrinology

Introduction
Papillary thyroid carcinoma (PTC) is the most common histological form of thyroid neoplasm, increasingly diagnosed at the microcarcinoma stage (tumor diameter $\leq$10 mm). The majority of papillary thyroid microcarcinomas (PTMC) are not recognizable during physical exam and are commonly diagnosed fortuitously during histopathologic analysis of thyroid specimens following surgery for benign thyroid conditions. The aim of our study was to identify different clinical and pathological characteristics of PTMC.
Patients and Methods
A retrospective study including 51 patients who were followed for PTMC, at the department of nuclear medicine at Habib Bourguiba hospital, Sfax-Tunisia. Clinical, pathological and therapeutic characteristics were analyzed.
Results
The average age of patients was 44.6 $\pm$ 8,9 years. There were 46females and only 3 males PTMC was diagnosed after thyroid nodule and nodular goiter surgery in 41.25% and 23,5 % of cases, respectively. Cervical lympadenopathy was found in 25.5% of cases. Only one patient had a lymph node metastasis. All patients underwent total thyroidectomy and cervical lymphadenectomy was performed in 80 % of patients. Pathological examination revealed a vesicular variant in 23.5% of patients and a classic variant of PTC in 76.5% of patients. Multifodality was found in 68% of patients. The mean tumor diameter was of 3.9 mm (1 mm-10 mm). Lymph node involvement was confirmed in 20 % of patients. Lymphocytic thyroiditis was observed in 35.4% of patients. Capsular rupture was found in 43.1% of surgical specimens.
Conclusions
PTMC present various clinical and histopathological features that emplace them on the borderline of benignity. However, regular follow-up is of a great importance in the management of the tumors, as late recurrence may occur.

Environmental Endocrinology

EP171

Unraveling the connection between celiac disease and autoimmune endocrinopathies: a comprehensive review of 18 cases"

Lamya Echchad[1], Rifai Kaoutar[1], Iraqi Hinde[1] & Gharbi Mohamed El Hassan[1]
[1]Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Celiac disease is an autoimmune disorder related to gluten ingestion in genetically predisposed individuals. Its clinical expression is polymorphic, rendering it a true systemic disease, and its management is based on a gluten-free diet (GFD). Autoimmune endocrinopathies are disorders affecting endocrine glands such as the thyroid or adrenal glands, also stemming from autoimmune reactions with complex pathophysiological mechanisms involving environmental, genetic, and immunological factors. While the impact of celiac disease on the digestive system is well-established, less is known about the connections between celiac disease and autoimmune endocrinopathies.
Patients & methods
This is a retrospective descriptive study which focuses on 18 cases of Celiac Disease presenting with autoimmune endocrinopathies, with follow-up managed by the Endocrinology and Metabolic Diseases Department of Ibn Sina University Hospital of Rabat. The study spans a 4-year period from October 2018 to October 2022. The aim of our study is to assess the prevalence of autoimmune endocrinopathies in patients with celiac disease and to better identify common underlying mechanisms.
Results
The mean age of our patients was 30.6 $\pm$ 12.6 years, with a female predominance. Autoimmune thyroiditis (Hashimoto's) was present in 16 cases (89%), while type 1 diabetes was present in 4 cases (22%). One case (5.56%) had corticotropin deficiency due to autoimmune hypophysitis. Six patients had 2 to 3 autoimmune pathologies associated with celiac disease, representing 33%.
Discussion & Conclusion
Celiac disease and autoimmune endocrine disorders are intricately interconnected medical conditions. Patients diagnosed with celiac disease exhibit an elevated susceptibility to the onset of endocrine disorders such as autoimmune thyroiditis, type 1 diabetes, and Addison's disease. Through our study, we have illuminated this association by examining a series of 18 cases where individuals with celiac disease concurrently presented with autoimmune endocrinopathies. The intricate mechanisms behind this association remain incompletely understood, with suggestions pointing to the potential involvement of genetic, immune, and environmental factors. It has been proposed that gluten ingestion in celiac disease may trigger an inflammatory response, disrupting the immune equilibrium and resulting in endocrine dysfunction. This association emphasizes the critical need for a systematic assessment of endocrine function in individuals with celiac disease. Likewise, individuals diagnosed with autoimmune endocrine disorders should undergo screening for the possibility of celiac disease, facilitating early and effective intervention.

An unusual cause of a head and neck mass: about 18 cases

Houas Jihene[1], Heyfa Belhadj-Miled[1], Monia Ghammam[1], El Ghali Wassim[2], Malika El Omri[1], Abir Meherzi[1], Mouna Bellakhdhar[1], Yosra Hasni El Abed[3], Wassim Kermani[1] & Mohamed Abdelkafi[1]
[1]Farhat Hached Hospital, ENT Department, Sousse, Tunisia, [2], Department of Anaesthesia, Sousse, Tunisia, [3], Department of Endocrinology, Sousse, Tunisia

Introduction
This study aims to investigate the epidemiological, clinical, and therapeutic dimensions of cervicofacial hydatidosis.
Materials and Methods
A retrospective analysis was conducted on 18 patients who underwent surgery for cervicofacial hydatid cysts between 1982 and 2018.

Results
The average age of the patients was 26 years, ranging from 2 to 79 years. The distribution of cysts included cervical muscle in 8 cases, thyroid in 5 cases, parotid in 2 cases, cervicothoracic in 1 case, laryngeal in 1 case, and jugal in 1 case. One case presented with cyst fistulization to the skin. Preoperative suspicion of hydatid cyst was noted in 6 cases. Surgical treatment was tailored to each cyst's location and confirmed intraoperatively based on macroscopic observations and histopathological findings.
Conclusion
Cervicofacial localization of hydatid cysts is a rare occurrence, even in highly endemic regions. Clinical symptoms vary depending on the cyst's location and size, making preoperative diagnosis challenging. Treatment consists exclusively of surgical intervention to excise the cyst without rupture. The prognosis is excellent in hydatid cyst cases treated with total removal of the cyst without rupture.

Factitious hypoglycemia: about 16 cases

Rajaa Mashal[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy- University Hassan II – Casablanca-Morocco, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Departement , Casablanca, Morocco

Introduction
Adult factitious hypoglycemia is due to self-administration of insulin or insulin secretagogue, and is the most common cause of Münchhausen syndrome. The objective is to study the epidemiological profile of patients hospitalized for artificial hypoglycemia for better management.
Patients and methods
Retrospective study carried out at the Endocrinology and Metabolic Diseases Department, Ibn Rochd University Hospital - Casablanca, on patients hospitalized from January 2018 to December 2023 for factitious hypoglycemia.
Results
In our study, 16 patients were included, including 4 men and 12 women. Of these, 10 patients (62.5%) were known type 1 diabetics with an average age of 26.1 years (15 years - 35 years) and an average duration of diabetes of 13 years. And 6 patients not known to be diabetic, with an average age of 19.5 years (15 years - 29 years). the 16 patients were admitted to the department with severe hypoglycemia at 0.3 and 0.6 g/l that persisted despite discontinuation of insulin therapy in diabetic patients. all our patients underwent a hormonal work-up with a jeün test. Hormonal assays showed elevated and appropriate cortisol levels in all our patients, with elevated insulin and normal C-peptide levels in 6 patients (3 T1DM and 3 non-diabetic patients), and elevated and inappropriate insulin and C-peptide levels in the other patients. A psychological interview revealed the presence of parental conflicts for our 10 young patients and 6 patients in an anxio-depressive state, with the notion of dummy intake of rapid insulin in 14 patients and dummy intake of gliclazides for 1 non-diabetic patient.
Discussion and conclusion
Factitious hypoglycemia is a difficult-to-diagnose psychiatric disorder. They are most often found in female patients with easy access to hypoglycemic treatments. Psychiatric follow-up is necessary to avoid recurrences, which can be life-threatening in this situation.

Can the exposure to the UV-B filter octinoxate modify the response to exogenous triiodothyronine in zebrafish embryos?

Margarida Lorigo[1,2,3], Elisa Cairrao[1,2], Marta Monteiro[3], Luiza Breitenfeld[1,2], Amadeu Soares[3] & Carla Quintaneiro[3]
[1]CICS-UBI, Health Sciences Research Centre, University of Beira Interior, Covilhã, Portugal, [2]FCS - UBI, Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal, [3]Department of Biology & CESAM (Centre for Environmental and Marine Studies), University of Aveiro, Aveiro, Portugal

The harmful impact of exposure to ultraviolet (UV) filters is a topic of widespread concern due to human toxicological effects. Exposure to these environmental contaminants has emerged due to their extensive use as ingredients in personal care products and their incomplete removal in wastewater treatment plants. Due to their lipophilicity, UV filters are prone to bioaccumulate in aquatic biota, presenting potential adverse effects on both aquatic organisms and humans. The octinoxate (OMC) is one of the most used UV filters as ingredient in the cosmetic industry. Currently, OMC is included in the Community rolling action plan (CoRAP) list (REACH) and List II (EC/List No. 629-661-9) of substances under evaluation for endocrine-disrupting properties under EU legislation. It is known that OMC is an endocrine-disrupting compound (EDC), which interacts with the Hypothalamus-Pituitary-Thyroid (HPT)-axis. Despite this, the toxicological effects induced by OMC on the thyroid hormone (TH) system are not completely understood. Zebrafish (Danio rerio: Cyprinidae, Teleostei) is one of the most widely used model species in developmental biology and biomedicine for endocrine disruption prediction studies. Several studies have reported the crucial role of TH in normal development and physiological homeostasis during the life cycle of zebrafish, including morphogenesis, neurodevelopment, pigmentation, metabolism, and growth. Due to the highly conserved HPT-axis with humans, zebrafish is a promising alternative model for mechanistic studies of TH regulation. Furthermore, zebrafish embryos can be used as a non-animal alternative up to 5-days post fertilization (dpf) (Directive 2010/63/EU, 2010). In this context, this work aimed to understand if and how the exposure to UV-filter OMC modifies the response to exogenous triiodothyronine (T3) and impairs normal zebrafish embryo development. To achieve this, an integrative approach from apical to transcriptional endpoints was used. Zebrafish embryos were exposed to sub-lethal concentrations of OMC (0.04 – 4 mg/l) during 120 hours in binary mixture with T3 (0.02 mg/l). The endpoints evaluated included fish embryo development (hatching and malformations), heart rate, and behaviour. Moreover, the expression of a suite of genes involved in the HPT axis were also assessed as transcriptional endpoint. By unveiling the thyroid-disrupting effects of OMC in zebrafish-developing embryos, we will contribute to increase the knowledge of the OMC mode of action in order to develop measures to promote human thyroid health.

Macro-vitamin b12 as a new medical entity

Tamar Peshkova[1], Liana Jashi[2], Koba Kamashidze[3], Irina Nakashidze[1] & Ketevan Dundua[2]
[1]Batumi Shota Rustaveli State University, Batumi, Georgia, [2]David Aghmashenebeli University Of Georgia, T'bilisi, Georgia, [3]The University of Georgia, Tbilisi, Georgia

Introduction
The plasma vitamin B12 (B12) measurement is mainly conducted to detect B12 deficiency. But incidental finding of elevated B12 is not uncommon and may be a sign of serious disease, like solid cancers or caused by over-supplementation. However, there are cases in which high B12 levels are seen in the absence of supplements.
Case
A 57-year-old female presented to our outpatient endocrinology clinic with complaints of headache, hot flashes, dizziness and she was concerned about persistent high level of serum vitamin B12 (2058 pg/ml; 1795 pg/ml; 2521 pg/ml) without supplementation. Her medical history and the documentation she presented revealed that patient was diagnosed with scleroderma, and she has been treated for 25 years. She had autoimmune thyroid disease, impaired glucose tolerance test. In 2023 she had undergone brain aneurysm clipping. At present laboratory investigations, her thyroid function test was compatible with isolated hypothyroxinemia (TSH -2.6 mIU/ml; FT4- 8.98 ng/ml; FT3- 5.88 pmol/l). HbA1c – 5.1%, prolactine 8.33 ng/ml (4.79-23.3), low level of folate – 7.42 nmol/l (10.4-78.9); elevated homocysteine – 14.69 mkmol/l ($<$12.00). Paradoxic combination of hypercobalaminemia and hypercysteinemia got us confused. An MRI scan of the brain as well a CT scan of abdomen, gastroscopy and colonoscopy did not revealed any abnormalities as solid lesions; on an X-ray of chest was shown interstitial opacification suggestive of scleroderma lung disease. We hypothesized the possible pitfalls of measurement and interpretation of vitamin B12. Accordingly, we requested B12 measurement after PEG (polyethylene glycol) precipitation which showed normal concentrations of cobalamin.
Conclusion
Macro-vitamin B12 is an underestimated cause of supra-physiological cobalamin plasma levels and deserves appropriate attention to avoid potential erroneous clinical decisions.

Sodium disturbances in hospitalised patients with COVID-19

Vasiliki Filippou[1] & Rebecca Gorrigan[2]
[1]Queen Mary University of London, United Kingdom, [2]Barts Health NHS Trust, United Kingdom

Background
In March 2020, COVID-19, a disease caused by the coronavirus SARS-CoV-2, was declared a global pandemic, posing a significant threat to global health. Whilst predominantly a respiratory disease, extra-pulmonary manifestations have been reported, including endocrine and electrolyte disturbances. Thus, this study evaluates the incidence of serum sodium testing and abnormalities recorded in patients admitted with COVID-19 infection at the Royal London Hospital (RLH) between 1st March and 1st May 2020.
Methods
This single-centre audit collected retrospective data from 279 patients treated for COVID-19 infection between March 1st 2020 and May 1st 2020 at the RLH. Data on serum sodium testing and abnormalities were obtained from the electronic patient healthcare records.
Results
100% of patients had their sodium level checked and 47.7% had an abnormal result. The commonest sodium disturbance was hypernatraemia. Disease severity, classified according to 4C score, was associated with a statistically significant increase in risk of sodium disturbance. Prolonged hospital stay ($\geq$14 days) was associated with a significantly increased risk of developing an abnormality in serum sodium ($P<0.001$).
Conclusion
Abnormalities in serum sodium are common in patients hospitalised with COVID-19 infection. Incidence of abnormal serum sodium levels was higher in patients with more severe disease as well as longer lengths of hospital stay. These findings suggest that routine evaluation of sodium in COVID-19 inpatients is warranted. It is a frequent occurrence that hospitalised patients develop disturbances in sodium levels, but the relationship between more severe COVID-19 and sodium dysregulation, particularly hypernatraemia should be further investigated. If higher serum sodium levels in COVID-19 patients are linked with higher mortality, closer monitoring and earlier corrections and may aid in preventing disease severity and improve outcomes of hospitalised patients with COVID-19.

Pituitary metastasis from breast cancer: a report of three cases

Andreia Martins Fernandes[1], Leandro Augusto Silva[1], Ana Rita Elvas[1], Joana Couto[1], Raquel G. Martins[1], Jacinta Santos[1], Teresa Martins[1] & Fernando Rodrigues[1]
[1]IPO Coimbra, Endocrinology Department, Portugal

Introduction
Pituitary metastases are rare, accounting for only 1% of intracranial metastases and predominantly originating from breast and lung tumors. Pituitary involvement is observed in only 6–8% of breast cancer cases, with an overall unfavorable prognosis.
Case series
A 53-year-old woman, with a six-year history of breast cancer metastasized to the lungs, presented with a three-month history of headaches, visual disturbances, asthenia, weight loss and polyuria. Head MRI revealed a 20mm lesion in the sellar and suprasellar region, causing obliteration of the suprasellar cistern and compression of the optic chiasm and third ventricle. Assessment of pituitary function revealed low levels of 0800 hours cortisol (0.5 mg/dl), FT4 (0.2 ng/dl), FSH (5.8 IU/l) and LH ($<$0.07 IU/l), and low urine density. Treatment included hydrocortisone 20 mg, levothyroxine 50 µg and desmopressin 0.06 mg. No visual field changes were observed. Transsphenoidal surgery confirmed pituitary metastasis, and she died shortly after due to advancing systemic disease. A 46-year-old woman recently diagnosed with breast cancer presented with dizziness, nausea, somnolence, blurry vision, asthenia, weight loss, and polyuria. Assessment of pituitary function showed low levels of 0800 hours cortisol (0.8 mg/dl), FT4 (0.44 ng/dl) and IGF-1 (37.3 ng/ml). Additionally, she exhibited low urine osmolality (260 mOsm/kg) and a high serum sodium concentration. Head MRI showed a 26mm sellar and suprasellar lesion, obliterating the cisterna and compressing the third ventricle and optic chiasm. Treatment included hydrocortisone 15 mg, levothyroxine 75 µg, and desmopressin 0.06 mg. She died a few months later from disease progression. A 61-year-old woman, with a six-year history of breast carcinoma and subsequent metastatic progression to the liver, bones, lungs, and mediastinal lymph nodes, presented with headache, vomiting, disinhibition, dysarthria, and diplopia. Neurological examination revealed bilateral dysmetria, ataxia, and left lateral rectus paresis. Laboratory tests revealed low levels of FT4 (0.58 ng/dl), FT3 (0.59 pg/ml), FSH ($<$0.3 IU/l), LH ($<$0.07 IU/l) and IGF-1 (52.1 ng/ml). Head MRI revealed left cerebellar and pituitary metastases with optic chiasm compression. Treatment included levothyroxine 100 µg, palliative hormonal therapy, and whole-brain radiotherapy. She died two years later due to neoplastic disease progression.
Conclusion
While pituitary metastases are rare, they should be considered in the differential diagnosis when there is evidence of pituitary involvement in malignant disease. Despite the devastating impact on a patient's survival prognosis, significant potential for symptom relief exists, emphasizing the crucial need for high clinical suspicion for prompt identification and management.

The importance of a multidisciplinary approach in the management of glucagonomas. a case report

Ismene Bilbao Garay[1], Nerea Egaña[1], Jorge Rojo[1], Maite Perez de Ciriza[1], Beatriz Sanchez[2], Cristina Garcia[1], Ane Amilibia[1], Amaia Mendia[1] & Alfredo Yoldi[1]
[1]Hospital Universitario Donostia, Endocrinologia y Nutricion, San Sebastian, Spain; [2]Hospital Universitario Donostia, Oncologia Medica, San Sebastian, Spain

Introduction
Glucagonoma is an extremely rare PNET which presenting symptoms can be varied but the most common include necrolytic migratory erythema, diabetes, diarrhea and weight loss. Treatment involves a multidisciplinary approach, as most of them are large and present with metastasis at diagnosis, and would need nutritional support, an expert management of pancreatic exocrine insuffiency and diabetes. The different therapeutic options could potentially also cause nutritional and metabolic disturbances that might need a close monitoring and constant adjusting. We present the case of a patient diagnosed with a stage IVB, glucagon producing GRADE 2 pNET who required a multidisciplinary approach to improve her overall survival and quality of life.
Case report
A 69 year old woman with a new diagnosis type 2 DM and no other previous relevant history, presented with chronic abdominal pain and weight loss. CT scan disclosed a 10$\times$3 cm hypervascular mass in the pancreatic tail, with multiple hypervasular lesions in the liver. A 18FDG PET confirmed abnormal uptake (SUV 4,8) at the distal pancreas, correlating with the CT scan and the Octreo-scan as well (krening 4) Biopsy of the hepatic lesion confirmed metastatic grade 2 PNET. The laboratory values were normal except for an elevated serum glucagon level (830 pg/ml, Ref. 50–150), and increased levels of Cromogranin A 360 (0-108) and NSE 17,20 (0-16,3) accompanied by low levels of Cupper and Zinc. The patient was treated with octreotide lar, which lowered the serum glucagon levels by 73% for 10 months and the tumor size remained stable for 15 months of follow up, but soon after glucagon levels elevated and liver metastases where shown in the MRI. The patient underwent 19 cycles of Everolimus, until progression was assessed and treatment with ^{177}Lu-DOTATATE decided. 6 months after completing the treatment, glucagon levels had gone down by 50% and a 40% reduction in liver metastatic size and a 10% reduction in pancreatic tumor mass were shown by the MRI. The patient had not presented significant treatment-related toxicity and her insulin needs were cut by half. During the whole process the patient's nutrtitional needs, gastric enzymes and insulin requirements were adjusted to ensure the best outcome and improve her quality of life.
Conclusions
Glucagonoma is difficult to diagnose and once diagnosed a challenge to manage. An interprofessional team must work together to monitor the patient as needs as they navigate through the wide range of treatment modalities and their side effects.

Delayed diagnosis of pituitary stalk interruption syndrome in a girl with short stature, spaniomenorrhea and normal secondary sexual characteristics: a case report

Soumia Laib[1]
[1]University Hospital Center Touhami Benflis. University of Batna 2, Metabolism, Endocrinology & Diabetes, Batna, Algeria

Pituitary stalk interruption syndrome (PSIS) is a rare developmental defect identified by magnetic resonance imaging and characterized by a thin or interrupted pituitary stalk, aplasia or hypoplasia of the anterior pituitary and absent or ectopic posterior pituitary. The presenting phenotype and symptomatology vary widely. It includes variable degree of isolated or combined pituitary hormone deficiencies with progressive onset, most commonly growth hormone or gonadotropin and extrapituitary malformations. Although PSIS is most frequently diagnosed during childhood and the neonatal period, some individuals may not be diagnosed until adulthood. We report an 18-year-old girl with a history of irregular menstruation that had started 2 years prior to the visit. she born out of non-consanguineous marriage, There was no history of any systemic illness, drug intake or head injury. The pregnancy, labor, delivery and neonatal period had been unremarkable. Family history was not significant. On examination she weighed 75 kg with a BMI of 35.76 kg/m, the waist circumference was 109 cm, and her height was 145 cm (-3SDS, height age 12 years, target height 156,5 cm, upper to lower segment ratio1,13). She had severe proportionate short stature with typical facies of growth hormone(GH) deficiency as a cherubic facial appearance with flat nasal bridge, frontal bossing and midface hypoplasia. She had normal pubertal onset and development without galactorrhea. She had no history of polydipsia, polyuria, headache and visual defects. She had no associated malformations or features of Turner syndrome. After exclusion of systemic disorders, endocrine analysis, showed isolated GH deficiency with hyperprolactinemia. The remainder pituitary evaluation was normal. Others causes of hyperprolactinemia have been excluded. Hand Bone age was ∼17 year and X ray evaluation of iliac apophysis was found in Risser Grade V. Pelvic ultrasound showed no abnormality of pelvic structures and neck ultrasound showed normal thyroid. Magnetic resonance imaging (MRI) of brain showed nonvisible stalk with ectopic posterior pituitary and hypoplastic anterior pituitary. The diagnosis of PSIS was made because of association of physical exam and endocrine findings with magnetic resonance imaging. Late diagnosis of PSIS leads to definitive adult short stature and psychosocial problems. Prompt and appropriate hormone substitution improve final adult height. Our case is interesting because, it highlights the importance of physician clinical awareness and early identification and referral for children with growth disorders to pediatric endocrinologists and because the unique association of GH deficiency and hyperprolactinemia in PSIS with resultant spaniomenorrhea despite having a conserved pituitary gonadal axis and normal pubertal development.

Studies on anti-rabphilin-3a antibodies in 15 consecutive patients presenting with central diabetes insipidus at a single referral center

Yoshihisa Sugimura[1], Zenei Arihara[2], Shozo Yamada[3], Naoko Inoshita[3], Naoko Iwata[4], Haruki Fujisawa[1] & Atsushi Suzuki[1]
[1]Fujita Health University, Toyoake, Japan; [2]National Hospital Organization Sendai Medical Center, Sendai, Japan; [3]Moriyama memorial hospital, Edogawa City, Japan; [4]Daido Hospital, Nagoya, Japan

Central diabetes insipidus (CDI) is a rare condition caused by various underlying diseases including inflammatory and autoimmune diseases, neoplasms (such as germinomas and craniopharyngiomas), infiltrative diseases (such as Langerhans cell histiocytosis), neurosurgery, trauma, and genetic defects in vasopressin synthesis. However, up to 15% of CDI causes remain idiopathic, although, a recent report showed idiopathic CDI is a very uncommon condition. An autoimmune process involving destruction of the neurohypophysis may be involved in many patients with idiopathic CDI. When a definitive cause of CDI is not found, most cases of CDI will be labeled idiopathic, but an autoimmune process should always be considered. Lymphocytic hypophysitis, including Lymphocytic infundibuloneurohypophysitis (LINH) accounts for a substantial subset of autoimmune CDI cases and is characterized by lymphocytic inflammation of the posterior pituitary and infundibular stalk. Obtaining an accurate definitive diagnosis of the underlying cause of CDI is difficult. Pathological examination is required for a definitive diagnosis. Recently, anti-rabphilin-3A antibodies were demonstrated to be a highly sensitive and specific marker of LINH. Here, we report a detailed case series, and evaluated the significance of anti-rabphilin-3A antibodies in differentiating the etiologies of CDI. A prospective analysis was conducted in 15 consecutive patients with CDI from 2013 to 2020 at a single referral center. All patients presenting with polyuria and polydipsia underwent endocrinological tests, including the hypertonic saline infusion test, and cranial magnetic resonance imaging. Anti-rabphilin-3A antibodies were measured and the relationship between antibody positivity and the clinical/histopathological diagnoses was evaluated. Among 15 CDI patients, the positive anti-rabphilin-3A antibodies were found in 4 of 5 LINH cases, 3 of 4 lymphocytic panhypophysitis (LPH) cases (including 2 of the 3 biopsy-proven samples), a subtype of lymphocytic hypophysitis that affects both of the anterior and posterior pituitary gland and causes CDI. The positive anti-rabphilin-3A antibodies were found in one intracranial germinoma case, and were negative in two Rathke cleft cyst cases and one craniopharyngioma case. After the treatment with steroid in patient with LPH who were positive for anti-rabphilin-3A antibodies, GH and/or gonadotropin levels were restored. In conclusion, this is the first case series to evaluate the presence of anti-rabphilin-3A antibodies in consecutive patients with CDI. We found that anti-rabphilin-3A antibodies positivity in CDI patients with biopsy-proven LPH and confirm that measurement of anti-rabphilin-3A antibodies may be valuable for differentiating CDI etiologies.

Neuroendocrine tumor secreting proinsulin – an overlooked entity

Leandro Augusto Silva[1], Andreia Martins Fernandes[1], Ana Rita Elvas[1], Raquel G. Martins[1], Joana Couto[1], Teresa Martins[1], Jacinta Santos[1], Nuno Cunha[2], Rui Martins[3] & Fernando Rodrigues[1]
[1]IPO Coimbra, Endocrinology; [2]IPO Coimbra, Clinical Pathology; [3]IPO Coimbra, General Surgery

Introduction
Proinsulinoma is an infrequent subtype of pancreatic neuroendocrine tumor (pNET), characterized by the excessive secretion of proinsulin, leading to pronounced hypoglycemia. Clinical manifestations comprise neuroglycopenic and autonomic symptoms, including cognitive impairment, seizures, visual disturbances, diaphoresis, tremors, syncope or coma. Diagnostic modalities involve blood assays and imaging to detect heightened proinsulin production and determine the tumor's location within the pancreas. Surgical intervention stands as the primary modality for curative intent and relief of symptoms in locoregional disease. In scenarios where surgical excision is unfeasible, alternative therapeutic modalities may be explored for symptomatic management.
Clinical Case
A 25-year-old male with normal body weight exhibiting a four-year history of hypoglycemia. Initially asymptomatic, the condition was identified during routine laboratory examinations and subsequently manifesting symptoms such as confusion, fatigue and incoherent speech, all of which were resolved following carbohydrates intake. Relevant medical history includes allergic rhinitis, profilin allergy, and eosinophilic esophagitis. Presently under medication involving proton pump inhibitor (IBP), nasal fluticasone and antihistamine on an as-needed basis. Admitted for elective study of hypoglycemia, underwent a 5-hour fasting test which revealed symptomatic hypoglycemia of 45 mg/dl with confusion, sweating and tachycardia, all resolved after carbohydrates intake. Analytical study during fasting test revealed elevated serum proinsulin (141.4 pmol/l), while serum C-peptide and insulin levels were inappropriately normal (2.41 ng/ml and 10.2 μU/ml, respectively). Beta-hydroxybutyrate was within reference values (0.21 nmol/l). The patient underwent imaging studies (abdomen CT and MRI) identifying an 8 mm hypervascular nodule in the pancreatic body consistent with a pNET. The ^{68}Ga-SSA-PET-CT was negative. The patient underwent surgical resection of tumor. The anatomopathological examination confirmed a 13 mm grade 1 neuroendocrine tumor (the immunohistochemistry study showed strong diffuse positivity for synaptophysin and chromogranin A, with Ki67 $<2\%$, with complete resection (pT1N0), confirming the diagnosis of a proinsulin secreting pNET.
Conclusions
Given the rarity of proinsulinoma, recently recognized as a distinct entity from insulinoma, it is essential to maintain heightened awareness of its nonspecific clinical symptoms. Diagnosing proinsulinoma can be challenging due to its uncommon occurrence and its diagnostic criteria not yet fully defined on a globally agreed-upon basis. Prompt recognition of subtle signs is crucial to prevent delays in diagnosis and ensure accurate treatment.

Xanthogranulomatous hypophysitis succesfully treated with rituximab in a teenage female: a case report

Carmen Soriano[1,2], Maria del Carmen Lopez[1,3], María Niveiro[1,4,5], Javier Abarca[1,4,6], Elena García-Garrigos[1,4,7], Joaquín Serrano[1,2,4] & Antonio Pico[1,2,4,8,9]
[1]Hospital General Universitario Dr. Balmis; [2]Endocrinology & Nutrition; [3]Reumatology; [4]Instituto de Investigación Sanitaria y Biomédica de Alicante (ISABIAL); [5]Pathology; [6]Neurosurgery; [7]Radiology; [8]University Miguel Hernandez; [9]CIBERER

Introduction
Hypophysitis, an infrequent inflammatory condition of the pituitary gland, is typically managed with glucocorticoids, reserving surgery for significant mass effects and considering immunosuppressants or radiotherapy for refractory cases. Recent reports indicate positive outcomes with immunosuppressants. Here, we present a case of recurrent xanthogranulomatous hypophysitis in a 16-year-old female successfully treated with Rituximab.
Case Report
A 16-year-old female with no pertinent medical history presented to our emergency department with a severe frontal headache, diplopia, nausea, amenorrhea, polyuria, and polydipsia persisting for 4 months. Physical examination revealed a mild afferent pupillary defect along with complete six-nerve and partial third-nerve palsies. MRI indicated a solid selar mass with a central cystic area, intense peripheral contrast enhancement, and pituitary stalk infiltration displaying intense and homogeneous contrast enhancement. Blood tests revealed deficiencies in corticotroph, gonadotroph, and thyrotroph axis, along with arginine vasopressin deficiency. Somatotroph axis and prolactin levels remained unaffected. Additional tests showed positive antithyroid antibodies, with negative alpha-fetoprotein and Beta-HCG in both serum and cerebrospinal fluid. The patient received high-dose glucocorticoid therapy, leading to significant clinical and radiological improvement. However, after corticosteroid tapering, a relapse occurred, requiring transsphenoidal surgery. Pathological analysis revealed chronic inflammation with predominantly CD20-positive B-cell infiltration, consistent with xanthogranulomatous hypophysitis. Following surgery, a relapse occurred, prompting the use of Rituximab, a monoclonal antibody targeting CD20-positive B cells. The patient received two doses of 1000 mg IV four weeks apart, followed by a single dose of 750 mg IV every 6 months. After four doses, the patient successfully discontinued corticosteroid therapy, experiencing sustained disease remission and excellent symptomatic control.
Conclusion
Rituximab emerges as an effective and sustainable treatment for hypophysitis, providing a valuable alternative to prolonged corticosteroid therapy or surgery.

Corticotropic deficiency secondary to wilson disease

Hager Khiari[1], Sabrine Mekni[1], Sawsen Essayeh[1], Imen Rojbi[1], Bennacef Ibtissem[1], Youssef Lakhoua[1], Nadia Mchirgui[1] & Karima Khiari[1]
[1]Charles nicolle hospital, Endocrinology, Tunisia

Introduction
Wilson's disease is a rare and serious genetic disorder. The accumulation of copper in glands causes several endocrine pathologies. Herein, we report a rare case of hypophysitis with corticotropic deficiency caused by Wilson's disease.
Observation
A 33-years-old female patient was referred to the endocrinology department for hypoglycemia. She had a history of Wilson's disease diagnosed at the age of nine complicated by cirrhosis and neurological damage. She presented with fatigue and recurrent hypoglycemia for 3 months and had irregular menses. On physical examination, she had motor incoordination and was in a wheelchair. She was pale. Biological exams revealed corticotropic deficiency with a baseline serum cortisol level of 130 nmol/l and a low serum ACTH (8.62 pg/ml). Liver and renal functions were normal (TP = 80%, Serum creatinine = 60 y mol/l). She had no thyrotropic deficiency (FT4 = 0.76 ng/dl, TSH = 3.11 mIU/l), no gonadotropic deficiency (estradiol = 80 pg/ml, FSH/lH = 6.7/23.63 UI/l) and no somatotropic deficiency (serum IGF1 = 200 yg/l) but had moderate hyperprolactinemia (serum prolactin = 60 ng/ml). Magnetic resonance imaging of the hypothalamo–pituitary region did not show an adenoma and revealed a thickened pituitary stalk. She had no other endocrine disorders related to Wilson's disease like diabetes mellitus (HbA1c = 5%), hypoparathyroidism (serum calcium = 2.27 mmom/l, PTH = 31.6 pg/ml) or peripheral hypothyroidism (TSH = 3.11 mIU/l). The patient was treated by 20 mg of hydrocortisone hemisuccinate daily. The evolution was characterized by an improvement of the fatigue and the disappearance of hypoglycemia.
Conclusion
Wilson's disease is a rare inherited condition. Hypophysitis due to Wilson's disease is rarely reported in the literature. Corticotropic deficiency increases the risk of hypoglycemia and is life-threatening.

Growth without growth hormone: an unusual presentation of a pituitary stalk interruption syndrome

Maria Lavinia Popa[1], Preda Diana[1,2], Alexandra Mirica[1,2], Radomir Lidia[3], Enyedi Mihaly[2,4] & Iuliana Gherlan[2,3]
[1]'Grigore Alexandrescu' Emergency Clinical Hospital for Children, Bucharest, Romania, Endocrinology, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania, Romania; [3]National Institute of Endocrinology "CI Parhon", Pediatric Endocrinology, Bucharest, Romania; [4]Diagnostic and Treatment Center "Dr. Victor Babes", Radiology, Bucharest, Romania

Introduction
Pituitary Stalk Interruption Syndrome (PSIS) is a congenital developmental anomaly affecting the pituitary gland. Characterized by a triad of features including a thin or absent pituitary stalk, adenohypophysis hypoplasia, and ectopic neurohypophysis on MRI, PSIS can lead to isolated or combined pituitary hormone deficiency. Symptoms may manifest at various life stages, with 70% of cases identified in childhood due to growth retardation. Notably, some patients exhibit normal growth despite growth hormone deficiency.
Case report
A 7 year old boy presented to endocrinology clinic with concerns of genital hypoplasia and a history of bilateral cryptorchidism. Review of the patient's birth history demonstrated an uncomplicated full-term gestation with delivery by cesarean section with a birth weight of 3.2 kg. His motor and language development was normal. Family history was negative. Father's height was 170 cm; mother's height was 173 cm; midparental height was 178 cm (+0.15 DS). Recurrent hospitalisations for pneumonia with dehydration were noted in the past medical history, but no history of seizures. On physical examination, the patient's height was 116.5 cm (-1.26 DS), he had no growth records; his weight was 26.3 kg with a body mass index (BMI) of 19.4 kg/m^2 (at the 96th percentile). He had no signs of thyroid or cortisol deficiency. The sexual maturity rate was Tanner stage I, with a hypoplastic scrotum, a 4.5 cm penile length, covered by suprapubic fat. Laboratory studies demonstrated low free thyroxine (T4) with only slightly above normal thyroid-stimulating hormone (TSH) values. Repeated and extended hormonal analysis demonstrated a pattern of panhypopituitarism with low morning serum cortisol (0.9 µg/dl, normal 5-25), low normal ACTH (12 pg/ml, normal, 7.2-63.3), low freeT4 (0.4 ng/dl, normal 0.65-2.3) with slightly elevated TSH (5.9 µUI/ml, normal 0.5-4.5), normal prolactin, low IGF1 values (18.7 ng/ml and 17.8 ng/ml, -2.81 SDS for Tanner I) and an inhibin B level of 21.7 pg/ml (2.5-10th centile). The diagnosis of GHD (confirmation with stimulation tests) was not extended at that time due to the inability to treat GH as part of the therapeutic program of a patient with a normal height. The bone age was delayed, 3.5 years old, compared to chronological age. MRI confirmed PSIS, revealing hypoplasia of the adenohypophysis, ectopic neurohypophysis, and an absent pituitary stalk
Conclusion
Herein, we report a pediatric obese patient with an unusual presentation and normal growth despite combined pituitary hormone deficiency in the course of pituitary stalk interruption syndrome (PSIS).

EP88

A case of aggressive corticotropinoma in a patient after combined treatment and bilateral adrenalectomy

Daria Lisina[1], Laura Ebanoidze[1], Ekaterina Pigarova[1], Patimat Khandaeva[1], Larisa Dzeranova[1] & Elena Przhiyalkovskaya[1]
[1]Endocrinology Research Center, Neuroendocrinology, Moscow, Russian Federation

Introduction
Corticotropinomas constitute up to 45% of aggressive pituitary tumors, which characterized by rapid and invasive growth, a high Ki-67 index, resistance to conventional treatments and recurrence in 15-20% of the cases. Progression of corticotroph tumor after bilateral adrenalectomy or Nelson's syndrome is a frequent severe complication and may present with aggressive tumor behavior.

Clinical case
A Cushing disease was diagnosed in a woman of 19 years of age (2010) for which she underwent a transsphenoidal adenomectomy in 2010 and 2011 (immunohistochemical study was not performed) with the development of secondary hypothyroidism and hypogonadism. Then due to persistence of the disease in 2012 a stereotactic radiosurgery (Gamma-knife, 36 Grey) was performed. Due to its absent effect on ACTH secretion (>2000 pg/l) in 2014 the patient had a bilateral laparoscopic adrenalectomy which led in 2017 to development of Nelson's syndrome with right sided diplopia, ptosis, and severe headache; MRI noted a tumor 25x24x38 mm with invasive growth to the right cavernous sinus, spreading forward to the entrance to the right orbit. The patient was treated by repeated transsphenoidal adenomectomy followed by conformal external stereotactic radiotherapy (morphology - pituitary adenoma of oxyphilic cells with a solid alveolar structure; immunohistochemistry - ACTH expression in most tumor cells with uneven nuclear expression of Ki-67 (label index from 3,8% to 9,4%) and negative expression of P53; absent methylation of MGMT gene) with complete elimination of neurophthalmic features. In 2023 these clinical features returned, MRI described tumor measuring $27\times20\times38$ mm in the right cavernous sinus with involvement and narrowing of the right carotid artery, extending to the right orbit and the right contour of the pons. The patient was consulted by a neurosurgeon, however, due to the fact that surgical treatment for this patient seemed overly traumatic and non-radical, by decision of the council temozolomide therapy was prescribed at a dose of 150-200 mg/m^2 daily for 5 days every 4 weeks for 3 courses followed by MRI control in order to determine further treatment tactics. The treatment led to clinically significant reduction in diplopia and headache.
Conclusion
This clinical case demonstrates aggressive corticotropinoma and progression of the rapid and invasive growth despite multimodal treatment even with repetitions. Total adrenalectomy avoided the complications of hypercortisolism for more than 10 years, but the patient needs further treatment of the most aggressive adenoma using oncological therapy methods of which temozolomide is recognized as the first line of therapy.

Clinical and paraclinical characteristics of women with sheehan's syndrome

Salma Salhi[1], Ibtissem Oueslati[1], Cyrine Chehaider[1], Anis Grassa[1], Amani Terzi[1], Fatma Chaker[1], Meriem Yazidi[1] & Melika Chihaoui[1]
[1]La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Sheehan's syndrome is a rare cause of hypopituitarism. It is defined by an ischemic necrosis of the pituitary gland following postpartum hemorrhage. Sheehan syndrome is characterized by various endocrine deficiencies. The aim of the present study was to determine the clinical and paraclinical characteristics of women with Sheehan syndrome.
Methods
This was a monocentric cross-sectional study including 50 women followed for Sheehan's syndrome in the Department of Endocrinology of La Rabta University Hospital of Tunis. Clinical and paraclinical data were collected.
Results
The mean age of participants was 62.2 ± 9.4 years. Diagnostic delay of SS was 11.1 ± 9.4 years [Range: 0-37 years]. The mean duration of the disease was 31.6 ± 9.9 years. Postpartum hemorrhage occurred in all patients, with 12% of them required hysterectomy. The disease was revealed by acute adrenal insufficiency in 86% of patients, secondary amenorrhea in 10%, and secondary hypothyroidism in 4% of cases. Laboratory investigations revealed complete anterior pituitary deficiency in all patients with no case of central diabetes insipidus. Magnetic resonance imaging showed empty sella turcica in all cases. The mean hydrocortisone dose was 20.30 ± 2.75 mg/day. A daily dose >20 mg was prescribed in 10% of cases. The mean levothyroxine dose was 1.60 ± 0.54 µg/kg/day. Only 21 women (42%) received estrogen-progesterone therapy. GH treatment was not prescribed in all participants.
Conclusions
Women with Sheehan syndrome have important exposure to hormonal deficiencies due to the long diagnostic delay, which make them at higher risk of complications compared to other pituitary deficient patients.

Evaluation of the clinical and biological profile in patients with congenital pituitary deficiency

Yosra Hasni[1], Hamza Elfekih[1], Oumayma Zarrouk[1], Yasmine Salem[2], Jihene Ben Abdallah[2], Saoussen Mrad[2], Amira Yanes[1], Nassim Ben Hadj Slama[1], Salima Ferchichi[2] & Molka Chadli Chaieb[1]
[1]University Hospital of Farhat Hached, Endocrinology Departement, Sousse; [2]University Hospital of Farhat Hached, Biochemistry Laboratory, Sousse

Introduction
Pituitary deficiency, or hypopituitarism, is defined by insufficient synthesis or secretion of one or more anterior pituitary hormones. These hormones, including growth hormone, are considerably involved, directly and indirectly, in several metabolisms such as hepatic, carbohydrate, lipid metabolisms and the regulation of protein synthesis. The objective of this study was to study the clinical and biological profiles of patients followed for anterior pituitary insufficiency.
Methods
A cross-sectional study was conducted, including patients followed in the Endocrinology department of Farhat Hached University Hospital, Sousse for isolated GH deficiency and/or associated with other anterior pituitary hormonal deficiencies. Data were collected over a period of 9 months from January to September 2022.
Results
Our study included 55 subjects divided into 3 groups: 15 patients followed for an isolated GH deficiency (G1), 20 followed for multiple congenital pituitary deficiencies (G2) and 20 control subjects (control group). The average age of our patients at the time of diagnosis was eleven and a half. A male predominance was noted in G1 (73.3%) and G2 (60%). The evaluation of clinical characteristics such as age, body mass index, blood pressure and waist circumference did not show a statistically significant difference between G1 and G2. The evaluation of metabolic, renal, hepatic, calcium and lipid balance did not show any significant difference between the three groups of the study apart from alkaline phosphatase which was higher in G1 (200.4 ± 106.1 U/l) compared to G2 (169.6 ± 94.1 U/l) and the control group (72.7 ± 23.1 U/l) with a statistically significant difference between the control group and each of the other two groups. Comparing hormonal parameters between G2 and control group, we found a significant difference linked to the male sex in thyrotropic insufficiency, as well as a lower level of sex hormones in both sexes. No significant difference was found between these two groups for gonadotropins, prolactin, and cortisol.
Conclusions
The clinical and biological profile of patients with congenital pituitary deficiency was almost similar between the group with isolated GH deficiency and the group with combined anterior pituitary deficiencies. For hormonal parameters, only TSH, FT4 and sex hormones were different between the two groups.

Clinical and paraclinical characteristics of incidentally discovered pheochromocytoma

Abid Arige[1], Mariam Mabrouk[1], Ibtissem Oueslati[1], Elyes Kamoun[1], Faten Cherchir[1], Meriem Yazidi[1] & Melika Chihaoui[1]
[1]RABTA Hospital, Endocrinology, Tunis, Tunisia

Introduction
Pheochromocytoma is a rare tumor originating from chromaffin cells of the adrenal medulla secreting catecholamines. The typical symptoms of pheochromocytoma include hypertension, headache, heart palpitations, anxiety, and profuse sweating. However, some patients with pheochromocytomas remain asymptomatic. The aim of this study was to determine the clinical and paraclinical characteristics of incidentally discovered pheochromocytomas.
Methods
This was a single center retrospective study including patients with confirmed pheochromocytoma. Clinical and paraclinical data were recorder from patients' medical files. Patients were divided into two groups: group 1: patients with incidentally discovered pheochromocytoma and group 2: patients with clinically patent pheochromocytoma.
Results
Fifty-three patients with pheochromocytoma were enrolled in this study. Pheochromocytoma was incidentally discovered in 43 % of cases ($n=23$, 12 women and 11 men). The median age was 51 years (IQR: 36 – 56) in group 1 and 47 years (IQR: 31 – 55) in group 2 ($P=0.271$). There was no statistical difference between the two groups regarding the prevalence of overweight, obesity, and diabetes. Among the clinical findings, the symptom triad made of headache, palpitations and profuse sweating was found in 13% of cases in group 1 and in 57%

of cases in group 2 ($P=0.001$). The prevalence of hypertension was 30% in group 1 and 83% in group 2 ($P<0.001$). Systolic ($P=0.043$) and diastolic ($P=0.029$) blood pressure levels were significantly higher in group 1 than in group 2. The majority of tumors in the two groups secreted normetanephrines only. The blood levels of normetanephrines were 6.5 times the normal range (IQR: 3.5-14.8) in group 1 and 7.15 times the normal range (IQR: 3.6-10.1) in group 2 ($P=0.642$). The median size of the tumor was 50.5 mm (IQR: 38.1-70.5) in group 1 and 49.5 mm (IQR: 37.5-64.7) in group 2 ($P=0.734$). Pheochromocytoma was malignant in 35% of cases in group 1 and 22% in group 2 ($P=0.392$).

Conclusions

It is important to explore all adrenal incidentalomas since some of them turn out to be silent pheochromocytomas and therefore need as much of an urgent management as the clinically patent ones.

Acromegaly of immature PIT-1 origin

Aysel Ünver Özkahraman[1], Mert Doğukan[2], Özlem Kandemir Alibakan[1], Burak Koçak[3], Ebubekir Akpınar[4], Mutlu Niyazoğlu[1] & Esra Şüheda Hatipoğlu[1]

[1]Basaksehir Cam and Sakura City Hospital, Endocrine and Metabolism Diseases; [2]Basaksehir Cam and Sakura City Hospital, Pathology; [3]Basaksehir Cam and Sakura City Hospital, Radiology; [4]Basaksehir Cam and Sakura City Hospital, Neurosurgery

Introduction

Acromegaly is a rare pathological condition characterized by excessive growth hormone (GH) secretion, leading to elevated levels of insulin-like growth factor 1 (IGF-1). According to the 2022 World Health Organization classification, GH-secreting pituitary adenomas fall under the PIT1-lineage. Pure GH-secreting adenomas selectively release growth hormone and may exhibit dense or sparse granulation patterns. Other subtypes include mammosomatotroph adenomas, mature plurihormonal adenomas, immature plurihormonal adenomas, and acidophil stem-cell adenomas, all expressing multiple hormones. Immature PIT1-lineage tumors consist of immature cells expressing PIT1 but lack morphologic and immunohistochemical features of fully differentiated cells.

Case report

A 50-year-old male patient reported a chief complaint of escalating joint pain over the past four years. A comprehensive examination revealed distinctive features indicative of acromegaly, including an enlarged nose, prominent forehead, jaw prognathism, widened tooth gap, enlargement of hands, and increase in foot size. The patient's tests IGF-1: 1150 ng/ml (N:76,7-203) GH:5,1 ng/ml (N:0.03-2,47) was detected. Other hormone profiles were normal. During the OGTT test, the values at 60th minute glucose:224,3 mg/dl GH:37.5 ng/ml were pathological. Pituitary MR imaging showed an adenoma with a diameter of approximately 1.8 cm in the left half of the pituitary gland extending to the cavernous sinus and inferior optic chiasm. The visual field test was normal. Transsphenoidal endoscopic pituitary surgery was performed and immunohistochemical findings on pathology were as follows; chromogranin: +, PIT-1: +, SF-1:-, GATA-3:-, Estrogen receptor:-, GH: diffuse +, Prolactin: diffuse +, TSH:-, ACTH:-, LH:-, FSH:-, NKX2.2:-, SSTR2A: Sparse cell +, Ki-67:5%, PHH3:6 mitoses/10 large magnification area, PAS:-. Histomorphologic and immunohistochemical findings were consistent with an immature PIT-1-origin adenoma. In the 3rd postoperative month; IGF-1: 326 mg/ml (N:76.7-203) GH: 0.54 ng/ml (N:0.03-2,47), 75 g OGTT test; 30. min glucose:145 mg/dl GH:0.7 ng/ml was detected. Control pituitary MRI showed no residual and recurrence.

Discussion

Immature PIT1-lineage tumors, displaying lower differentiation levels, present with a variable clinical profile, with approximately 10–20% of affected patients exhibiting GH excess. TSH overproduction is more common, hyperprolactinemia is often attributed to direct tumor secretion. Imaging consistently reveals these as large, invasive tumors, requiring multiple surgeries, radiation, and systemic therapies due to their aggressive nature. In the light of all this information, which class of acromegaly the patient is in may give us crucial clues for the clinical prognosis.

Long-term outcomes of non-functioning pituitary macroadenomas following surgery

Mirsala Solak[1], Ivana Kraljevic[1,2], Roman Brekalo[2], Tanja Skoric Polovina[1], Annemarie Balasko[1], Karin Zibar Tomsic[1], Hrvoje Popovac[1], Tina Dusek[1,2] & Darko Kastelan[1,2]

[1]University Hospital Center Zagreb, Department of endocrinology, Zagreb, Croatia; [2]School of Medicine, University of Zagreb, Zagreb, Croatia

Background

Systematic or randomised studies on the natural course of non-functioning pituitary macroadenomas after surgery (NFPA) are lacking.

Objectives

This study aimed to evaluate the long-term outcomes of residual NFPA following pituitary surgery.

Methods

In this retrospective study, we included 130 patients with NPFA who underwent pituitary surgery between 2005 and 2018 at University Hospital Centre Zagreb. The median age of participants was 57 (18-78) years, and 65.4% were male. Data on demographics, surgical outcomes, histology, imaging, and management were collected. The median follow-up time was 90.5 (36-223) months after surgery. Patients with less than three years of follow-up were excluded from the study.

Results

The median adenoma size was 29.2 (10-55) mm, and in 58 (44.6%) cases, infiltration into the cavernous sinus was observed. In the group of patients who had complete tumour resection ($n=45$), ten (22.2%) experienced adenoma recurrence after a median follow-up period of 73.5 (22-216) months. They showed no differences in age, gender, adenoma size, cavernous sinus invasion, or Ki-67 expression when compared to patients without residual adenomas following surgery. Among the 85 (65.4%) patients who had residual adenomas following primary surgery, 13 (15.3%) demonstrated an increase in size after a median follow-up of 44 (16-120) months. These patients tended to be older ($P=0.058$) and exhibited higher Ki-67 expression ($P=0.05$) compared to patients with stable residual adenomas.

Conclusion

Our results emphasize the importance of prolonged post-surgical monitoring for patients with NFPA to promptly detect potential tumour recurrence or an increase in residual tumour size, which are common occurrences in this patient group. Such a proactive approach can significantly impact treatment strategies and improve overall patient outcomes.

Pituitary neuroendocrine tumors in elderly patients: clinical and surgical outcomes in a tertiary hospital

Inés Borrego Soriano[1], Paola Parra Ramírez[1], Patricia Martin Rojas-Marcos[1], Carlos Pérez López[2], Pablo García Feijoo[2], Arturo Lisbona Catalán[1], Paula Vázquez Pérez[1] & Maria Cristina Alvarez Escola[1]

[1]Hospital Universitario La Paz, Endocrinología y Nutrición, Madrid, Spain; [2]Hospital Universitario La Paz, Neurocirugía, Madrid, Spain

Introduction and aim

The current population is experiencing an increase in life expectancy, with a consequent change in the demographic structure of the society. It is common, therefore, to find elderly patients with pituitary neuroendocrine tumors (PitNET) in our usual clinical practice. Currently, there are no specific recommendations for treatment and data of outcomes in elderly are scarce. The aim of our study was to compare the clinical characteristics and surgical outcomes of elderly ($\geq$65 years) and younger patients ($<$65 years) undergoing transphenoidal surgery.

Material and methods

A retrospective study was performed. We included all patients who underwent transphenoidal surgery for PitNET in a tertiary hospital from 2018 to 2023. We stratified the population according to age, considering 65 as the threshold for older age. IBM SPSS26 statistical analysis was used.

Results

124 patients were included. 32 (26%) of them were $\geq$ 65 years old. Most elderly patients had non-functioning PitNET while most young patients had functioning PitNET (15.6% vs 62% $P<0.001$). Besides, most elderly patients had hypopituitarism before surgery (40.6% vs 8.7%, $P<0.001$). Elderly patients underwent surgery more frequently due to visual compromise while young people due to functionality (31.3% vs 51.1% $P=0.012$). Larger pituitary tumors were detected in the elderly patients group (20.5 mm vs 18.1 mm, $P=0.021$). No differences were detected in surgical complications (bleeding, fistula or infection, $P=0.752$) nor hormonal or electrolyte alterations in the immediate postsurgical period ($P=1$) between age groups. However, older patients had a longer hospital stay than younger patients (8 days vs 6 days $P=0.048$). At long-term follow-up (12 months after surgery), no differences were observed between both groups in the rate of biochemical cure of functioning PitNET (60% vs 59.6%, $P=0.988$) and the rate of normal pituitary hormonal profile (34.4% vs 26.1%, $P=0.37$).

There were differences in the rate of hypopituitarism (50% vs 16.3%, $P<0.001$) due to the hormonal situation prior to surgery ($P<0.001$) and not to age differences ($P=0.072$). In addition, improvement of visual disturbances (31.3% vs 12%, $P=0.095$) and persistence of remaining adenoma at radiological follow-up (50% vs 44.6%, $P=0.830$) were similar between older and younger patients.
Conclusions
In our study, older patients with PitNET had a lower prevalence of hormone-secreting tumors, greater prevalence of hypopituitarism, larger tumors and greater visual impairment as an indication for surgery. They had similar surgical outcomes compared to young patients, except for the longer hospital stay.

Neuroendocrine involvement in wegener's granulomatosis

Raida Ben Salah[1], Faten Hadj Kacem[2], Siddiqa Saumouro[2], Mohamed Abid[2] & Bahloul Zouhir[1]
[1]Sfax University, Internal Medicine; [2]Sfax University, Endocrinology

Introduction
Wegener's granulomatosis is a necrotizing vasculitis that can affect the central nervous system. Pituitary involvement is exceptional, but may be underestimated. Pituitary involvement in Wegener's disease is rare, and is mainly expressed as diabetes insipidus.
Clinical case
A 33-year-old man was admitted to hospital in 2009 with bilateral optic neuropathy, altered general condition revealing Wegener's disease with rhinosinus involvement, pachymeningitis and pulmonary involvement. The patient was treated with high-dose corticosteroids and monthly boli of Endoxan®, with stabilization of his disease. In 2011, he presented with polyuro-polydypsia. The diagnosis, of central diabetes insipidus, was confirmed by a water restriction test with desmopressin injection. Pituitary MRI showed a disappearance of the usual hypersignal of the post-pituitary on T1-weighted sequences. There was no anteropituitary deficit or hyperprolactinemia. The patient was started on methotrexate 30 mg/week and high-dose corticosteroids, methotrexate and desmopressin. Progression was marked by persistent symptomatology requiring maintenance of desmopressin.
Conclusion
Diabetes insipidus often regresses with general treatment of Wegener's disease. Nevertheless, desmopressin substitution is often necessary, at least initially. Occasionally, pituitary involvement persists despite effective treatment of Wegener's granulomatosis, suggesting glandular destruction.

DOI: 10.1530/endoabs.99.EP154

Predicting the development of hyponatremia in patients after transnasal adenomectomy

Khava Fargieva[1], Nino Katamadze[1], Anastasia Milyutina[1], Oksana Ivashchenko[1], Vilen Azizyan[1], Andrey Grigoriev[1], Elena Przhiyalkovskaya[1], Ekaterina Pigarova[1] & Larisa Dzeranova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Transsphenoidal surgery is the gold standard of treatment for most masses of the hypothalamic-pituitary region. Given the frequency of its performance in large hospitals, water-electrolyte complications are quite common and are the second most common cause of re-hospitalization of patients. Water-electrolyte disorders after transnasal adenomectomy in up to 30% of cases are associated with the development of severe neurological symptoms, decrease in the quality of life of patients, and increase in the duration of their stay in hospital, thus, the search for ways of early prediction is an extremely urgent task.
Objective
To analyze preoperative patient parameters to develop a prognostic model for the development of hyponatremia in patients after transnasal adenomectomy.
Materials and methods
A total of 117 patients were included in the analysis, 36 of which (31%) were men. Patients were divided into two groups: with developed hyponatremia by the 7th day after surgery and with its absence. Both groups were comparable in sex ($P=0.26$) and age (50.5 years [33.5; 61.5] vs 46 years [36; 57], $P=0.43$). These groups were compared according to 21 characteristics, including hormonal background parameters (ACTH, cortisol, TSH, FT4), presence of cardiovascular diseases, disorders of carbohydrate metabolismand hypogonadism, current drug therapy, as well as tumor characteristics according to MRI and characteristics of the surgical intervention protocol.
Results
According to the analysis performed, no significant differences were found in both groups for any of the input features ($P>0.05$). The same groups were then compared in terms of laboratory parameters depending on the reference interval of the laboratories (TSH/ACTH/cortisol/FT4 above/below/or equal to the reference interval), tumor characteristics (color, consistency, position relative to the pituitary gland, tumor bleeding, etc.) and tumor morphology. No differences were found for any of the characteristics for which the groups were compared (all $P>0.05$). Thus, the groups with hyponatremia on the 7th day after surgery and without hyponatremia on the 7th day after surgery did not differ statistically significantly, which did not allow to build a prognostic mathematical model of this complication.
Conclusions
The inability to predict the development of postoperative hyponatremia on the basis of preoperative parameters, peculiarities of surgical intervention, dictates the necessity of blood sodium monitoring up to 10-14 days after transnasal adenomectomy.

Combined endocrine-related adverse effects of immune checkpoint inhibitors in a male patient with advanced cutaneous melanoma and multiple co-morbidities

Irina A. Vaychulis[1]
[1]South-Ural State Medical University, Internal Medicine Department, Chelyabinsk, Russian Federation

A 72-year-old male patient was referred to endocrinologist in June 2023. He had known arterial hypertension, aortosclerosis, ascending aorta and aortic valve replacement, chronic cerebral ischemia. In November 2022 stage IV cutaneous melanoma with lung metastasis had been revealed. For 6 months after tumour resection he received anti-PD-1 immune checkpoint inhibitor therapy which was well tolerated. After the 7th cycle of treatment short-term fever and skin rash had appeared, followed by rapid memory deterioration, progressive asthenia, physical and mental slowness during 2 weeks. On examination no signs of brain metastasis, unremarkable complete blood count, normal fasting blood glucose and serum electrolyte levels, but decreased TSH – 0.02-0.005 (normal range 0.27-4.2) IU/l, increased fT4 – 23.6-29.7 (12-22) pmol/l and fT3 – 11.8 (3.1-6.8) pmol/l, negative TPOAb, negative TRAb were found, and the patient was referred to endocrinologist. He presented with psychomotor sluggishness, traces of skin rash, BMI of 28 kg/m^2, blood pressure of 108/76 mmHg, heart rate of 74 beats per minute, slight hand tremor. No thyroid enlargement or other clinical signs of thyrotoxicosis were revealed. Further testing, administered by endocrinologist, had demonstrated TSH <0.0083 (0.4-4.0) IU/l, fT4 – 17.5 (9-19) pmol/l, fT3 – 6.3 (3.0-5.6) pmol/l, elevated TgAb – 161 (<4.1) IU/ml, low morning plasma cortisol – 34 (101.2 - 535.7) nmol/l and low ACTH (<5 pg/ml) levels with tendency to hypotension. The diagnosis of immunotherapy-induced thyroiditis (hyperthyroid phase) and hypophysitis with the secondary adrenal insufficiency was established. Glucocorticoids (GCs) had been initiated. After 2 months of low-dose GCs treatment his TSH, fT4, prolactin, FSH, LH, K, Na, blood pressure levels were within in the normal range, ACTH remained low – 3.4 (7.2-63.6) pg/ml with improvement in physical and cognitive performance, confirming the diagnosis. GCs treatment and monitoring has been continued. Immune checkpoint inhibitors are increasingly used in cancer therapy. Data accumulation regarding side effects of these drugs is important for early detection and clinical success. Both oncologists and endocrinologists should be aware of various possible endocrine-related adverse effects at any step of treatment, requiring specific individual approach. This case emphasizes that periodic assessment of thyroid and pituitary-adrenal function in such patients is needed because clinical symptoms of endocrine disorders may be unclear, masked, atypical, controversial, or absent, especially in older individuals with multiple co-morbidities.

Successful medical management of giant prolactinomas: a comprehensive case report

Carolina Monteiro Antunes[1], Leonor Guia Lopes[1], Paula Sprovera[1], Margarida Oliveira[1], Bruna Pimentel[1], Catarina Gama[1], Francisco Sousa Santos[1] & João Sequeira Duarte[1]
[1]Hospital Egas Moniz, Lisboa, Portugal

Introduction
Giant prolactinomas (diameter >4 cm) account for less than 5% of all prolactinomas and are usually associated with markedly elevated prolactin (PRL) levels. Despite their benign nature, these tumors can be invasive, potentially leading to mass effect symptoms in affected patients.
Case Report
We report a case of a 40-year-old male admitted to the emergency department with a one-week history of headaches, right palpebral edema, and ptosis of the right eye. He had a prior medical history of idiopathic peripheral facial paralysis and was not taking any medication. Upon examination, bitemporal hemianopsia with a deficit of the superior right eye field was evident. A head CT showed a large expansive lesion (41x58x63mm) centered to the sella turcica lateralized to the right side with clivus erosion and invasion of the right carotid canal and foramen oval. The patient was started on dexamethasone and was admitted to the Neurosurgery ward. Laboratory tests showed a PRL of 26,623 ng/ml, TSH 1.54 µU/ml with fT4 10.3 pmol/l (12-22), follicular stimulating hormone (FSH) 1.82 IU/l, luteinizing hormone (LH) 2.36 IU/l, total testosterone 70 ng/dl (249-836), insulin-like growth factor 1 (IGF-1) of 212 ng/ml. He initiated cabergoline 2.5 mg/week, levothyroxine 50 µg/day and switched dexamethasone to hydrocortisone. After discharge, an ambulatory corticotroph axis evaluation ruled out adrenal insufficiency. Three months after starting cabergoline, prolactin levels decreased to 520 ng/ml and testosterone improved to 280 ng/dl. Pituitary MRI confirmed an infiltrative sellar lesion, demonstrating invasion into the cavernous sinus and a suprasellar extension reaching the optic chiasm, with a reduction in size compared to the initial CT scan (27×18 mm). Headaches and ptosis of the right eye lid also improved significantly. The patient continued cabergoline treatment, experiencing a progressive decrease in prolactin levels and further radiological improvement. No side effects were reported. Genetic studies for MEN1 and AIP yielded negative results.
Conclusion
Giant prolactinomas can present as invasive masses giving rise to compressive symptoms such as visual field abnormalities. It is crucial to assess the hypothalamic-pituitary axis for potential hypopituitarism and treatment should be promptly initiated. In this case we highlight that despite its clinical aggressiveness, medical management can be a successful therapeutic option. Close monitoring through imaging and laboratory assessments is essential to evaluate treatment response.

High-grade astrocytoma with piloid features: case report

Aicha Lachkhem[1] & Abdelkader Yahi[1], ould kablia samia[1], bensalah meriem[1], abderrahim Derriche[2], Staifi Ahcen[3], Derradji Hakim[4] & Yousfi Yamina[5]
[1]Army Central Army, Endocrinology, Algiers, Algeria, [2]Army Central Army, Radiology, Algiers, Algeria, [3]Army Central Hospital, Ophtalmology, Algiers, Algeria, [4]Army Central Hospital, Neurosurgery, Algiers, Algeria, [5]Anatomopathology, Algiers, Algeria

Introduction
High-grade astrocytoma with piloid features (HGAP) is arecently described brain tumor entity defined by a specific DNA methylation profile. HGAP has been integrated in the World Health Organization classification of central nervous system tumors 2021.
Clinical presentation
A 53-year -old woman was admitted to our department with chief complaints of headache with rapid deterioration in visual acuity over a period of 6 months. During the course of the disease, the patient experienced progressive worsening of symptoms of diabetes insipidus with a daily urine output of approximately 11000 mL. Physical examination revealed thyroid tenderness,decreased visual acuity, bi- temporal visual deficit, and signs of disorientation and memory loss. Laboratory examination revealed TSH (0.69 µIU/ml; reference level: 0.25-5 µIU/ml), decreased FT4 (9.26 pmol/l; reference: 9-20 pmol/l, FSH (2.82 ui/ml; reference level 1.55-9.74), LH (<0.1 ui/ml; reference level 7.7-58.5), Estradiol(<9 nmol/l; reference level 5-54.7), IGF1 (47.1 ng/ml; reference level 71-210). Pituitary function tests revealed markedly elevated serum prolactin level (249 ng/ml; reference: 7-20 ng/ml). There was no significant past history. The MRI brain showed a large ovoid shaped lesion (size: 3.2 cmæ 3.3 cmæ 4.1 cm) involving the intra-sellar and the suprasellar region. The margins of the lesion were not well-defined; the lesion was relatively homogenous with iso-intense T1 and hyperintense T2 signals. Following intravenous Gd-DTPA injection, the lesion showed significant heterogenous enhancement; the lesion had enveloped the internal carotid arteries on both sides and had infiltrated the bilateral cavernous sinuses, the floor of the third ventricle and the hypothalamus region. The sellar floor was mildly enlarged; the imaging of the pituitary gland was unclear. The initial differential diagnosis was between sellar chordoma, pituitary adenoma, lymphoma, glioma and metastatic lesion, a transphenoidal was selected for tumor removal, The histopathological exam showed high histopathological appearance and immunohistochemical profile consistent with a glial morphology process (ATRX lost, Olig 2+) of grade anaplasia, suspicion of a tumor associated with the CMMRE syndrome (constitinal mismatch repair defeciency). The patient was presented in pituitary CPR and a STUPP protocol was decided, The patient died six months after the surgery.
Conclusion
Until larger case series are published allowing better management of these tumors, patients still showed short intervals between diagnosis and tumor progression or death even after extensive multimodal therapy.

Kallmann-de morsier syndrome: about a case

Mariem Souissi[1], Boubaker Fadia[1], Houcem Elomma Mrabet[1], Oumaima Dimassi[2], Alaya Wafa[1] & Sfar Mohamed Habib[1]
[1]Taher Sfar University Hospital, the endocrinology department of the Taher Sfar University Hospital of Mahdia, Mahdia, Tunisia; [2]Taher Sfar University Hospital, the endocrinology department of the Taher Sfar University Hospital of Mahdia, Mahdia

Introduction
Kallmann-de Morsier Syndrome is a rare genetic disorder characterized by the combination of hypogonadotropic hypogonadism and anosmia or hyposmia. It is more prevalent in males compared to females. In this case report, we present the case of an adolescent with Kallmann-de Morsier Syndrome.
Case Presentation
An 18-year-old patient was referred to our endocrinology clinic by gynecologists for the investigation of pubertal delay. The patient's parents were not consanguineous. There were not a family history of pubertal delay or infertility. The patient has a history of epilepsy since childhood, managed with medication, and reports a long-standing hyposmia. Upon examination, the patient exhibited facial dysmorphia, including a broad forehead, protruding ears, a flat nose, and full lips. She was at Tanner stage S2P4A2. Neurological examination revealed cerebellar syndrome. Hormonal exploration identified hypogonadotropic hypogonadism and lactotroph insufficiency. Corticotrope and thyrotrope insufficiency were ruled out. Pelvic ultrasound showed an underdeveloped uterus with normal ovaries. The Karyotype was 46 XX. Hypothalamus-hypophysis and olfactory bulb MRI revealed agenesis of the olfactory bulbs, strongly suggesting Kallmann-de Morsier Syndrome. Renal ultrasound showed no anomalies. Hormonal treatment, based on estrogen, was initiated until breast development was complete. Subsequently, a progestin was added to induce menarche.
Discussion
Kallmann-de Morsier Syndrome (KS) or olfacto-genital dysplasia results from prenatal anomalies in the migration of GnRH neurons, often associated with olfactory bulb atrophy. This disease is four times less frequent in females. Primary amenorrhea is the presenting circumstance in over 90% of cases in females. Breast development varies. Diagnosis is confirmed by hypoplasia of olfactory bulbs on MRI. Besides clinical features, it is crucial to explore associated conditions such as renal or dental agenesis, cerebellar syndrome (as observed in this case), cleft lip/palate, or synkinesias. The sporadic form is more common than the familial form, and in 60-65% of patients, no mutations are identified.
Conclusion
Early diagnosis of Kallmann-de Morsier Syndrome is crucial to mitigate the organic and psychological impact of pubertal delay. The clinical and radiological context plays a pivotal role in diagnosis, as genetic studies are often inconclusive. Hormonal treatment facilitates puberty, and long-term fertility can be achieved

Lipid profile in women with sheehan's syndrome: a case-control study

Salma Salhi[1], Ibtissem Oueslati[1], Emna Talbi[2], Anis Grassa[1], Kacem Ben Fradj[2], Moncef Feki[2], Meriem Yazidi[1] & Melika Chihaoui[1]

[1]La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia; [2]La Rabta University Hospital, Laboratory of Biochemistry, Tunis, Tunisia

Introduction
Sheehan's syndrome (SS) is a rare cause of hypopituitarism. It results from ischemic necrosis of the pituitary gland following severe postpartum hemorrhage. There is growing interest in understanding the lipid profile alterations in patients with SS, potentially contributing to an increased risk of cardiovascular complications. The aim of this study was to evaluate the lipid profile in women with SS.
Methods
We conducted a cross-sectional study including 50 patients with a complete anterior hypopituitarism secondary to SS and 50 age and body-mass index (BMI) -matched controls. Participants underwent physical examination and laboratory tests including lipid measurements.
Results
The mean age was 62.2±9.4 years in patients vs 60.6±8.4 years in controls ($P=0.385$). The mean BMI was 29.6±6.0 kg/m^2 in women with SS vs 30.0±5.0 kg/m^2 in controls ($P=0.741$). Patients with SS had significantly higher levels of triglycerides (respectively: 1.8±0.8 mmol/l vs 1.4±0.6 mmol/l, $P=0.046$) and triglycerides/HDL-cholesterol ratio (respectively: 1.6±1.2 vs 1.1±0.5, $P=0.016$) compared to controls. The prevalence of dyslipidemia was 66% in patients and 38% in controls ($P=0.005$). SS was positively associated with dyslipidemia with an Odds Ratio of 3.2 (95%-confidence interval (CI): 1.39-7.17, $P=0.005$). Factors associated with dyslipidemia in women with SS included a family history of dyslipidemia (OR=4.4, 95%-CI: 1.2-16.4, $P=0.022$), diabetes (OR=8, 95%-CI: 0.9-68.4, $P=0.031$), and insulin resistance (OR=7.97, 95%-CI: 1.6-40.5, $P=0.006$). However, age, diagnostic delay, disease duration, GH levels, FT4 levels, daily dose of levothyroxine, daily and cumulative dose of hydrocortisone, and estroprogestative therapy were not associated with dyslipidemia.
Conclusions
The prevalence of dyslipidemia was significantly higher in patients with SS than in controls. Its associated factors were family history of dyslipidemia, insulin resistance, and diabetes. Regular lipid profile assessments and lifestyle management are necessary in women with SS.

Transsphenoidal surgery (TSS) of the hypothalamic-pituitary region is the approach of choice because of its lower morbidity compared to the transcranial approach. However, its results are highly variable and depend on many factors related to the tumor itself, to the medical team, and to technical issues. We review the situation of this procedure in a nationwide retrospective multicenter evaluation. Data were collected from centers participating in the TESSPAIN (TranssphEnoidal Surgery in SPAIN) registry, that included all TSS performed in each center during a 5-year period (2018-2022). Each center recorded the number of neurosurgeons performing TSS, the technical aspects, the number of procedures/year/surgeon, the pathology operated on, the goals set and their achievement, and the occurrence of long-term complications following the procedure. The 29 centers included performed a total of 2815 TSS procedures. Seventeen centers had more than one dedicated neurosurgeon, four of which had one neurosurgeon performing more than 75% of TSS. Twelve centers had one dedicated neurosurgeon (n:9) or two neurosurgeons who always operated together (n:3). An ENT surgeon always performed the nasal phase of the procedure in 21 of 29 centers, while it was performed by the dedicated neurosurgeon in five centers. In the remaining three centers the ENT surgeon was only required for very complex approaches. No one center averaged more than 40 TSS/year. Only six centers averaged more than 25 TSS/year. Only one center did not use an endoscopic approach. Extended approach to the cavernous sinus was reported by 27 centers. The most common pathology was clinically nonproducing pituitary adenomas ($n=1421$;50.5%), followed by producing pituitary adenomas (n: 911 (32.4%): 436 GH-producing, 323 Cushing's disease, 127 prolactinomas and 25 TSH-secreting adenomas). 483 TSS (17.1%) were performed for the treatment of non-adenomatous tumors, usually with extrasellar extension including craniopharyngiomas, RCC, meningiomas, chordomas, and others. The percentage of TSS for nonproducing pituitary adenomas was negatively correlated with the total number of TSS (p:0.016), and the percentage of TSS for non-adenomatous tumors showed a positive correlation with the total number of TSS (p:0.012). TSS in Spain shows an inhomogeneous picture, with a high geographical dispersion and low surgical volume in each center, despite the recommendations of scientific societies. Almost all neurosurgeons use an endoscopic approach and perform a cavernous sinus approach. Centers with higher surgical volume have a higher percentage of TSS for non-adenomatous tumors, while centers with lower surgical volume operate more frequently on nonproducing pituitary adenomas.

Oral health-related quality of life in patients with acromegaly vs patients with non-functioning pituitary adenomas

Sandra Blum[1], Linda Daume[2], Rohith Illuri[1], Johannes Kleinheinz[2], Jonel Trebicka[1] & Elena Vorona[1]
[1]Münster University Hospital, Gastroenterology, Hepatology, Endocrinology, Infectiology, Münster, Germany; [2]Münster University Hospital, Cranio-Maxillofacial Surgery, Münster, Germany

Introduction
Acromegaly is a rare endocrinologic disease most commonly caused by an excess of growth hormone (GH) produced by a benign pituitary adenoma. Besides diverse systemic manifestations, acromegaly is also associated with a range of oral-dental problems. To date limited research has been conducted on how oral-dental pathologies affect the oral health-related quality of life (OHRQoL) in patients with acromegaly and growth hormone-producing pituitary adenomas. To our knowledge this is the first study which compares the OHRQoL between acromegaly patients and those with non-functioning pituitary adenomas. The aim of this study is to improve understanding of acromegaly's dental effects and the impact of OHRQoL and to enhance future treatment and patient outcomes.
Methods
41 patients with diagnosis of growth hormone-producing pituitary adenomas and patients with non-functioning pituitary adenoma were included in the study. All participants were asked to complete a german version of the oral health impact profile 14 questionnaire (OHIP-14). For included patients data from the clinical profile were collected. Comparative analysis of both groups were performed. Patients diagnosed with acromegaly and growth hormone-producing pituitary adenomas were additionally examined in regard of their oral-dental health condition by a speacialist and had to answer 3 additional questions referring to their oral-dental care by dentist. Based on the examination, a specialist medical diagnostic of the problem and, if necessary, appropriate treatment is offered.

Results
Mean age of the acromegalic patients was 55,95 years and 26 patients were females. The average OHIP-14 score for an acromegalic patient was 9,95 points. Female acromegalic patients present a higher OHIP-14 Score (12.15 points) than males (6.13 points). The questionnaire domains most affected were psychological discomfort (mean 2.05 ± 2.27) and psychological disability (mean 2.05 ± 2.07) and physical pain (mean 1.53 ± 1.7). 89.7% of acromegalic patients are satisfied with dental care and 95% had no difficulty finding a dentist due to acromegaly. However, 77.4% of acromegaly patients have the impression that the dentist is not familiar with their disease.
Conclusion
the analyses of our data will take a crucial step forward in providing deeper insights into the impact of oral health conditions and associated comorbidities as well as OHRQoL in patients with acromegaly.

Pseudoacromegaly – a challenging entity in the endocrine clinic: why you need to know about it?

Pedro Marques[1,2], Inês Sapinho[3] & Marta Korbonits[4]
[1]Hospital CUF Descobertas, Lisbon, Portugal, Endocrinology Department, Lisbon, Portugal; [2]Faculdade de Medicina, Universidade Católica Portuguesa, Lisbon, Portugal; [3]Hospital CUF Descobertas, Endocrinology Department, Lisbon, Portugal; [4]William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, Centre for Endocrinology, London, United Kingdom

Introduction
Pseudoacromegaly encompasses a group of conditions in which patients have clinical features of acromegaly or gigantism, but no GH or IGF-1 excess. With systematically reviewing all published cases ($n = 76$) of patients with pseudoacromegaly who were evaluated due to a clinical suspicion of acromegaly, we identified key distinguishing features which need to be recognized.
Materials and Methods
A systematic search using the terms pseudoacromegaly, acromegaloidism and acromegaloid was conducted. Pseudoacromegaly cases were carefully checked to ensure they met eligibility criteria: 1) presentation suggestive of acromegaly and investigation triggered by acromegaly-related manifestations; 2) acromegaly was excluded based on normal serum GH, IGF-1 and/or GH suppression on oral glucose tolerance test (OGTT-GH); 3) definitive diagnosis of the underlying pseudoacromegaly condition was established.
Results
Of the 76 included cases, 47 (62%) were males, with mean ages at presentation 28 ± 16 yrs (mean ± SD) and at first acromegaloid symptoms 17 ± 10 yrs. Most cases were reported from Asia (42%). Over half 57% were directly referred to Endocrine departments. The most common conditions were pachydermoperiostosis (47%) and insulin-mediated pseudoacromegaly (24%), followed by Cantú (8%) and Berardinelli-Seip (4%) syndromes. Insulin-mediated pseudoacromegaly cases were more often referred to endocrine departments, whereas pachydermoperiostosis to non-endocrine physicians. Acromegaloid facies (75%) and acral enlargement (80%) were the most common features; other prevalent acromegaloid features included hyperhidrosis (36%), pachydermia (32%), arthralgia (29%), macroglossia (25%), prognathism (25%), acanthosis nigricans (25%) and tall stature (20%). Prevalence of acromegaloid physical features and tall stature was higher in cases referred to endocrine specialists (33% vs 6%; $P = 0.003$). GH/IGF-1 axis assessment was heterogeneous: random GH was reported in 65%, IGF-1 in 79%, OGTT-GH in 51%. GH excess was more frequently ruled out based on 2 tests combined (53%); 3 tests were applied in 22%. Pituitary MRI was performed in 30 cases, being normal in 19, while a pituitary adenoma or hyperplasia were reported in 8 and 3 patients, respectively. Investigation patterns differed between cases managed by endocrine and non-endocrine specialists, the former requesting more often IGF-1, OGTT-GH and pituitary MRI.
Conclusions
Pseudoacromegaly is a challenging entity that may be encountered by endocrinologists, with pachydermoperiostosis and insulin-mediated pseudoacromegaly being the conditions most identified as mimicking acromegaly. Adequate assessment of GH/IGF-1 is crucial to rule out acromegaly, which may be better performed by endocrine specialists. Pituitary incidentalomas are common in the pseudoacromegaly setting and require careful judgment to prevent inadequate management.

Cannulated prolactin test for the diagnosis of hyperprolactinemia syndrome

Tatiana Mokhort[1], Natalia Karlovich[1], Maryia Malyshko[2], Olga Shishko[3] & Elena Yurenya[3]
[1]Belarusian State Medical University, Endocrinology Department, Minsk, Belarus; [2]16th Outpatient Clinic, Endocrinology Department, Minsk, Belarus; [3]Minsk City Clinical Endocrinological Center, Minsk, Belarus

The aim was to evaluate the results of a cannulated test for prolactin in patients of reproductive age with hyperprolactinemia (HP) and analyze the frequency of specific and nonspecific complaints, the presence of obesity and overweight.
Materials and methods
We examined 120 patients, 93w, 27m; age 31.4 ± 9.0 yrs. After the catheterization of the vein, a venous cannula was installed, blood was taken immediately after the cannulation (P0), then 60 minutes (P1) and 120 minutes (P2). The results of the cannulated prolactin test (CPT) were considered positive - with HP remaining in all three samples (P0, P1, P2), questionable - if HP was retained at P0 and P1, and negative if HP was only at P0. HP was diagnosed in accordance with the recommendations of the Endocrine Society: > 20 ng/ml (424 mU/l) in men and > 25 ng/ml (530 mU/l) in women.
Results
99 patients (87.1% of women and 66.7% of men) had complaints, of them 67 patients (68.8% women and 11.1% men) had specific to HP syndrome (galactorrhea, menstrual disorders, reduced libido, pregnancy-free), 52 patients (39.7% of women and 59.3% of men) had non-specific complaints (breast pain, scrotum pain, weight gain, acne, headache, dizziness, fatigue). Overweight and obesity occurred in 31.8% of patients. Positive CPT was detected in 36.7% of patients. Patients with stress-induced HP (negative CPT) and patients with true HP (positive CPT) had no statistically significant differences in age and frequency of occurrence of specific and non-specific complaints and symptoms for HP. A decrease in serum PRL (P2 vs P0) was found in 113 patients (94.2%), with a median decrease of 158.9 mME/l. Patients with positive CPT had a higher PRL at P0 (888.5 mME/l, $P < 0.001$). Among patients with a negative CPT, i.e. with stress-induced HP, the proportion of overweight and obese was 52.6% vs 22.7% among patients with true HP ($P < 0.001$), and obesity was 21.0% vs 11.3%, $P < 0.05$.
Conclusion
Our results shown that patients with a moderate HP have positive CPT in 36.7% of cases. A negative test, indicating the absence of true HP, is more often recorded in men, as well as in individuals with overweight and obesity. The presence of complaints and symptoms, especially nonspecific ones, does not have a significant impact on the test result. We can assume that CPT is a promising method for excluding physiological (stress-induced) HP in young people of reproductive age with HP.

Assessment of muscle hormonal function in adult patients treated with growth hormone (GH)

Magdalena Goralska & Agnieszka Stańczyk, Piotr Wierzbowski, Zbigniew Bartoszewicz, Agnieszka Kondracka, Jarzy Małek, Urszula Ambroziak & Tomasz Bednarczuk Torres
Medical University of Warsaw, Endocrinology and Internal Diseases, Warszawa, Poland

Objective
Growth hormone (GH) is used for metabolic indications in the treatment of adult patients with GH deficiency (GHD). In addition to influencing growth processes in childhood, GH is important in regulating metabolic processes at every stage of life. GH, via insulin-like growth factor (IGF-1), has an anabolic effect on protein metabolism, also in skeletal muscles and cardiac muscle. Moreover, myokines produced by muscle fibers stimulated by muscle contraction, acting in an autocrine and paracrine manner, have a significant impact on metabolism. The most serious consequences of long-term, severe GHD in the adult population are the reduction of muscle and bone mass, which significantly increases the frequency of deaths due to cardiovascular complications and osteoporotic bone fractures, as well asdeteriorates the quality of life. The aim of the study is to assess the hormonal activity of muscles in adult patients treated with growth hormone: with confirmed growth hormone deficiency after a growth-promoting period and with Prader Willi syndrome. The project also aims to assess the impact of treatment on quality of life and physical condition. Patients with GHD who require GH therapy are classified into two groups: GHD that occurred in childhood (childhood-onset GHD - CO-GHD) and GHD acquired in adulthood (AO-GHD, adult-onset GHD).

Design
observational, cohort-prospective
Patients
Study participants: Patients with Prader Willi syndrome, patients with growth hormone deficiency, qualified for recombinant human growth hormone (rhGH) treatment and healthy volunteers.
Measurements
A subjective and physical examination was performed, assessing height, weight, BMI, body composition using the bioimpedance method, and assessing muscle, fat and bone tissue. Quality of life questionnaires, SF-36 and (QoL-AGRDA) were administered. Biochemical and hormonal determinations were made, including (IGF-1) and determinations of myokines like Irisin, Myostatin, IL4, I8, L6, IL15, Apelin and proteins binding insulin-like growth factor (IGFBP-3)
Results
The data obtained in the study allowed us to examine the impact on the hormonal activity of muscles and their function in patients undergoing treatment with human recombinant growth hormone. Hormonal activity of muscles influences metabolic processes and quality of life in patients treated with growth hormone.
Conclusions
Growth hormone deficiency in adults requires precise diagnostics and properly conducted substitution treatment

Pancreatic neuroendocrine tumour: from glucagonoma to aggressive insulinoma

Sara Santos[1], Raquel Calheiros[1], Pedro Souteiro[1], Joana Oliveira[1], Isabel Inácio[1], Ana Paula Santos[1] & Isabel Torres[1]
[1]Portuguese Institute Of Oncology of Porto, Endocrinology, Porto, Portugal

Introduction
Pancreatic neuroendocrine tumors (PNETs) originate from neuroendocrine islet cells and can therefore secrete several neuropeptides. Multiple and secondary hormone secretion have been described in a minority of cases, mostly with advanced disease, and it has been hypothesized that this complex secretion pattern can serve as a marker for tumor behavior.
Case report
Male patient, 69 years old, diagnosed with a glucagonoma with pulmonary and hepatic metastasis, in 2009. He was sequentially treated with chemotherapy (gemcitabine and CAPTEM), octreotide, PRRT and everolimus, and lastly with sunitinib. He also had diabetes *mellitus*, likely secondary to the glucagonoma, well controlled with insulin therapy. The patient presented with recurrent symptomatic hypoglycemia that persisted despite insulin suspension. Bloodwork showed glucose 36 mg/dl, C peptide 6,95 (1.1-5.0) ng/ml and insulin 39,2 (2.6-24.9) uUI/ml and the diagnosis of insulinoma was assumed. He started therapy with diazoxide and lanreotide, for hypersecretion control, with a later switch to pasireotide for its hyperglycemic effects. The ^{68}Ga-DOTANOC PET/CT showed hepatic disease progression and he was submitted to 2 additional cycles of PRRNT. None of these measures led to normoglycemia so corticotherapy was introduced. Recurrent severe hypoglycemia with frequent visits to the emergency department led to the patient's hospitalization in our center. Several measures were applied to try to rise his glycemic levels: glucagon perfusion, subcutaneous octreotide 3id, higher steroid doses, 30% glucose perfusion and everolimus (due to its hyperglycemic effect), with little benefit. Considering the hepatic disease progression, (radio) embolization was contemplated, but after discussion with interventional radiology and nuclear medicine, not deemed feasible due to porto-systemic shunt. During the hospital stay, the patient's clinical picture progressively deteriorated, and he passed away shortly after the diagnosis of SARS-COV2 infection.
Conclusion
This case highlights the PNETs ability to change their secretion profile, usually described in the context of advanced and aggressive disease. Several therapeutic lines were used in this patient, with no significant effect, underlying the need for new alternatives for aggressive and refractory insulinomas. Targeted alpha-particle therapies like ^{225}Ac-DOTATATE have been described with great results in this type of patients but, unfortunately, they are still not available in our country.

[1]University General Hospital of Heraklion, Department of Endocrinology Diabetes and Metabolic Diseases, Heraklion, Greece; [2]University of Crete, School of Medicine, Heraklion, Greece; [3]Evangelismos General Hospital, Department of Pathology, Athens, Greece; [4]Evangelismos General Hospital, Department of Endocrinology 'D.IKKOS" - Diabetes Center - Center of excellence for rare endocrine diseases (ENDO-ERN), Athens, Greece; [5]General Hospital of Nikaia - Piraeus "St. Panteleimon", Department of Neurosurgery, Athens, Greece; [6]King's College London, Centre for Craniofacial and Regenerative Biology, London, United Kingdom

Background/Aim
Pituitary neuroendocrine tumors (PitNETs), although usually indolent, may display aggressive behavior. YAP/TAZ signalling has been linked to pituitary development and stem cell regulation, with a preliminary study from our group revealing elevated levels and nuclear localization of YAP/TAZ in non-functioning PitNETs (NF-PitNETs). *CTGF*, a YAP/TAZ target gene, encodes a secreted factor involved in proliferation and angiogenesis, that has been implicated in tumor development. We aim to use specimens of human PitNETs to assess the expression of *CTGF* and correlate with clinical and pathology data.
Material and methods
The clinical and pathology data of 13 patients with PitNETs were initially investigated, including seven patients with functioning and six patients with NF-PitNETs. Their clinical characteristics were analyzed, including age, tumor size, and outcome (remission, recurrence, progression). The 5th edition of WHO classification was used. The expression of *CTGF* in pituitary tumor sections was assessed using RNAscope mRNA *in situ* hybridization (ACDBioTechne). *CTGF* expression was subdivided into four groups based on a semiquantitative scoring system (Very low 0, Low 1, Medium 2, High 3). The tumor subtype, Ki-67 proliferation index, and the MGMT presence ($>50\%$) were correlated with the clinical data and tumor behavior. This study was approved by the Institutional Review Board and all patients provided informed consent.
Results
Our preliminary results showed that *CTGF* is expressed statistically higher (Score 2-3) in patients with Ki-67 above 7% ($P<0.05$). Among six patients with NF-PitNETs, one patient had medium, and three had high levels of *CTGF* (16,6% and 50%, respectively), correlated with Ki-67 above 7% and a recurrence/progression rate of 100%. Interestingly, there was high expression of *CTGF* (Score 3) in two patients with immature POU1F1-lineage PitNETs, which lack terminal differentiation. In patients with functioning PitNETs, 3 out of 7 cases were characterized by medium levels of *CTGF* (Score 2) and were correlated with younger age (<40 years), with high Ki-67 levels above 10% and with MGMT presence (2 out of 3 cases, 66%). None of the remaining four functioning PitNETs with *CTGF* Score 0-1 and low Ki-67 $<3\%$ recurred.
Conclusion
Our preliminary data show increased expression of *CTGF* in NF-PitNETs, particularly in immature subtypes, with high levels of Ki-67 and in functioning PitNETs presenting in younger patients with high Ki-67 and MGMT expression. All patients with high expression of *CTGF* recurred/progressed. Our findings suggest that YAP/TAZ signalling may have a critical role in PitNETs with more aggressive behavior.

Sotos syndrome in two generations - a reminder that high suspicion is needed in milder phenotypes

Maria Ponte[1], Andreia Pataco[1], Regina Medeiros[1], Ana Luísa Rodrigues[2] & João Anselmo[1]
[1]Hospital do Divino Espírito Santo de Ponta Delgada, Endocrinologia e Nutrição, Ponta Delgada, Portugal; [2]Hospital do Divino Espírito Santo de Ponta Delgada, Pediatria, Ponta Delgada, Portugal

Introduction
The differential diagnosis of overgrowth includes constitutional tall stature, excess growth hormone (GH) and genetic syndromes. Sotos syndrome generally presents with overgrowth, dysmorphisms and early learning disabilities. Here in, we describe the diagnostic pathway of Sotos Syndrome in an adult male presenting with tall stature and mild morphological and cognitive features, prompted by his son's clear manifestation of the classic triad.
Case report
A male child was born at term and delivered by c-section due to fetopelvic incompatibility, weighing 3460 g (*z*-score 0.2; percentile 59.1), measuring 52.5

cm (*z*-score 1.4; percentile 91.6), with a cephalic perimeter of 38.2 cm (*z*-score 2.9; percentile 99.8). Newborn hearing screening detected congenital conductive hearing loss. Since his 3 months, he has been above the 95th percentile for height and weight. Regarding family history, his father was 2006 cm (*z*-score 4.14; percentile 99.9) and had macrocephaly, elongated face and high forehead. He had refused medical investigation as he always had normal psychomotor development and no clinical symptoms. He concluded high school and works in dust separation. Laboratory study of the son, including IGF-1 and IGFBP-3, was normal. At 18 months, cranial and pituitary CT scans showed only an arachnoid cyst. At 2 years and 6 months, left wrist radiography revealed advanced bone age of 3 years and 6 months. An abdominal echography did not identify any organomegaly or abdominal mass. Genetic karyotype and Fragile X Messenger Ribonucleoprotein (FMR1) gene analysis were normal. Psychomotor retardation was noticed, mainly since he was 3 years old, predominantly in oral communication, locomotor skills and personal-social functions, displaying some autistic-like behaviors. Some dysmorphic features also became evident, such as dolichocephaly, high forehead and ogive palate. Sotos Syndrome was hypothesized and confirmed by identification of a heterozygous variant in Nuclear receptor binding SET Domain Protein 1 (NSD1) gene - c.6604T>C p.(Cys2202Arg). His father was also heterozygotic for this variant. Currently, the child is 9 years old, heights 157.9 cm (*z*-score 3.72; percentile 99.9) and weighs 39 kg (*z*-score 1.37; percentile 91.47). He attends the 3rd year of primary school. Cardiac anomalies were excluded.

Conclusion

Sotos Syndrome may mimic gigantism when intellectual and social impairment are mild. Therefore, it should be considered while approaching overgrowth without GH excess. Recognizing Sotos Syndrome is essential for appropriate surveillance due to increased risk of certain tumors and cardiac and renal anomalies, and for providing genetic counseling.

Diagnostic challenges in cyclic cushing's syndrome: a rare case due to ectopic acth secretion by lung carcinoid

Roberto Colle[1,2], Stella Pigni[1,2], Simona Jaafar[1,2], Giacomo Cristofolini[1,2], Maria Francesca Birtolo[1,2], Elisabetta Lavezzi[2], Edoardo Bottoni[3], Silvia Uccella[1,4], Gherardo Mazziotti[1,2] & Andrea Lania[1,2]

[1]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele (MI), Italy; [2]IRCCS Humanitas Research Hospital, Endocrinology, Diabetology and Medical Andrology United Rozzano (MI), Italy; [3]IRCCS Humanitas Research Hospital, Thoracic Surgery Department, Rozzano (MI), Italy; [4]IRCCS Humanitas Research Hospital, Department of Pathology, Rozzano (MI), Italy

Introduction

Cyclic Cushing's syndrome (cCS) is a rare condition characterized by periods of excessive cortisol secretion (peaks), alternating with phases of eucortisolism (through). In most cases, cCS is caused by an ACTH-secreting pituitary tumor, while only few cases of cyclic ectopic ACTH secretion (cEAS) have been described.

Case presentation

In February 2023, a 58-year-old woman was referred to our Endocrine Unit due to a 10-year history of recurring episodes of decompensated diabetes, hypertension, and hypokalemia, coupled with body and facial swelling, and weight gain, occurring approximately once a year and alternated with periods of clinical remission. Physical examination during such episodes was highly suggestive of CS. Remarkably, the patient's family history disclosed several cases of functioning pituitary adenomas. Previous endocrine investigations in different centers had revealed a cyclical adrenocorticotropic hormone (ACTH) -dependent hypercortisolism, with high ACTH and 24h urine free cortisol, and lack of cortisol suppression after dexamethasone suppression test during disease periods, yet the precise localization of the disease remained elusive. Indeed, magnetic resonance imaging had identified a 3-mm 'possible pituitary adenoma', but inferior petrosal sinus sampling had demonstrated no center:periphery ACTH gradient, and 68-Ga-PET-CT had only shown focal uptake in the left thyroid lobe, prompting a subsequent total thyroidectomy with the diagnosis of a follicular adenoma. Upon the recurrence of a peak phase, we performed a corticotropin-releasing hormone test and a desmopressin test, both resulted in inadequate ACTH and cortisol responses suggestive of an ectopic source of ACTH hypersecretion. New 68-Ga-PET-CT and 18-FDG-PET-CT scans during this active period both revealed focal uptake in the middle lobe of the right lung, where a "fungus ball" lesion had been previously described. A pulmonary right middle lobectomy was indicated, while a 'bridge therapy' with Osilodrostat waiting for surgery allowed clinical and biochemical improvement. Histological examination identified a typical ACTH-staining carcinoid (Ki67 1.5%), and the diagnosis was confirmed by post-surgical hypoadrenalism, still persistent.

Conclusion

The diagnosis of cyclic ACTH-dependent hypercortisolism poses major difficulties due to its intermittent nature. Up to now, less than 40 cases of cEAS have been described in the literature, although its actual prevalence may be underestimated. The main pitfalls are the low diagnostic accuracy of both hormonal and imaging procedures, especially if performed irrespective of cortisolaemic status, and the intrisinc challeging diagnosis of ectopic neuroendocrine tumors. Thus, an exhaustive diagnostic work-up during periods of florid disease, as well clinical experience, are paramount to avoid misdiagnoses.

Epidemiology, clinical presentation, treatment and outcome of acromegaly in the island of crete, greece: experience of 3 tertiary centers over a four decade period

Maria Chrysoulaki[1], Vasiliki Daraki[2], Maria Sfakiotaki[1], Paraskevi Tzoutzouraki[3], Paraskevi Floroskoufi[4], Grigoria Betsi[2], Rodanthi Vamvoukaki[2], Stavrina Vergou[5], Stefanos Michailidis[5], Artemis Maria Makri[5], Elpida Mpouhlaki[5], Antonela Spanoudaki[5], Georgios Goulielmos[6], Christos Lionis[7], Katerina Stamataki[4] & Paraskevi Xekouki[1,5]

[1]University General Hospital of Heraklion, Endocrinology & Diabetes Clinic, Iraklio, Greece; [2]University General Hospital of Heraklion, Iraklio, Greece; [3]General Hospital St. George, Mournies, Greece; [4]Venizelio Hospital, Iraklio, Greece; [5]Medical School, University of Crete, Giofirakia, Greece; [6]Medical School, University of Crete, Section of Molecular Pathology and Human Genetics, Giofirakia, Greece; [7]Medical School, University of Crete, Clinic of Social and Family Medicine, Giofirakia, Greece

Acromegaly is a rare and insidious endocrine disease, with increased morbidity and mortality mainly due to delayed diagnosis and inadequate control. There are many population studies assessing the epidemiology of acromegaly in Europe while in Greece, there are no published data except for a few small studies regarding treatment outcome.

Aim

To determine the epidemiology, presentation and outcome in patients with acromegaly in Crete, Greece.

Methods

This is a retrospective observational study using data from the archives of three tertiary hospitals from Heraklion and Chania, for the period of 1983 to 2023. Age at diagnosis, estimated delay in diagnosis, clinical, biochemical, imaging data and disease outcome were recorded.

Results

Eighty-five patients were included in the analysis (51 females, 34 males). The mean age at diagnosis was 44.36±13 years and the mean follow-up time was 16±8 years. Forteen patients (16.4%) were younger than 30 years. The time lag from the onset of symptoms to diagnosis was 5.06 years. The most common presenting symptom was suspicious acromegalic features(coarse facial features/acral growth) followed by headaches (23.9%). A metabolic disease (diabetes, dislipidemia, hypertentsion) was present in 41.1% of patients Macroadenomas were found in 40%, while in 15% of patients, size data were missing. Sixty-four (72.41%) patients underwent surgery, 21 patients (27.6%) received medical treatment only (90% somatostatin analogs (SSAs)) and forty-three (50.1%) received adjuvant treatment; SSAs (50.5%), dopamine agonists (10.5%), radiotherapy (10.7%). Six patients had a second operation (7%). Histology reports were available for 28 cases. Tumor subtype analysis available for 16 patients revealed that densely granulated tumors were 1,4 times more frequent than sparsely granulated somatotropinomas (43.75 vs 31.25%), whereas 8.75% were mixed mamosomatotropinomas. A rare case of mixed gangliocytoma/sparsely-granulated somatotrophinoma was recorded as well. Disease remission was observed in 30 patients (35.2%). The mean time interval from treatment to biochemical control was approximately 3 years. Fourteen patients (16,4%) had persistent disease. Three patients died due to malignancies. There was one patient with gigantism in the context of Familial Isolated pituitary adenoma (FIPA) due to *AIP* mutation and one patient with hyperparathyroidism and VIPoma, in the context of *MEN1* syndrome. Genetic testing is ongoing.

Conclusions
Our epidemiological data does not differ from that reported in other published series. Surgery was the main treatment with a cure rate of 46,8% and SSAs the most used medication. The delay in biochemical control indicates suboptimal treatment which can have negative health effects.

Radioligand therapy in patients with unknown point of origin, other than gastroenteropancreatic or G3 grading neuroendocrine neoplasms

Grzegorz Kamiński[1], Adam Durma[1], Marek Saracyn[1], Maciej Kołodziej[1], Katarzyna Jóźwik-Plebanek[1], Beata Dmochowska[1], Adrianna Mróz[1], Wawrzyniec Żmudzki[1] & Grzegorz Kaminski[1]
[1]Military Institute of Medicine - National Research Institute, Endocrinology and Radioisotope Therapy, Warszawa, Poland

Background
Neuroendocrine neoplasms (NENs) are rare group of tumors with a different clinical course, prognosis and location. Radioligand therapy (RLT) is currently registered in gastroenteropancreatic (GEP) G1-G2 NENs. Tumors with an unknown point of origin, diagnosed outside the gastrointestinal tract and pancreas, or with Ki-67 > 20%, do not qualify in many countries to standard RLT.
Materials and Methods
48 patients with progressive NENs of unknown primary site, non-GEP-NENs, and G3 with good somatostatin receptor expression were qualified to the study. 32 patients received Lutetium-177 (7.4 GBq), while 16 received tandem therapy with Lutetium-177 and Yttrium-90 with equal activities (1.85 + 1.85 GBq) in 4 cycles every 10 weeks.
Results
Progression-free survival (PFS) before RLT was 34 months (IQR = 36) for the whole study group. In subgroups of patients with an unknown tumor location (n = 25), the median PFS was 19 months (IQR = 23), with 'other' locations (n = 21) 31 months (IQR = 28), and with NEN G3 (n = 7) 18 months (IQR = 40). Just after the RLT, disease stabilization or regression was observed in 42 (87.5%) patients. 43 patients reported to follow-up visit (median time after RLT - 14 months; IQR = 18). In 8 we noted progression, 9 patients died, and stabilization was noted in 26 individuals. PFS and OS probability (%) of surviving 12, 24, 36, 48 months (with 95% CI) were calculated. RLT did not cause statistically significant changes in creatinine or GFR values. Hematological parameters (RBC, WBC, PLT, HGB) as well as chromogranin A concentration decreased significantly during the treatment. There were no statistical differences between both subgroups regarding the type of radioisotope used (177-Lutetium vs 177-Lutetium and 90-Yttrium).
Conclusions
Patients with NENs who do not qualify for standard RLT at this moment due to a lack of registration could benefit from such therapy. There were no significant negative impacts on renal parameters. The reductions in blood counts were noticeably, but not clinically significant, which was acceptable in relation to the positive treatment outcomes.

Herniation of the subarachnoid space into the sella turcica results in empty or partially empty sella syndrome. Primary sella turcica syndrome is idiopathic, whereas secondary empty sella is a result of central nervous system pathologies, which may manifest as visual disorders, due to optic chiasm compression or displacement. The purpose of this study was to determine whether empty and partially empty sella—either primary or secondary—are risk factors for optic chiasm compression. The study involved hospital database analysis and selection of 594 patients, who underwent magnetic resonance imaging of the pituitary. Empty or partially empty sella was detected in 136 patients; in 87 patients the condition was primary and in 49 it was secondary. Optic chiasm compression was found in 26 patients. The patients were divided into two groups: patients with empty/partially empty sella (group 1, n = 136) and those with no empty/partially empty sella (group 2, n = 458). Study groups 1 and 2 showed no statistically significant differences in terms of optic chiasm compression rates (6 [4.4%] vs 20 [4.4%], P = 0.98). Univariate logistic regression demonstrated the presence of pituitary macroadenoma to be a statistically significant predictor of optic chiasm compression (OR 20.923, 95% CI 7.166–61.093, P = 0.001); whereas an empty and partially empty sella, either primary (1.351, [0.42-4.342], P = 0.613) or secondary (0.859, [0.174-4.24], P = 0.852); Rathke cleft cyst (OR 0.307 [0.039–2.386, P = 0.259), and pituitary cyst (OR 0.785 [0.168–3.656], P = 0.758) are not risk factors for optic chiasm compression. Empty and partially empty sella have no effect on optic chiasm compression or displacement, which means that they may not manifest with visual symptoms, such as visual field constriction or double vision.

Disentangling glucose metabolism during and after pregnancy in women with chronic hyperprolactinemia

Roberta Scairati[1] & Renata Simona Auriemma[1], Sara Di Meglio[1], Guendalina Del Vecchio[1], Rosa Pirchio[1], Chiara Graziadio[1], Claudia Pivonello[1], Rosario Pivonello[1,3,4] & Annamaria Colao[2,3]
[1]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Naples, Italy, [2]Università Federico II di Napoli, Dipartimento di Sanità Pubblica, Naples, Italy, [3]UNESCO Chair for Health Education and Sustainable Development, University Federico II, Naples, Italy, [4]Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia ed Andrologia, Unità di Andrologia e Medicina della Riproduzione e della Sessualità Maschile e Femminile (FERTISEX-CARES), Università Federico II di Napoli, Naples, Italy

Context
Prolactin (PRL) exerts a crucial role in the regulation of mammalian reproduction and in the promotion of lactation as response to the suckling reflex. Beyond this, it directly modulates gluco-insulinemic metabolism.
Objective
To dissect glucose metabolism during and after pregnancy in patients with chronic hyperprolactinemia (CTPE).
Methods
This longitudinal study included 52 reproductive aged women with CTPE due to pituitary adenomas (43 microadenomas, 9 macroadenomas), chronically treated with cabergoline (CAB) at the mean dose of 0.68 ± 0.6 mg/week for a mean duration of 62.5 ± 52.5 months. 21 out of 52 patients were normal weight (40.3%), 12 overweight (23%) and 8 obese (15.3%). Patients were evaluated before conception, at 12, 24 and 36 weeks of pregnancy and at 1, 2, 3, 4, 5 and 10 years after delivery. CAB was discontinued during pregnancy and restarted in 51.9% of patients after delivery due to recurrent hyperprolactinemia (RH). Anthropometric, hormonal (serum PRL) and metabolic (HbA1c, fasting glucose/FG, glucose tolerance) parameters were assessed.
Results
During pregnancy, serum PRL levels were significantly higher than levels before pregnancy (P < 0.001), while FG remained stable. An inverse correlation between serum PRL and FG was found in the first (P = 0.032) and third (P = 0.05) trimester. The percentage increase in serum PRL levels between first and second trimester

(Δ1, $P=0.048$) and first and third trimester (2, $P=0.001$) were inversely correlated with FG levels at third trimester. Serum PRL before conception emerged as a predictive biomarker of third trimester FG (=2.603; $P=0.048$). Older age was associated with decreased HbA1c in the first trimester ($P=0.048$;), reduced infant birth weight ($P=0.033$), and lower FG at 3 years after delivery ($P=0.025$;). Breastfeeding up to 6 months after delivery correlated with lower FG at 4 and 10 years postpartum. A positive correlation between pre-pregnancy body mass index and FG at 10 years after delivery ($P=0.017$) was observed, particularly in overweight/obese patients requiring higher CAB doses. Patients with RH who had to restart CAB showed shorter breastfeeding duration ($P=0.04$) and higher FG at 2 years after delivery ($P=0.015$).

Conclusion

An appropriate pre-conceptional metabolic management should be recommended in patients with CTPE to reduce the risk of glucose impairment during and after pregnancy. An excessive reduction in PRL levels due to CAB treatment before conception may predict increased blood glucose levels in the third trimester, which may result in an increased risk of GDM.

Introduction

Subcutaneous (sc) pasireotide effectively reduces cortisol levels and is generally well tolerated in Cushing's disease (CD) patients, as demonstrated by a Phase III study (NCT00434148). We report data from a non-interventional, multinational study (NCT02310269) evaluating long-term safety and efficacy of pasireotide sc for CD patients.

Methods

Adults with CD, for whom surgery has failed or is not an option, were analysed by time of pasireotide sc initiation (at study entry: 'new-use' [NU] patients; before study entry: 'prior-use' [PU] patients) and monitored for 3 years. The primary endpoint was incidence of pasireotide-related adverse events (AEs) and serious AEs (SAEs). A key secondary endpoint was the proportion of patients with mean urinary free cortisol (mUFC) ≤ upper limit of normal (ULN) over time.

Results

The full analysis set (FAS) included 152 patients (45 NU, 107 PU); the safety set (SS) included 148 patients (43 NU, 105 PU). In the SS, median (min–max) pasireotide sc exposure was: NU, 7 (0–37) months on study; PU, 34 (0–132) months from drug initiation. 50/105 (48%) PU patients received pasireotide sc for >36 months. Median (min–max) dose on study ($n=148$) was 1200 (300–1800) µg/day. Pasireotide-related AEs occurred in 59.5% ($n=88/148$) of SS patients (NU, 79.1% [$n=34/43$]; PU, 51.4% [$n=54/105$]), mostly (>15%) nausea (16.9% [$n=25/148$]). Hyperglycaemia occurred in 10.1% ($n=15/148$) of SS patients (NU, 23.3% [$n=10/43$]; PU, 4.8% [$n=5/105$]). Pasireotide-related SAEs occurred in 16.2% ($n=24/148$) of SS patients (NU, 25.6% [$n=11/43$]; PU, 12.4% [$n=13/105$]), mostly (>2.5%) hyperglycaemia (3.4% [$n=5/148$]). The only reported grade 4 pasireotide-related SAE was hyperglycaemia (NU, $n=1$). The proportion of patients who discontinued because of pasireotide-related AEs and SAEs were 23.6% ($n=35/148$; NU, 32.6% [$n=14/43$]; PU, 20.0% [$n=21/105$]) and 6.1% ($n=9/148$; NU, 9.3% [$n=4/43$]; PU, 4.8% [$n=5/105$]), respectively. The proportion of patients (FAS) with mUFC ≤ULN (138 nmol/24 h) at baseline and months 12, 24 and 36 were: NU, $n=4/23$ (17.4%), $n=3/10$ (30.0%), $n=5/7$ (71.4%), $n=1/3$; PU, $n=30/45$ (66.7%), $n=31/41$ (75.6%), $n=24/36$ (66.7%), $n=9/15$ (60.0%).

Conclusions

Pasireotide-related AEs and SAEs, including hyperglycaemia, occurred more frequently in NU than PU patients. This suggests that most AEs, including hyperglycaemia, typically occur in the early stages after pasireotide sc initiation and can be effectively managed long term. Most patients achieved/maintained cortisol control over 36 months. Pasireotide sc has a manageable safety profile and is effective for the long-term treatment of CD patients.

Sheehan syndrome: about 36 cases

Rajaa Mashal[1], Nassim Essabah Haraj[2], Siham El Aziz[2] & Asma Chadli[2]

[1]Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy- University Hassan II – Casablanca-Morocco, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Departement, CASABLANCA, Morocco; [2]Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy- University Hassan II – Casablanca-Morocco, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Departement, CASABLANCA, Morocco

Introduction

Sheehan syndrome (SS) is a potentially serious complication of the postpartum period, corresponding to ischemic necrosis of the anterior pituitary gland in connection with delivery hemorrhage, and remains a topical issue despite improvements in gyneco-obstetrical management. **The objective** of our study is to investigate the epidemiological, diagnostic and therapeutic aspects of sheehan's syndrome for better management.

Patients and methods

Retrospective study carried out at the Endocrinology and Metabolic Diseases Department, Ibn Rochd University Hospital - Casablanca, on patients hospitalized from January 2000 to December 2023 for partial or complete antehypophyseal insufficiency on sheehan syndrome.

Results

In our study, 38 patients were included. The average age of the patients was 55 years. The etiological factor was delivery hemorrhage, requiring hemostasis hysterectomy in 6 patients.The time to diagnosis was 20 years (40 days - 40 years) . Clinical symptomatology was dominated by the absence of lactation, amenorrhea, axillary or pubic depilation and signs of hypothyroidism. The hormonal assessment including an assay of the cortisolemia of 08h, FSH, LH and TSH was carried out in all our patients, showing a complete deficit of the 3 hormonal axes. Hypohyseal MRI was performed in 18 patients, showing an empty sella turcica in 16 and pituitary apoplexy in 2. Complications in our patients included diffuse bone demineralization in 20 cases and 8 cases of depression. all our patients received hormone replacement therapy with hydrocortisone 20 to 30 mg/d and L-thyroxine 50 to 100 mg/d. 11 patients were put on oestroprogestins, with a good evolution.

Conclusion

Sheehan's syndrome is usually diagnosed late. It should be considered in the case of absence of lactation with amenorrhea after a hemorrhagic delivery, and in the case of chronic asthenia in a woman with a gyneco-obstetrical history.

Hypoglycemia revealing an appendicular neuroendocrine tumor

Belhadi Leila[1], Haraj Nassim Essabah[1], El Aziz Siham[1] & Chadli Asma[1]

[1]University Hospital Center Ibn Rochd, Department of Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
Primary neuroendocrine tumors can develop in any organ of the digestive system, most commonly in the small intestine, pancreas, or appendix, followed by the stomach or rectum. Appendiceal neuroendocrine tumors are often discovered incidentally during an appendicular presentation or as part of a carcinoid syndrome, without symptoms of hypoglycemic crises. The association between hypoglycemia and appendicular neuroendocrine tumors remains a subject of debate.
Observation
A 19-year-old patient was admitted for recurrent hypoglycemia, with no specific medical history except for a diabetic mother on metformin and sulfonylureas for the past year. The disease history dates back to one month before admission when a severe hypoglycemic episode occurred with a recorded blood glucose level of 0.5 g/l, accompanied by adrenergic symptoms complicated by a convulsive crisis, which resolved with glucose administration and anticonvulsant therapy. The course was marked by successive hypoglycemic episodes associated with a Whipple triad. Throughout this period, the patient experienced weight loss of 2 kg in one month. Upon admission, the patient presented with a generalized convulsive crisis coinciding with a blood glucose level of 1.03 g/l, leading to status epilepticus and transfer to the intensive care unit. Brain CT and MRI were normal, hile an abdominal CT scan revealed a swollen appendix with a small amount of peritoneal fluid but without infiltration of adjacent fat or pancreatic lesions. An appendectomy was performed, and the pathology report indicated a grade 1 neuroendocrine tumor according to the WHO classification, measuring 2x4 mm, with immunohistochemical expression of chromogranin A and CD56, a Ki-67 proliferation index of 2%, and clear resection margins. Additionally, exploration of thyroid, renal, and hepatic function, cortisol levels returned normal. During post-appendectomy monitoring, the patient normalized blood glucose levels and did not experience further hypoglycemia. As part of the postoperative extension assessment, thoracic-abdominal-pelvic and pancreatic CT scans were performed, and urinary Chromogranin A and 5HIAA levels were negative. An octreoscan conducted 6 months after surgery revealed very moderate hyperfixation in the right iliac fossa.
Conclusion
This observation illustrates the possible endocrine effects of a non-pancreatic neuroendocrine tumor (NET), such as hypoglycemia, which has been described in only one case in the literature. Curative surgery appears to be an effective treatment for these localized tumors.

Cyst of the pineal gland: a case report
Redhouane Longo[1], Mourad Benrabah[2], Benabdelatif Katia[3], Abdelkader Yahi[3] & Ould Kablia Samia[3]
[1]Endocrinology department, Regional University Military Hospital of Oran, Algeria; [2]Nuclear Medicine Department, Regional University Military Hospital of Oran, Algeria; [3]Endocrinology Department, Central Military Hospital, Algiers, Algeria

Introduction
Tumors of the pineal region are rare, constitute 0.5% to 1% of intracranial tumors in adults in Europe and the United States. Anatomical location deeply buried under the cerebral hemispheres behind the third ventricle and the brainstem, and the variety of different histological types explain management difficulties. Cysts of the pineal gland, often calcified, may go unnoticed and be discovered during autopsy especially in the elderly, but some cysts are symptomatic and cause signs related to compression of the aqueduct of Sylvius or the tectal blade.
Observation
Patient aged 20, with no particular history, was brought by his father to the psychiatry department for behavioral disorder such as psychomotor instability with subtotal insomnia. During his stay in psychiatry, and given the negative dosage of toxicants, an organic cause was suspected justifying his transfer to our department where a brain magnetic resonance imaging revealed a simple cystic lesion of the pineal gland measuring 18.5 × 13 mm. However, there was no intracranial expansive process or hypothalamopituitary anomaly. 6-sulfatomelatonin in urine (ELISA) returned to 26.4 µg/24 hours (15.6-58.1), which is correct; plasma beta hCG returned to 0.1 mIU/ml (0-1) so normal, and the alpha-fetoprotein returned to 1.01 IU/ml (00-5.8) also normal. A neurosurgical opinion is requested recommending six-monthly radiological monitoring, with possible evacuation puncture at the slightest clinical deterioration or appearance of signs of compression.
Discussion-Conclusion
Epithelial cysts of the pineal region are benign formations with fluid content, asymptomatic in most cases, developed at the expense of the pineal parenchyma. Magnetic resonance imaging most often makes the diagnosis. Some of these cysts increase in size and cause clinical decompensation by compressing the quadrigeminal plate leading to extrinsic stenosis of the aqueduct of Sylvius or by mass syndrome in the posterior fossa.

Liraglutide regulates expression of enzymes involved in carbohydrate and lipid metabolism in brain cortex of female rat pups under maternal perinatal food restriction
Zainab Mastoor[1], Lucas Carmelo González-Matías[2], Federico Ferrer[3] & Yolanda Diz-Chaves[3]
[1]Laboratory of Endocrinology Centre for Biomedical Research (CINBIO) University of Vigo, Campus de Vigo, Endocrinology, Vigo, Spain; [2]Laboratory of Endocrinology Center for Research in Nanomaterials and Biomedicine (CINBIO) University of Vigo, Campus de Vigo, Vigo, Spain; [3]Laboratory of Endocrinology Centre for Biomedical Research (CINBIO) University of Vigo, Campus de Vigo, Endocrinology, CINBIO VIGO, Vigo, Spain

Introduction
The regulation of glucose and lipid metabolism in the brain is essential to ensure overall neurological health and proper functioning. Increased glycolysis and lipogenesis, if not properly regulated, can potentially lead to an imbalance between energy production in the brain. Glucose and lipid metabolic dysregulation contribute to the development and progression of various brain diseases. Besides other factors maternal undernutrition may alter glucose and lipid metabolism which persist after birth and might lead to pathogenesis of neurodegenerative diseases in the offspring.
Aim
The aim of the present study was to examine the effect of maternal perinatal food restriction (MPFR) on offspring and also determined the impact of Glucagon-like peptide-1 receptor (GLP-1R) agonist, liraglutide, on the enzymes involve in glucose and lipid metabolism in brain cortex of both male and female rat pups with maternal food restriction compared to control group.
Methods
Sprague-Dawley pregnant rats (300g) were randomly assigned to 50% food restriction (MPFR) or *ad libitum* control groups (CT) at day of pregnancy 12. From GD14 to parturition, pregnant MPFR and CT rats were treated with Liraglutide (100 µg/kg/12 hours, sc.) or vehicle (saline). At postnatal day 21 and before weaning, 16 CT and 16 MPFR male pups and 16 CT and 15 MPFR female pups, half of each group from Liraglutide treated mothers, were sacrificed and brain cortex were analysed by RT-PCR.
Results
Maternal food restriction increased mRNA expression of key enzymes involved in carbohydrate and lipid metabolism in brain cortex of female rat pups: Hexokinase-1, Phosphofructokinase-1, Pyruvate Dehydrogenase Kinase4, 6-Phosphofructo-2-Kinase/Fructose-2,6-Biphosphatase3, Glucose-6 phosphate dehydrogenase, Pyruvate Kinase M, Lactate dehydrogenase A, Fatty acid synthase, Acetyl-CoA carboxylase alpha, Carnitine palmitoyl transferase1. Liraglutide administration significantly reduced or completely restored the expression levels of all those enzymes. In male pups just Glucose-6 phosphate dehydrogenase expression was completely suppressed and levels of 6-Phosphofructo-2-Kinase/Fructose-2,6-Biphosphatase3 prominently increased in MPFR, and Liraglutide had no effect.
Conclusion
1. Maternal perinatal food restriction deeply affected the glucose and lipid metabolic activity in brain cortex of female rat pups but not in males by modifying the expression levels of the majority of key enzymes. As a whole MPFR promotes the increase of both glycolysis and lipolysis in the brain cortex just of females.
2. Liraglutide restored the expression of all those key enzymes and minimizes the effects of maternal food restriction and could offer a promising therapeutic approach for the prevention and treatment of brain diseases.

Gender related metabolic differences in hypopituitarism

Dragana Miljic[1,2], Marina Nikolic Djurovic[1,2], Mirjana Doknic[1,2], Sandra Djurdjevic[1,2], Marko Stojanovic[1,2], Zvezdana Jemuovic[1], Ivana Cekic[1], Ivan Jevtic[1] & Milan Petakov[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Belgrade, 11 000 Belgrade, Serbia, Neuroendocrinology; [2]University of Belgrade - Faculty of Medicine

Background
Hypopituitarism is characterised by multiple pituitary hormone deficiencies causing adverse metabolic milleu and body composition changes.
Aim
Our aim was to investigate the gender related differences in the prevalence of metabolic syndrome (MetS) and metabolic profiles in patients with hypopituitarism compared to obese controls.
Patients and methods
A retrospective study of 282 patients with hypopituitarism (136 women and 146 men) age 49.2 ± 15.1 years, and body mass index- BMI 27.9 ± 5.8 kg/m^2, has been performed. The most common cause of hypopituitarism was non-functioning pituitary tumor $n = 140$ (49.6%). Group of 246 obese control subjects (115 females, 131 males) age 42.9 ± 14.8 yrs BMI 30.5 ± 5.2 kg/m^2 was used for comparisson. Antropometric, metabolic and clinical parametars were collected and analyzed.
Results
MetS was diagnosed in 48.6% and 57.1% of patients with hypopituitarism using ATPIII and IDF criteria, compared to 35% and 39% prevalence in the control group ($P < 0.05$). Prevalence was higher in female compared to male patients with hypopituitarism according to IDF (63.2 vs 51.4%, $P < 0.05$) and ATP III criteria (54.4 vs 43.2%, $P < 0.05$). However, male patients with hypopituitarism had significantly greater waist circumference (98.6 vs 90.9 cm, $P < 0.001$), lower HDL cholesterol (1.17 vs 1.29 mmol/l, $P < 0.01$) and higher fasting blood glucose (4.72 vs 4.5 mmol/l, $P = 0.046$) than females. Compared to controls significantlly higher cholesterol and triglyceride levels, despite lower BMI and waist circumference in both sexes were found in patients with hypopituitarism (Table 1).

Parameters	Males			Females		
	Hypopit $n=146$	Control $n=131$		Hypopit $n=136$	Control $n=115$	
BMI (kg/m^2)	28.05	**31.77**	$P<0.01$	27.75	**29.00**	$P<0.01$
Waist circumference (cm)	98.65	**108.89**	$P<0.01$	90.92	**92.98**	$P<0.05$
Total cholesterol (mmol/l)	**6.67**	5.59	$P<0.01$	**6.73**	6.12	$P<0.05$
HDL (mmol/l)	1.17	1.07		1.29	1.40	
LDL (mmol/l)	**4.43**	3.35	$P<0.01$	**4.39**	3.93	$P<0.01$
Triglyceridies(mmol/l)	**2.56**	2.20	$P<0.01$	**2.33**	1.71	$P<0.01$

Conclusions
Female patients showed higher prevalence of MetS, while male patients with hypopituitarism had worse metabolic profiles. Compared to obese controls, hypopituitary patients had significantly worse lipid profiles and higher prevalence of MetSy.

Background
Acromegaly, a rare, chronic disorder, results from excessive growth hormone (GH) and insulin-like growth factor 1 (IGF-1). The need for convenient therapies that provide effective disease control led to the development of CAM2029, a novel, subcutaneous, octreotide depot designed for convenient monthly self-administration using pre-filled syringes/injection pens. In a 24-week Phase 3 trial (ACROINNOVA 1, NCT04076462) CAM2029 achieved superior IGF-1 control vs placebo (72.2 vs 37.5%; $P = 0.0018$) in patients with acromegaly controlled with standard of care (SoC; octreotide long-acting repeatable/lanreotide Autogel) at screening. Interim data from another CAM2029 Phase 3 trial (52-week, open-label [ACROINNOVA 2; NCT04125836]) are reported here, focusing on patients 'new to CAM2029'.
Methods
ACROINNOVA 2 enrolled patients from ACROINNOVA 1 (reported separately), and 'new to CAM2029' patients with controlled or uncontrolled IGF-1 ($\leq$2x upper limit of normal [ULN]) on stable SoC for $\geq$3 months. New patients received once-monthly CAM2029 20 mg for up to 52 weeks. The primary endpoint was adverse events (AEs). Secondary endpoints included the proportion of patients with IGF-1 $\leq$1x ULN (weeks 50/52 mean); the combined IGF-1/GH response; IGF-1 change from baseline; severity score of acromegaly clinical signs/symptoms, assessed using the Acromegaly Index of Severity (AIS). Baseline values reflect SoC treatment.
Results
Eighty-one 'new to CAM2029' patients were enrolled. At data cut-off (23 May 2023), 61 patients completed treatment at week 52, 15 were ongoing and 5 had discontinued. No new or unexpected safety signals were observed. The most common treatment-emergent AEs were injection-site reactions: 'new to CAM2029', 38.3%; overall population, 43%; none were Grade 3. The proportion of patients achieving IGF/GH control increased during CAM2029 treatment (Table 1). Estimated IGF-1 response (linear probability model, patients with evaluable data at weeks 50/52) increased 21.9% (95% confidence interval [CI]: 9.6, 34.1) from baseline to weeks 50/52. AIS score significantly decreased from SoC baseline to week 52 (mean of –1.3 [95% CI: –2.1, –0.5]).
Conclusions
CAM2029 improved IGF-1/GH control and clinical symptoms in patients 'new to CAM2029'. CAM2029 was well tolerated with a safety profile consistent with SoC. ACROINNOVA 2 reinforces the efficacy and safety of CAM2029 for treating acromegaly, including in patients with uncontrolled disease despite treatment with current SoC.

Table 1. Biochemical endpoints

Endpoint	Baseline n/N$_{all}$(%)	Weeks 50/52
IGF $\leq$1x ULN (weeks 50/52 mean)	12/81 (14.8)	20/60 (33.3)
IGF $\leq$1x ULN (weeks 50/52 mean) and GH $<$2.5 μg/l (week 52)	12/81 (14.8)	18/60 (30.0)

*Patients with evaluable data.

Background
Acromegaly is a neuroendocrine disorder, characterised by growth hormone (GH) and insulin-like growth factor 1 (IGF-1) overproduction. Persistent biochemical control to minimise adverse effects of prolonged excess GH/IGF-1 is a key treatment goal. CAM2029 is a novel octreotide depot, designed for convenient monthly subcutaneous self-administration, using pre-filled syringes/injection pens. A 24-week Phase 3 trial (ACROINNOVA 1, NCT04076462) evaluated CAM2029 in patients with acromegaly, controlled with standard of care (SoC; octreotide long-acting repeatable/lanreotide Autogel) at screening. CAM2029 met the primary endpoint, demonstrating superior IGF-1 control vs placebo (IGF-1 $\leq$upper limit of normal [ULN]: 72.2 vs 37.5%; $P=0.0018$). Interim analysis of patients who completed ACROINNOVA 1 and rolled over to the Phase 3, 52-week, open-label, long-term safety trial (ACROINNOVA 2, NCT04125836) is reported.
Methods
Patients received monthly CAM2029 20 mg for 28 weeks during ACROINNOVA 2. The primary endpoint was adverse events (AEs). Secondary endpoints included the proportion of evaluable patients with IGF-1 $\leq$1x ULN (weeks 50/52 mean); both IGF-1 $\leq$1x ULN (weeks 50/52 mean) and mean GH $<$2.5 µg/l (week 52); acromegaly clinical signs and symptoms severity score, assessed using the Acromegaly Index of Severity (AIS). Data are reported by treatment in ACROINNOVA 1; safety data are reported for the 52-week period.
Results
Of 64 patients completing ACROINNOVA 1, 54 entered ACROINNOVA 2 (prior-CAM2029, $n=36$; prior-placebo, $n=18$). CAM2029 was well tolerated. Fifty percent of patients (prior-CAM2029, 18/36; prior-placebo, 9/18) experienced injection-site treatment-emergent AEs (Grade $\leq$2). One serious treatment-related AE occurred in the prior placebo group (moderately severe cholelithiasis, resolved). In the prior-CAM2029 group, mean IGF-1 remained $<$ULN at weeks 50/52 in 89% of patients (Table 1). In the prior-placebo group, IGF-1 increased $\geq$1$\times$ ULN during ACROINNOVA 1; IGF-1 control was regained after switching to CAM2029. AIS score decreased significantly from SoC baseline to week 52 in prior-CAM2029 patients (–1.3 [95% CI: –2.3, –0.3]); in prior-placebo patients change in AIS score was –0.8 [95% CI: –2.1, 0.5]).
Conclusions
No new safety signals were observed; safety was consistent with SoC. CAM2029 provided persistent control of IGF-1/GH during treatment and improved clinical symptoms. Biochemical control of acromegaly was regained in placebo patients after switching to CAM2029.

Table 1. Biochemical endpoints

Endpoint	Prior-CAM2029	Prior-placebo
	n/N$_{all}$* (%)	
IGF $\leq$1x ULN (weeks 50/52 mean)	25/28 (89.3)	15/15 (100)
IGF $\leq$1x ULN (weeks 50/52 mean) and GH $<$2.5 µg/l (week 52)	23/26 (88.5)	14/14 (100)

*Patients with available data.

Background
Significant treatment-related burdens accompany standard-of-care (SoC) therapies for acromegaly, which typically require healthcare-provider administration. CAM2029 is a novel, subcutaneous octreotide depot conveniently self-administered monthly by pre-filled syringe/injection pen. In a 24-week Phase 3 trial of CAM2029 in patients with acromegaly (ACROINNOVA 1, NCT04076462), insulin-like growth factor 1 (IGF-1) response was 72.2% in patients receiving CAM2029 vs 37.5% with placebo. Interim analysis of overall patient-reported outcomes (PROs) from a 52-week Phase 3 trial of CAM2029 (ACROINNOVA 2, NCT04125836) is reported here.
Methods
ACROINNOVA 2 enrolled patients completing ACROINNOVA 1 (24 weeks; prior-CAM2029 or prior-placebo) and new patients (IGF-1 $\leq$2x upper limit of normal [ULN] during stable SoC [octreotide long-acting repeatable/lanreotide Autogel]) to receive monthly CAM2029 20 mg for up to 52 weeks (28 weeks for prior-placebo group [week 24–52]). The primary endpoint was adverse events. Secondary PRO endpoints included Acromegaly QoL Questionnaire (AcroQoL), EQ-5D-5L visual analogue scale (VAS), Treatment Satisfaction Questionnaire for Medication (TSQM), Patient Satisfaction Scale (PSS) and the Self-injection Assessment Questionnaire (SIAQ v2.0). Higher scores indicate improvement.
Results
Enrolled patients (81 new, 36 prior-CAM2029, 18 prior-placebo) had a mean CAM2029 exposure of 56.3 weeks at data cut-off (23 May 2023). CAM2029 was well tolerated with no unexpected safety signals. From SoC baseline to week 52, mean scores increased for AcroQoL, EQ-5D-5L VAS, and TSQM (Table 1). SIAQ increased from SoC baseline to week 48 during CAM2029 treatment. Mean PSS (scale 0–5) at week 52 was 4.1 (95% confidence intervals [CI] 3.9, 4.3).
Conclusions
PRO scores indicated improvement in patients treated with CAM2029, including those previously controlled with SoC. The safety profile of CAM2029 was consistent with current SoC; no new safety signals were observed. These data support the clinical benefit of CAM2029 and its potential to address unmet needs for patients with acromegaly.

Table 1. PRO endpoints

Assesment	Domain	Mean change from SoC baseline (95% CI) at week 52
QoL: AcroQoL	Total score	3.5 (1.3, 5.7)
	Physical score	1.9 (–0.5, 4.3)
	Psychological total score	4.4 (2.0, 6.8)
QoL: EQ-5D-5L	Visual analogue scale	3.2 (0.5, 5.9)
Treatment satisfaction: TSQM	Convenience	15.6 (11.8, 19.3)
	Effectiveness	6.3 (2.8, 9.8)
	Satisfaction	4.7 (1.1, 8.4)
	Side effects	2.4 (–2.0, 6.8)
		Mean change from SoC baseline (95% CI) at week 48
Self-administration satisfaction: SIAQ	Satisfaction with current way of taking medication	1.6 (0.9, 2.2)
	Feelings about injections	0.8 (0.3, 1.3)
	Self-confidence	0.8 (0.3, 1.4)

PET/CT with 68ga-dota-peptides in patients with parathyroid neuroendocrine neoplasms

Uliana Tsoy[1], Karina Pogosian[1], Daria Ryzhkova[1], Olga Yudina[1], Ksenia Yakovenko[1], Pavel Ryazanov[1], Polina Sokolnikova[1], Tatiana Karonova[1] & Elena Grineva[1]
[1]Almazov National Medical Research Centre

Background
Parathyroid tumors are considered to be parathyroid neuroendocrine neoplasia (NEN), according to the recent IARC-WHO classification updates. Primary hyperparathyroidism (PHPT) develops commonly in patients with multiple neuroendocrine neoplasia syndromes (MEN), when it occurs along with pituitary, gastro-entero-pancreatic or other NENs. The latter requires total-body 68Ga-

DOTA-peptides PET/CT. Its major advantage is to detect additional tumors with other localizations, particularly if CT is performed with contrast enhancement. Therefore, simultaneously this technique may reveal parathyroid NENs.
Aims
To determine Ga68-DOTA-peptide PET/CT utilities in parathyroid NENs diagnostics in PHPT patients.
Materials and methods
Sixteen patients with PHPT were included in the study, 11 patients were newly diagnosed, 5 patients had PHPT recurrence. 13 patients were tested for MEN1 mutation, and 7 harbored it. Parathyroid adenomas were localized with neck ultrasound, Tc99m-sestamibi parathyroid scintigraphy or SPECT/CT, CT, PET/CT with 11C-methionine or 11C-choline. Ga68-DOTA-peptide PET/CT was performed in all patients: Ga68-DOTA-TATE PET/CT in 14 patients and Ga68-DOTA-NOC PET/CT – in 2 patients. Parathyroidectomy (PTX) was performed in 10 patients.
Results
16 patients had 27 parathyroid adenomas; 23/27 were found by conventional imaging and 4/27 – through bilateral cervical exploration. Among operated patients ($n=10$) pathology examination revealed 17 parathyroid adenomas, while 6 patients were not operated on due to various reasons. Eight patients harbored single adenomas, five patients – double adenomas, three patients – triple adenomas. Ga68-DOTA-peptide high uptake was found in 18/27 lesions and all of them appeared to be parathyroid adenomas; 12/18 adenomas were verified by the histological examination, the remaining 6/18 – by the conventional imaging since they did not undergo PTX. In five patients 9/27 parathyroid adenomas did not show Ga68-DOTA-peptide uptake and were found by other imaging techniques (5/9) or during PTX (4/9). All these five patients had MEN1 syndrome. Thus, among 27 parathyroid adenomas PET/CT with Ga68-DOTA-peptide revealed 18 lesions, and the sensitivity of the method was 67%. All focuses of Ga68-DOTA-peptide uptake corresponded to parathyroid NENs, hence the specificity was 100%. Therefore parathyroid adenomas' ability to accumulate Ga68-DOTA-peptides during PET/CT is not an exclusive property of MEN1-assosiated parathyroid NENs.
Conclusion
Incidentally localized focuses of high Ga68-DOTA-peptides uptake on PET/CT in the parathyroid glands' allocation may be a reason to exclude PHPT. In case the diagnosis is confirmed, additional conventional imaging may be avoided and patient may be referred directly to PTX, particularly, if PET/CT is performed with contrast enhancement and other PET-negative lesions suspected for parathyroid NENs are not found.

AVP-deficiency (central diabetes insipidus) registry in Russia: epidemiology and clinical characteristics

Alexander Lutsenko[1], Daria Sazonova[1], Artem Yu. Zhukov[1], Nino Katamadze[1], Ekaterina Pigarova[1], Larisa Dzeranova[1], Zhanna Belaya[1], Olga Vikulova[1] & Natalia Mokrysheva[1]
[1]Endocrinology Research Center, Moskva, Russian Federation

Background
Epidemiological data on AVP-deficiency is scarce, with non-univocal reported prevalence of 4 per 100.000 for all cases of central and nephrogenic DI without clear gender predominance. Disease registries are major tools for the assessment of epidemiological data, as well as real-life clinical practice, which could be quite valuable for AVP-d.
Aim.
To assess the epidemiological data on ADH-D in Russian Registry for Central Diabetes Insipidus (RCDI)
Materials and method
Database of the Russian Registry for Central Diabetes Insipidus, which includes data from 51 region. Date of analysis – 20-Nov-2023.
Results
Currently, our registry includes information on 3081 patients with AVP-d, from 51 regions of Russia: median age 32.4 years [18.0; 46.8], female-to-male ratio 1786(58%): 1295(42%), age at diagnosis: 32.4 years [18.0;46.8]. The most common causes of AVD-d were postoperative (16.4%), pathology of hypothalamic-pituitary development (9.7%), head trauma (6.6%) and hereditary forms of AVP-d (4.4%). Rare forms accounted for approximately 4% of the patients: neuroinfection, Langergans cell hystiocytosis, sarcoidosis, Sheehan syndrome, DIDMOAD syndrome and hypophysitis. Idiopathic ADH-D was registered in 41.5% of patients. Overall prevalence of AVP-d in Russia according to the National registry is 2.1 cases per 100 000 population. Among participating regions, the highest prevalence is seen in Moscow region (5.4 cases per 100 000 population), which could be attributed to a more thorough registration in tertiary care centers in Moscow. Data on current therapy was available in 2853 patients. Most of the patients receive oral desmopressin ($n=1594$, 55.9%), followed by sublingual ($n=984$, 34.5%) and intranasal ($n=275$, 9.6%) forms.
Conclusions
Russian Registry for AVP-deficiency provides valuable data on demography, etiology, treatment modalities. Continued improvment of the registry will provide more balanced epidemiological data, which is currently lacking worldwide.

Bromocriptine test response and its correlation to prolactin levels and MRI characteristics in patients with acromegaly

Shahriar Atai[1,2], Jens Petter Berg[2,3], Jens Bollerslev[2], Kristin Øystese[1,2] & Ansgar Heck[1,2]
[1]Oslo universitetssykehus HF, Rikshospitalet, Endocrinology, Oslo, Norway; [2]University of Oslo, Faculty of Medicine, Oslo, Norway; [3]Oslo University hospital, Oslo, Norway

Introduction
The 2022 WHO classification identifies seven different pituitary tumour subtypes with growth hormone (GH) secretion and/or expression, with or without concurrent prolactin expression. The response to dopamine agonist (DA) treatment in these subtypes requires further investigation. The bromocriptine test has historically been a part of the acromegaly evaluation and may provide insights to DA treatment responsiveness. We aimed to explore the correlations between baseline serum-prolactin concentrations, bromocriptine test response and radiological features in patients with acromegaly to formulate hypotheses for future histological, molecular and clinical studies.
Material and methods
We included patients diagnosed with acromegaly from 2008 to 2017 who underwent a bromocriptine test (2.5 mg). The test was considered positive if the GH levels declined by $>50\%$ at 2, 4 or 6 hours (nadir value) after bromocriptine administration. We correlated baseline serum-hormone concentrations and MR images at diagnosis with test responses. Assessment of MR images included tumour size and volume, invasiveness based on the KNOSP criteria, T1 and T2 intensity and visual assessment of pituitary stalk affection (stalk deviation, dislocation or no visible stalk due to large tumour size).
Results
The study comprised 60 patients (34 males, 26 females) with a median age of 45 years (IQR 34-56). Thirty-five (58%) had a positive and 25 (42%) had a negative bromocriptine test. We found a significant correlation between baseline prolactin above upper reference limit and a positive bromocriptine test ($P=0.02$). The positive test result group also had a significantly higher median baseline prolactin compared to the negative test result group (382 mU/l (IQR 254-727) vs 224 mU/l (IQR 181-475), $P=0.03$). Further, there was a correlation between a positive test and lower invasiveness (KNOSP) ($P=0.02$). There were no significant differences between pituitary stalk affection and test results or prolactin levels.
Conclusions
Patients with $>50\%$ GH decline after a 2.5 mg bromocriptine dose had higher baseline serum-prolactin and less tumour invasiveness. Future studies are warranted to evaluate the association between the bromocriptine test, markers of tumour aggressiveness and treatment response.

Volumetric parameters of 68[Ga]Ga-DOTA-TATE PET/CT in the prediction of response to treatment with long-acting somatostatin analogues in patients with well-differentiated NETs

Karolina Morawiec-Sławek[1], Marta Opalińska[1], Wioletta Lenda-Tracz[2] & Alicja Hubalewska-Dydejczyk[1]
[1]Jagiellonian University Medical College, Chair and Department of Endocrinology, Kracow, Poland; [2]Facult, of Health Sciences, Jagiellonian University Medical College, Krakow, Poland

Introduction
Somatostatin analogues (SSA) are recommended as the first-line systemic therapy, to control tumour growth for advanced or metastatic well-differentiated neuroendocrine tumours (WD NET), with good expression of the somatostatin receptors. [68Ga]Ga-DOTA-SSA PT/CT has become the gold standard in the diagnosis, staging and monitoring therapy, of WD NET.
Aim
The aim of the study was to evaluate the predictive role of standardized uptake values (SUVs) and volumetric parameters obtained from pretreatment [68Ga]Ga-DOTA-SSA for response to SSA therapy, in patients with NET.

Material and Methods
42 patients (21 women, 21 men; age range: 46-84 years) with histologicall, confirmed, metastatic, NET (15 pancreatic, 15 small-intestinal, 4 lung, 7 unknow, 1 cecum; WHO G1 13, G2 28, 1 unknown; median Ki-67 index 5%, range 1-16) who received long acting SSA as a first line treatment were included to the study. All of them underwent [68Ga]Ga-DOTA-TATE PET/CT before receiving SSA as a first-line treatment. For each [68Ga]Ga-DOTA-TATE avid lesion, SUVmax and SUVmean were measured as well as TBR was calculated as SUVmean of tumours/metastases divided b, SUVmean of normal spleen. Furthermore, two volumetric parameters were calculated: somatostatin receptor expression tumour volume (STV) and total lesion somatostatin receptor expression (TLD). Finally the sum of STV (total STV, TSTV) and TLD (total TLD, TTLD) was calculated for each patient and used in the analysis.
Results
At the time of the analysis, 14 patients showed stable disease (33,3%), 28 patients were progressive (66,7%); among whom 12 patients died. The median progression-free survival (PFS) and overall survival (OS) were 26.5 and 46.5 months, respectively. The median SUVmax, SUVmean and TBR ratio was 38.5 (range 12.9-99.1), 21.4 (range 10.4-51.9) and 0.93 (range 0.38-3.29), respectively. The median TSTV was 41.4 cm^3 (range 1.0-1446.7) and the median TTLD was 650.7 (range 10.6-16156.8). In the univariate analysis, in the whole population study TBR ratio (HR = 1.96, 95% CI 1.058-3.62, $P = 0.03$) was the only, parameters that was significantly, associated with PFS. Among patients with small intestinal NETs, TSTV (HR = 1.00, $P = 0.023$) and TTLD (HR = 1.00, $P = 0.026$) were significantly, associated with PFS in the univariate analyses. No significant correlation was found between measured volumetric parameters and OS.
Conclusions
>Standardized uptake values and volumetric parameters of pretreatment 68[Ga]Ga-DOTA-TATE PET/CT may, be potentially, useful in prediction of the response to SSA (used in monotherapy, as a first-line therapy,) in patients with NET.

Hypogonadotropic hypogonadism, phenotype genotype correlation

Hana Charfi[1], Hamdi Frikha[1], Wajdi Safi[1], Mouna Elleuch[1], Nesrine Dhieb[1], Dhoha Ben Salah[1], Fatma Mnif[1], Nadia Charfi[1], Faten Haj Kacem Akid[1], Mouna Mnif[1], Mohamed Abid[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker Hospital, Sfax, Tunisia

Introduction
Congenital hypogonadotropic hypogonadism (CHH) of hypothalamic or pituitary origin is a rare condition (1 in 5000 births). Clinical manifestations var, depending on the patient's age and the severity, of the deficiency. CHH is often diagnosed in the context of delayed puberty, without impaired stature, typically, associated with tall stature.
Patients and Methods
This is a bicentric study conducted at the Endocrinology Department of Hedi Chaker University Hospital in Sfax and Fattouma Bourguiba University Hospital in Monastir. It is a retrospective descriptive and analytical study involving 29 cases of CHH, followed between 1991 and 2019. Patients with chronic conditions potentially, affecting pituitary function, those with acquired organic causes of pituitary dysfunction leading to significant hormonal deficiency and those with somatotropic axis deficiency, were excluded.
Results
A clear male predominance was noted with a sex ratio of 2M/1F. The average age at diagnosis was 18.5 years [2-32]. Family, consanguinity, was reported in 62.7% of cases. The most common reason for consultation was delayed puberty, in 73% of cases. The average height of patients was 165.85 cm [123-193]. Sixty, percent of patients had above-average stature at the time of diagnosis, and 16% had a stature delay, between -2 SD and -4 SD, related to molecular abnormalities of sex chromosomes or associated congenital bone anomalies. Ninety, percent of our population reached pubertal bone age at the time of diagnosis. Extra-pituitary involvement was present in 50% of patients: anosmia (30%) and neurosensory impairment (20%). Anterior pituitary exploration revealed corticotrope and lactotrope insufficiency in 5 and 3 patients, respectively. Hypothalamic-pituitary MRI was abnormal in 30% of cases, with pituitary hypoplasia in 6 cases (20%), one of which was associated with corpus callosum atrophy. The posterior pituitary was found in a normal position in all patients. Genetic testing was performed in 9 patients, including 4 relatives, revealing a missense mutation (c.386C > A, p.T129K) in the homozygous state of the KISS1-R gene in 3 relatives.
Conclusion
Although genetic analysis could only, be performed in 9 patients, we attempted to correlate phenotypic aspects with the various biomolecular abnormalities found. The genotype-phenotype correlation for this type of mutation remains challenging due to its modulation by, the cellular and molecular environment.

Establishment and representativeness of the stockholm sodium cohort: a laboratorial and pharmacoepidemiologic database covering 1.6 million individuals in the stockholm county

Issa Issa[1], Buster Mannheimer[1], Mikael Franko[1], Jakob Skov[2], Jonatan Lindh[3] & Henrik Falhammar[4]
[1]Södersjukhuset, internal medicine, stockholm, Sweden; [2]Karlstad University Sweden; [3]Tandvårds- & läkemedelsförmånsverket TLV, Sweden; [4]Karolinska Institute, Sweden

Objective
Hyponatremia is associated with considerable morbidity, and mortality but causal links have been difficult to establish. Here, we describe the establishment and representativeness of the Stockholm Sodium Cohort (SSC), designed to study etiologies and outcomes of hyponatremia.
Study, Design and Setting
All residents of Stockholm County, undertaking at least one serum sodium test between 2005-2018 were included in the SSC. Individual-level test results from over 100 Laboratory parameters relevant to hyponatremia were collected and linked to data on demographics, socioeconomic status, healthcare contacts, diagnoses and dispensed prescription medications using national registers.
Results
A total of 1 632 249 individuals, corresponding to 64% of the population of Stockholm County were included in the SSC. Coverage increased with advancing age, ranging from 32% in children and adolescents ($\leq$18 years) to 97% among the oldest ($\geq$80 years). The coverage of SSC included the vast majority of patients in Stockholm County, diagnosed with diabetes mellitus (93%), myocardial infarction (98%), ischemic stroke (97%), cancer (85%), pneumonias requiring inpatient care (95%) and deaths (88%).
Conclusion
SSC is the first cohort specifically, designed to investigate sodium levels in a large, population-based setting. It includes a wide range of administrative health data and Laboratory analyses. The coverage is high, particularly, among elderly, and individuals with comorbidities. Consequently the cohort has a large potential for exploration of various aspects of hyponatremia.

Keywords: Dysnatremia, Stockholm, Sodium, registry SSC, hyponatremia

Growth differentiation factor 15 in patients with acromegaly: a case-control study

Hayri Bostan[1], Sema Hepsen[2], Umran Gul[2], Hakan Duger[3], Serdar Kayıhan[2], Aykut Cimsir[2], Özgür Özçelik[2], İlknur Ozturk Unsal[2], Murat Calapkulu[4], Bekir Ucan[2], Erman Cakal[2] & Muhammed Kizilgul[2]
[1]Canakkale Mehmet Akif Ersoy State Hospital, Endocrinology and Metabolism, Turkey; [2]Ankara Etlik City Hospital, Endocrinology and Metabolism, Turkey; [3]Defa Life Hospital, Endocrinology and Metabolism, Turkey; [4]Igdir State Hospital, Endocrinology and Metabolism, Turkey

Background
It was previously shown that the levels of several biomarkers increase due to acromegaly disease-related inflammation and that some markers are parallel to the activity of the disease. It was also known that growth differentiation factor 15 (GDF-15) is increased in several cardiovascular inflammatory and metabolic diseases. The present study aimed to investigate the possible relationship of GDF-15 with acromegaly disease activity by comparing it with healthy individuals.
Methods
This study was designed as a single-center case-control study. A total of 40 acromegaly patients (25 active/15 controlled) (47.7 $\pm$ 9.4 years, 20 female/20 male) and 24 healthy, individuals (49.9 $\pm$ 10.1 years, 13 female/11 male) with age-sex-body mass index (BMI) similar to the patient group were included in the study. Demographic and anthropometric data, metabolic parameters, growth hormone (GH), insulin-like growth factor-1 (IGF-1), and GDF-15 levels of the study population were studied.

Results
The median GDF-15 levels were significantly higher in patients with acromegaly compared to healthy subjects (HS) (280.4 (197.0-553.2) vs 213.3 (179.9-297.2) ng/l, $P=0.01$). Median fasting plasma glucose (FPG), HbA1c, and systolic and diastolic blood pressure levels were significantly higher in patients with acromegaly compared to HS ($P<0.01$). Patients with acromegaly were divided into two groups according to disease control status: active patient group (aPG) ($n=25$) and controlled patient group (cPG) ($n=15$). The duration of symptoms before diagnosis and the frequency of obesity diabetes, and hypertension were similar in both active and controlled acromegaly patients ($P>0.05$). Serum GDF-15 levels of these groups were comparable ($P=0.39$). Interestingly compared to HS, GDF-15 levels were significantly higher in cPG ($P=0.01$), whereas GDF-15 levels tended to be higher in aPG, but did not reach statistical significance ($P=0.06$) (Figure 1). GDF-15 levels were observed to be positively correlated with fasting plasma glucose ($r=0.304$, $P=0.01$) and HbA1c ($r=0.292$, $P=0.02$). In the linear regression analysis, no independent relationship was observed between GDF-15 levels and age, gender, BMI, HbA1c, systolic and diastolic blood pressures, GH, IGF-1, and serum lipid levels ($P>0.05$). When evaluated across the entire cohort, GDF-15 levels were found to be higher in diabetic patients compared to non-diabetic individuals ($P=0.04$).
Conclusions
Plasma GDF-15 levels were increased in the patients with acromegaly compared to healthy subjects. This increment may be due to accompanying diseases such as diabetes rather than a disease-specific effect.

Are giant prolactinomas different from macroprolactinomas? The single-centre observation

Maria Aleksandra Komisarz-Calik[1], Anna Bogusławska[1], Aleksandra Gilis-Januszewska[1] & Alicja Hubalewska-Dydejczyk[1]
[1]Jagiellonian University Medical College, Chair and Department of Endocrinology Cracow, Poland

Introduction
The data on giant prolactinomas (the rare (3%) subtype of lactotroph PitNET ($\geq$40 mm)), often causing clinical and therapeutic difficulties are scarce.
Aim
We studied clinical/biochemical and treatment outcomes differences between giant and macroprolactinomas.
Materials and methods
Consecutive patients with giant prolactinomas $\geq$40 mm (GP) and macroprolactinomas $>$10 mm $<$40 mm (MP) treated in the tertiary clinical center in 2022-2023 were included.
Results
There were 41 patients with macroprolactinomas: 15 GP (87% men) and 26 MP (65, 4% men). The age at the diagnosis was 41 in GP vs 48 in MP ($P=0.265$). In GP and MP groups the most frequent symptoms included headaches (10/66, 7% vs 15/57, 7%, $P=0.640$), vision disturbances (10/66, 7% vs 6/23, 1%, $P=0.021$) and hypogonadism (14/93, 3% vs 18/69, 2%, $P=0.267$). Hypogonadism, TSH and ACTH deficiency were significantly more frequent in patients with GP than MP (8/53, 3% vs 5/19, 2%, $P=0.013$). In GP group FSH concentration was markedly lower than in MP (average 1,12 ulU/ml vs 3,09 ulU/ml, $P=0.005$). The baseline prolactin levels were relevantly higher in GP than in MP group (172026 ulU/ml vs 14224 ulU/ml, $P<0.001$). The optic chiasm compression was more common in GP than in MP (12/80% vs 9/34, 6%, $P=0.021$, respectively). The apoplexy occurred only in two patients with GP. Cabergoline was the most common dopamine agonist administered in 24 cases of MP and 12 cases of GP ($P=0.512$). The surgery was performed in 4/26, 8% of GP vs 4/15, 2% of MP ($P=0.565$). Among GP patients one underwent the surgery 2 times and another one 3 times. Other therapeutical options implemented only in GP subgroup included Lanterotide (two cases), with no biochemical and clinical effecty in one case Pasireotide with a remarkable analgetic effect. In one case of aggressive tumour Temozolomide was implemented with a disease stabilization. Cabergoline resistance was observed in 5/33% of GP vs 1/3, 85% of MP, $P=0.327$). The tumour decrease was observed in 11/73, 3% of GP and 13/50% of MP cases. The percentage of tumour shrinkage was significantly higher in patients with GP compared to MP (average 57% vs 32%, $P=0.040$).
Conclusions
The majority of GP and MP patients are men. Pituitary axis deficiencies and visual deficits occur more frequently in GP group. The incidence of tumour shrinkage is similar in GP and MP, however in GP the tumour decrease is higher. Cabergoline resistance and surgery procedures are more common in GP group. Further studies are needed to understand the biology and natural course of GP and MP.

Diagnosing acromegaly using artificial intelligence

Sebnem Burhan[1], Mehmet Zahit Yılmaz[2], Benginur Sokmen[2], Dilara Tekin Uzman[1], Zeynep Karaali[2], Mutlu Niyazoglu[1] & Esra Hatipoglu[1]
[1]Basaksehir Cam and Sakura City Hospital, Endocrinology and Metabolic Diseases; [2]Basaksehir Cam and Sakura City Hospital, Internal Medicine

Objective
Even with advancements in diagnostic techniques, acromegaly continues to be diagnosed late. This study aimed to employ deep learning methods to automatically identify acromegaly disease from images of faces, hands, and feet to enhance the efficiency of disease detection.
Design
Cross-sectionaly single-center study with deep learning
Methods
The study included 71 acromegaly patients and 65 healthy controls. All patients had images of their faces and hands; images of the feet were available for 63 acromegaly patients and 48 control patients. The images were processed with TensorFlow to increase the sample size through various transformations such as black and white transformationy rotation, zoom, and shearing. The Convolutional Neural Network (CNN) algorithm was employed across 8 layers in the neural network model. 'Adam' was utilized as the optimizer, and the binary cross-entropy loss function was employed. Early stopping was implemented to monitor the loss.
Results
The average age of the acromegaly group was 46.9 (SD:11.2), while the control group had an average age of 45.2 (SD:13.5). There were 33 males 46.5% in the acromegaly group and 25 males 39.1% in the control group. When the gender distribution and age averages were examined between the groups using the chi-square test and Student t-test, no significant differences were found. In the acromegaly group, the average duration of the disease was 4.12 (SD:4.88), ears, with 28 (39.4%) of them being in remission. The algorithm achieved an accuracy of 69.37% on facial photos, with a sensitivity of 57.14% and specifiCity of 85.42%. For hand photos, the accuracy was 92.79%, sensitivity was 92.06%, and specifiCity was 93.75%. In the case of foot photos, the algorithm demonstrated an accuracy of 70.27%, sensitivity of 49.21%, and specifiCity of 97.92%.
Conclusions
The CNN-based neural network exhibited varying accuracies across facialy hand, and foot photos, with notable accuracy for hands and moderate accuracy for facial photos. However, its performance on foot images was less robust. Incorporating the Random Forest ensemble method significantly boosted the overall accuracy to 94.59%, emphasizing the effectiveness of combining these algorithms for improved performance across diverse image datasets. The study validated the potential of the deep learning model in detecting acromegaly from facial images, highlighting the potential role of artificial intelligence programs in future acromegaly diagnosis.

EP354

Hypogonadism in acromegaly a single-center experience

Aleksandra Derwich-Rudowicz[1], Nadia Sawicka-Gutaj[1], Kacper Nijakowski[2] & Marek Ruchała[1]
[1]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland;[2]Poznan University of Medical Sciences, Department of Conservative Dentistry and Endodontics, Poznan, Poland

Background
Acromegaly is a rare endocrine disorder characterized by excess growth hormone (GH) secretion. GH hypersecretion leads to the overproduction of insulin-like growth factor 1 (IGF-1), which has both somatic and metabolic effects. Hypogonadotropic hypogonadism is present in nearly 30%–50% of acromegaly patients. There is a close correlation between somatotropic axis and gonadal function. The aim of this study was to investigate the prevalence of hypogonadism in male patients with acromegaly and the effect of surgical treatment during follow-up.
Material and methods
The study has a retrospective design. Medical records of patients diagnosed with acromegaly, hospitalized pre- and postoperative between January 2015 and December 2022 have been analyzed. Clinical history, laboratory results and endocrine tests were routinely recorded. All patients underwent a pituitary MRI to determine tumor size and invasion type. The significance level was set at $\alpha = 0.05$ for all analyses. The statistical analysis was performed with Statistica 13.3 (StatSoft, Cracow, Poland).
Results
The analysis involved a total of 62 pre-operative and 60 post-operative male patients. Hypogonadism was diagnosed in 48 males pre-operative (77.42%).

Following surgery, the prevalence of hypogonadism decreased to 60%, ($n=36$). Fisher's Exact Test yielded $P=0.00174$. Most of the patients presented with macroadenoma (53.22%). Postoperative testosterone concentrations increased significantly (8.7 vs 12.0 nmol/l; $P<0.001$), particularly in patients with preoperative hypogonadism (7.2 vs 10.2 nmol/l; $P<0.001$). Gonadotropin levels postoperatively demonstrated a significant elevation (LH: 3.4 vs 3.75 mlU/ml; $P=0.007$; FSH: 5.35 vs 5.90 mlU/ml; $P=0.032$), especially in patients with preoperative hypogonadism (LH: 2.85 vs 3.20 mlU/ml; $P=0.003$; FSH: 5.10 vs 6.05 mlU/ml; $P=0.032$). Testosterone levels were found to be statistically significantly lower in patients with macroadenoma compared to microadenoma (7.2 nmol/l vs 11.05 nmol/l; $P=0.038$). Hypogonadism manifested more frequently in younger patients (<50 years). Prolactin levels were elevated in patients with preoperative hypogonadism and macroadenoma (304 μIU/ml; $P=0.036$). GH and IGF-1 concentrations postoperatively decreased (GH: 3.0 vs 1.4 ng/ml; $P=0.002$; IGF-1: 506 vs 278 ng/ml; $P<0.001$). Patients with preoperative hypogonadism presented higher median baseline values of GH and IGF-1 (GH: 3.74 ng/ml; IGF-1: 556) compared to those without hypogonadism (GH: 1.42 ng/ml; IGF-1: 379.5 ng/ml). Total cholesterol and low-density lipoprotein (Ldl) values experienced a statistically significant reduction post-operatively across all cohorts ($P<0.001$).
Conclusions:
Younger patients diagnosed with macroadenoma, and hyperprolactinemia exhibit a higher predisposition to pre-operative hypogonadism. Neurosurgical treatment can lead to the normalization of GH and IGF-1, but also LH, FSH, and total testosterone.

Macroprolactinoma diagnosis and treatment in the setting of schizophrenia

Gabriel Tan[1]
[1]Tan Tock Seng Hospital, Singapore, Singapore

Prolactinomas are the most common pituitary lesion, and respond well to treatment with dopamine agonists. It presents a diagnostic and therapeutic challenge when there is concurrent psychosis, the treatment of which involves dopamine antagonists. A 69-year-old post-menopausal lady with schizophrenia, on olanzapine 5mg ever, evening, presented with unstead, gait. MRI brain scan showed a 3.3 x 1.8 x 2.4 cm pituitary macroadenoma with optic chiasm indentation. Visual field testing showed bitemporal hemianopia. There was marked hyperprolactinemia, low free thyroxine with inappropriatel, normal TSH, inappropriate low FSH and LH for post-menopausal state. Her ACTH stimulation test was robust. She was diagnosed with macroprolactinoma complicated by visual involvement, central hypothyroidism, central hypogonadism. After discussion with psychiatry and neurosurgery olanzapine was stopped and she started on bromocriptine and levothyroxine. She developed giddiness with bromocriptine, hence we switched to cabergoline 0.25mg/week with gradual dose escalation. Follow up showed improvement in her prolactin and free thyroxine. Repeat MRI demonstrated interval decrease in macroadenoma size (2.7 x 2.2 x 1.7 cm) and reduced mass effect on the optic chiasm with clinical improvement in visual fields. This case illustrates diagnostic pitfalls in hyperprolactinemia. Prolactin should be checked in all pituitary lesions. After excluding high dose hook effect, the degree of prolactin elevation can help differentiate between prolactinoma, stalk effect or drug induced hyperprolactinemia. Antipsychotics may worsen hyperprolactinemia, enhance macroprolactinoma growth, and blunt effect of dopamine agonist treatment. Cessation of her antipsychotics needs to be balanced against risk of psychotic exacerbation. Close psychiatry follow-up and cautious uptitration of dopamine agonists is recommended.

Investigations 06/10/2022

Test	Units	Reference
Prolactin (on dilution)	80,370	91–650 mIU/l
ACTH	8.3	1.6–13.9 pmol/l
Cortisol 8am	294	nmol/l
Cortisol 0 min (at 2pm)	194	nmol/l
Cortisol 30 min	509	
Cortisol 60 min	616	
Free thyroxine	7	8–16 pmol/l
TSH	2.02	0.45–4.5 mIU/l
Luteinizing hormone	< 1	11–59 IU/l
Follicular stimulating hormone	1	17–144 IU/l
Estradiol	< 73	pmol/l
IGF-1	67 mg/l	54–163 mg/l
Sodium	145 mmol/l	135–145 mmol/l
Potassium	3.2 mmol/l	3.5–5.1mmol/l
Creatinine	53 umol/l	40-75 umol/l

Follow up

Test	Date	Value	Treatment
Prolactin	06/10/2022	80,370	Bromocriptine 1.25 mg ON then 2.5 mg ON
	03/11/2022	31,658	Bromocriptine 5 mg ON
	28/11/2022	49,352	Cabergoline 0.25 mg once/week then 0.25 mg 2 times/week
	19/01/2023	20,561

Diagnostic mirage: pseudo-cushing's state and the challenges of coexisting pituitary macroadenoma

Nada Aitkassi[1], Essafir Nouhaila[1] & Guerboub Ahmed Anas[1]
[1]Mohamed V Militar, Hospital

Introduction and importance
Pseudo-Cushing's syndrome (PCS) encompasses a spectrum of medical conditions, both physiological and non-physiological, that replicate the clinical features of Cushing's syndrome (CS). In PCS, there is a presence of mild biochemical hypercortisolaemia, which is carefully regulated by physiological feedback hormonal control mechanisms. Physiological conditions contributing to PCS include factors like pregnancy surgical or emotional stress, severe illness, intense chronic exercise, while non-physiological contributors encompass chronic alcoholism, obesity metabolic syndrome, poorly controlled diabetes mellitus, major depression, malnutrition, and anorexia nervosa. The differentiation between pseudo-Cushing's states (PCS) and Cushing's syndrome (CS) presents a significant clinical puzzle, posing a formidable challenge even for experienced endocrinologists.
Case presentation
We present the case of a 46-year-old patient with no History of diabetes mellitus, depression, or excessive alcohol intake. The patient was admitted for the exploration of a pituitary macroadenoma; pituitary contrast-enhanced MRI showed a pituitary tumour ($11\times11\times7.5$ mm). Clinical examination revealed a Grade I obesity (body mass index 33 kg/m^2) with an android phenotype, along with a moon face and a buffalo hump. Secretory assessments were conducted: The midnight cortisol level came back elevated (**67 ng/**dl), a 24-hour urine collection showed a normal level of free cortisol, and overnight administration of 1 mg of dexamethasone reduced the serum cortisol level. And additional investigations have been supplemented by a standard dexamethasone suppression test; the patient demonstrated appropriate suppression during the conducted test.
Conclusion
PCS, a condition mimicking overt hypercortisolism, poses a considerable challenge in the differential diagnosis with Cushing's disease (CD). Patients with obesity metabolic syndrome, polycystic ovary syndrome, chronic alcoholism, depression, and extreme physical stress are recognized as prone to developing PCS. Obese individuals, such as our patient, have been reported to exhibit hyperactivation of the hypothalamus–pituitary–adrenal (HPA) axis in response to both physical and psychosocial stressors. The concomitant discover, of a non-functioning pituitary adenoma added complexit, to the diagnosis in our case.

Effective management of SIADH-Induced hyponatremia with tolvaptan: a case report

Besa Osmani[1], Ana Matijaca[2], Dino Kasumović[1] & Ivica Horvatić[1]
[1]Clinical Hospital Dubrava, Department of Nephrology and Dialysis, Zagreb, Croatia; [2]Clinical Hospital Dubrava, Department of Endocrinology and Diabetology Zagreb

We present a case of a 70-year-old female patient without comorbidities who was admitted to our institution following head trauma leading to subsequent subarachnoid hemorrhage and vertigo. Conservative management was

implemented successfully. Throughout the hospitalization, lab monitoring revealed the emergence of hyponatremia which was corrected by fluid restriction and hypertonic solution administration. The patient was discharged without residual vertiginous complications. Shortly post-discharge, the patient presented to the emergency department manifesting severe hyponatremia (116 mmol/l). Diagnostic investigations revealed reduced plasma osmolality alongside normal urine osmolality and normal sodium urine levels with normal TSH and cortisol values. Notably the absence of chronic therapy and urine sodium concentration >50 mmol/l further underscored the diagnosis of Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH) due to head injury. Because of prolonged duration of SIADH, which was more than a month since the head injury and without improvement with time which would be expected, we also did thorough work up to exclude other causes of SIADH, including neoplastic process. Patient continued check-ups and despite corrective measures (dietary intervention with increase solute intake and increase of oral sodium chloride) repeatedly had decrease in serum sodium concentration and was repeatedly hospitalized, with the latest admission to the Nephrology Department. Dietary interventions coupled with fluid restriction and parenteral administration of hypertonic solution were implemented in successfully correcting severe symptomatic euvolemic hyponatremia. The follow-ups were then continued via the Nephrology outpatient clinic. Despite adhering to dietary recommendations and fluid intake restrictions, the patient persisted in experiencing hyponatremic episodes with moderate to severe vertiginous symptoms. Consequently a decision was made to introduce a selective Oral Vasopressin V2-Receptor Antagonist into the therapeutic regimen, specifically tolvaptan at 15 mg once daily. The initiation of tolvaptan was conducted with the approval from the Hospital Committee for Medicinal Products. Following the commencement of this targeted therapy normonatremia was consistently maintained, with transient occurrences of mild hypernatremia leading to brief interruptions in tolvaptan administration which then led to hyponatremic relapses. Since the initiation of tolvaptan, the patient has remained free from hospitalization. Regular checkups including electrolyte levels, liver function parameters, renal function and body weight are conducted via Nephrology clinic. To date, the patient has exhibited no noteworth, adverse effects associated with tolvaptan treatment. Despite existing controvers, in using vasopressin receptor antagonists in treatment of chronic hyponatremia we wanted to present case in which prolonged posttraumatic SIADH was successfully managed using tolvaptan.

Secondary radiation-induced sarcoma occurring as a rare complication of radiotherapy for a gonadotroph tumour

Prishila Fookeerah[1,2], Angela Bayly[3], Winny Varikatt[3,4], Robert Smee[5,6], Mark Dexter[4,7], Sue Lynn Lau[1,2] & Mark McLean[1,2]
[1]Westmead Hospital, Diabetes and Endocrinology Sydney Australia; [2]Western Sydney University School of Medicine, Sydney Australia; [3]Westmead Hospital, Tissue Pathology and Diagnostic Oncology Sydney Australia; [4]University of Sydney Westmead Clinical School, Sydney Australia; [5]Prince of Wales Hospital, Radiation Oncology Sydney Australia; [6]University of New South Wales, Prince of Wales Clinical School, Sydney Australia; [7]Westmead Hospital, Neurosurgery Sydney Australia

Background
Secondary malignant sarcoma in the sella after radiotherapy for pituitary tumours is rare. Osteogenic sarcoma arising within the fossa after pituitary irradiation has only been described in a few case reports.
Clinical Case
A 31-year-old male patient without significant medical History presented in 2012 with bitemporal hemianopia. There were no associated headaches or clinical features of excess hormone secretion. MRI demonstrated a 26×30×28 mm mass in the pituitary fossay with suprasellar extension and compression of the optic chiasm. There was no invasion of the cavernous sinus. Biochemical investigations showed a mildly elevated serum prolactin of 851 mIU/l (normal range <500), low morning cortisol of 19 nmol/l, low testosterone of 1.8 nmol/l and normal thyroid function- TSH 3.60 mIU/l, free T4 10.4 pmol/l, consistent with a non-functioning pituitary tumour with partial hypopituitarism. He underwent urgent transsphenoidal resection of the tumoury resulting in normalization of vision and a small intrasellar tumour remnant. Three years later repeat surgery was undertaken due to tumour regrowth, now measuring 32×23×30 mm. Histopathological evaluation confirmed a pituitary neuroendocrine tumour of gonadotroph lineage, with expression of SF1 but negative hormonal immunoreactivity. There was no histological invasion or mitoses. Ki-67 was 8%. Because of a significant tumour remnant, he then received postoperative radiotherapy (49.2 G, in 30 fractions). yearly imaging showed stable and asymptomatic residual tumour. 8 years after radiotherapy he experienced worsening visual disturbance and headaches. Repeat MRI showed pituitary mass regrowth to 44×32×44 mm with a large area of unenhanced low T1 and T2 signal intensity and macrocalcification. A third transsphenoidal resection of the recurrent pituitary tumour was undertaken. Histopathology assessment now revealed a gonadotroph tumour seen closely intermingled with a malignant spindle cell component. Focal areas of osteoid production were seen. These cells demonstrated expression of SATB2, loss of H3K27me3 and high Ki67 of 60%. A diagnosis of radiation-induced sarcoma was favoured over sarcomatous transformation in view of the latency period between radiotherapy and the development of this neoplasm in the field of radiation.
Conclusion
This case describes a rare and serious complication of radiotherapy occurring 8 years after treatment of a pituitary gonadotroph tumour, highlighting the need for careful long-term radiological monitoring.

Metastasis or macroadenoma – the role of pituitary biopsy in a non-typical clinical presentation – a case report

Olivia Cyran-Stańczak[1], Sonia Kaniuka-Jakubowska[1], Natalia Ostrowska-Mrozowska[1], Tomasz Nowicki[2] & Renata Świątkowska-Stodulska[1]
[1]Department of Endocrinology and Internal Medicine, Faculty of Medicine, Medical University of Gdansk, Poland; [2]2nd Department of Radiology Faculty of Health Sciences with the Institute of Maritime and Tropical Medicine, Medical University of Gdansk, Poland

Metastatic involvement of the pituitary gland is a rare phenomenon with various clinical and radiological manifestations, but it is clinically important and requires appropriate and early diagnosis. The posterior lobe of the pituitary gland is more often involved, so we expect that AVP deficiency would be the most common clinical manifestation of pituitary metastasis. Presentation without involvement of the posterior lobe, without AVP deficiency and with anterior lobe hypofunction is rather an unexpected course. Pituitary biopsy especially when pituitary metastasis is the first detected manifestation of cancer, is an important method for diagnosing metastatic lesions. A 66-year-old female patient with no History of chronic diseases was admitted to the Department of Neurology in March 2023 due to increasing headaches for two months and double vision since the day of admission to the hospital. CT scan and head MR were performed, and a lesion measuring 27×19×25 mm was described in the sella turcica region and part of the posterior sphenoid sinuses; the pituitary infundibulum remained unchanged, moved upwards and forwards. The examination suggested a metastatic involvement of the pituitary gland or a pituitary macroadenoma. Laboratory tests revealed hypofunction of the anterior pituitary lobe in the thyrotropic and corticotropic axes (L-thyroxine substitution and steroid therapy were implemented). In March 2023 the patient was consulted by neurosurgeons to assess the possibility of surgical intervention – however, regarding the risk of metastasis and incomplete resection, they suggested further diagnosis and did not perform adenomectomy. In May 2023, a lesion biopsy using a transsphenoidal approach was performed at the Department of Otolaryngology. Additionally chest CT revealed a tumour in section 3 of the right lung; a biopsy of the lung lesion was performed. The results of the biopsies showed the presence of mucinous adenocarcinoma with primary location in the lung. In June 2023, the patient began palliative radiotherapy in the sphenoid sinus area and passed away in the same month. The described case demonstrates that the clinical and radiological picture of pituitary metastases may be varied and the differential diagnosis is difficult. AVP deficiency is not always a clinical symptom that distinguishes pituitary metastases from PitNET. Our case also highlights the role of pituitary biopsy which should be more common in justified indications, and in this case, performed earlier, could have contributed to earlier implementation of the treatment. This case sustains that a multidisciplinary approach to patients with pituitary lesions is crucial.

Challenges in managing acromegaly: choosing the right therapeutic option

Ema Schonberger[1,2], Ines Bilić-Ćurčić[1,2], Romana Marušić[2,3], Kristina Steiner[1], Klara Ormanac[1,2] & Silvija Canecki-Varžić[1,2]
[1]Clinical Hospital Center Osijek, Department of Endocrinology Osijek, Croatia; [2]Facult, of Medicine Osijek, Osijek, Croatia; [3]General Hospital Vukovar, Department of Internal Medicine, Vukovar, Croatia

Introduction
Pituitary tumors leading to acromegaly are typically diagnosed as macroadenomas with the potential to infiltrate nearby tissues. If left untreated, acromegaly can result in systemic complications, such as hypertension, glucose intolerance, type 2 diabetes, and cardiovascular disease, leading to substantial comorbidities and a higher mortality rate.
Case report
We present a case of a 57-year-old patient who initially presented in 1993 with galactorrhea and hyperprolactinemia, treated with bromocriptine. Despite these symptoms, an MRI of the pituitary gland was not conducted. Over the years, the patient developed arterial hypertension and type 2 diabetes mellitus, along with a noticeable increase in shoe size, but did not seek medical help. The diagnosis of acromegaly was ultimately made in December 2020 during hospitalization for neurological symptoms (syncope). Brain MRI revealed an extensive pituitary macroadenoma measuring 50×37×40 mm with bilateral compression of the internal carotid arteries. Initial values of insulin-like growth factor 1 (IGF-1) were 95.9 nmol/l (reference interval 7.2-31.3), and growth hormone (GH) was insuppressible in an oral glucose tolerance test (OGTT). After two months, a partial transsphenoidal resection of the tumor was performed, with which neither clinical nor biochemical control of the disease was achieved. Following the multidisciplinary team's decision, she received adjuvant Gamma-Knife radiotherapy for two months, and treatment with the octreotide was started. Since she was unresponsive to the first-generation somatostatin analog therapy pasireotide was introduced. After the administration of the second dose, symptomatic atrial fibrillation (AF) was recorded in the patient. Although AF is not described as a possible adverse event with pasireotide therapy considering the described prolongation of QT interval and possible worsening of arrhythmiay the therapy was discontinued. Given the circumstances, pegvisomant was considered as the next therapeutic option.
Conclusion
The challenge of achieving complete removal of the GH-producing pituitary macroadenoma during surgery increases the risk of a disease recurrence, and additional treatment methods, such as somatostatin analogs, dopamine agonists, and radiotherapy are often required. However, this population of patients is extremely vulnerable due to the development of complications such as various cardiac conditions and type 2 diabetes, making it difficult to choose the most appropriate pharmacotherapeutic option given their possible side effects and the potential for worsening comorbidities. Nevertheless, it is important to find the best therapeutic option for the patient to improve outcomes and prevent further progression of existing complications.

Endocrinologic evaluation in a case series of adult meningiomas: what can we improve?

Miruna-Viorela Nacu[1], Sorina Martin[1,2], Anca Sirbu[1,2], Carmen Barbu[1,2] & Simona Fica[1,2]
[1]"Elias" Emergency University Hospital, Department of Endocrinology Diabetes Mellitus, Nutrition and Metabolic Disorders, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy Department of Endocrinology Diabetes Mellitus, Nutrition and Metabolic Disorders, Bucharest, Romania

Introduction
Meningiomas, already one of the most frequent types of primary central nervous system tumors, have been increasing in incidence in the past decade. Considering their location and histologic particularities, radiation therapy (RT), alone or in combination with neurosurgery, is often necessary and can have a negative impact on adjacent structures such as the pituitary gland. More studies investigating the endocrinologic disturbances in this pathology are necessary in order to meet the needs for developing a specific protocol.
Design
We compiled a case series of patients diagnosed with perisellar meningiomas between 2007-2022, who underwent endocrinologic evaluation in our clinic.
Results
Seven cases were found, six females and one male, aged 57-68 years. Onset of symptoms was reported in three cases, one presented with hypopituitarism and two patients with left palpebral ptosis. Six lesions had cavernous sinus invasion and one was located in the left cerebellopontine angle. Tumor dimensions varied from 25/27/25 mm to 22/47/34 mm. Neurosurgery was performed in two cases, one for a parietal lesion in a meningiomatosis patient and one for a sellar meningioma. Histopathologic exam revealed meningothelial meningiomas in both cases. Six patients underwent Gamma Knife radiation therapy. One patient received anti-inflammatory doses of glucocorticoids for almost 2 years prior RT. Hormonal evaluation was performed using basal determinations and no dynamic tests were performed. Endocrinologic assessment prior to RT was available in three cases, one investigating only the adrenal axis, one in the patient receiving glucocorticoids, showing mildly suppressed TSH with normal freeT4, which normalized at the end of the treatment and one in the hypopituitarism case. Mean time from RT until last endocrine workup was 4.8 years (1-11 years). Two patients were on levothyroxine treatment for primary hypothyroidism and apart from the patient with hypopituitarism, the remaining cases had normal thyroid, adrenal and gonadal function. Three patients had elevated prolactin levels, two before treatment and another at one year after RT. Two patients had decreased IGF-1 levels, measured at 2 and 6 years, respectively after RT.
Conclusions
Pituitary disturbances can occur in a wide time frame after RT and active surveillance must be done, balancing over- and under-testing. There is a need for a dedicated protocol for this pathology with adequate selection criteria, adjusted testing intervals and use of appropriate tests in order to identify subclinical deficiencies. Until then, clinicians should aim at correctly documenting radiation therapy dosages, and emphasizing the importance of repeated testing over the years.

Atypical dermatological manifestations in cushing's disease: about a case report

Emna Naccache[1,2], Hadami Ben Yamna[1], Ines Kammoun[3] & Radhouen Gharbi[2]
[1]National Institute of Nutrition, Endocrinology Tunis; [2]Tunisia, Endocrinology Tunis; [3]National Institute of Nutrition, Endocrinology Tunis, Tunisia

Introduction
The diagnosis of Cushing's syndrome is frequently invoked by the presence of clincal signs of hypercatabolism. It actually may be associated with a variety of dermatological manifestations which can be atypical. Here, we report the case of a patient having vulvar warts co-occuring with Cushing's syndrome.
Observation
We present the case of a 31-year-old patient presenting with typical signs of Cushing's syndrome: Facial erythrosis, facio-truncular fat distribution, buffalo hump, abdominal obesity with a waist circumference of 98 cm and purple stretch marks on the abdominal and axillary areas, he also had muscular amyotrophy in te lower limbs and BP: 18/10. While examining the patient, we identified atypical dermatological manifestations: vulgar warts on the dorsal surfaces of the both hands simultaneously with the appearance of signs of Cushing's disease. We confirmed a cushing's syndrome by a low-dose dexamethasone suppression test which was positive, an elevated ACTH, the absence of braking in the High-dose dexamethasone suppression Test. The MRI showed a pituitary microadenoma. The other axes were explored and he presented with isolated hypogonadtrophic hypogonadism. As for the complications he presented diabetes, hypertension and osteoporosis.
Conclusion
Long-term exposure to intrinsic corticosteroids during cushing's disease induct immunosuppression which can be the cause of these atypical dermatological manifestations. It is crucial to know how to invoke endocrinopathies like Cushing's syndrome in patients presenting not only the typical signs of the pathology but also atpyical manifestations.

Post-operative evaluation of pituitary adenomas operated at the clinical hospital of valladolid

Esther Delgado Garcia[1,2], Juan Jose Lopez Gomez[1,2], Paloma Perez Lopez[1,2], Beatriz Torres Torres[1,2], Laura Herguedas Herguedas[3], Marta Boya Fernandez[3] & Daniel De Luis Román[1,2]
[1]Servicio Endocrinologiay Nutricion, Hospital Clinico Universitario de Valladolid, Valladolid, Spain; [2]Centro de Investigación de Endocrinología y Nutrición Clínica, Facultad de Medicina de Valladolid, Valladolid, Spain; [3]Facultad de Medicina de Valladolid, Valladolid, Spain

Introduction
Pituitary adenomas are neoplasms originating in the pituitary gland. They represent 15.5% of tumor pathology of the central nervous system and their incidence is estimated at 3.4 cases per 100,000 inhabitants/year.
Objective
To evaluate the postoperative results of adenomas operated on at the Hospital Clinico de Valladolid (HCUV)

Material and Methods
Observational, transversal and retrospective study of operated adenoma from 2001 to 2016 in HCUV. Variables studied were epidemiology clinical, radiography pathology surgery radiotherapy and treatment
Results
139 patients were evaluated, 61 (43.9%) being men with a mean age of 51 (42-63) years. The main cause of adenomas presentation was compressive symptoms (41.7%), followed by hormonal excess (26.9%) (table 1) 117 (84.2%) were macroadenomas with a mean size of 17.8 cm^3 and 77.7% had suprasellar or lateral extension. The average reduction in tumor size was 32%. The immunohistochemical phenotype was performed on 64 (38.8%) tumors; the most numerous group was prolactinomas, followed by GH secreters and ACTH secreters. 11 (7.9%) patients had postsurgical complications: 8 diabetes insipidus, 2 SIADH, 1 respiratory distress. 9 patients had to undergo reoperation and 59 required radiotherapy. The long-term patient outcome was cure in 25 (18%) patients; persistence in 111 (79.9%) patients; recurrence in 2 (1.4%) patients and 1 (0.7%) patient died.
Conclusions
Pituitary adenomas are rare lesions that manifest mainly due to compressive symptoms or hormonal hyperproduction. Those who require surgery in the hands of expert surgeons have good results

CLINICAL PRESENTATION	N (%)
Compressive	58 (41,7%)
Hormonal excess	36 (25,9%)
Incidentaloma	25 (18%)
Hormonal deficiency	5 (3,6%)
Compressive/Excess	8 (5,8%)
Compressive/deficit	3 (2,2%)
Excess/deficit	3 (2,2%)
Compressive/deficit/Excess	1 (0,7%)

SOX9-positive pituitary stem cells differ according to their position in the gland and maintenance of their progeny depends on context

Karine Rizzoti[1], Robin Lovell-Badge[2], Probir Chakravarty[2] & Daniel Sheridan[1]
[1]The Francis Crick Institute, Stem cell biology and developmental genetics, London, United Kingdom; [2]The Francis Crick Institute, Bioinformatics Core, London, United Kingdom

SOX9-positive pituitary stem cells differ according to their position in the gland and maintenance of their progeny depends on context. We and others have previously characterised a population of adult stem cells (SCs) in the murine pituitary gland. We showed that while these SCs are relatively quiescent in normal conditions, they undergo activation following target organ ablation, providing a well-characterized paradigm to study an adaptative response in the context of the endocrine axes. We have here used single cell technologies to characterize SC heterogeneity and mobilization. We show that the transcriptional profile of SCs varies according to their localization in the gland, revealing different compartemnts and properties. Following target organ ablation, analyses of mobilized SCs reveal that differentiation occurs more frequently than previously thought, and that their progeny is more diverse than demonstrated by the lineage tracing experiments. Comparison of SC progeny following short and long term lineage tracing suggests that maintenance of selected nascent cells underlies SC output, highlighting a trophic role for the microenvironment. Consequently, analyses of cell trajectories further predict pathways and potential new regulators. In conclusion, our data highlight the herogeneity of the adult pituitary SC population while our mobization paradigm provides a valuable model to study the influence of evolving states on the mechanisms of SC mobilization and the role of local interactions.

Vasopressin and androgen receptors as potential therapeutic targets in corticotroph pitnets

Maria Francesca Birtolo[1,2], Antoan Stefan Sojat[3], Bertrand Baussart[1,4], Camille Sollier[5], Nesrine Benanteur[1], Xavier Bertagna[5], Anne Jouinot[1,5], Jerome Bertherat[1,5], Guillaume Assié[1,5] & Chiara Villa[1,6]
[1]INSERM U1016, Université Paris Cité, CNRS, Inserm, Institut Cochin, Genomics and signaling of endocrine tumors, Paris, France;[2]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele (MI), Italy;[3]University Clinical Centre of Serbia, National Centre for Infertility and Endocrinology of Gender, Clinic for Endocrinology Diabetes and Metabolic Diseases, Belgrade, Serbia;[4]Hôpital Universitaire Pitié-Salpêtrière, APHP, Sorbonne Université, Department of Neurosurgery, Paris, France;[5]Métabolisme Et Cancer, CHU Cochin, APHP, Université Paris Cité, Département Endocrinologie, Paris, France;[6]Hôpital Universitaire Pitié-Salpêtrière, APHP, Sorbonne Université, Department of Neuropathology, Paris, France

Corticotroph Pituitary Neuroendocrine Tumours (Co-PitNETs) show significant differences in cortisol secretion, responses to existing therapies and gene expression andstill pose a challenge for patient management.
Aim
to explore possible novel therapeutic targets in Co-PitNETs (functioning and silent) through transcriptome analysis (RNA sequencing) and immunohistochemistry.
Methods
Transcriptomic data from a previously reported dataset of 134 PitNETs (T-cohort) (*Neou M, Cancer Cell. 2020*) were used to select potential therapeutic targets that were overexpressed in Co-PitNETs in comparison to other PitNETs types. Among the overexpressed genes, *AVPR1B*, encoding the Vasopressin V1b receptor, and *AR*, encoding the androgen receptor (AR) were validated in two cohorts including all PitNETs types (VI-cohort = 94 PitNETs and ARI-cohort = 66 PitNETs) by immunohistochemical analysis.
Results
In the T-cohort, *AVPR1B* gene was the most differentially overexpressed gene in each transcriptomic group of Co-PitNETs, independent of their clinical presentation (functionning vs silent) and the *USP8* status (Kruskal-Wallis, $P<10^{-14}$). Focusing on hormone receptors, *AR* gene was significantly over-expressed in corticotroph groups when compared to other PitNETs types. The immunohistochemical analysis of the VI-cohort confirmed higher AVPR1B immunostaining in Co-PitNETs than in other PitNET types (Kruskal-Wallis, $P<10^{-6}$). Silent Co-PitNETs largely expressed *AVPR1B* (median 70%), more than functioning Co-PitNETs (median 20%, Wilcoxon $P=0.04$). In the ARI-cohort, *AR* was more expressed in Co-PitNETs, mostly in functioning ones (Wilcoxon, $P=0.04$), and significantly more than in other PitNET types (Kruskal-Wallis, $P<10^{-6}$).
Conclusion
AVPR1B and *AR* are overexpressed in Co-PitNETs representing a possible novel targets for future medical treatments.

PAM expression in pituitary neuroendocrine tumors (PitNETs)

Maria Francesca Birtolo[1,2], Bertrand Baussart[1,3], Nesrine Benanteur[1], Anne Jouinot[1,4], Adrian Daly[5], Andrea Lania[2,6], Jerome Bertherat[1,4], Constantine Stratakis[7], Guillaume Assié[1,4], Chiara Villa[1,8] & Giampaolo Trivellin[2]
[1]INSERM U1016, Université Paris Cité, CNRS, Inserm, Institut Cochin, Genomics and signaling of endocrine tumors, Paris, France;[2]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele (MI), Italy;[3]Hôpital Universitaire Pitié-Salpêtrière, APHP, Sorbonne Université, Department of Neurosurgery, Paris, France;[4]Métabolisme Et Cancer, CHU Cochin, APHP, Université Paris Cité, Département Endocrinologie, Paris, France;[5]Centre Hospitalier Universitaire de Liège, University of Liège, Domaine Universitaire du Sart-Tilman, Department of Endocrinology, Liège, Belgium;[6]IRCCS Humanitas Research Hospital, Endocrinology, Diabetology and Andrology United, Milan, Italy;[7]IMBB, FORTH, Heraklion, Greece & NICHD, NIH, Human Genetics & Precision Medicine, Bethesda, United States;[8]Hôpital Universitaire Pitié-Salpêtrière, APHP, Sorbonne Université, Department of Neuropathology, Paris, France

PAM encodes a multifunctional protein recognized as an important regulator of hormone amidation and secretion. Since *PAM* germline mutations have been recently identified in patients with PitNETs, it has been proposed as a candidate gene associated with pituitary hypersecretion.
Aim
To characterize PAM expression in a large cohort of PitNETs through immunohistochemistry and transcriptome analysis (RNA sequencing).
Methods
Immunohistochemistry analysis was performed on FFPE samples from normal pituitary, 102 PitNETs of all hystotypes (16 functioning and 13 silent corticotrophs, 19 somatotrophs, 20 gonadotrophs, 8 null-cell, 19 prolactinomas, and 7 thyrotrophs) and 5 PitNETs with recognized *PAM* variants. PAM immunoreactivity was graded considering the percentage of positive cells and the staining intensity (scored from 0 to 3). The final score was obtained as follow: score = (%x0)+(%x1)+(%x2)+(%x3). PAM expression was assessed through transcriptome analysis on a previously reported dataset of 134 PitNETs (Neou M, Assié G. *Cancer Cell*. 2020).
Results
PAM immunostaining was positive almost in all samples with variable patterns of expression. However, the immunohistochemistry score was lower in corticotroph

tumors with overt Cushing disease compared to the other groups (Kruskal-Wallis, $P=3.69e-05$). Transcriptome analysis confirmed this finding (Kruskal-Wallis, $P=3.888e-10$). Interestingly we found weak and negative staining for PAM in 5 patients (2 acromegalic and 3 with overt Cushing disease) in whom *PAM* variants have recently been identified (Trivellin G, Stratakis CA. *Front Endocrinol*. 2023).
Conclusion
Our preliminary results add to the characterization of *PAM* function in PitNETs. A reduced expression in corticotroph PitNETs with overt Cushing disease opens new insights into the pathogenesis of -and secretion by corticotroph tumor cells.

Prolactin impact on aging bone health
Danijela Radojkovic[1,2], Milan Radojkovic[2,3], Milica Pesic[1,2], Vojislav Ciric[1,2], Saša Radenković[1,2], Marija Vukelic Nikolic[2] & Tatjana Jevtovic Stoimenov[2]
[1]Clinical Centre of Niš, Endocrinology Niš, Serbia; [2]University of Niš, Niš, Serbia; [3]Clinical Centre of Niš, Surgery Niš, Serbia

Introduction
The aim of this study was to evaluate potential alterations in prolactin receptor gene expression (*Prlr*) in the duodenum, vertebra, and kidney - key organs in calcium metabolism, across the aging process.
Methods
Wistar female rats were divided into: Group A (10 rats, 5 weeks old), Group B (10 rats, 18 weeks old) and Group C (7 rats, 21 weeks old). Laboratory analysis included: prolactin, serum ionized calcium, phosphorus, urinary calcium and phosphorous excretion, alkaline phosphatase (ALP), osteocalcin (OC) and serum procollagen type 1 N-terminal propeptide (P1NP). Relative quantification of prolactin receptor (*Prlr*) gene expression in duodenum, vertebra and kidney was determined by quantitative real time polymerase chain reaction.
Results
PRL concentrations were significantly higher in group A compared to B and C ($P<0,001$). In the youngest rats (A) serum ionized calcium was significantly decreased compared to B ($P<0,05$) and C ($P<0,01$); serum phosphorus was significantly increased compared to B and C ($P<0,001$); urinary calcium was decreased compared to B and C ($P<0,001$); urinary phosphorous was significantly increased compared to B ($P<0,05$) and without significant changes compared to C. All bone turnover markers, ALP, OC and P1NP, were significantly increased in the Group A compared to B and C ($P<0,001$). In the youngest group of rats (A) expression of *Prlr gene* was higher in the duodenum comperd to the B and C, but without statistical significance. In the kidney there was significantly increased expression of *Prlr gene* in the A compared to C ($P<0,05$). While in the vertebra, significantly dicreased expression of *Prlr gene* was verified in the Group A compared to C ($P<0,01$).
Conclusions
Prlr gene expression undergoes significant changes during aging in tissues critical for calcium homeostasis, potentiall, contributing to adverse effects on bone metabolism. A considerable reduction in *Prlr* gene expression in the kidne, ma, explain the markedl, elevated calciumuresis in older experimental groups. To sustain normal calcium levels, the urinar, loss of calcium is compensated b, extracting calcium from the bones, facilitated b, the heightened expression of the *Prlr* gene, thereb, causing additional harm to the skeletal system in the aging process.

Growth hormone deficiency: a series of 102 tunisian observations
Yosra Hasni[1], Hamza Elfekih[1], Oumayma Zarrouk[1], Amira Yanes[1], Amel Maaroufi[1], Wided Debbabi[1] & Molka Chadli Chaieb[1]
[1]University Hospital of Farhat Hached, Endocrinology Diabetolog, Department, Sousse

Introduction
Growth hormone deficiency (GHD) is a rare cause of growth retardation whose diagnosis remains relatively late. Its etiologies are multiple, and its treatment could improve the stature prognosis of the children. The objective of this study was to describe the clinical, biological, radiological, and therapeutic characteristics of GHD, and its outcomes after treatment.
Methods
A cross-sectional study was conducted in the Endocrinology department of Farhat Hached University Hospital in Sousse, between January 2000 and December 2015, collecting 102 patients following for GHD.
Results
The average age at diagnosis was 12 ± 3.83 years with a sex ratio of 1.61. The average height was -3 ± 0.9 SD. The mean bone age was 9.4 ± 3.7 years with an average of 2.7 ± 2 years delay comparing to the chronological age. GHD was associated with other pituitary deficiency in 38.2% of patients and it was complete in 63.7% of cases. A partial GHD (36.3%) was associated significantly with isolated GHD ($P=0.02$) and idiopathic GHD ($P=10^{-3}$). Pituitary MRI was normal in 63.5% of cases, otherwise, it showed an interruption of the pituitary stalk (17.5%), a tumor (12.7%), an empty Sella (3.17%) and hypoplasia of the anterior pituitary (3.17%). Most patients (73.5%) were treated with somatropin with an average dose of 0.7 U/kg/week and an average duration of 3 years. The average height gain under treatment was 1 ± 0.9 SD. Height recovery was significant during the first year of treatment. No side effects of rhGH were observed. A statistically significant negative correlation between height gain and chronological age, height in SD and bone age at the start of treatment were found. Also, there was a statistically significant positive correlation between the height gain and the therapeutic compliance as well as an injection rhythm at 5/7 days, and especially the duration of the treatment.
Conclusions
Our study revealed a diagnostic delay in children with GHD. We insist on early diagnosis and treatment to improve the stature prognosis of these children. We must improve therapeutic compliance, necessary for a better response to treatment, through regular monitoring and good education of the child and those around him.

Utility of the Metoclopramide Test in the Differential Diagnosis of Hyperprolactinaemia
Estíbaliz Alegre[1], Álvaro González[1], Marta Zaballos[2], Henar Casal[2], Javier Salvador[2] & Juan Carlos Galofré[21]
[1]CIÚnica Universidad de Navarra, Biochemistry, Pamplona, Spain, [2]CIÚnica Universidad de Navarra, Endocrinology, Pamplona, Spain

Introduction
In addition to physiological causes, the hyperprolactinemia spectrum includes iatrogenesis, pituitary adenomas, various diseases and functional disorders. Hyperprolactinemia accurate etiological diagnosis is essential for appropriate treatment. Non-functioning pituitary incidentalomas occur in approximately 10% of the population and tiny microprolactinomas could be elusive to imaging by magnetic resonance (MRI). Therefore, the coincidence of hyperprolactinemia and a pituitary mass does not necessarily mean that the patient has a prolactinoma and vice-versa. Dynamic testing with dopamine antagonists to distinguish adenoma-related hyperprolactinaemia from other causes, such as metoclopramide test (MCPT), were described several decades ago. Although their use is not universal, they have been shown to be useful in the differential diagnosis of hyperprolactinemia. The MCPT protocol includes a fasting serum sample drawn to determine prolactin (PRL) and TSH at baseline (PRL0), taken 30' and 60' after 10 mg MCP IV injection. The relative PRL increase is calculated as (PRL_{max}-PRL0)/PRL0 expressed as percentage (%PRL). PRL_{max} is the highest PRL post-infusion. An absolute >2.1 mU/l increase in TSH_{max} over TSH0 indicates a high dopaminergic tone. Although there may be overlapping, generally a $>100\%$ increase in PRL_{max} over PRL0 is considered a normal response. Prolactinomas typically display a flat PRL response (usually $<100\%$ increase) with a >2.1 mU/l TSH_{max} increase.
Material and Methods
We selected 98 patients (80% female) with hyperprolactinemia who had undergone MCPT and pituitary MRI. Patients were divided into three groups according to PRL_{max} response: Group A ($<100\%$) (N=35), Group B ($\geq$100-300%) ($n=16$) and Group C ($\geq300\%$) ($n=47$).
Results
Mean (range) PRL0, PRL_{max} (ng/dL) and%PRL increase were: GrA: 153 (41-1246), 171 (72-1214) and 45.5% (-7.1-97.8%); GrB: 123 (19-141), 281 (49-461) and 178.0% (106.9-272.8%); GrC: 31 (3-75), 257 (93-498) and 1470.8% (324.3-15224.0%). Mean (range) TSH_{max} (mU/mL) were: GrA: 2.4 (-2.2-11.2); GrB: 1.9 (-0.1-5.1); GrC: 0.5 (-1.9-3). A positive MRI pituitary image was found: GrA: 28/35 (80%); GrB: 9/16 (56%); GrC: 3/47 (6%). All 3 GrC microadenomas behaved like non-secreting incidentalomas.
Conclusion
In prolactinomas, the PRL_{max} after MCPT usually exhibits an increase $<300\%$. Therefore, MCPT is superior to baseline PRL in accuracy regarding the origin of hyperprolactinaemia. MCPT results guide the therapeutic intervention and may reduce the need for a pituitary MRI.

Assessment of gonadotropic and lactotropic function in patients previously infected with SARS-COV-2

Nassim Ben Hadj Slama[1], Taieb ACH[1], Ghada Saad[1], Asma Ben abdelkrim[1], Molka Chaieb[1] & Koussay ACH[1]
[1]Farhat Hached University Hospital, Endocrinology, Soussa, Tunisia

Introduction
The most recent declared pandemic is attributed to COVID-19, caused by the novel coronavirus SARS-CoV-2. The angiotensin-converting enzyme 2, the principal receptor for SARS-CoV-2, exhibits expression in various tissues, prominently within gonadal and hypothalamo-hypophyseal domains. Long COVID, characterized by persistent symptoms post-infection, manifests in certain individuals and includes manifestations associated with the genitourinary system, such as sexual and menstrual dysregulation. The objective of this study is to systematically evaluate the gonadotropic and lactotropic functions in individuals with a history of SARS-CoV-2 infection.
Patients & Methods
This prospective study, conducted from January to December 2022, was carried out at the Endocrinology Department of Farhat Hached University Hospital in Sousse. The study included patients with a history of SARS-CoV-2 infection, categorized into those who had fully recovered (G1) and those experiencing Long COVID (G2). Gonadotropic function was systematically assessed through the measurement of gonadotropins (FSH and LH), Prolactin (PRL), and Estradiol (E2) levels in women, and Testosterone levels in men.
Results
A cohort of 64 patients underwent hormonal evaluation. Each group was composed of 32 patients. The median duration for hormonal exploration was comparable between G1 and G2 with respective values of 11.5 months [Q1–Q3]=[9-14] and 11 months [Q1–Q3]=[6-14] ($P=0.498$). Predominant symptoms in Long COVID patients included asthenia (84.4%) and cognitive disturbances (93.8%). Sexual disorders were reported by only 9.3% of G2 patients. The mean prolactin levels were 243.25 ± 223.71 mIU/l for G1 and 212.46 ± 135.48 mIU/l for G2 ($P=0.508$). Across all groups, 6.3% exhibited moderate hyperprolactinemia ($P=0.88$). In male patients, the mean testosterone levels were 5.25 ± 1.25 ng/ml for G1 and 6.45 ± 3.39 ng/ml for G2 ($P=0.269$). Female patients displayed average estradiol levels of 62.94 ± 68.46 pg/ml for G1 and 88.59 ± 89.05 pg/ml for G2 ($P=0.314$). Hypogonadotropic hypogonadism was observed in 4.6% of the overall study population, with a comparable distribution between G1 and G2 ($P=1$). No cases of peripheral hypogonadism were detected.
Conclusion
Despite reports in the literature documenting gonadal dysfunctions linked to COVID-19, our findings indicate that gonadotropic function remains intact in the majority of Long COVID patients. However, a notable 9.3% of our cohort presented with sexual disorders. Comprehensive studies focusing specifically on the gonadotropic and lactotropic axes in Long COVID patients with sexual dysfunctions are imperative to deepen our understanding of the endocrine intricacies associated with this lingering condition.

Patient reported perspectives of disease burden in acromegaly: data from the acromegaly community patient-focused drug development meeting

Nidhi Agrawal[1], Kevin CJ Yuen[2], Vivien Bonert[3], Wenyu Huang[4] & Jill Sisco[5]
[1]NYU;[2]Barrow Pituitary Center;[3]Cedars Sinai Medical Center;[4]Northwestern University;[5]Acromegaly Community

Acromegaly is a rare disease most commonly caused by benign pituitary adenomas producing excess growth hormone. A profound mismatch between biological control and symptom control creates a high disease burden despite optimal disease management. To learn more about the patient experience, Acromegaly Community hosted a virtual Externally Led Patient-Focused Drug Development meeting in January 2021. There were 304 registered attendees, including 128 people with acromegaly and their family members, caregivers, and friends; industry, advocacy, and regulatory representatives; scientists; and healthcare providers. A >90-page report[1] prepared by Acromegaly Community captures participants' input on acromegaly symptoms and daily impacts and on current and future approaches to treatment, providing a valuable opportunity to learn about acromegaly directly from those most affected by it. We hereby summarize the key findings of the report. Overall acromegaly negatively impacts all aspects of daily living (Table 1). Fatigue/muscle weakness (reported by 92% of respondents) and joint problems/arthritis (90%) are the most commonly experienced and most troublesome symptoms (a top health concern of 63% and 65% of respondents, respectively). Some insightful statements pa include: 'I struggle with simple tasks… lifting laundry, carrying groceries, or mowing my lawn and doing simple housework' 'Living with acromegaly affects patients' mental health'.'Mental illness tore apart my family.' Anxiety/depression is experienced by 75% and is a top concern of 33% of respondents. acrorage and mo relationships. Most patients underwent pituitary surgery (83%) had with a wide range of surgical outcomes. Many require ongoing medical therapy, which is expensive, inconvenient, and frequently painful and can have severe side effects. Most patients have tried medications that reduce growth hormone secretion (71%), block its action (43%), or lower hormone levels (38%). Many patients use other medications to treat secondary symptoms such as diabetes and hypothyroidism (35%) and/or depression or anxiety (37%). Patients fail various combinations of medications before finding the right regimen. In the future, patients aspire more effective treatments for fatigue/muscle weakness and joint issues; more effective, tolerable, and easily administered drugs for biological and symptom control that shrink tumors; and effective treatments for hunger and weight gain, along with dietary advice and physical therapy.

Routine monitoring for acromegaly-associated complications and recurrence: a single-centre audit

Asif Nawaz[1], David Williams[1], Fiona Guy[1], Thinzar Min[1,2] & Win Yin[1]
[1]Swansea Bay University Health Board, Endocrinology and Diabetes, Swansea, United Kingdom;[2]Diabetes Research Group, Swansea University Medical School, Endocrinology and Diabetes, Swansea, United Kingdom

Introduction
Endocrine society guidelines advocate early colonoscopy and monitoring for acromegaly-associated complications and recurrence. We aimed to establish whether people with acromegaly under our care received appropriate monitoring.
Methods
Patients under follow-up with acromegaly diagnosed 1989-2021 were included. Electronic health records were accessed for clinic letters, colonoscopy reports, blood and imaging results from the diagnosis to recent follow-up.
Results
Twenty-two patients are included, with a mean age 47.5 ± 17.1 years at diagnosis, mean disease duration 15.3 ± 10.5 years, 2 (9.1%) had pre-existing type 2 diabetes (T2D), and 11 (50.0%) are male. Surgery was undertaken in 18 (81.8%), of whom 2 developed recurrent disease, and 4 managed medically from diagnosis. Five (22.7%) patients had colonoscopy within 12 months of diagnosis and a total of 11 (50.0%) patients had a colonoscopy since their diagnosis of acromegaly. Of these, three demonstrated colonic polyps of whom one had repeat colonoscopy within 5 years, one declined further endoscopy, and the other had no repeat endoscopy in 6 years. Over follow-up, 4 (18.2%) developed new T2D. In the last year, 18/22 (81.8%) had a serum IGF-1, 12/22 (54.5%) had HbA1c, and in the last 3 years 16/22 (72.7%) had repeat pituitary imaging. Of the 6 patients on somatostatin analogues or growth hormone antagonists, 4 (66.7%) had liver function tests in the last 6 months.
Discussion
Patients with acromegaly under our care infrequently had colonoscopy surveillance, and almost half did not have diabetes screening in the last year. We will develop local practice standards for annual review, and re-audit.

[1]Clinical Centre of Montenegro, Faculty of Medicine, University of Montenegro, Montenegro;[2]Faculty of Medicine, Belgrade University, Serbia; Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Belgrade, 11 000 Belgrade, Serbia;[3]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Belgrade, 11 000 Belgrade, Serbia

Introduction
The aim of the study was to establish the predictive factors for endocrine disease-induced hyponatremia.
Patients and methods
Fifty-two patients with hyponatremia (Na <135 nmol/l) were referred to Department of Neuroendocrinology, University Clinical Center of Serbia from January 2015 to March 2023 ($n=52$; 31 females, 60%) mean age 60.5 ± 14.1 years, mean serum sodium level 124.9 ± 9.0 mmol/l. Seven patients (13.4%) with translocational hyponatremia, caused by hyperglycemia were excluded from the analysis.
Results
No significant differences between the non-endocrine (NEhypoNa) and endocrine hyponatremia (ENhypoNa) group was detected regarding the age ($P=0.439$), gender ($P=0.899$), body mass index ($P=0.236$) and smoking habits ($P=0.668$). Compared to patients in NEhypoNa group ($n=27$, 60%), patients with ENhypoNa ($n=18$, 40%) more frequently presented with rapid-onset hyponatremia (77.8% vs 25.9%, $P<0.05$). Although mean serum Na was not significantly different between groups (122.8 vs 124.4 mmol/l; $P=0.583$), severe symptoms were predictive factors for endocrine cause, found in 77.7% of ENhypoNa patients vs 37% in NEhypoNa group ($P=0.05$). Hypertension was associated with non-endocrine causes of hyponatremia (66.7% in NEhypoNa vs 27.8% in ENhypoNa group; $P=0.011$), most commonly caused by syndrome of inappropriate diuresis (SIAD). Chronic comorbidities like type 2 diabetes, obesity and osteoporosis were more frequently present in NEhypoNa, but the sample was small so the statistical significance was not reached. In 2/3 of patients in ENhypoNa group hyponatremia unmasked previously unrecognized primary or secondary adrenal insufficiency and hypopituitarism, diagnosed in 6 (13.3%) and 12 (26.7%) patients respectively.
Conclusion
Acute and severe hyponatremia on admission with less chronic comorbidities (diabetes, obesity, hypertension, osteoporosis), more frequently reflected underlying endocrine cause of hyponatremia.

Bone health and skeletal fragility in second- and third-line medical therapies for acromegaly: preliminary results from a pilot monocenter experience

Sabrina Chiloiro[1], Antonella Giampietro[2], Amato Infante[3], Pier Paolo Mattogno[4], Consolato Gulli[3], Liverana Lauretti[4], Alessandro Olivi[4], Alfredo Pontecorvi[2], Laura De Marinis[2], Francesco Doglietto[4] & Antonio Bianchi[2]
[1]Università Cattolica del Sacro Cuore, Dipartimento di Medicina e Chirurgia traslazionale, Rome, Italy;[2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Medicina e Chirurgia traslazionale, Rome, Italy;[3]Fondazione Policlinico Universitario A. Gemelli IRCCS, Department of Diagnostic Imaging, Oncological Radiotherapy, and Hematology, Rome, Italy;[4]Fondazione Policlinico Universitario A. Gemelli IRCCS, Department of Neurosurgery, Rome, Italy

Introduction
Skeletal fragility is a relevant and not-reversible complication of acromegaly, involving around 30-40% of patients since the disease diagnosis. Few studies have investigated the effects on skeletal health of medical therapies for acromegaly. We aim to investigate the frequency of incident vertebral fractures (i-VFs) in patients treated with Pasireotide Lar + Pegvisomant (study group), after at least 24 consecutive treatment months and to compare the i-VFs frequency in the study group with controls: patients treated with Pasireotide Lar, Pegvisomant in monotherapy (m-Peg-V), and in association to first-generation somatostatin receptor ligands (fg-SRLs + Peg-V).
Subjects and methods
A retrospective, longitudinal, observational was designed. For the study cohort, inclusion criteria were: (1) ascertained diagnosis of acromegaly; (2) age older than eighteen years; (3) not-controlled acromegaly during treatment for at least 12 consecutive months with fg-SRLs and further 12 consecutive months of treatment with Pasireotide Lar or Pegvisomant in monotherapy or in combination with fg-SRLs; (6) treatment with Pasi-Lar + Peg-V for at least 24 consecutive months. For the control groups, inclusion criteria were: (1) ascertained diagnosis of acromegaly; (2) age older than 18 years; (3) not-controlled acromegaly during treatment for at least 12 consecutive months with fg-SRLs; (4) controlled acromegaly after at least twelve consecutive months with Pasi-Lar or Pegvisomant in monotherapy or in combination with fg-SRLs. The exclusion criteria (both for the study cohort and for the control groups) were: (1) diagnosis of active neoplasia; (2) previous or current treatment with drugs known to cause fragility fractures, except for glucocorticoid replacement therapy for central adrenal insufficiency; (3) history of spine surgery or trauma.
Results
Six patients were treated with Pasi-Lar + Peg-V, 6 patients with Peg-V in monotherapy (m-Peg-V), 16 patients with fg-SRLs + Peg-V and 10 patients with Pasi-Lar. Eight patients experienced i-VFs. None Pasi-Lar + Peg-V treated patient experienced i-VFs. The i-VFs frequency was lower in Pasi-Lar + Peg-V treated patients (0/8; 0%), as compared to those observed in m-Peg-V treated patients (4/8; 50%, $P=0.03$). The i-VFs frequency was slightly higher in Pasi-Lar treated patients (1/8; 12.5% $P=0.062$) and in fg-SRLs + Peg-V treated patients (3/8; 37.5% $P=0.364$), concerning those treated with Pasi-Lar + Peg-V (0/8; 0%). I-VFs occurred more frequently in patients with higher GH levels at acromegaly diagnosis ($P=0.04$), and in patients who experienced a BMD worsening ($P=0.005$).
Conclusion
Our preliminary data suggested that in conventional and multi-drug resistant acromegaly, the combination therapy Pasi-Lar + Peg-V may prevent the i-VFs occurrence. Prospective studies should further validate these results and ascertain underlying physiopathology mechanisms.

EP462

Difficulties in treating acromegaly: what treatment? when to start?

Esra Eraslan Aydemir[1], Sinem Başak Tan Öksüz[1] & Sevim Güllü[1]
[1]Ankara University Hospital, Endocrinology and Metabolism, Turkey

Introduction
Acromegaly is a disorder caused by excessive secretion of growth hormone, often due to pituitary masses. The first step in treatment is transsphenoidal surgery. Cabergoline, somatostatin receptor ligands or pegvisomant may be used in patients with an inadequate response after surgery. Finally, radiotherapy may be used in patients with inadequate response to medical treatment.
Methods
In this retrospective study, data of 89 patients (59 females, 30 males) diagnosed with acromegaly in Ankara University Hospitals between 2002 and 2024 were analysed.
Results
The mean age at diagnosis was 40.2 ± 11.4 years and the mean follow-up was 97.6 ± 77.9 months. Pituitary surgery was performed in 82 of 89 patients and the postoperative remission rate was 31.7% ($n=26/82$). Patients ($n=62$) who did not achieve remission or who relapsed during follow-up underwent reoperation ($n=22/62$, 35.4%) and/or radiotherapy ($n=17/62$, 27.4%) and/or medical therapy ($n=54/62$, 62%). Of the 60 patients treated with medical therapy, 36 (60%) received monotherapy and 24 (40%) received combination therapy. Remission was achieved in 38 (63.3%) patients. Of the 60 patients, 33 (55%) were treated with somatostatin receptor ligand (SRL) monotherapy, 3 (5%) with dopamine agonist (DA) monotherapy, 16 (26.6%) with SRL and DA combination, 5 (8.3%) with SRL, DA and pegvisomant combination, 3 (5%) with SRL and pegvisomant combination. When analysing the patients who were receiving medical treatment, it was observed that there was a delay in treatment change in 6 patients. The mean delay in switching treatment was 61.5 months. The economic status of the patients, the Covid pandemic, referrals to different and inappropriate centres and patient non-compliance were found to be the reasons for this delay.
Conclusion
Despite many advances in medical and surgical treatment, some patients with acromegaly are not adequately treated. In cases SRLs are insufficient, switching to pegvisomant or a combination therapy of pegvisomant and SRLs is recommended.[1] Switching to new treatment regimens based on patient characteristics in all patients who do not achieve remission will increase the success of acromegaly treatment. The success of acromegaly treatment can also be increased by evaluating patients in experienced centers.

A retrospective evaluation of operated non-functional pituitary adenomas over four decades in the maltese population

Jessica Mangion[1,2], Josanne Vassallo[1,2] & Mark Gruppetta[1,2]
[1]Mater Dei Hospital, Neuroendocrine Clinic, Msida, Malta;[2]University of Malta, Faculty of Medicine and Surgery, Msida, Malta

Introduction
Surgery in nonfunctional pituitary adenomas (NFPAs) is usually indicated when there is mass effect or progressive increase in size. Our study aims to analyze NFPAs which were operated until the end of 2023 in a well-defined population.
Methods
A retrospective analysis of 128 operated patients with NPFAs, diagnosed at the only central national service hospital in Malta, between January 1980 and December 2023, was performed. Detailed clinical data was obtained for each patient and the pre- and post-operative MR pituitary scans were analysed. Univariate and multivariate analyses were done to establish which variables can predict the presence of residual and/or recurrence post-operatively.
Results
72 (56.3%) were males and the median age was 56 years (IQR 42.5-64.5). The median tumour size was 27.6mm (IQR 21.5-35.1) with giant macroadenomas making up 10.2%. The median follow-up was 10.5 years (IQR 5-17). Most patients were operated once, 11 were operated twice, and only 2 thrice. During the study period 24 (18.8%) patients passed away. 103 patients (80.5%) had an accessible baseline MR pituitary, of which 95 (74.2%) tumours had chiasmal compression, 120 (93.8%) had suprasellar extension and 56 (43.8%) had cavernous sinus invasion. A residual post-operatively was detected in 80 (62.5%) patients. During follow-up, regrowth was detected in 25 (19.5%) patients with a median of 38 months from surgery (IQR 17-60). Univariate analysis revealed a statistically significant association between tumour residual and cavernous sinus invasion ($P<0.001$), largest tumour diameter ($P<0.001$), tumour volume ($P<0.001$), suprasellar extension ($P=0.04$) and infrasellar extension ($P<0.001$). The largest tumour diameter remained an independent predictor of having a residual post-operatively after logistic regression ($P=0.008$; OR 1.34 95% CI 1.08-1.68). Using ROC analysis to predict the presence of residual post-operatively, an infrasellar dimension of 5.2 mm was 80% sensitive and 70% specific (ROC-AUC 0.786, $P<0.001$). Tumour regrowth was statistically significantly associated with cavernous sinus invasion ($P=0.002$), tumour residual ($P=0.003$), largest tumour diameter ($P=0.032$) and transverse dimension ($P<0.001$). The transverse dimension remained an independent predictor of regrowth after logistic regression ($P=0.005$ OR 1.24 95% CI 1.07-1.44). There was no significant association between mortality and tumour residual or regrowth post-operatively.
Conclusion
The majority of operated NFPAs have good prognoses with few having significant regrowth despite residual tumours. An infrasellar dimension of 5.2mm was 80% sensitive and 70% specific to predict tumour residual post-operatively whilst the transverse dimension preoperatively was found to be independently associated with risk of regrowth.

TSHoma: mapping the indolent journey

Tala Nasrini[1] & Adnan Ajmal[2]
[1]Koc University Hospital, Istanbul, Turkey; [2]Cleveland Clinic Abu Dhabi كلينك أبوظبي مستشفى كليفلاند, Abu Dhabi, United Arab Emirates

Background
Thyroid stimulation hormone producing pituitary adenomas [TSHoma] are very rare and present a diagnostic and management challenge due to limited clinical guidance. Indolent presentations such as multinodular goiter and mild hyperthyroidism can easily mislead the management. Moreover, we would also like to emphasize limitations of TSH with a reflex free T4 [FT4] test in such scenarios.
Clinical Presentation
Forty-three years old female was experiencing mild hyperthyroid symptoms and progressively enlarging multinodular goiter for few years. She was advised to get thyroidectomy after biopsy proven benign nodules. Interestingly, free thyroid hormones were mildly higher than ULN of 19.8 pmol/l for FT4 and 6.8 pmo/l for free T3 over last 5 years with inadequate TSH suppression with TSH between 1.4-2.1 mIU/l. Presurgical CT neck showed incidental sellar mass with subsequent MRI showing a 1.8 cm pituitary adenoma invading the right cavernous sinus and almost encircling the right cavernous carotid. Additional biochemical work up including elevated alpha subunit 2.7 ng/ml, SHBG 194.5 nmol/l with high alpha subunit/TSH ratio strongly suggested TSHoma. Due to invasive nature of the tumour, we employed primary pharmacotherapy with somatostatin receptor ligand (SRL) which holds promising potential, with reported instances of tumour regression in ~ 40% of cases. She was treated with octreotide LAR 20 mg every 4 weeks with subsequent follow ups over last 6 months showing very significant clinical, biochemical and radiologic improvement in goiter and pituitary tumour. Thyroid hormone levels are completely normalized now with resolution of hyperthyroid symptoms. Six months follow up pituitary MRI shows pituitary adenoma size is significantly decreased from 1.8 cm to 1.1 cm with regression of invasion.
Conclusion
TSHoma compromise 0.5-3% of pituitary adenomas. Majority of the cases come to attention as sellar mass affect so high index of suspicion is warranted especially when presentation is more indolent. High free hormones with inadequate TSH suppression should raise suspicion also highlighting the limitations of TSH with reflex FT4 test employed at many practices. TSH remained completely normal during her clinical course. Trans-sphenoidal resection is the most common primary treatment, but primary pharmacotherapy with SRL is also employed in select cases with limited success. Patient preference, lack of chiasmal compression, Knosp 3B-4 cavernous sinus invasion with gross total resection unlikely and progressively enlarging multinodular goiter were the factors that guided us to resort to SRL as primary treatment. Subsequent significant improvement highlights the importance of considering such therapy in carefully selected patients.

Magnetic resonance imaging of pituitary formations diagnostics using neural networks

Elena Brutskaya-Stempkovskaya[1], Yulia Dydyshka[1], Siarhei Kavetski[2], Volha Shyshko[1,3], Ivan Vasilevich[1] & Artsiom Alperyn[4]
[1]Belarusian State Medical University Minsk, Belarus; [2]Republican clinical hospital of medical rehabilitation, Belarus; [3]Minsk City clinical Endocrinology center, Belarus; [4]Belarusian State University Belarus

The introduction of the brain magnetic resonance imaging (MRI) of into routine clinical practice has led to a significant increase of pituitary masses detection, including as incidental findings. An increase in the frequency of detection of pituitary gland formations entails a significant increase in costs for clinical and hormonal examination, MRI monitoring and dynamic observation by an endocrinologist. However, only a small number of identified formations require radical treatment. An important clinical problem is to determine the malignancy, predictors of potential growth and hormonal activity of pituitary incidentalomas. The development of an automated algorithm for diagnosing pituitary formations to identify groups of patients for priority examination is of great practical importance.
Materials and methods
A cross-sectional study of 746 patients was conducted for development a neural network program for automated MRI pituitary formations screening. All patients underwent the pituitary MRI without contrast at the Republican Clinical Hospital of Medical Rehabilitation in 2019-2022, coronal (T1, T2) and sagittal (T1) projections were studied. The MRI assessment was carried out by a radiologist; the clinical diagnosis was verified by endocrinologists.16 000 (30%) MR images from the original sample were manually labeled. Neural network architecture has been developed that is capable of performing multi-class classification using segmented images of the pituitary gland obtained as the output of the Faster-RCNN neural network (pretrained model) with a ResNet 50-FPN framework. The ratio of the intersection area of the predicted area and that obtained as a result of manual marking to their merging area, averaged over all images, was used as a metric. The test sample size was 25% of the original one.
Results
The average age 40.9 ± 16.5 years. Structure of diagnosis: 176 – normal, 336 – microadenoma, 68 – macroadenoma, 108 – postoperative changes, 58 – other pathology of the pituitary gland. A trained neural network analyzed MRI of pituitary formations.
Results
Accuracy (proportion of correct answers) by class: normal – 84%, microadenoma – 77%, microadenoma – 90%, postoperative changes – 91%, others – 91% (total – 86%). Precision (accuracy)$=0.63$, Recall (completeness)$=0.7$, F1-measure$=0.66$. Thus, the efficiency of predictions is sufficient for automated screening of the proposed groups of pituitary formations.
Conclusions
The results of the study prove the possibility of MRI pituitary formations automated screening using a developed neural network with a high degree of reliability.

Incidence of neoplasia in acromegaly in Polish centre – retrospective study

Aleksandra Jawiarczyk-Przybyłowska[1], Justyna Kuliczkowska-Plaksej[1], Martyna Strzelec[1], Łukasz Gojny[1], Małgorzata Rolla[1], Anna Brona[1] & Marek Bolanowski[1]
[1]Wroclaw Medical University Endocrinology Diabetes and Isotope Therapy Wrocław, Poland

Introduction
Acromegaly is a rare, chronic and progressive disease caused by a pituitary adenoma. Excessive secretion of growth hormone (GH) and insulin-like growth factor-I (IGF-I) leads to cell proliferation and differentiation, which results in changes in external appearance and causes various systemic complications. Elevated levels of GH and IGF-I are also thought to promote the development of cancer and some studies have shown that acromegaly is a disease with a high risk of developing cancer. The aim of our study was to assess the incidence of benign and malignant neoplasms among patients with acromegaly and the relationship between their prevalence and disease activity, the time of diagnosis of acromegaly and the time of occurrence of the first symptoms of this disease.
Materials and Methods
The retrospective study included a statistical analysis of the medical records of 230 patients with acromegaly treated at the Department of Endocrinology, Diabetes and Isotope Therapy in Wroclaw (Poland) in 1990-2023 in order to estimate the incidence of neoplasms among them. Statistical analysis was performed using Statistica for Windows, version 13.1 by StatSoft (USA).
Results
We observed 171 cases of neoplasms, including 144 benign tumours and 27 malignant tumours. Among the malignant tumors, the most common were breast cancer, thyroid cancer and hematologic cancer, and among benign tumors, colorectal polyps. Both neoplasms and benign tumors were diagnosed both in the short and long term after the diagnosis of acromegaly, but in the longer term only malignant tumors were diagnosed. Both types of tumors occurred more frequently in controlled acromegaly than in cured acromegaly. The incidence of cancer, regardless of type, was higher in patients with active acromegaly compared to cured patients.
Conclusions
This study confirmed the association between the activity of acromegaly as well as the time from diagnosis of the disease with the prevalence of neoplasms. For this reason, oncological vigilant and active search for cancer among patients with acromegaly at every stage of the disease are necessary.

Purpose
The present study aimed at investigating the morphology and function of reproductive system in women with hyperprolactinemia (HPRL) receiving chronic treatment with cabergoline (CAB)
Methods
Twenty-three women(aged 34.21 ± 10.09 yrs) with HPRL, including 17 with microprolactinoma, 3 with macroprolactinoma and 3 with iatrogenic HPRL, entered the study. All patients were well-controlled with CAB treatment (medium dose 0.46 ± 0.45 mg/week). In population study, PRL at diagnosis (PRL0), PRL at evaluation (PRL1), FSH, LH,17B-estradiol (E2) and AMH in the early follicular phase(2°-5° days), and PRL(PRL2) and progesterone(PRO) in luteal phase(16°-25°day) were evaluated. Age at diagnosis(A0), age at evaluation(A1), CAB dose at evaluation (CE), mean (CM) and cumulative CAB dose (CD) and treatment duration (TD) were also evaluated. In both follicular and luteal phases, a transvaginal ultrasound was performed to evaluate: hysterometry (HS), endometrial thickness (ET), ovary length(dl), height (DAP), width (DT) and volume (OV), uterine volume (UV), right (AFR) and left (AFL) antral follicles count, right(RRI) and left (LFI) uterine artery resistance index, right (RPI) and left (LPI) pulsatility index. Based on CM, patients were stratified in Group 1 ($CM < 0.35$ mg/week) and Group 2 ($CM > 0.35$ mg/week). Based on TD, patients were stratified in Group 3 ($TD < 62$ months) and Group 4 ($TD > 62$ months).
Results
In Group 1, right DL ($P = 0.04$), DT ($P = 0.016$), DAP ($P = 0.023$) and OV ($P = 0.002$) during follicular phase were significantly higher than in Group 2. In Group3, right DL ($P = 0.004$), DAP ($P = 0.023$), DT ($P = 0.016$) and OV ($P = 0.002$) during follicular phase, and LPI ($P = 0.004$) in luteal phase were significantly higher than in Group 4. In Group1, LH ($P = 0.044$) and estradiol ($P = 0.023$) during luteal phase were significantly higher than in Group 2, while no significant differences were found in hormonal profile between Group3 and Group4. In whole study population ($n = 23$), PRL0 directly correlated with AMH ($P = 0.01$) and PRO ($P = 0.002$), whereas PRL1 with RRI ($P < 0.001$) and PRL2 with AMH ($P = 0.02$). TD indirectly correlated with ET ($P = 0.007$), right DT ($P = 0.05$) and DL ($P = 0.01$), LPI ($P = 0.05$) and RPI ($P = 0.0033$), and directly with UV ($P = 0.02$). CD indirectly correlated with LH ($P = 0.05$) and right DL ($P = 0.048$). A0 correlated indirectly with AFR ($P = 0.002$), AFL ($P = 0.002$) and AMH ($P = 0.012$), and directly with UV ($P = 0.027$) and CE ($P < 0.001$). Similarly, A1 indirectly correlated with AFR ($P = 0.027$), AFL ($P = 0.039$) and AMH ($P = 0.003$). E2 correlated directly with HS ($P = 0.044$) and RRI ($P = 0.003$), and indirectly with CD ($P = 0.036$). In turn, AMH directly correlated with CE ($P < 0{,}0001$), LPI ($P < 0{,}0001$), and left DT ($P = 0.031$).
Conclusion
CAB might have a direct beneficial effect on uterine and ovarian morphology and function, mainly improving uterine vascular flow parameters.

Pasireotide as first line medical therapy for treatment of selected patients with acromegaly

Nicoleta Olarescu[1,2,3], Jens Bollerslev[1,2], Anders Jørgensen[1,2] & Ansgar Heck[1]
[1]Section of Specialized Endocrinology, Department of Endocrinology, Oslo University Hospital (OUS), Oslo;[2]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway;[3]Research Institute of Internal Medicine, Oslo University Hospital (OUS), Oslo, Norway

Objective
Pasireotide is a second-generation somatostatin receptor ligands (SRLs) with highest affinity for somatostatin receptor (SST)5, followed by SST2. It is considered, so far, in patients resistant to first-generation SRLs, after surgical failure. Histological characteristics and T2-weighted MRI can predict resistance to first-generation SRLs in patients with somatotroph adenomas. Previous studies primarily assessed efficacy of pasireotide as 2nd or 3rd line medical treatment. However, pasireotide might be an option in patients expected to be resistant to first-generation SRLs (e.g. hyperintensity T2-weighted MRI signal and/or sparsely granulated immunohistochemical pattern). We describe the efficacy of pasireotide as the first pharmacological treatment.
Methods
Clinical and biochemical parameters, T2-weighted MRI signal intensity, histological diagnosis and efficacy of pasireotide treatment on GH and IGF-1 levels, and tumour volume (by ellipsoid formula), were recorded in four patients (two treated as primary treatment, two after debulking surgery), expected to be resistant to first-generation SRL.
Results
Table 1 presents age, GH and IGF-1 levels, and tumour volume before and after treatment with pasireotide median 5.6 (range 4.5-6.6) months. All tumours were hyperintense on T2-weighted MRI and sparsely granulated somatotroph adenomas were identified in the operated patients. Variability in GH and IGF-1 reduction was observed. Tumour volume decreased at least with 31% and the effect occured early. One patient started ad-on cabergoline therapy two months after pasireotide. At last visit, 18-58 months after treatment initiation, all patients still received pasireotide, two in combination with pegvisomant, one with cabergoline and one patient was additionally treated by radiotherapy. Two patients had normalised IGF-1, two patients further improved IGF-1. HbA1c remained stable in two patients and worsened in two patients with further need of anti-diabetic treatment.

Table 1. Patients' characteristics before and after treatment with pasireotide

	Baseline					Follow-up				Change (%)		
sex	Age yrs	GH µg/l	IGF-1 nmol/l	IGF-1/ ULN	Tumour volume cm^3	GH µg/l	IGF-1 nmol/l	IGF-1/ ULN	Tumour volume cm^3	GH	IGF-1	Tumour volume
#1_female	31	4.0	68	2.3	7447	2.1	26	0.9	4556	47	62	39
#2_male	51	2.9	60	2.7	47158	2.7	58	2.6	28540	7	3	39
#3_female	35	1.6	55	1.9	5457	1.5	39	1.3	3749	6	29	31
#4_female	30	200.0	114	3.9	7758	3.8	81	3.8	3360	98	29	56

Conclusions
In patients with T2-hyperintense MRI adenomas and presumed resistance to first-generation SRLs, pasireotide may be considered as first line medical treatment, facilitating rapid tumour control and decreased disease activity.

Congenital growth hormone deficiency associated with hypopituitarism: experience from the endocrinology department of hedi chaker university hospital in sfax

Hamdi Frikha[1], Mouna Elleuch[1], Nesrine Dhieb[1], Dhoha Ben Salah[1], Wajdi Sefi[1], Faten Haj Kacem Akid[1], Fatma Mnif[1], Nadia Charfi[1], Mouna Mnif[1], Mohamed Abid[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology

Introduction
Congenital hypopituitarism is considered a study model to understand the mechanisms of development and the physiological functioning specific to the pituitary gland. Its exact prevalence is challenging to establish. In this report, we present the experience of the endocrinology department at Hedi Chaker University Hospital in Sfax regarding the diagnosis and management of patients with antehypopituitarism associated with growth hormone deficiency (GHD).
Methods
A retrospective descriptive and analytical study was conducted, collecting data from patients with antehypopituitarism and GHD who were followed at the endocrinology department of Hedi Chaker University Hospital in Sfax.
Results
We included 87 patients with antehypopituitarism and GHD. The median age at diagnosis in our cohort was 14 years, with a gender ratio of 1 female to 2 males. Growth projection on the growth curve indicated severe growth retardation of more than -3 standard deviations (SD) in 73.5% of cases. In 25.9% of cases, two or three pituitary axes were affected, while four axes were involved in 17.6% of patients. Finally, 10.6% of our patients had involvement of all antehypopituitary axes. Hypoplastic pituitary was the most frequent morphological anomaly, found in 48% of cases on pituitary imaging. In our study, a positive correlation was found between the early discovery of hypopituitarism and the presence of pituitary hypoplasia, as well as with the severity of growth retardation and the number of affected axes ($P=0.009$; 0.016; 0.02, respectively). Therapeutically, our study highlighted heterogeneity in the response to growth hormone treatment, with an average statural gain of 1.4 ± 1.2 SD (0, +4 SD). The target height was reduced by an average of 17.4 ± 14.8 cm in boys and 10.3 ± 4.6 cm in girls. Molecular analysis revealed mutations in exon 2 of the ProP-1 gene in all familial cases and two sporadic cases with highly heterogeneous phenotypic expression.
Conclusion
These results are consistent with existing literature on antehypopituitarism with growth retardation. They highlight the importance of early diagnosis, clinical and genetic variability of the disease, and the variable response to growth hormone treatment. These findings contribute to a better understanding of GHD and can help optimize the clinical management of these patients. The mutations in exon 2 of the ProP-1 gene identified in all familial cases and two sporadic cases in our cohort emphasize the genetic complexity of isolated growth hormone deficiency.

Infundibuloneurohypophysitis in sjögren's syndrome: a case report

Ameni Terzi[1], Jemel Manel[1], Chehaider Cyrine[1], Adel Meriem[1], Chiboub Marwa[1], Kandara Hajer[1] & Kammoun Ines[1]
[1]National Institute of Nutrition, Endocrinology department, Tunis

Introduction
Infundibuloneurohypophysitis (INH) is an autoimmune disease that typically presents as central diabetes insipidus (CDI). It is often more common in women with an autoimmune background. Here, we have the opportunity to describe an unusual case of a female patient who developed Sjögren' syndrome (SJS) following CDI.
Case presentation
A 55-year-old female was admitted to our department for exploration of polyuoropolydipsic syndrome evolving for 8 years, of abrupt onset, estimated at 12L per day and associated with nyctiuria. The urine density was low at 1005. The urinary osmolarity was 60 mosml/l. The patient underwent the two-stage water deprivation test that strongly indicated the presence of CDI. After hydric restriction, the antidiuretic hormone vasopressin level was low (0.5 pmol/l). The pituitary MRI displayed the absence of classical posterior pituitary lobe hyperintensity in T1 and a decrease in anterior pituitary gland height with partial intrasellar arachnoidocele. Further endocrinological assessment did not reveal any pituitary axes impairement. The patient started oral desmopressin, experiencing a marked relief of polyuria, as well as polydipsia. After 2 years, the patient developed dry eye and mouth syndrome that were explored. She presented pulmonary and central neurological involvement characterized by demyelinating encephalic lesions. Immunological tests revealed positive antinuclear, antiSSA52 and antiSSA60 antibodies. The diagnosis of primary SGS was established based on 4 out of the 6 American-European criteria. She was treated with corticosteroids.
Conclusion
The diagnosis of the underlying condition of CDI is challenging and raises several concerns for patients as it requires long-term follow-up. This report outlines the notably rare association between INH, an inflammatory disorder of the pituitary gland revealed herein by CDI and primary SJS. The pathogenesis is poorly understood. However, the autoimmune origin is strongly suggested by its association with connective tissue disorders, particularly SJS.

Diseases of the pituitary stalk

Hana Charfi[1], Dhoha Ben Salah[1], Mouna Elleuch[1], Yesmine Elloumi[1], Fatma Mnif[1], Nadia Charfi[1], Mouna Mnif[1], Faten Haj Kacem Akid[1], Mohamed Abid[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker Hospital, Endocrinology-Diabetology Departement, Sfax, Tunisia

Introduction
The pituitary stalk (PS) can be the target of various congenital or acquired pathologies. These conditions are increasingly encountered with the advent and development of magnetic resonance imaging (MRI). Clinically, PS pathology is often revealed by the occurrence of diabetes insipidus. However, other clinical manifestations related to hypothalamo-hypophysial involvement may also be variably associated.
Objective
To identify the circumstances of discovery, clinical features, hormonal aspects, and radiological findings related to pituitary stalk pathology.
Materials and Methods
A retrospective study of 34 patients with pituitary stalk anomalies, hospitalized at the Endocrinology Department of Hedi Chaker University Hospital in Sfax over a 24-year period.
Results
The average age of our patients at the time of diagnosis was 28 years. A male predominance was noted with a sex ratio of 1.2. The most common circumstances of discovery were polyuro-polydipsic syndrome and growth delay in 41% of cases each. Anterior pituitary insufficiency was present in 73% of patients. Diabetes insipidus was diagnosed in 52% of cases. Pituitary stalk hypertrophy, described in 44% of cases, was secondary to granulomatosis (40%), metastatic origin (26.66%), lymphocytic hypophysitis (13.33%), and idiopathic (20%). Pituitary stalk interruption, present in 56% of patients, was post-surgical, post-traumatic, and idiopathic in 21%, 10.5%, and 68.5%, respectively.
Conclusion
The spectrum of pituitary stalk pathologies is extensive, posing a diagnostic challenge. Knowledge of the main differential diagnoses is crucial for better management.

Standing balance control in patients with acromegaly

Michaela Title[1], Yuqi Wang[1], Melanie Posiewko[1], Lisa Tramble[2], Syed Ahmad[2], David Clarke[3], Syed Imran[2] & Michel Ladouceur[1]
[1]Dalhousie University Kinesiology Halifax, Canada; [2]Dalhousie University Endocrinology Halifax, Canada; [3]Dalhousie University Neurosurgery Halifax, Canada

Patients with acromegaly (PWA) experience higher rates of falls and fall-related injuries than age-matched Canadian adults. Previous studies of standing balance revealed increased sway in PWA compared to healthy controls but failed to control for the effects of the pituitary adenoma. Therefore, the aim of the present study was to determine if acromegaly influenced the neuromuscular control of standing balance. Bipedal standing balance was evaluated in PWA ($n=13$) in biochemical remission and a control group of patients with non-functioning pituitary adenomas (PNA, $n=13$). The groups were of similar age, sex, and BMI and all participants underwent surgery to remove the pituitary adenoma. Self-reported survey data was used to compare joint pain, functional disability scores, and history of joint surgery between groups. PWA reported significantly higher back ($P=0.004$), hip ($P=0.007$), and knee ($P=0.007$) pain and greater functional disability of the hip ($P=0.041$) and knee ($P=0.041$) than PNA. However, the history of joint surgery did not significantly differ between groups. Bipedal standing balance trials were repeated with eyes open, and eyes closed. Bipedal centre of pressure (COP) was measured using two AMTI force plates with one underneath each foot. Centre of mass (COM) was measured using a 14 body segment model with anatomical 3D positions recorded using a 14-camera OptiTrack motion capture system. The force plates and motion capture systems were synchronized and sampled at 200 Hz. Primary outcome measures included COP 95% prediction ellipse area and anteroposterior (AP) and mediolateral (ml) components of COP range, COP mean velocity, COP median frequency, root mean square (RMS) difference between COP and COM, cross-correlation between COP and COM, and time lag between COP and COM. PWA exhibited significantly greater RMS difference of COP and COM than PNA in both the AP ($P=0.042$) and ml ($P=0.006$) axes. No other balance measures were significantly different between the groups. There was no significant interaction between vision and acromegaly for any of the balance outcome measures. In conclusion, the larger RMS difference between COP and COM may indicate impaired sagittal plane ankle stiffness and impaired frontal plane hip mechanics in PWA.

EP473

Walking balance in patient with acromegaly

Yuqi Wang[1], Michaela Title[1], Melanie Posiewko[1], Lisa Tramble[2], Syed Ahmad[2], David Clarke[3], Syed Imran[2] & Michel Ladouceur[1]
[1]Dalhousie University Kinesiology Halifax, Canada; [2]Dalhousie University Endocrinology Halifax, Canada; [3]Dalhousie University Neurosurgery Halifax, Canada

Acromegaly triggers, and is associated with, peripheral nervous system modifications and joint degenerations, which are considered to impact the walking balance of patients with acromegaly (PWA). Therefore, to better understand if these systemic degenerations impact the transitory adaptations in locomotor patterns of these patients, this study aims to establish the walking balance deficits of PWA. Walking balance was evaluated in PWA ($n=8$) in biochemical remission and a control group of patients with non-functioning pituitary adenomas (PNA, $n=8$). The groups were of similar age, sex, and BMI and all participants underwent surgery to remove the pituitary adenoma. Self-reported survey data was used to compare joint pain, functional disability scores, and history of joint surgery between groups. PWA reported significantly higher back, hip, and knee pain and greater functional disability of the hip and knee than PNA. However, the history of joint surgery did not significantly differ between groups. Walking balance was assessed using the Timed Up and Go (TUG) test, the Dynamic Gait Index (DGI) score, and muscle energy patterns during obstructed walking (10% leg length obstacle). The kinematics and kinetics of walking were calculated by measuring bipedal ground reaction forces and centre of pressure (COP) using two AMTI force plates with one underneath each foot. Lower limb kinematics were measured using a 7-body segment model with anatomical 3D positions recorded using a 14-camera OptiTrack motion capture system. Force plate and motion capture systems were synchronized and sampled at 200 Hz. Lower limb kinematics and kinetics were calculated using Visual 3D. The outcome measures of the study consisted of TUG time, DGI score, and differences in joint power during obstructed walking. PWA took more time to complete the TUG task but did not have a lower DGI score (ceiling effect). There was no significant difference found in obstructed walking speed or obstructed walking stride length between the PWA and PNA groups. The muscle energy pattern adaptations required for crossing obstacles show a possible trend with a decrease in frontal plane energy generation by the hip abductors of the support leg and sagittal plane energy absorption by the knee extensors of the passing leg. These findings suggest that PWA may employ a different strategy to control hip abduction when adapting to an obstacle compared to PNA. These results show that changes in the mechanics of walking in PWA may indicate a potential alteration in muscle activation strategies.

GH and ACTH co-secretion by two pituitary microadenomas

Dominika Ondruskova[1], Peter Vanuga[2] & Anna Pávaiová[2]
[1]National Institute of Diabetes and Endocrinology, n.o., endocrinology, Lubochna, Slovakia;[2]National Institute of Diabetes and Endocrinology, n.o., endocrinology, Lubochna

Introduction
Pituitary ACTH-dependent Cushinǵs disease and acromegaly are rare conditions. Pituitary adenomas co-secreting GH and ACTH are even more unusual.
Case report
A 29-year-old patient, mother of three children, long-term follow-up by an endocrinologist for a thyroid struma without an autoimmune basis, was sent in April 2023 for further examination for detection of hypercortisolemia and insufficient suppressibility in the overnight 1 mg dexamethason test. The patient reported irregular menstruation, slight weight gain, intense sweating, swelling of her hands and feet. From objective symptoms facies lunata was noticeable, without other remarkable features. According to the diurnal profile of cortisol, the patient did not have preserved circadian variability of cortisolemia, we detected an elevation of cortisoluria, ACTH was within the normal range. On the basis of dexamethasone suppression test, we repeatedly confirmed the diagnosis of ACTH dependent Cushing syndrome, Cushing's disease. Due to the high level of IGF-1, we repeatedly performed the oral glusoce tolerance test with STH, in which up to the 120th minute there was insufficient suppression of STH. This condition was evaluated as hypersomatotropism. Other pituitary functions were normal. We completed an MRI examination of the pituitary gland because of the suspicion of pathology in this area, which verified two 2 and 4 mm large microadenomas. Than we started treatment with a steroidogenesis inhibitor and a somatostatin analogue before neurosurgery. On 27th of August 2023, transsphenoidal extirpation of both pituitary microadenomas was performed. Histologically, in both material fragments a corticotroph PIT NET, Crookés cell adenoma was verified. Immunohistochemically, growth hormone overproduction was not detected. Four months have passed since the time of diagnosis until the date of the operation. The patient noticed an increase in the size of foot by 1 number. After surgery, there was a remission of acromegaly and Cushing's disease. Central hypocorticism was newly developed, therefore we started replacement therapy with Hydrocortisone. Subsequently, the patient reported a regular menstrual cycle, less intense sweating, reduction of swelling on the hands and feet. We objectively observed a weight loss of a total of 3 kg in 3 months.
Conclusion
Early detection of two pituitary hormone overproductions and a quick neurosurgical solution protected the patient from the possible development of a number of comorbidities associated with GH and ACTH overproduction. Due to the aggressive variant of corticotroph adenoma, intensive monitoring of the patient will be necessary.

EP475

A rare case of partial hypopituitarism secondary to hereditary hemochromatosis presenting as unexplained hypotension

Mohamed Mortagy[1], Thake Kaung[1] & Frank Murphy[1]
[1]Hampshire Hospitals NHS Foundation Trust, Gastroenterology Winchester, United Kingdom

Introduction
Hereditary hemochromatosis is a common disorder in white population with a prevalence of 4-6.4%. It is a systemic disorder that affects multiple organs. It could affect the pituitary gland leading to hypogonadotropic hypogonadism and could affect other pituitary hormones to a lesser extent. We present a rare case of hereditary hemochromatosis leading to hypotension most likely due to iron infiltration of the pituitary gland.

Case presentation
A middle aged male presented to the emergency department with a gradual onset of progressive dyspnoea, abdominal distension, bilateral leg swelling and jaundice. His past medical history is remarkable for alcohol related liver cirrhosis. He cut off his alcohol 3 months prior to this presentation and last alcohol intake was 2 weeks prior. He was afebrile, tachycardic, on oxygen with normal blood pressure. He had jugular venous distension, bilateral crackles, ascites, and bilateral lower limb oedema. Chest Xray showed right sided pleural effusion. Echocardiography was unremarkable with normal ejection fraction. Abdominal ultrasound and CT were only remarkable for liver cirrhosis with minimal ascites. He had very high ferritin levels (4059 mg/l) and transferrin saturation (89%). He became hypotensive (systolic blood pressure <80) for a few days despite stopping furosemide, giving IV fluids and albumin. With his prolonged persistent hypotension, there was a question whether he has developed hypopituitarism secondary to hemochromatosis. His Serum FSH (1.0 u/l), LH (<1.0 u/l), testosterone (3.2 nmol/l), and AM cortisol were low (104nmol/l). Prolactin (454 mu/l) was high. TSH (2.04 mu/l) and Free T4 (18.9 pmol/l) were normal. He was suspected to have partial hypopituitarism secondary to hemochromatosis. Hydrocortisone was started and his blood pressure improved significantly.
Discussion
Hereditary hemochromatosis causes iron deposition in many organs specially the liver, the heart and the pancreas leading to multi-system affection and consequently liver cirrhosis, heart failure and diabetes. This patient had only liver cirrhosis with no other known organ affection. He was hypotensive despite appropriate treatment. His pituitary hormonal profile showed low gonadotropins, low cortisol despite normal thyroid function. This implies that he had partial hypopituitarism secondary to iron deposition in the pituitary gland secondary to his hemochromatosis. His hypotension resolved once hydrocortisone was started.
Conclusion
Clinicians should be aware that hypopituitarism should be suspected in patients with unexplained hypotension with history of hemochromatosis.

Sellar and supra-sellar cavernous hemangioma: a rare case report

Zineb Ait Si Ali[1], Nada El Idrissi Dafali[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction
Sellar and supra-sellar hemangioma is a very rare, benign tumor, presenting a differential diagnostic difficulty with pituitary adenomas, especially as its imaging aspects are non-specific. We report an unusual case of an intrasellar and suprasellar cavernous hemangioma that was initially thought to be an invasive pituitary macroadenoma.
Case report
A 65-year-old female patient presented with headaches and visual disturbances that had been evolving for 10 years, in a context of preserved general condition. The evolution of the symptoms had been marked by a worsening for the last 3 months. Clinical examination was unremarkable. Work-up: hypothalamic-pituitary MRI visualized a voluminous expansive sellar and supra-sellar lesion measuring $68\times57\times44$ mm, consistent with an invasive macroadenoma. Cortisolaemia: 5.3 mg/dl Prolactinaemia: 10.7 ng/ml, T4l: 8 pmol/l. The patient was started on hydrocortisone and L-thyroxine replacement therapy. She underwent an initial biopsy, the anatomopathological study concluded to a vascular tumor proliferation in favor of a cavernous hemangioma with no sign of malignancy. The patient was scheduled for trans-sphenoidal tumor resection.
Discussion and conclusion
Hemangioma is a benign vascular tumor, arising preferentially in the liver and skin. Cerebral localization is rare (0.5%), and sellar and supra-sellar involvement is extremely rare, with a slight female predominance. The clinical and radiological presentation is not characteristic enough to differentiate cavernous hemangiomas from other pathologies more frequently encountered in the sellar and supra-sellar region, such as pituitary adenomas, meningioma, optic glioma, craniopharyngioma, germinoma... It is important to differentiate sellar cavernous hemangioma from pituitary tumors because of the risk of severe hemorrhage during operation, as these tumors are vascular lesions and postulated to be dural based, and the possible complications in the postoperative period Diagnosis of certainty remains the prerogative of anatomopathological examination. Given the high risk of bleeding, subtotal tumor resection with decompression of surrounding tissue, followed by radiotherapy, may be considered the safest and most effective strategy.

Clinical characteristics of acrmegaly in men

Souleima Trigui[1], Dhoha Ben Salah[1], Mouna Elleuch[1], Kouloud Boujelben[1], Mouna Mnif[1], Elleuch Mouna[1], Nadia Charfi[1], Mohamed Abid[1] & Nabila Mejdoub[1]
[1]Chu Hedi Chaker, Endocrinology Sfax

Introduction
Acromegaly is a rare pathology characterized by chronic hypersecretion of Growth Hormone (GH) and Insulin-like Growth Factor-1 (IGF-1) that causes somatic, metabolic, and systemic changes. There are few data in the literature on the impact of the disease in male.
Patients and methods
Retrospective descriptive study including 15 adult males with acromegaly hospitalized in the endocrinology department of the Hedi Chaker Sfax university hospital over the period from 1998 to 2020. Acromegaly was diagnosed at an average age of 46.6 years with a peak incidence between the ages of 40 and 59 years. Acromegaly was revealed at an age beyond 60 years in 3 patients (20%). The diagnosis time was, on the average of 7.2 years ±6.1 with extremes ranging from 2 days to 17 years. Acrofacial dysmorphic syndrome was the most common discovery circumstance (53.3% of cases, $n=8$). Two patients among these 8 were diagnosed with diabetes mellitus during follow-up (13.3%). The tumor mass syndrome was the revealing symptom of the adenoma in 5 cases (33.3%) and antepituitary insufficiency was the revealing symptom in 2 cases. Decreased libido and erectile dysfunction were reported during the interview by 33.3% and 26.6% of patients respectively. Joint manifestations were found in 7 patients (46.6%) such as paresthesias in 4 patients (26.6%) and carpal tunnel syndrome in 3 patients (20%). Hypertension was observed in 5 patients (33.3%) and hypertrophic cardiomyopathy in 3 patients (20%). Sleep apnea syndrome (SAS) was diagnosed in 4 patients (26.6%). A homogeneous multinodular euthyroid goiter was observed in 2 patients (20%). Digestive colonoscopy showed colonic polyps in 2 patients (20%). One patient had segmental and focal hyalinosis and one patient had Wolf Parkinson's white syndrome. A gonadotropic deficiency was noted in 26.6% of patients ($n=4$), a thyrotropic deficiency in the same percentage and a corticotropic deficiency in 13.3% of patients ($n=2$). Carbohydrate tolerance disorders were noted in 7 patients (46.6%): prediabetes in 2 cases (13.3%) and diabetes in 5 cases (33.3%). Macroadenomas were the most common (73.3%). However, We did not detect giant somatotropic adenomas.
Conclusion
Production of GH has deleterious effects on many aspects of male sexuality. It induces hypogonadism through mass effect and through increase of prolactinemia. Moreover, hypogonadism is also one of the factors linking acromegaly to erectile dysfunction (ED), and metabolic complications of acromegaly.

Sheehan syndrome and thyrotropic insufficiency

Ismail Sid Ahmed[1], Amal Ourdi[1], Khawla Rhouzali[1], Abdessamad Malki[1], Siham Rouf[1,2] & Hanane Latrech[2]
[1]Endocrinology-Diabetology and Nutrition Department Chu Mohamed VI Oujda, Faculty of Medicine and Pharmacy, Mohammed First University Oujda, Morocco, Oujda, Morocco;[2]Endocrinology-Diabetology and Nutrition Department Chu Mohamed VI Oujda, Faculty of Medicine and Pharmacy, Mohammed First University Oujda, Morocco, laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy, Mohammed First University Oujda, Morocco, Oujda, Morocco

Introduction
Sheehan Syndrome can be determined as partial or complete hypopituitarism occurring after massive postpartum uterine hemorrhage leading to pituitary infarction. The first symptom classically described is the absence of milk flow. It is a rare and lethal condition, especially in underprivileged countries around the world. The resulting hypothyroidism is often diagnosed late, involving long-term complications. The aim of this study is to determine the prevalence of thyrotropic insufficiency associated with Sheehan Syndrome.
Methods
This is a retrospective descriptive study, including 5 patients with Sheehan Syndrome involving thyrotropic insufficiency, hospitalized in the Department of Endocrinology, diabetology and nutrition at the University Hospital of Oujda-Morocco during the period of October 2015 to December 2023. Data were analyzed by SPSS V 21.

Results-Discussion
The average age was 41.6 ± 15.14 years with an average diagnosis time of 11.5 years. Delivery hemorrhage was observed in 3 patients (60%), while the absence of milk flow was observed in 2 patients (40%). The clinical signs were dominated by secondary amenorrhea in 60% of cases. All patients expressed signs of hypothyroidism. The TSHus varied between 0.17 mIU/l and 2.88 mIU/l, and FT4 was low in all cases, with an average of 4.28 pmol ± 4.56 pmol/l. Hypothalamic-pituitary MRI imaging was in favor of an arachnoidocele in all our patients. All patients were treated with levothyroxine with good clinical improvement.
Conclusion
Thyroid insufficiency is one of the most important endocrine disorders, due to its cardiovascular risk. Furthermore, in the presence of massive post-partum haemorrhage, strict surveillance is required to early detection of Sheehan syndrome.

New onset pituitary adenoma after cushing's disease: recurrence or coincidence

Ana Quítalo[1], Francisca Leitão[1], Sara Franco[1], Margarida Lagarto[2], Henrique Vara Luiz[1] & Luísa Raimundo[1]
[1]Hospital Garcia de Orta, Almada, Portugal;[2]Hospital de São Francisco Xavier, Lisboa, Portugal

Introduction
Multiple pituitary adenomas (PA) have a prevalence of 0.2-2.6% of all resected PAs. However, most of them are simultaneously diagnosed and in the setting of acromegaly. In a 2019 surgical series with 22 cases of multiple PAs, only one case was asynchronous and all of them had a positive immunohistochemical staining.
Case report
A 32-year-old woman (1996) was referred to na Endocrinology appointment with amenorrhea and weight gain for the last 6 months and recent diagnosed hypertension. Central obesity, moon facies, hirsutism and violaceous abdominal striae were present at physical examination. The initial evaluation revealed serum cortisol 28 mg/dl (6.24-18), ACTH 151 pg/ml (9-50) and urinary free cortisol (UFC) 3 times the upper limit of normal. No suppression was found after 2 and 8mg dexamethasone tests and the CRH test was negative. Pituitary MRI showed a left inferolateral microadenoma (8 mm) and the inferior petrosal sinus sampling confirmed the ACTH gradient. After transsphenoidal surgery, histology confirmed the diagnosis of Cushing's disease. UFC levels normalized and the patient needed hydrocortisone for a year. The 6-month post operation MRI showed no evidence of residual lesions. Tem years later (2006), a follow up MRI described a median PA with 8x9x10mm, protruding to the suprasellar cistern. The patient reported symptoms of new weight gain and easy bruising. UFC levels were persistently elevated with no suppression in the 2 mg dexamethasone test, but serum ACTH was normal with a peak $<50\%$ in the CRH test. However, by this time, the patient was taking antiepileptic drugs. With the suspicion of recurrent Cushing's disease, a second transsphenoidal surgery was performed. Histology revealed a null cell adenoma with negative immunostaining. Fifteen years later (2015), the residual lesion increased in size with $21 \times 14 \times 12$ mm and invasion of the left cavernous sinus. With no evidence of hypercortisolism, she underwent fractionated stereotaxic radiotherapy. The most recent blood work showed normal pituitary function and the last MRI (2021) described a residual lesion with $9.7 \times 3.5 \times 4$ mm.
Conclusion
Double PAs are a very rare entity that can pose a significant challenge. Detailed hormonal assessment and immunohistochemical staining are essential for correct diagnosis. This case illustrates a rare diagnosis of a corticotroph and a null cell adenoma. However, molecular analysis is currently in charge of providing a more accurate characterization of the last PA.

Dynamic changes of fibroblast growth factor 21 levels in response to acute and chronic alcohol consumption

Cyril Vogel[1], Clara Sailer[1], Christ-Crain Mirjam[1], Bettina Winzeler[1] & Julie Céline Refardt[1]
[1]Universitätsspital Basel, Basel, Switzerland

Background
Fibroblast growth factor 21 (FGF21) is a hormone induced in the liver by metabolic stressors including starvation, sugars, and ethanol. Alcohol consumption increases endogenous FGF21 levels in humans while administration of FGF21 has been shown to reduce alcohol consumption in non-human primates. The effect of acute moderate alcohol consumption and long-term alcohol cessation on FGF21 levels in humans is controversial. We hypothesize that even moderate alcohol consumption increases FGF21 levels and that reduced long-term alcohol consumption lowers FGF21 levels.
Methods
We included data from two prospective intervention studies: first, a randomized, crossover design with 10 healthy men consuming beer (goal blood alcohol concentration of 0.8‰) or water. Blood samples were collected at six time points over the observation period of 720 minutes. The primary endpoint was difference in FGF-21 levels following both interventions. Second, 147 alcohol-drinking individuals participating in a randomized, placebo-controlled trial investigating the effect of glucagon-like peptide 1 (GLP-1) receptor agonist dulaglutide on smoking cessation. Alcohol consumption was assessed at baseline and after 12 weeks of treatment. The primary endpoint was change in FGF21 levels in persistent drinkers and those who had stopped drinking.
Results
In healthy volunteers, blood alcohol concentration peaked at 90 min and FGF21 levels increased from 125.5 pg/ml to 3149.6 pg/ml at 240 min after beer intake and from 142.0 pg/ml to 184.8 pg/ml after water intake (estimated difference 1386.0 (95% CI 934.55, 1837.44), $P<0.001$). FGF21 levels remained elevated at 720 min after beer intake (525.3 pg/ml vs 302.7 pg/ml, $P=0.028$). In the individuals striving for smoking cessation, median (IQR) baseline alcohol consumption was 3 glasses/week (2, 7) and median (IQR) FGF21 levels were 458.87 pg/ml (278.81, 779.81). At 12 weeks, 27 had stopped drinking alcohol which correlated with lower FGF21 levels (356.18 pg/ml (228.17, 720.75) vs 413.07 pg/ml (223.58, 717.83), estimated difference 228.65 pg/ml (95% CI 14.57, 440.35), $P=0.03$). The results were independent of age, sex, BMI, or smoking status. There was no difference in FGF21 levels between intervention ($P=0.3$) or smoking status ($P=0.1$).
Conclusions
Our findings suggest a dynamic response in FGF21 levels, with moderate acute alcohol consumption inducing elevated FGF21 levels, reflecting metabolic liver stress. In contrast, the reduction in long-term moderate alcohol consumption was associated with lower FGF21 levels, indicative of potential liver recovery These insights contribute to our understanding of the interplay between alcohol consumption and FGF21 dynamics, emphasizing the importance of both short and long-term considerations in liver health.

Evaluation of serum prolidase levels in acromegaly patients

Cansu Bezgincan Cayli[1], ÖZGE ÖZER[2], Huseyin Kayadibi[3], Aysen Akalin[2], Medine Nur Kebapci[2], Ozben Ozden Isiklar[3] & Goknur Yorulmaz[2]
[1]Eskisehir Osmangazi University, Meselik Campus, İnternal Medicine, Eskisehir, Turkey;[2]Eskisehir Osmangazi University, Meselik Campus, Endocrinology, Eskisehir, Turkey;[3]Eskisehir Osmangazi University, Meselik Campus, Medical Biochemistry, Eskisehir

Introduction
Acromegaly is a rare disease with high morbidity and mortality rates that occurs due to growth hormone (GH) hypersecretion from adenoma in somatotroph cells in the pituitary gland. It is thought that chronically high GH and Insulin-like Growth Factor-I (IGF-1) levels in its pathogenesis increase tissue collagen synthesis due to fibroblast activation. Prolidase enzyme is also the catalyst of the rate-limiting step of collagen synthesis. In our study, we planned to investigate prolidase enzyme levels in acromegaly patients who applied to our clinic.
Patients and Methods
31 acromegaly patients and 26 healthy volunteers were included in the study. The patients' age, gender, age at diagnosis, disease duration, diagnosis and current GH and IGF-1 levels, sedimentation, CRP, white blood cell values, serum prolidase enzyme level, imaging, and medical treatments were scanned from their files.
Results
The average age at diagnosis of the acromegaly group was 44.64 ± 11.58. The lowest age at diagnosis was 19, and the highest age at diagnosis was 72. The average disease duration was 6.8 ± 4.77 years. While the average prolidase level in the patients was 1111 ± 179.5 U/l, it was 1270.5 ± 282 U/l in the control group. There was no statistically significant difference between the acromegaly group

and the control group ($P=0.17$). There was no correlation between acromegaly disease duration and prolidase level ($r=0.938$). It was observed that there was a correlation between the development of visual field defect and prolidase level ($P=0.019$).
Conclusion
There is a few study in the literature evaluating prolidase enzyme activity in the acromegaly patient group. The results in our study may be related to the effect of examining a limited patient group. Further studies are needed to examine different parameter dynamics with long-term follow-up in large patient groups to elucidate the relationship between acromegaly and prolidase enzyme.

Hyperprolactinaemia as a reason for referral to specialist consultation

Jose Alvaro Romero Porcel[1], Celia Gallego Díaz[1], Sara Hami Gil[1], Pavle Puzigaca[1] & María Victoria Cózar León[1]
[1]Hospital Virgen de Valme, Endocrinología, Nutrición, Sevilla, Spain

Objective
Analysis of referrals from Primary Care to the Endocrinology Department for analytical findings of elevated prolactin levels and their subsequent management after initial assessment.
Material and methods
Retrospective descriptive study of 118 patients who were referred to the Endocrinology and Nutrition department of the Dos Hermanas Peripheral Specialities Centre between October 2020 and December 2022. Patients already diagnosed with hyperprolactinaemia who were lost to follow-up and those who did not carry out the requested tests and could not be re-evaluated after the first consultation were excluded from the analysis.
Results
Most referrals were women (95.8%) with a peak age between 18 and 25 years (40.7%). The most frequent reason for requesting the initial blood test by their primary care physician was oligomenorrhoea (35.6%), followed by those with no stated or confirmed reason (22%). The prolactin levels for which they were referred were less than 100 pg/ml (mean value 65.3 ± 40.4 pg/ml) in 92.3%, with the smallest proportion (37%) being performed correctly (in follicular phase, at rest and with extraction 30 minutes after venipuncture). Of this total, 76% were normalised following our extraction recommendations. These non-pathological results were reported telematically in 47.9% of cases.
Conclusions
Most referrals for hyperprolactinaemia could be avoided with a correct blood collection, given the high rate of normalisation in this way, without requiring referral to a specialist clinic. For this reason, and once referred, the telematic review of results is an effective option for informing patients, avoiding the need to be present in person and the associated waiting time.

Body composition in patients with acromegaly: the impact of disease control and medical treatment

Dario De Alcubierre[1], Tiziana Feola[1], Ludovica Vincenzi[1], Lucrezia Lamorgese[1], Valentina Sada[1], Giulia Puliani[2], Alessia Cozzolino[1], Emilia Sbardella[1], Marie-Lise Jaffrain-Rea[3] & Andrea Isidori[1]
[1]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy;[2]IRCCS Regina Elena National Cancer Institute, Rome, Italy;[3]Neuromed Institute, IRCCS, Neuroendocrinology, Pozzilli, Italy

Background
Acromegaly is associated with increased lean mass (LM) and reduced fat mass (FM), therefore body mass index is not a reliable parameter of body composition in this context. Moreover, the contributing factors to these alterations, along with their potential reversibility after achieving disease control, remain poorly understood. This study aimed to detect body composition alterations, as well as to investigate the impact of biochemical control and different medical treatments, in patients with acromegaly.
Methods
In this cross-sectional, case-control study, consecutive patients with active acromegaly (ACRO) were compared with age and sex-matched healthy controls (CTRL). Anthropometric and hormonal parameters were recorded. Total and region-specific body composition parameters were assessed via dual-energy x-ray absorptiometry (DEXA) scanning, measuring visceral adipose tissue (VAT), LM, and FM percentages. Appendicular lean tissue (ALT) and overall skeletal muscle index (SMI) were then calculated according to standardized *formulae*. Disease control of acromegaly was defined by IGF1 levels per upper limit of normal (IGF1 $\times$ ULN) <1.2. Statistical analysis was performed with parametric and non-parametric tests, as appropriate. Data are expressed as mean $\pm$ standard deviation or median (interquartile range) according to data distribution. Statistical significance was set at $P<0.05$.
Results
40 patients with active acromegaly (ACRO) [22 males, median age 56.5 (41-64)] and 20 matched controls were enrolled. Among ACROs, 23 patients presented with biochemical control, 23 were on somatostatin analogs (SSAs), 9 were on pegvisomant (PEG), either as monotherapy or in combination with SSAs, and 8 patients were naïve to medical treatment. ACROs exhibited higher ALT ($P=0.032$) and a trend towards higher SMI ($P=0.065$) compared to CTRLs. In ACROs, no differences in body composition parameters were detected based on disease control status, except for a trend towards lower trunk fat ($P=0.056$) and higher total lean mass percentage ($P=0.070$) in poorly controlled patients. GH negatively correlated with VAT ($r=$-0.404, $P=0.016$), total ($r=$-0.486, $P=0.003$) and trunk ($r=$-0.564, $P<0.001$) fat percentage; IGF1xULN positively correlated with total lean mass percentage ($r=0.312$, $P=0.050$). Lastly, after stratifying ACROs according to type of medical treatment, no significant differences in body composition parameters were observed among SSA-treated, PEG-treated, and naïve patients.
Conclusions
Our analysis revealed increased lean tissue and skeletal muscle mass in patients with acromegaly compared to matched controls. These changes seem, in part, linked to the direct impact of hormonal excess; however, the role of different medical treatments requires further clarification.

Measurement of visceral fat area in women with hypopituitarism receiving conventional hormone replacement therapy: a case-control study

Salma Salhi[1], Ibtissem Oueslati[1], Seif Boukriba[2], Elyes Kamoun[1], Meriem Yazidi[1], Nadia Khessairi[1], Fatma Chaker[1], Habiba Mizouni[2] & Melika Chihaoui[1]
[1]La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia;[2]La Rabta University Hospital, Department of Radiology, Tunis, Tunisia

Introduction
Visceral fat area (VFA) represents the amount of fat stored in the abdominal cavity around internal organs. It is increasingly recognized as a crucial marker of metabolic health and cardiovascular risk. The aims of the present study were to measure VFA and to assess its associated factors in women with complete anterior hypopituitarism.
Methods
We conducted a cross-sectional study including 50 patients with a complete anterior hypopituitarism secondary to Sheehan syndrome, receiving conventional hormone replacement therapy, and 50 age and body-mass index (BMI)-matched controls. Participants had a clinical examination, laboratory tests and an abdominal computed tomography scan to calculate the VFA.
Results
The mean age was 62.2 ± 9.4 years in the patients and 60.6 ± 8.4 years in controls ($P=0.385$). The mean BMI was 29.6 ± 6.0 kg/m^2 in patients and 30.0 ± 5.0 kg/m^2 in controls ($P=0.741$). Patients had a significantly higher waist circumference than controls (respectively: 101.3 ± 10.2 cm vs 95.7 ± 10.5 cm; $P=0.007$). Parietal fat area was comparable between the two groups (patients: 270.2 ± 97.7 cm^2; controls: 242.7 ± 107.3 cm^2; $P=0.154$). However, VFA was significantly higher in patients (170.6 ± 58.8 cm^2) than in controls (148.8 ± 73.8 cm^2) ($P=0.030$). Visceral adiposity, defined by a VFA ≥ 150 cm^2, was observed in 64% of patients and 39% of controls ($P=0.014$). Sheehan syndrome was positively associated with visceral adiposity (Odds Ratio $=2.78$, 95%-Confidence interval: 1.21-6.37; $P=0.014$). Age ($P=0.022$) and sedentary ($P=0.010$) were associated with visceral adiposity. However, diagnostic delay, duration of the disease, family history of metabolic disorders, as well as GH and FT4 levels, and hormone replacement therapy were not associated with visceral adiposity.
Conclusions
VFA was significantly higher in women with hypopituitarism than in controls. Visceral adiposity was more prevalent in patients compared to age and BMI matched controls. Its associated factors were age and sedentary.

Diagnostic discordance of osteoporosis in acromegaly: a comparison of quantitative computed tomography and dual-energy X-ray absorptiometry

Chen Shuaiming[1], Li Jing[2], Yu Yerong[2] & Li Jianwei[2,2]
[1]West China Hospital, Sichuan University, Department of Endocrinology & Metabolism, Chengdu;[2]West China Hospital, Sichuan University, Department of Endocrinology & Metabolism, Chengdu, China

Background
Patients with acromegaly have an increased risk of vertebral fractures, yet normal or elevated bone mineral density (BMD) by dual-energy X-ray absorptiometry (DXA). This suggests that DXA may not be a reliable tool for assessing BMD in acromegalic patients. Multiple studies have suggested that patients with acromegaly have compromised trabecular bone but not cortical bone. Quantitative computed tomography (QCT) represents a three-dimensional technique for quantifying volumetric trabecular bone density, which is not affected by osteophytes and scoliosis commonly seen in acromegalic patients.
Objective
To examine the diagnostic discordance of osteoporosis between QCT and DXA in patients with acromegaly, and explore influencing factors of BMD in spine by DXA and QCT, separately.
Methods
We enrolled patients diagnosed with acromegaly consecutively at West China Hospital between January 2021 and December 2023, and excluded patients with plurihormonal PIT-1 positive pituitary adenoma. The diagnostic criteria established by the World Health Organization in 1994 for DXA were employed to diagnose osteoporosis and osteopenia, while the criteria endorsed by the International Society of Clinical Densitometry were utilized for QCT. Minor discordance was defined as the presence of adjacent diagnostic classes between the two techniques, whereas major discordance arose when one method diagnosed osteoporosis while the other indicated normal bone health.
Results
We enrolled 53 participants (28 females/25 males), with a median age of 44 years old. Three participants were diagnosed with osteoporosis/low bone mass by DXA, and 5 with osteoporosis by QCT. Major discordance, minor discordance, and concordance in diagnoses between the two techniques were 3.8%, 18.9%, and 77.4%, respectively. Patients consistently diagnosed with osteoporosis had higher age (59 vs 42 years old, $P<0.005$) and lower BMD by QCT (110.1 g/cc vs 153.8 g/cc, $P<0.005$) compared to patients without discordant diagnoses. Multiple linear regression analyses showed that age ($\beta=-0.516$, $P<0.005$), body mass index ($\beta=-0.209$, $P=0.024$), growth hormone ($\beta=0.187$, $P=0.023$), and female ($\beta=-0.178$, $P=0.039$) were independent factors of BMD by QCT, while none of them were independent factors of BMD by DXA. The adjusted R2 of this model was 0.429.
Conclusion
Our study demonstrated that QCT might be a more sensitive tool to assess bone health in patients with acromegaly, especially in those who are younger and have less severe bone loss. BMD data by QCT can be largely explained by clinical features of acromegalic patients but not by DXA, which suggests that QCT may be a superior diagnostic tool in this population compared with DXA.

Neurosteroids and cognition in cushing disease

Sebnem Burhan[1], Ebubekir Akpınar[2], Sevim Eyupoglu[3], Buruç Erkan[2], Mutlu Niyazoglu[1] & Esra Hatipoglu[1]
[1]University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Department of Endocrinology and Metabolism Diseases, Istanbul, Turkey;[2]University of Health Sciences, Basaksehir Cam ve Sakura City Hospital, Department of Neurosurgery, Istanbul, Turkey;[3]Brain 360 Special Psychology Laboratory, Psychology

Objective
Neurosteroids, a unique hormone group, are recognized for their impact on cognitive processes. The primary objective is to assess the correlation between cognitive function and NS levels in cases of Cushing's disease and a control group of nonfunctional pituitary adenoma (NFPA).
Design
The study comprised 26 individuals diagnosed with Cushing's disease (CDG), while a control group (CG) consisted of 14 age-gender matched participants with NFPA. Eighteen different neurosteroid levels were investigated. Montreal Cognitive Assessment Test (MoCA) to evaluate attention, sustained attention, information processing speed; Selective Recall Test (SRT) to evaluate verbal learning and delayed recall; Spatial Recall Test (SPART) to evaluate visuospatial learning and delayed recall; Symbol Digit Modalities (SDM) to evaluate attention and processing speed; Animal Naming Test (ANT) to evaluate verbal fluency and semantic memory, Verbal Fluency Test (FAS) for evaluate verbal fluency.
Results
There was no statistically significant difference in age between CDG and CG ($P=0.918$). The median age of the CDG was 49.5 years and the median age of the CG was 44 years. (IQR: 40.5-58.0, IQR: 34.5-64.0) There were 5 males, 19.2% and 21 females, 80.2% in CDG, and 4 males, 28.6%, and 10 females, 71.4% in CG. There was no difference between the sexes ($P=0.5$). There was no difference in cognitive function tests in patients with CDG and CG. In CG, there was a negative correlation between verbal memory performance measured by SRT test and aldosterone level ($r=-.667$, $P=.009$). In CG, there was a positive correlation between FAS and corticosterone, 7-OH-Pregnenolone, and dihydrotestosterone ($r=.731$, $P=.003$, $r=.738$, $P=.003$, $r=.969$, $P=.031$). In CG, ANT was positively correlated with corticosterone and 7-OH-Pregnenolone ($r=.787$ $P=.001$, $r=.767$ $P=.001$). In CG, there was a positive correlation between the SDM and corticosterone and 7-OH-Pregnenolone ($r=541$ $P=.046$, $r=.545$ $P=.044$). In CDG, there was a positive correlation between learning verbal memory, corticosterone, and deoxycorticosterone ($r=.401$ $P=.042$, $r=.446$, $P=.043$). In CDG, MoCA scores tend to be negatively associated with aldosterone levels ($r=-405$ $P=.062$). There was a negative correlation between the visuospatial attention test and allopregnanolone($r=-.571$, $P=.021$). In CDG, deoxycortisol levels were positively correlated with ANT($r=.391$, $P=.048$), and cortisol, corticosterone, and deoxycorticosterone levels tended to be associated with ANT ($r=.385$, $P=.052$, $r=.361$ $P=0.070$, $r=.423$, $P=.056$). Visio-spatial memory and allopregnanolone levels tend to be negatively correlated ($r=-467$, $P=.068$).
Conclusion
Some particular neurosteroids could potentially influence certain cognitive abilities in cases with CD.

Prolactinomas and macroprolactin: the complexity of interpreting macroprolactin data

Sjana Kos[1] & Jorn Assmann[1]
[1]Maasstad Hospital, Clinical Chemistry Rotterdam, Netherlands

Hyperprolactinemia is a condition that can present itself in many different contexts ranging from physiological during pregnancy, pharmacological (e.g., due to antidepressants or antipsychotics) or truly pathological. Pathological mechanisms of hyperprolactinemia include pituitary tumors, tumor metastases, autoimmune diseases and ectopic prolactin producing tumors. In addition, prolactin values may be elevated due to macroprolactin. Detection of macroprolactin through PEG-precipitation is performed under various conditions in different laboratories and reporting of post PEG-prolactin is performed through different approaches. Also, prolactin assays have distinct sensitivity towards macroprolactin. We show the impact of switch from one prolactin measuring method (Siemens Immulite XPi) to another (Roche Cobas Pro®). Should gender specific prolactin monomeric reference values be used, on average approximately 25% of all hyperprolactinemic samples are deemed hyperprolactinemic measured by both methods (Table 1). When adding $<50\%$ recovery (Percent recovery = (post-PEG prolactin ÷ pre-PEG prolactin) × 100; $<50\%$ Recovery means that more than 50% of the measured pre-PEG prolactin comprises of prolactin adducts (e.g., macroprolactin).) to the abovementioned rule of leveling within the monomeric reference intervals, a substantially smaller percentage of Siemens and Roche samples would be assumed to be macroprolactinemic with 10.8% and 2.3% respectively. This would especially be impactful if no post-PEG prolactin value would be reported along with the%-recovery and exemplifies the importance of being acquainted with the rules a laboratory sets for the presence of macroprolactin, but also the assay the lab utilizes. Unfortunately, such technicalities can impossibly be captured in guidelines and might be unknown to the clinician even though they could potentially impact decision making (especially when the post-PEG prolactin value is not reported and laboratory reports only recovery value). Thus, in final reporting, it is very important to define laboratory specific monomeric reference intervals when the presence of macroprolactin is defined by normalizing within monomeric reference intervals. In addition, post-PEG prolactin values should be reported when utilizing recovery as a defining factor for the presence of macroprolactin in order to prevent misdiagnosis. Differences between both reporting strategies might be smaller or larger depending on the assay used and its sensitivity to macroprolactin. Therefore, the likelihood of the presence of true pathological hyperprolactinemia always needs to be assessed in the context of the assay used, the sensitivity of the assay to prolactin adducts, type of PEG polymer used and the manner in which prolactin adducts are reported by the laboratory.

Hormonal implication in pediatric intracranial hypertension

Rekik Mona[1], Kammoun Sonda[1], Jallouli Aida[1], Nabila Rekik Majdoub[2] & Trigui Amira[1]
[1]Habib Bourguiba Hospital, Department of ophthalmology; [2]Hedi Chaker Hospital, Department of endocrinology

Introduction
Pediatric intracranial hypertension (PIH) refers to increased pressure within the skull in children. While it is less common than in adults, hormonal factors can play a role in certain cases. Changes in hormone levels during puberty, particularly in girls, may contribute to this condition. This form is sometimes referred to as Idiopathic Intracranial Hypertension of Adolescence. We report a case of bilateral papilledema revealing idiopathic intracranial hypertension related to puberty
Observation
A 13-year-old patient, with no medical history, presented with complains of headache and diplopia for 3 days. The ophthalmological examination found visual acuity at 10/10 in both eyes, left VI nerve palsy, and bilateral papilledema. Goldman visual field testing revealed an enlargement of the blind spot in both eyes. Body mass index, brain magnetic resonance imaging, and laboratory tests including endocrine assessment were normal. Lumbar puncture showed an intracranial pressure of 50 mmHg. The diagnosis of idiopathic intracranial hypertension related to puberty was established. The patient was treated with acetazolamide and underwent depletive lumbar puncture. Outcome was favorable with complete regression of headaches, oculomotor disorders and normalization of intracranial pressure. After 5 years of follow-up, the patient remained stable without any recurrence
Conclusion
PIH is a rare condition, sometimes leading to severe visual involvement. The pathogenic mechanisms of this condition remain poorly understood. The association between PIH and puberty has been demonstrated. Indeed, puberty is characterized by an increase in growth hormone (GH) levels that crosses the blood-brain barrier and enhances cerebrospinal fluid production by the choroid plexus.

Hypogonadism in male patients with cushing's syndrome: prevalence and outcome

Elisabeth Nowak[1], Frederick Vogel[1], Leah Braun[1], Stephanie Zopp[1], German Rubinstein[1], Pia Adam[1], Junia Schweizer[1], Katrin Ritzel[1], Felix Beuschlein[2] & Martin Reincke[1]
[1]Department of Medicine IV, LMU University Hospital, LMU Munich, Germany;[2]Department of Endocrinology, Diabetology, and Clinical Nutrition, University Hospital Zurich, Zurich, Switzerland

Background
Secondary hypogonadism (SH) is a common comorbidity of Cushing's syndrome (CS) in men. There is a large overlap in associated symptoms and comorbidities between hypogonadism and hypercortisolism. To date, the influence of coexistent SH on clinical and biochemical parameters in CS is largely unknown and longitudinal data investigating its recovery during the remission phase are scarce.
Hypothesis
We hypothesized that SH is a frequent and important risk factor for adverse outcomes of myopathy and osteoporosis.
Participants and Methods
We included 30 treatment-naïve adult men with overt CS diagnosed since 2012 with available baseline testosterone data. Hypogonadism was diagnosed based on age-specific cut-offs of total testosterone (TT). Outcomes were compared to 30 age- and BMI-matched male controls. In a subgroup of 20 men with CS, a longitudinal analysis after remission was conducted at 6, 12, and 24 months.
Results
Men with CS had significantly lower levels of TT, bioavailable T, and free T compared to controls ($P<0.0001$) with lowest levels in ectopic CS. At baseline, 16 (53%) men with CS had SH: 9/21 (42%) with pituitary, 5/6 (83%) with adrenal, and 2/3 (67%) with ectopic CS. Glucocorticoid excess measured by late night salivary cortisol was weakly but significantly inversely correlated with bioavailable T ($r=-0.396$, $P=0.0499$) and other reproductive hormones and there was a similar trend for serum cortisol ($r=-0.373$, $P=0.0605$). As expected, muscle function, both self-reported and confirmed by hand-grip strength, was significantly lower in men with CS ($P<0.0001$ and $P=0.0482$), whereas osteoporosis was more frequent in men with CS vs controls (50% vs 7%, $P<0.0001$). However, when stratified according to presence or absence of SH there was no significant difference in signs and symptoms of CS. SHBG correlated negatively and significantly with red blood cell (RBC) parameters (Haemoglobin, haematocrit, erythrocytes, and MCH, $r=-0.42$ to $-0,47$, $P<0.05$), with a similar trend for related reproductive hormones. Following successful surgery, testosterone levels increased significantly ($P=0.0010$), reaching normal levels six months after remission. Despite normalisation of SHBG levels, RBC parameters remained lower in men with CS even two years after remission.
Conclusion
SH is a common comorbidity in men with all types of endogenous CS and is reversible in most patients after six months of successful therapy. Despite being related to glucocorticoid excess, SH was not directly associated with myopathy. However, there seems to be a correlation with RBC parameters, some of which do not normalise even two years after remission.

Personalized dosimetry as a key for optimizing radioligand therapy (RLT) with 177Lu- or 177Lu/90Y-DOTA-TATE in patients with well-differentiated neuroendocrine tumors – an update on the initial results of the DUONEN multicenter study

Marta Opalinska[1], Grzegorz Kamiński[2], Marek Dedecjus[3], Aldona Kowalska[4], Maciej Kolodziej[2], Marek Saracyn[2], Piotr Garnuszek[5], Wioletta Lenda-Tracz[6], Danuta Gąsior-Perczak[4], Anna Borkowska[6], Joanna Januszkiewicz-Caulier[3], Joanna Długosińksa[3], Anna Sowa Staszczak[1], Anna Budzyńska[7], Agata Kubik[7], Krzysztof Kacperski[7], Wioletta Chalewska[3], Paulina Cegła[3], Alicja Hubalewska-Dydejczyk[1] & Renata Mikolajczak[5]
[1]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow;[2]Military Institute of Medicine - National Research Institute, Department of Endocrinology and Isotope Therapy, Warsaw;[3]National Institute of Oncology, National Institute of Oncology, Warsaw;[4]Jan Kochanowski University in Kielce, Collegium Medicum, Kielce, Poland;[5]National Centre for Nuclear Research, Radioisotope Center Polatom, Otwock-Swierk;[6]Jagiellonian University Medical College, Faculty of Health Sciences, Kraków, Poland;[7]Military Institute of Medicine - National Research Institute, Department of Nuclear Medicine, Warsaw

Aim/Introduction
Peptide Receptor Radionuclide Therapy (PRRT) is an effective treatment for disseminated neuroendocrine tumors (NETs) expressing somatostatin receptors. Despite many published studies, the consensus on the optimal PRRT treatment algorithm has not been reached yet. The main objective of the DUONEN multicenter, randomized, phase III study (EUDRACT No: 2020-006068-99) is the development of a dosimetry-based personalized PRRT algorithm. The second goal includes the assessment of the efficacy of dosimetry-based personalized therapy with mixed [^{177}Lu]Lu- and [^{90}Y]Y-DOTA-TATE in comparison to [^{177}Lu]Lu-DOTA-TATE in standard radioactivity doses (7400 MBq). The personalized dosimetry is designed to deliver maximal radiation dose to the tumor tissue while maintaining the safety of critical organs.
Materials and Methods
Adult patients with advanced, unresectable well-differentiated (G1 and G2) NETs, progressing on long-acting somatostatin analogues are randomized into four arms: A - treated with [^{177}Lu]Lu -DOTA-TATE with constant radioactivity of 7400MBq per cycle B - treated with mixed [^{177}Lu]Lu-DOTA-TATE and [^{90}Y]Y-DOTA-TATE, initially at a ratio of 3700:1850MBq/MBq. The [^{177}Lu]Lu-DOTATATE radioactivity remains constant in all cycles, and the [^{90}Y]Y-DOTA-TATE radioactivity is adjusted in the next cycles, based on bone marrow and kidney dosimetry to the highest radiation dose in the tumor tissue C - analogous to arm B, except that here the radioactivity of [^{90}Y]Y-DOTA-TATE remains constant and the radioactivity of [^{177}Lu]Lu-DOTA-TATE is adjusted depending on the dosimetry results D – first dose analogous to arm A and individualized in the next cycles based on dosimetry results. The treatment efficacy is evaluated on morphological imaging (CT or MR) according to RECIST 1.1 criteria. The safety of PRRT is assessed by the kidney and bone marrow biochemical function.
Results
35 patients have been enrolled to the study (arm A-9, arm B-9, arm C-9, arm D-8). Six patients discontinued therapy due to disease progression or its side effects. By now 94 cycles of PRRT were administered, including 57 fixed doses (first doses or arm A). Out of the 37 doses adjusted based on personalized dosimetry, the radioactivity dose was increased in 16 and decreased in 21. The first eight patients were evaluated post-PRRT according to RECIST 1.1 criteria achieving stable disease in 3 cases, and partial and complete response in 4 and 1 case, respectively.
Conclusions
Personalized renal and bone marrow dosimetry affects individual PRRT doses in each subsequent treatment cycle. Acknowledgments: The study is funded by the Medical Research Agency (Project number 2019/ABM/01/00077-00).

Imaging the sella turcica in sheehan syndrome: is there a correlation with clinical presentation?

Sawsen Nouira[1], Hamza Elfekih[1], Amel Maaroufi[1], Koussay Ach[1], Yosra Hasni[1] & Molka Chaieb[1]
[1]University Hospital Farhat Hached, Endocrinology Sousse

Introduction
Few studies have considered the natural history of pituitary anatomy in Sheehan syndrome (SS), as seen on magnetic resonance imaging (MRI) or CT scan. An imaging study of the sella turcica was carried out in patients with SS. The aim was to look for correlations between radiological findings and the degree of endocrine insufficiency on the one hand, and diagnosis delay on the other.
Methods
This is a retrospective study carried out between 1977 and 2021 on patients with SS followed at the endocrinology department of the Farhat Hached Hospital in Sousse, Tunisia. Clinical and radiological findings were documented and reviewed.
Results
Fifty-four patients diagnosed with SS were included. The mean age at diagnosis was 47 ± 14 years. The mean diagnostic delay was 15 years. Twenty patients had complete anterior hypopituitarism, 34 with at least one preserved pituitary function. Pituitary imaging was normal in 7 cases. The sella turcica was totally empty in 15 patients, partially empty in 32 cases. A remnant of pituitary tissue was found more frequently (56%; $n=22$) in those with dissociated hypopituitarism ($P \leq 0.005$). Patients with an empty sella turcica at the time of diagnosis had a longer diagnostic delay (18vs14 years; $P \leq 10^{-3}$).
Conclusion
The presence of a pituitary remnant is inversely correlated with the duration and extent of the disease. The empty sella should be the end point of the process, indicating the necrosis that has occurred. In women whose diagnosis has been delayed, the discovery of an empty sella is frequent.

Oral mucosal lesions and dental hygiene assessment in acromegaly patients

Burak Can Cengiz[1,1], Sefika Polat[2], Elif Yildizer[3] & Ihsan Ates[1]
[1]Ankara Bilkent City Hospital, Internal Medicine, Ankara, Turkey;[2]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey;[3]Ankara Yildirim Beyazit University, Oral, Dental and Maxillofacial Radiology, Ankara, Turkey

Aim
There is a lack of studies in the literature evaluating the relationship between oral health, oral mucosal lesions, dental hygiene status, and disease prognosis in acromegaly patients. Our study aimed to assess oral mucosa in acromegaly patients, predict dental problems that may develop, correlate oral lesions and mucosal status with patients' IGF-1 levels, investigate the relationship with the treatment method used, and evaluate the oral mucosal damage caused by concomitant and secondary chronic diseases accompanying acromegaly
Methods
The study includes acromegaly patients aged 18-65 and a control group of healthy volunteers with similar demographics. Data collection involves demographic information, clinical history, laboratory findings, and a 6-item questionnaire. Intraoral examinations are conducted by an experienced specialist using dental tools and probes.
Results
Results reveal no significant age difference between patients and the control group. TSH values are lower, while HbA1c and fasting glucose values are higher in patients. Tongue lesions are significantly more prevalent in patients. However, periodontal and plaque indices, as well as oral dryness scores, are similar between the groups. No correlation is found between disease duration, hormonal levels, and oral hygiene parameters.
Discussion
In our study, we found that oral mucosal lesions in acromegaly patients increased significantly compared to the control group. Especially, tongue lesions and the rate of having tongue lesions were observed to be higher. These results suggest that oral health status in acromegaly patients might reflect the disease's specific nature. Additionally, an impact on glucose metabolism and potential increased diabetes risk in acromegaly patients was observed. However, these effects were not considered clinically significant. The findings highlight the importance of regularly monitoring oral health status in acromegaly patients.

Ophthalmological complications during acromegaly: about 76 cases

Alida Mireille Uwimana[1], Nassim Essabah Haraj[1], Siham El aziz[1] & Asma Chadli[1]
[1]CHU Ibn Rochd, Department of Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
Acromegaly is a rare disease with an insidious course characterized by several complications that determine its prognosis. This is a case study about 76 patients treated at CHU Ibn Rochd to evaluate the ophthalmological impact of this disease.
Material and methods
This is a retrospective study of 76 cases of acromegaly followed in the endocrinology department of Ibn Rochd University Hospital from January 2005 to October 2023. All our patients benefited from an ophthalmological evaluation and visual field. The statistical analysis was done by EXCEL software.
Results
The average age was 49 years with a sex ratio F/M of: 0.33. The average BMI rate was 29 kg/m^2 with overweight in 12 patients (20.8%), and obesity in 23 patients (41.6%). The average duration of the disease was 9 and a half years; The average IGF1 level was 2.3 times normal and the etiological diagnosis was a pituitary adenoma in all patients. Pituitary tumor syndrome (THS) (96%) and acro -facial dysmorphia (93%) were the main reasons for consultation. Visual disturbances linked to STH were noted in 50% of our patients, including blindness ($n=2$), diplopia ($n=9$) and visual blur ($n=38$). A decrease in visual acuity was observed in 91.2%. Ophthalmological examination detected papillary pallor in 30%, glaucoma in 6.5% and diabetic retinopathy in 7.8%. The visual field showed bitemporal hemianopia in 40.35%, diplopia in 1.75%, amputation of the visual field in 10.52%, a slight bitemporal deficit in 14.9%, a slight peripheral deficit in 8, 77% Bitemporal hemianopia and visual field amputation were the most common visual field alterations
Discussion
Somatotropic adenomas are characterized by an insidious evolution and a generally late diagnosis during a tumor syndrome and visual disturbances which reflect tumor invasion at the expense of the cavernous sinus and the optical pathways.
Conclusion
Preserving the visual prognosis remains one of the major objectives of treatment. It is therefore important to evaluate the visual impact by an ophthalmological and visual field examination during the initial diagnosis and during the follow-up of acromegaly. Close collaboration between endocrinologist, neurosurgeon and ophthalmologist is necessary.

Cured by apoplexy-a case series

Stefanie Gross[1], Ionut Petre[1], Theodora-Mădălina Pavel[1], Dan Alexandru Niculescu[1,2], Cristina Capatina[1,2,3], Constantin Cucu[1,2] & Catalina Poiana[1,2]
[1]"C.I. Parhon" National Institute for Endocrinology, Endocrinology I, Bucharest, Romania;[2]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania;[3]

Pituitary apoplexy, a rare but impactful complication of pituitary adenomas, involves sudden hemorrhage or infarction within the pituitary gland, leading to diverse clinical presentations and complications, ranging from severe headaches to panhypopituitarism. This case series explores the intersection of pituitary apoplexy and the subsequent cessation of tumor secretion in five patients with various secreting pituitary adenomas, offering unique insights into potential curative effects. In the first case, a male with a 6 mm ACTH-secreting microadenoma experienced one year of remission post-apoplexy, only to face a subsequent relapse necessitating enrollment in a cortisol receptor blocker clinical study. In the second case, the patient experienced a critical episode characterized by intense headache, vomiting, and loss of consciousness two months prior to presenting at our department. Upon examination, the patient displayed acromegaloid clinical features and presented with newly discovered diabetes type 2. However, blood tests indicated panhypopituitarism, marking a significant clinical paradox. The MRI findings further substantiated the diagnosis, revealing signs of necrosis that strongly suggested the occurrence of pituitary apoplexy. This case underscores the complexity of pituitary apoplexy's clinical manifestations, where symptoms spanning acromegaly and panhypopituitarism coexist, necessitating a meticulous diagnostic approach for appropriate management In another case, an acromegaly patient with modest symptoms but biochemical evidence encountered pituitary apoplexy just before scheduled neurosurgery, subsequently considered cured. The final patient, diagnosed with a GH and prolactin secreting adenoma, experienced pituitary apoplexy resulting in a cure. Remarkably, in this case, a patient with a prolactin and GH-secreting macroadenoma showed GH secretion cessation post-apoplexy, managed with dopamine agonists, with a notable tumor volume reduction

two weeks later. This series collectively highlights the complex and variable outcomes associated with pituitary apoplexy, emphasizing its potential curative impact on different types of secreting pituitary adenomas. The observed changes in hormonal secretion and tumor volume provide valuable insights into the dynamic nature of these adenomas post-apoplexy. If patients successfully overcome the acute phase, pituitary apoplexy may play a beneficial role in achieving a cure for hypersecretion in pituitary adenomas.

Differences between genders in acromegaly

Plotuna Iulia-Ştefania[1,2], Melania Balas[1,2], Ioana Golu[1,2], Daniela-Georgiana Amzar[1,2] & Mihaela Vlad[1,2]
[1]"Victor Babeş" University of Medicine and Pharmacy, 2nd Department of Internal Medicine, Endocrinology, Timişoara, Romania;[2]Timiş County Emergency Clinical Hospital, Enocrinology, Timişoara, Romania

Background
Acromegaly is a rare condition associated with increased secretion of growth hormone (GH), most frequently from a pituitary adenoma. Gender can influence the secretion of growth hormone and insulin growth factor 1 (IGF-1). Healthy females appear to have higher spontaneous GH levels. In comparison, active acromegaly is associated with lower IGF-1 levels, possibly due to the inhibitory influence of circulating estrogen on the hepatic production of IGF-1.
Objectives
Our study aimed to evaluate gender-specific differences in patients diagnosed with acromegaly.
Material and Method
The study group included 23 acromegalic patients, aged between 20 and 72 years, 9 men (39.13%) and 14 women (60.85%). The mean age at diagnosis was 55 for females and 43.5 years for males. Data was collected retrospectively, including personal history, clinical examination, laboratory assessment, and magnetic resonance imaging results.
Results
In our cohort of patients, the female sex was predominant. Women were older than men at diagnosis ($P<0.05$) and had a longer estimated disease duration, an aspect that was not statistically significant. The duration of the disease was comparable between groups. GH and IGF-1 were similar between groups, as well as the size of the adenoma. Disease control was achieved in 78% of male and 71% of female patients. The prevalence of pituitary insufficiency was similar between groups. Hypertension was more frequent among women, while obesity and sleep apnea were diagnosed predominantly in men, but without statistical significance. Diabetes mellitus and malignancies were present only in women, but probably due to the small sample size, the results did not reach significance.
Conclusions
Disease control, GH, IGF-1, and disease duration were similar between females and males. Women were older at diagnosis and were more prone to develop DM and malignancies. Men were diagnosed more frequently with sleep apnea, these results are consistent with the fact that they were also more prone to developing obesity.

Apoplexy of microprolactinoma after cabergoline therapy: rare situation but big emergency

El Jadi Hamza[1] & Moustaghit Imane[2]
[1]Oued Eddahab Military Hospital, Endocrinology, Agadir, Morocco;[2]Oued Eddahab Military Hospital, Endocrinology, Agadir, Morocco

Summary
Pituitary apoplexy (PA) is a rare clinical situation caused by pituitary infarction with or without hemorrhage. Although it is usually spontaneous, dopaminergic agonists (DA) are known to be predisposing factors, particularly Bromocriptine, more rarely Cabergoline. We report the case of a 31 years old female patient, with no notable pathological history, consulted for headaches and menstrual irregularities. Pituitary hormone levels were normal except for hyperprolactinemia at 110 ng/ml (<25). MRI showed a pituitary microadenoma of 7x3 mm. Cabergoline was started at a dose of 0.5 mg per week, which brought the prolactin level down to the normal range (21 ng/ml). Five months later, the patient presented to the emergency room with a sudden headache and decreased visual acuity. The physical examination revealed a patient in good general conditions without shock, the ophthalmological examination showed bilateral papilledema and preserved visual acuity. The visual field showed bilateral scotomas and the brain MRI revealed a necrotic-hemorrhagic transformation of the adenoma with an empty sella turcica. The endocrine work-up did not reveal any hormonal dysfunction. The patient was put on high doses of corticosteroids. The evolution is marked by a clear improvement of the visual field and papillary oedema. PA is a rare situation. The management of apoplexy is multidisciplinary, with hospitalization in a neurosurgical or endocrinological setting in close proximity to a neurosurgical center recommended. Glucocorticoid treatment should be started immediately in case of (near constant) corticotropic insufficiency, hemodynamic instability and altered consciousness. Decompression surgery is indicated in cases of impaired consciousness, recent or worsening severe visual impairment. Isolated oculomotor damage may be an indication for surgery for some teams but not for others. Conservative treatment is considered under the cover of corticosteroid therapy and clinical and ophthalmological monitoring. It is indicated in cases of contraindication to surgery (when the benefit/risk balance is against surgery), stable or long-standing moderate visual disorders or isolated oculomotor paralysis. Often reported with Bromocriptine, PA can also occur with Cabergoline. Due to the high mortality and morbidity of apoplexy, it should be borne in mind that close monitoring is necessary when treatment with DA is prescribed and the patient should be informed of this risk. Although DA precipitate risk, treatment can be continued for hormonal and anti-tumor remission.

Gemelli IRCCS, Department of Life Sciences and Public Health, Section of Anatomic Pathology, Rome, Italy

Introduction
The Morris syndrome, is a rare X-linked disorder in which patients with XY chromosomal makeup (corresponding to a male genotype) develop female sexual characteristics. Acromegaly is a rare disease related to excessive production of growth hormone (GH) and insulin growth factor-I (IGF-I). Rarely, acromegaly was reported to be associated to a chromosomal microduplications of Xq26.3, responsible for early onset form of acro-gigantism. However, cases of acromegaly associated with Morris syndrome have never been documented in the literature.
Case-report
We present the case of a 49-year-old woman with Morris syndrome, diagnosed in 1992 and undergoing gonadectomy and hormone replacement therapy for about 15 years, who came to our attention in June 2022 after removal of a somatotropinoma. The diagnosis of acromegaly was suspected by finding typical facies and acral extremity growth, reported to have arisen from 10 years. The patient underwent mandibular reduction surgery and removal of tubular adenoma of the colon in 2010. In June 2021, the patient performed random GH, IGF-I and prolactin (PRL) dosages which was found to be altered (GH: 7.14 mg/l, IGF-I: 686 ng/mL, PRL: 17.9 ng/ml). The GH dosages after 75 grams oral glucose tolerance test showed a GH paradoxical response (60 minutes after glucose administration GH was 8.99 mg/l, after 120 minutes GH was 13.40 mg/l). A contrasted pituitary MRI showed the presence of an 8 mm intrasellar lesion. Therefore, a transsphenoidal resection of the pituitary tumor was conducted in September 2021. The histological examination proved the diagnosis of somatotropinoma, with diffuse positive immunohistochemistry for GH and weak and focal positive immunohistochemistry for prolactin, also expressing Pit-1, p53, SSTR2A, synaptophysin and CAM5.2 and with Ki-67 = 1%. The patient also reported in previous clinical history: multinodular thyroid goiter, primary hypothyroidism under treatment with levothyroxine, hypovitaminosis D under cholecalciferol replacement therapy, hypertension being treated with beta-blockers and thiazide diuretic, obesity (BMI 40). At the last follow-up at our center in June 2023, the patient presented in fair general clinical condition, with improvement of related acromegaly symptoms, normalized baseline GH (0.1 ng/ml) and IGF-I (84 ng/ml) values, and negative pituitary MRI for signs of

somatotropinoma recurrence. The clinical, laboratory and morphological picture documented remission from acromegaly.
Conclusions
Our clinical case describes for the first time to our knowledge the clinical association between Morris syndrome and acromegaly. Although this condition is rare, further genetic studies are needed to demonstrate a genetic association between these two conditions.

[1]Hedi Chaker University Hospital, Department of Endocrinology;[2]Center of Biotechnology of Sfax, Laboratory of Molecular and Cellular Screening Processes;[3]College of Sciences, University of Sharjah, Department of Applied Biology, United Arab Emirates

Introduction
The KISS1 gene codes for the G protein-coupled receptor 54 (KISS1R) and plays a crucial role in the regulation of reproduction and pubertal maturation. Mutations in the KISS1-R gene are extremely rare and usually implicated in isolated hypogonadotropic hypogonadism. Here, we report three cases of a familial mutation in the KISS1 gene responsible for combined hypopituitarism.
Observations
Three related patients (including two twins) from a first-degree consanguineous union presented with delayed puberty at the ages of 15 and 16, respectively. Clinical examination revealed growth retardation and the absence of pubertal development signs without anosmia. Exploration confirmed combined hypopituitarism in all three patients (complete growth hormone deficiency, gonadotropin deficiency, and corticotropin deficiency). Magnetic resonance imaging was normal for all patients. Genetic study showed a non-stop mutation c.1195T>C, p.X399R in the KISS1 gene.
Conclusion
This mutation was absent in 100 controls from the Tunisian population, as well as in all accessible international genomic databases, indicating a de novo character. These observations challenge the distinction between different forms of hypopituitarism, suggesting instead a phenotypic continuum and a multifaceted pathology.

Immunohistochemical staining patterns of non-functioning pituitary adenomas and presentation of secondary hormonal deficiencies

Alex Corriveau[1], Andrea Hebb[2], Lisa Tramble[3], David Clarke[2] & Syed Imran[4]
[1]Dalhousie University, Pathology;[2]Dalhousie University, Division of Neurosurgery, Canada;[3]Dalhousie University, Division of Endocrinology & Metabolism, Canada;[4]Dalhousie University, Halifax, NS, Division of Endocrinology & Metabolism, Canada

Introduction
Secondary hormonal deficiencies (SHD) are frequently observed in patients with pituitary adenomas. We previously reported that pituitary tumour clinical subtypes were associated with specific patterns of SHD, and nonfunctioning adenomas (NFAs) were more likely to present with multiple SHD. We extended our work to examine if the immunohistochemical staining patterns of NFAs impacted SHD.
Methods
All clinically NFAs surgically removed between November 2005 to December 2018 were identified through the Halifax Neuropituitary database. A total of 135 patients met the inclusion criteria and their pathology specimens were analyzed. NFAs were classified based on those without any hormonal staining or those staining with either/or growth hormone (GH), adrenocorticotropin (ACTH), thyroid stimulating hormone (TSH), luteinizing hormone (LH), follicle stimulating hormone (FSH) and prolactin (PRL). We reviewed their pattern of SHD at presentation.
Results
Of the 135 patients, 78 showed positive immunoreactivity to at least one of the above pituitary hormones while 57 showed no staining; 75 patients had SHD, while 60 patients had no evidence of SHD at presentation. As expected, macroadenomas were more likely to be associated with SHD than microadenomas ($P<0.001$). When comparing SHD patterns, tumors with and without any staining there were significant differences in the patterns of SHD regardless of tumour size ($P<0.01$). Patients with TSH staining tumors were overall more likely to experience SHD ($P<0.01$).
Conclusion
This novel study will allow us to understand the relationship between tumor pathology and SHD. The analyzed data suggests that SHD patterns vary based on the immunohistochemical profile of NFA.

Lymphocytic pituitary revealed by diabetes insipidus

Hana Charfi[1], Fatma Mnif[1], Dhoha Ben Salah[1], Mouna Elleuch[1], Mouna Mnif[1], Nadia Charfi[1], Faten Haj Kacem Akid[1], Mohamed Abid[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker Hospital, Sfax, Tunisia

Introduction
Lymphocytic hypophysitis (LH) is most likely of autoimmune origin, as it is associated with other autoimmune diseases in 20 to 25% of cases, with the most common being lymphocytic thyroiditis. It is common in young women in late pregnancy or postpartum. Diabetes insipidus (DI) occurs in approximately 35% of patients with LH. To link DI to LH, we investigated the clinical, biological, and radiological characteristics of patients with DI.
Patients and Methods
A retrospective and monocentric descriptive study conducted in the Endocrinology Department of Hedi Chaker University Hospital in Sfax over a 20-year period (2000-2020). We identified 44 cases of DI, examined the records, and selected 6 cases of DI secondary to LH.
Results
All our patients were female with an average age of 36.16 years [22-47]. The discovery circumstance was secondary polyuria and polydipsia (SPUPD) in all patients. Family autoimmunity (AI) was reported in 33.33% of cases. Personal AI was described in 50% of cases, with Hashimoto's thyroiditis in two patients. Water deprivation test was performed in all patients, except one who underwent an initial pituitary MRI, leading to the diagnosis of partial central diabetes insipidus (DIC) in 20% of cases and complete DIC in the remaining cases. Pituitary hypertrophy was described in 33.33% of patients, initially suggesting a diagnosis of granulomatosis, eliminated by the negativity of specific investigations.
Conclusion
Recognition of LH in the context of DI is crucial for prompt diagnosis and appropriate management, particularly given its potential autoimmune origin and frequent association with other autoimmune conditions. This insight can guide clinicians in refining diagnostic approaches and optimizing patient care for individuals presenting with DI.

Predictive factors determining adequate response during insulin tolerance test

Sahar Abidi[1], Nadia Khessairi[1], Sabrina Ayari[1], Kammoun Elyes[1], Ibtissem Oueslati[1] & Melika Chihaoui[1]
[1]Endocrinology department, Rabta Hospital, Tunis, Tunisia

Introduction
The insulin tolerance test (ITT) is the gold standard for hypothalamic-pituitray adrenal axis assessment. An adequate response of serum cortisol level above or equal to 18 µg/dl confirms the integrity of the adrenal axis. Otherwise, it confirms adrenal insufficiency (AI). The aim of our study was to investigate clinical and biological factors for the prediction of an adequate response during the ITT.
Methods
We conducted a cross-sectional descriptive study. It involved 100 patients with suspected AI. The ITT protocol consisted of blood samples for fasting blood glucose and baseline cortisol, followed by intravenous injection of rapid insulin at a dose of 0.1 to 0.2 IU/kg. A second sample was taken at the time of hypoglycemia, followed by blood samples every 10 minutes for 60 minutes after hypoglycemia. An adequate response was defined as a serum cortisol level above or equal to 18 µg/dl after a serum glucose level below 0.40 g/l.
Results
The mean age was 41.4 ± 15.12 years and the gender ratio (F/H) was 0.2. Forty-two patients (42%) had an adequate response and 58 patients (58%) had an inadequate response. There was no difference of the mean age between the two

groups ($P=0.94$). Anorexia and orthostatic hypotension were more frequent in patients with AI. ($P=0.028$; $P<10^{-3}$). Weight and BMI were comparable between the two groups. Fasting blood glucose and nadir blood glucose were comparable between the two groups (0.91 ± 0.14 g/l vs 0.92 ± 0.14 g/l; $P=0.91$) and (0.29 ± 0.01 g/l vs 0.29 ± 0.01 g/l; $P=0.84$). Basal cortisol level in the group with normal axis were significantly higher than in the AI group (11 ± 4.1 µg/dl vs 8.3 ± 2.4 µg/dl; $P<0.001$). A basal cortisol of 9.75 µg/dl had a sensitivity of 59% and a specificity of 73% to predict an adequate response. On the other hand, a cutoff point of 13.3 µg/dl had a sensitivity of 100% but a specificity of 26%.

Conclusions

Dynamic test is required to assess the integrity of the adrenal axis. Our study suggests that a basal cortisol of 9.75 µg/dl reliably predicts adequate cortisol response.

Giant pituitary adenomas: therapeutic and prognostic complexities

Hind Ouakrim[1,2], Salsabil Haouach[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]

[1]Chu Mohamed Vi Marrakesh - Drh, Marrakech, Morocco; [2]Chu Mohamed Vi Marrakesh - Drh, Marrakech

Introduction

Giant pituitary adenomas are defined as tumors with a largest diameter of ≥ 40 mm. They are characterized by high invasiveness, causing compression of adjacent structures and hormonal dysfunction. The aim of this case report is to highlight the diagnostic, therapeutic, and prognostic challenges associated with this rare entity.

Case report

A 35-year-old male, diagnosed with diabetes under insulin therapy, along with Hashimoto's thyroiditis managed with levothyroxine, presented urgently with a sudden onset of headache, vomiting, and a decline in bilateral visual acuity. Magnetic Resonance Imaging (MRI) of the head revealed a substantial 60x34 mm lesion in the sellar and suprasellar regions, causing compression of the optic pathways and V3, accompanied by active hydrocephalus. Laboratory investigations indicated gonadotropin deficiency, a slightly elevated prolactin level of 39.9 ng/mL, and cortisol at 15 µg/dl. Visual field examination revealed a complete loss of vision in both eyes. The patient underwent surgical removal of the cerebral lesion via a trans-sphenoidal approach. Histopathological examination identified a pituitary adenoma (PA) expressing growth hormone (GH), prolactin, and thyroid-stimulating hormone (TSH). Postoperatively, the patient developed diabetes insipidus and corticotrope deficiency. The patient is under hormonal medical treatment, including hydrocortisone (15 µg/day), levothyroxine (100 mg/day), desmopressin (60 µg, 2 tablets/day), and androtardyl. At the three-month follow-up, imaging revealed a sellar and suprasellar lesion involving both cavernous sinuses, measuring $44.3\times36\times36.4$ mm. Repeat surgery was indicated, with treatment plans incorporating dostinex and somatuline 120 mg LP. Unfortunately, the patient died immediately post-operatively.

Discussion

Giant pituitary adenomas are uncommon tumors, with a prevalence estimated at 6-10% of all pituitary adenomas. They present a therapeutic challenge due to their size, invasiveness, and frequent extrasellar extensions. The initial presentation is determined by the lesion's mass effect and hormonal dysfunction. Surgery remains the treatment of choice, although achieving complete tumor excision in such large tumors is challenging. Histopathological study with immunostaining is crucial to confirm the diagnosis and define medical therapy. The literature reports high mortality rates following excision of giant pituitary adenomas.

Conclusion

Giant pituitary adenomas represent a challenge in clinical endocrinology, requiring multidisciplinary management in diagnosis, therapeutic management, and long-term follow-up.

An artificial intelligence system for estimating the improvement of clinical and paraclinical parameters after therapy in pituitary tumors

Ana-Silvia Corlan[1], Babuc Diogen[2], Costi Flavia[2], Mihaela Vlad[1], Melania Balas[1], Ioana Golu[1], Daniela-Georgiana Amzar[1] & Onchis Darian[2]

[1]University of Medicine and Pharmacy Timisoara, Endocrinology, Timisoara, Romania; [2]West University of Timisoara, Computer Science, Timisoara, Romania

Pituitary tumors usually have an excellent prognosis after targeted treatment involving surgery, radiotherapy and medical therapy. Metabolic abnormalities are encountered in 22.3-52.5% of pituitary adenoma patients and are correlated with disease progression and prognosis. Therefore, in this study, we propose an artificial intelligence system for estimating the improvement of clinical and paraclinical parameters for patients undergoing therapy. The patient cohort is made out of 107 patients with a panel of clinical and paraclinical parameters recorded before (for 45 patients) and after therapy (for 62 patients). We first made a classification of tumor activity in case of functioning pituitary tumors. Secondly, we made a classification, distinguishing between symptomatic and asymptomatic patients for non-functioning pituitary adenomas. We trained a supervised deep neural network having as input the variable parameters of remaining tumor size after therapy, total volume and the clinical (systolic, diastolic blood pressure and body mass index) and paraclinical parameters (fasting plasma glucose, total cholesterol, LDL-cholesterol, HDL-cholesterol, triglycerides, uric acid, aspartate aminotransferase, alanine aminotransferase and C-reactive protein serum levels), and the fixed parameter treatment. Our target was the estimation of a cut-off value for symptomatic pituitary tumors. The versatile artificial intelligence system reached an accuracy of 85.71% for the patients after treatment, giving to the patient and the attending physician, valuable information regarding the prospective success of the treatment.

A pituitary metastasis from occult neuroendocrine carcinoma

Luigi Demarchis[1], Sabrina Chiloiro[2], Pier Paolo Mattogno[3], Antonella Giampietro[2], Maria Grazia Maratta[4], Liverana Lauretti[3], Giovanni Schinzari[4], Rosalinda Calandrelli[5], Simona Gaudino[5], Guido Rindi[6], Alessandro Olivi[3], Giampaolo Tortora[4], Francesco Doglietto[3], Laura De Marinis[2], Alfredo Pontecorvi[2], Antonio Bianchi[2] & Marco Gessi[6]

[1]Fondazione Policlinico Universitario A. Gemelli IRCCS, Pituitary United; [2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Pituitary United; [3]Fondazione Policlinico Universitario A. Gemelli IRCCS, Neurosurgery; [4]Fondazione Policlinico Universitario A. Gemelli IRCCS, Medical Oncology; [5]Fondazione Policlinico Universitario A. Gemelli IRCCS, Radiology; [6]Fondazione Policlinico Universitario A. Gemelli IRCCS, Anatomic Pathology Section

Background

Pituitary metastases are rare findings and account for 1% of surgically treated pituitary lesions. Despite the low incidence, given the frequent compression exerted on surrounding structures, pituitary metastases can present with major symptoms such as headache, visual disturbances and visual field. Ultimately, damage to the pituitary gland may be associated with electrolyte disturbances.

Clinical case

A 57-year-old male patient was admitted to our hospital for ptosis, lacrimation and diplopia, previously treated with corticosteroids without benefit. A brain contrasted MRI examination showed a sellar lesion, in contact with the optic chiasma, infiltrating the right cavernous sinus, the clivus and the clinoid. Biochemical and hormone examinations showed slight hyperprolactinemia (47 ng/ml) in absence of electrolyte disturbances and deficits of pituitary hormones. The visual field examination detected a left superior-temporal campimetric deficit. Pre-surgery chest X-ray was negative. A sub-total transsphenoidal excision of the lesion was conducted and histologic examination identified a 'neoplasm with well-differentiated neuroendocrine morphology, relatively monomorphic round cells, intense expression of synaptophysin, chromogranin, 2A-somatostatin receptor, insulinoma-associated protein-1 (INSM1), thyroid transcription factor-1 (TTF1). Neoplastic cells were Pit1-, Tpit-, GATA3-, SF1-, CDX2-, ISLET1-, CAM5.2- and AE1/AE- negative. Proliferative index (MIB1) was 5-7%. Comment: localization of a neuroendocrine tumor (NET). Immunohistochemical pattern suggests a pulmonary origin (possible atypical carcinoid, NET G2)'. The patient underwent a 68-Gallium-DOTA-TOC Positron Emission Tomography/-computed tomography (PET-CT) showed the residual sellar tumor with increased SSTR expression. A contrasted total body CT confirmed the residual neoplasia of maximum diameter of 24 millimeters in the right lateral and posterior sellar region, eroding the lamina quadrilateralis and the ipsilateral posterior clinoid process, extending extra compartmentally into the cavernous sinus, encompassing the intracranial portion at the internal carotid artery. Finally, the patient underwent 18-F-fluorodeoxyglucos PET-CT, which detected a more functionally active area in the right parasellar region. All radiological investigations did not reveal the primary tumour and other metastasis. Therefore, according to NET grading, non-detection of primary tumor and persistence of local disease, it is decided to treat the patient with somatostatin receptor ligand and to re-evaluate the status of disease, also considering the possibility of radiotherapy on the residual tumor.

Conclusions

Our case is intended to emphasize the importance of considering the pituitary not only as a site of primary tumor but also as a possible site of metastasis, mainly from

breast, lung, and colon cancers, without excluding firstly possible rarer primaries as occult or other side of NETs.

Clinical presentation and MRI findings in patients with hypophysitis - a single center experience

Izabella Czajka-Oraniec[1], Karolina Cylke-Falkowska[1], Maria Stelmachowska-Banas[1] & Wojciech Zgliczyński[1]
[1]Centre of Postgraduate Medical Education

Introduction
Hypophysitis is a very rare and heterogenous condition characterized by pituitary inflammation that leads to hypopituitarism, diabetes insipidus and symptoms associated with mass effect such as headaches and visual disturbances. Studies on large groups of patients with hypophysitis are scarce. The aim: We performed an analysis of clinical symptoms, pituitary function, and management of patients diagnosed with hypophysitis.
Material and Methods
This was a retrospective single-centre study of 30 consecutive patients diagnosed with hypophysitis in the Department of Endocrinology at Bielanski Hospital in Warsaw for the last 10 years (between 2014 and 2023). We evaluated medical records of the patients, hormonal and MRI results, and treatment outcomes.
Results
Patients with hypophysitis represented 0.38% of all patients admitted to the Department during this period. Female gender was predominant (78.1%) but the association with pregnancy occurred only in one case. The mean age at diagnosis was 41.9 ± 15.5 years and ranged from 15 to 71 years. The most common symptoms at diagnosis were headache (43.8%) and diabetes insipidus (56.3%). The gonadotropic, thyrotropic and corticotropic axis were affected in 65.6%, 56.3% and 59.4%, respectively. The most typical MRI findings were infundibular thickening (65.6%), enlarged pituitary gland (56.6%) and the lack of typical posterior pituitary signal in T1-weighted images (25.0%). Diagnosis of hypophysitis was mostly based on clinical presentation, laboratory and imaging results, and the response to glucocorticoid treatment. Histopathological diagnosis was confirmed in 4 patients (13.3%). There were 6 cases of secondary hypophysitis - 2 sarcoidosis, 1 Langerhans's cell histiocytosis and 3 induced by immune checkpoint inhibitors. The remaining cases were diagnosed as primary hypophysitis. Nine patients (30.0%) had positive anti-thyroid antibodies and the autoimmune thyroid disease was the most common autoimmune disease in a family history. Twelve patients (37.5%) received high-dose glucocorticosteroid therapy with prompt improvement of symptoms. However the relapse of the disease was observed in 4 of them. Two patients with a recurrent hypophysitis received a second line treatment with azathioprine and mycophenolate mofetil and they have remained in remission.
Conclusions
The diagnosis of hypophysitis is commonly made based on the clinical, radiological, and hormonal picture. It typically occurs in middle-aged women but pregnancy does not seem to be a risk factor. Our results confirmed that the gonadotropic axis was the most frequently affected. Treatment with high-dose glucocorticosteroids had a beneficial effect in terms of at least partial relief of symptoms, especially headaches.

EP701

TSH and GH co-secreting macroadenoma: a case report

Meriem Adel[1], Radhouen Gharbi[2], Emna Naccache[1], Manel Jemel[1], Hajer Kandara[1] & Ines Kammoun[1]
[1]National institute of nutrition and food technology, Endocrinology, Tunis;[2]Tunisia, Endocrinology, Tunis

Introduction
Thyroid-stimulating hormone-secreting pituitary adenomas (TSH-omas) are infrequent, constituting 0.5%-3.0% of pituitary adenomas (PAs). Additionally, the co-secretion of growth hormone (GH) and TSH in PAs is notably rare, accounting for only 16% to 19.7% of TSH-producing PAs. Limited cases have been reported.
Observation
We report the case of a 59-year-old woman who presented with asthenia and weight loss; she was referred to the endocrinology department for further investigation as a dysmorphic syndrome suggestive of acromegaly was noted. She had no previous medical or surgical history. On physical examination she has an enlargement of hands and feet, enlarged tongue and thickened lips, enlarged and protruding mandible. Blood pressure was 130/80 and pulse was 65 bpm. Laboratory results showed: IGF-1, 397.9 ng/ml; non-suppressible GH levels after oral glucose loading; free thyroxine (FT4), 61.47 pmol/l (12-22 pmol/l); TSH, 0.41 µU/ml. Adrenocorticotropic hormone (ACTH), <1.5 ng/l; cortisol 918.4 nmol/l; follicle stimulating hormone (FSH), 22.72 mU/l; PRL, 116 mUI/l; estradiol, 26 pg/ml; Alpha subunit was 0,87 mUI/ml with elevated α-TSH/TSH molar ratio at 3.48. Magnetic resonance imaging showed a macroadenoma measuring 10 mm × 11 mm. The patient was prescribed 30 mg of methimazole. Follow-up thyroid assessments one month later indicated a TSH level of 0.19 mIU/ml and an FT4 level of 44.07 pmol/l. After restoring FT4 to normal levels, a transsphenoidal excision surgery for the pituitary adenoma is planned.
Conclusion
This is a rare case of a pituitary macroadenoma producing both GH and TSH. This may be due to the fact that Pit-1-producing cells have been shown to be the source of both somatotrophs and thyrotrophs during differentiation into mature pituitary cells. Early diagnosis, multidisciplinary management and vigilant surveillance are essential to improve the prognosis of this co-secreting PAs.

Long-term exposure of corticotroph pituitary tumor cells to glucocorticoid results in resistance to its anti-proliferative effect

Ticiana Silva[1], Fadime Dogan[2], Anand Iyer[2], Peter van Koetsveld[2], Richard Feelders[2] & Leo Hofland[2]
[1]Erasmus MC Cancer Institute, Erasmus MCy; [2]Erasmus Mc, Department of Internal Medicine, Division of Endocrinology Rotterdam, Netherlands

Background
Cortisol has a suppressive effect on corticotroph proliferation. In Cushing's disease (CD), the relative resistance to glucocorticoid (GC) action may favor corticotroph tumor formation and autonomous ACTH secretion.
Objective
To analyze the consequences of long-term GC exposure on corticotroph tumor cell proliferation and to evaluate the modification of gene expression attributable to prolonged GC treatment.
Methods
Mouse AtT20 corticotroph pituitary tumor cells were used. Cells were treated continuously with dexamethasone (DEX) for 10-weeks at a dose of 10nM which is supraphysiological and achievable in the case of CD. Subsequently, cells were cultured in DEX-free medium for up to 5-weeks (washout period). AtT20 cells cultured only in DEX-free medium served as control. After 1- and 5-week of washout, dose-response experiments were performed to determine cell sensitivity to DEX. Quantitative PCR was performed on control cells and cells previously treated with DEX at 1- and 5-week washout periods (DEX-treated cells). mRNA analysis was performed at 72-hr of DEX (100 nM).
Results
DEX inhibited the proliferation of control AtT20 cells in a dose-dependent manner. In long-term DEX-treated cells, DEX failed to inhibit cell growth despite 1- and 5-week washout period. No differences were observed between control and DEX-treated cells regarding DEX-induced effects on mRNA expression of the glucocorticoid receptor, *Pomc* and *Fkbp5*. However, DEX induced expression of the proapoptotic *Bid* gene in control cells but had no effect in DEX-treated cells. DEX did not affect *Bad* gene expression in control cells but suppressed its expression in DEX-treated cells. For cell cycle related genes, DEX induced a strong upregulation of *Cdkn1a*, a cell cycle inhibitory gene, in control cells, whereas this induction was lower in DEX-treated cells.
Conclusion
Long-term treatment of corticotroph tumor cells with GC results in cells resistant to the growth inhibition by GC, despite an unchanged sensitivity of genes directly related to GR activation indicating differential effects on (long-term) gene expression. Continued exposure of GC may thus superimpose adaptive changes, in which acute GC challenge elicit a different pattern of gene expression less committed to cell growth inhibition, such as lower expression of proapoptotic genes and less induction of the cell cycle inhibitor *CDKN1a*.

EP706

Historic unveiling; ground breaking encounter of non-functioning pituitary macroadenoma coexisting with myasthenia gravis- debut case report

Umer Qazi[1] & Molly Scott[1]
[1]Watford, Diabetes, Watford, United Kingdom

Background
The correlation linking Myasthenia Gravis (MG) and pituitary adenomas is exceedingly uncommon. Our thorough investigation of medical literature uncovered merely eight documented cases showcasing this association. Notably, five of these cases specifically involved adenomas that secreted prolactin[1]. Two instances implicated a non-functional pituitary adenoma in this rare association[2]. Solely one case was identified involving a growth hormone (GH)-secreting adenoma in this context[3]. So, to our knowledge, this marks the inaugural documentation of a non-secreting adenoma detected in a patient diagnosed with myasthenia.
Case detail
A 72 years of age gentleman, Mr X, was admitted to the hospital on 8/11/23 due to eye symptoms and was found to have both a pituitary macroadenoma and myasthenia gravis. He had a medical history including retinopathy, cataract surgery, YLC procedure, hypertension, type 2 diabetes, prostate cancer, and bowel cancer. Over two months, he experienced double vision and eyelid drooping, worsening by the end of the day and more pronounced in the left eye. Additionally, he reported dull eye discomfort intermittently. Mr X also had new-onset breathlessness and fatigue for about three weeks, worse with exertion and at day's end. He felt more tired than usual but had no issues with swallowing, breathing, or speech. Physical examination revealed bilateral ptosis with equally sized pupils reacting to light. An incidental finding of a $13\times12\times16$ pituitary macroadenoma was discovered on MRI orbit without compressing the optic chiasm or optic nerve abnormalities. His CT head (19/10/23) showed no significant intracranial issues, and subsequent imaging ruled out thymus malignancy. Blood tests indicated acetylcholine receptor antibodies at a level of 292, TSH receptor antibodies <0.3, TPO <4, random cortisol 775, and ACTH 54, Prolactin of 158 mu/l (normal), growth hormone level of 0.74 mg/l (Normal), IGF-1 is 20.9 nmol/l (Normal) and with normal FSH. LH and testosterone levels. He commenced IVIG treatment followed by an up-titrating course of prednisolone under neurology guidance, monitoring CBGs. He will receive continued care from neurology and endocrine clinics, with a follow-up contrast MRI scheduled in six months.
Conclusion
In conclusion, the simultaneous presentation of myasthenia gravis and pituitary macroadenomas represents an exceedingly rare occurrence. This unique co-occurrence underscores the complexity and diversity of potential medical conditions and highlights the importance of comprehensive assessment and collaborative multidisciplinary care for such exceptional cases. Continued research and clinical observation are essential to better understand the underlying mechanisms linking these two distinct conditions when they occur together

A rare cause of gonadotropic insufficiency

Raida Ben Salah[1], Seddiqa Somauroo[2], Faten Hadjkacem[2], Mohamed Abid[2] & Zouhir Bahloul[1]
[1]Sfax University Internal Medicine; [2]Sfax University Endocrinology

Introduction
The causes of gonadotropic insufficiency are many and varied. Pituitary lymphomas are a rare and difficult-to-diagnose cause.
Case report
We report the case of a 30-year-old female patient who was admitted to the internal medicine department for an altered general condition with febrile headache. She reported secondary amenorrhea evolving for three months. The pregnancy test was negative. On physical examination, the patient was cachectic and pale. She had ptosis of the right eye, associated with extrinsic nerve III paralysis and anesthesia of the right hemiface. Specialized biology of the hypothalamic-pituitary axis showed gonadotropic insufficiency, with follicle-stimulating hormone at 1.2 mIU/l (1.5-2.4) and luteinizing hormone below 0.1 mIU/l (1.7-8.6), with moderate hyperprolactinemia at 26 ng/ml ($n<15$). The corticotropic, thyrotropic and somatotropic axes were normal. Pituitary MRI revealed a voluminous 21 mm long axis T1, T2 iso-signal sellar process with heterogeneous enhancement after gadolinium injection associated with diffuse pachymeningeal enhancement. Abdominal CT showed infiltrative pancreatic, lymph node and bone involvement. A diagnosis of lymphoblastic B lymphoma was made on peritoneal CT biopsy with multiple localizations: abdominal, bone and pituitary. The patient was treated with chemotherapy.
Conclusions
Lymphomas of the pituitary stem are extremely rare tumours, with symptoms dominated by headache, asthenia and diplopia. Imaging can determine whether this thickening is isolated or associated with other lesions, which are more easily accessible to biopsy.

Panhypopituitarism revealing pituitary tuberculosis: a case report

Redhouane Longo[1], Mourad Benrabah[2], Abdelkader Yahi[3], Benabdelatif Katia[3] & Ould Kablia Samia[3]
[1]Endocrinology department, Regional University Military Hospital of Oran, Algeria;[2]Nuclear Medicine Department, Regional University Military Hospital of Oran, Algeria;[3]Endocrinology Department, Central Military Hospital, Algiers, Algeria

Introduction
Tuberculosis is a serious disease which is on the increase worldwide, particularly in poor and developing countries, killing 3.000.000 people every year. Preferential localization is lungs, kidneys and the bones. Rare at the brain, it's exceptional at the pituitary gland. Diagnosis is usually very difficult, even simulate a pituitary adenoma, thus imposing a surgical treatment, and it is the pathologist who will rectify the diagnosis.
Observation
This is a 23-year-old patient admitted with anterior pituitary insufficiency with palpebral ptosis and polyuropolydypsia syndrome. Patient had a history of tuberculous meningoencephalitis for 05 months still under treatment. Endocrine assessment revealed global anterior pituitary insufficiency with hyperprolactinemia, associated with post pituitary insufficiency. Hypothalamohypophyseal magnetic resonance imaging revealed a suprasellar collection centred on the pituitary stalk measuring $10\times11\times18$ mm in diameter with a liquid signal. Patient was put on hormone replacement therapy, which is currently being monitored.
Discussion
Pituitary tuberculosis remains an exceptional pathology, frequency is difficult to determine because only a few rare sporadic cases have been published in the literature. Clinical symptomatology mimics that of a non-secreting pituitary adenoma. Damage to the cavernous sinus is very frequently observed. Diagnosis is difficult when a late complication of a primary tuberculosis infection that goes unnoticed, less after tuberculosis meningitis.
Conclusion
Common challenge for clinician and radiologist is to determine which patients are likely to have a tuberculoma, diagnosis must be rapid, given the possibility of cure through early and well-conducted medical treatment.

Rheumatological diseases and acromegaly: a clinical case

Margarita Perepelova[1], Larisa Dzeranova[1], Taras Panevin[1], Elena Przhiyalkovskaya[1], Ekaterina Pigarova[1], Ekaterina Troshina[1] & Evgeny Zotkin[1]
[1]Endocrinology Research Centre

Background
Acromegaly is a chronic endocrine disease characterized by excessive secretion of somatotropic hormone (GH), which in turn leads to increased secretion of insulin-like growth factor 1 (IGF-1) in the liver. Many cells in the body are targets for these hormones. Excess of GH, in the vast majority of cases caused by hormone-producing pituitary adenoma, and IGF-1 leads to cellular and tissue growth of practically all organs and systems, including the bone and joint apparatus.
Case presentation
Patient A., 56 years old, since 2021 was observed for diabetes mellitus by an endocrinologist, subsequently the doctor paid attention to the enlargement of feet, joint pains. Examinations showed GH, IGF-1 elevation, and pituitary adenoma was visualized on MRI which led to diagnosis of acromegaly. In March 2023 a transnasal adenomectomy was performed. A dynamic examination after 6 months confirmed the absence of remission of acromegaly - IGF-1 498.5 ng/ml (82-283), and therefore therapy with octreotide 20 mg once every 28 days was initiated. During the examination, attention was drawn to complaints of pain in large joints, according to the results of a blood test: rheumatoid factor 37.7 IU/ml (0-30),

antistreptolysin O 50 IU/ml (0-200), C-reactive protein 1.5 mg/l (0.1-5). Consulted with a rheumatologist, taking into account the clinical picture (Raynaud's phenomenon, swelling of the hands, arthritis, arthralgia and myalgia) and laboratory and instrumental examination (immunological disorders, primary muscular process without exacerbation according to ENMG, synovitis according to ultrasound of the hands), the diagnosis was verified - mixed connective tissue disease tissues: arthritis, arthralgia, proximal muscle weakness, swelling of the hands, Raynaud's phenomenon, Gottron's papules, immunological disorders (antinuclear factor 1/2560, AT to RNP-70 >300.0, rheumatoid factor 85.0). Due to the presence of articular syndrome, methotrexate 15 mg/week and methylprednisolone 8 mg/day were initiated. During treatment, the patient noted a significant decrease in joint pain.

Conclusions

Thus, the presented clinical case emphasizes the importance of differential diagnosis of articular syndrome in acromegaly at the initial stage, since the identification of an immunoinflammatory rheumatic disease requires a completely different tactic that helps improve the patient's well-being and relieve pain. Particular attention should be paid to patients who continue to have joint pain after achieving biochemical remission of acromegaly. In this regard, it is necessary not only to carry out a differential diagnosis of acromegalic arthropathy and rheumatological diseases, but also to provide multidisciplinary monitoring, in particular by a rheumatologist and an endocrinologist.

Challenges in diagnosis and management of silent corticotroph adenomas: insights from three case studies and literature review

Xinyi Zhao[1,2], Zhenyi Li[1] & Chun Wang[1]
[1]West China Hospital, Sichuan University Department of Endocrinology and Metabolism, Chengdu, China; [2]Chengdu First People's Hospital, Department of Endocrinology and Metabolism, Chengdu, China

Silent Corticotroph Adenomas (SCAs) are a type of pituitary tumor that is discovered without obvious clinical symptoms. SCAs are considered to be one of the five "high-risk" tumors due to their aggressive behavior, characterized by high levels of proliferation, rapid progression, and recurrence. Unlike functional corticotropin adenomas, SCAs do not exhibit any clinical or biochemical signs of hypercortisolemia. When the tumor is detected, it often exhibits invasive growth and poses a challenge for complete surgical excision. Positive immunoreactivity for ACTH or/and T-PIT in the pathological examination of the resected tumor after surgery may be the only evidence for the diagnosis of SCAs. The introduction of pituitary-restricted transcription factor (T-PIT) has enhanced the diagnostic precision of SCAs. Even cell lineage-specific pituitary transcription factors are the only diagnostic basis, as shown in case 3, ACTH expression is negative and finally diagnosed by positive T-PIT expression. Currently, the management of intractable SCAs remains an active subject of investigation. This article discusses three clinical cases and conducts a literature review to underscore the significance of timely radiotherapy after surgical intervention for residual or recurrent tumors. Therefore, our patients in this article received adjuvant radiotherapy after surgery. Unfortunately, the patient of case 1 could not be relieved even after surgery and twice gamma knife treatment and required a second operation. Nevertheless, the prognosis of case 3 was better than that of the first two patients after radiotherapy because early intervention was determined once diagnosis of SCA was confirmed. The management of refractory SCAs remains an area of ongoing exploration. Aggressive macroadenomas usually have low expression of O6 -methylguanine-DNA methyltransferase in Cushing's Disease. Therefore, temozolomide (TMZ) may be a novel therapeutic option to treat invasive pituitary tumors. The European Society of Endocrinology has adopted TMZ as the primary therapy for invasive pituitary tumors that have not responded to conventional treatment. In case 1, there was no significant tumor growth after TZM treatment. This article underscores the potential of TMZ as an alternative in cases resistant to conventional therapies.

Pituitary stalk interruption syndrome: a case report

Redhouane Longo[1], Mourad Benrabah[2], Benabdelatif Katia[3], Abdelkader Yahi[3] & Ould Kablia Samia[3]
[1]Endocrinology Department, Regional University Militar, Hospital of Oran, Algeria; [2]Nuclear Medicine Department, Regional University Militar, Hospital of Oran, Algeria; [3]Endocrinology Department, Central Militar, Hospital, Algiers, Algeria

Introduction

Pituitary stalk interruption syndrome is a congenital anomaly of the pituitary gland responsible for GH deficiency or global pituitary insufficiency, characterized by abnormalities visible on Magnetic Resonance Imaging (MRI) associating a thin or interrupted pituitary stalk, ectopic posterior pituitary, and hypoplastic anterior pituitary. Mutations in the HESX1 transcription factor or the LHX4 gene may be the cause of this anomaly, but a prenatal origin cannot be ruled out. This syndrome is often revealed during the neonatal period and childhood, but sometimes the symptoms can be overlooked and the diagnosis will therefore be delayed. We report a case of this syndrome diagnosed at a late stage.

Observation

17-year-old patient admitted for failure to thrive and delayed puberty. Clinical examination reveals a harmonious dwarfism, a height of 156 cm (−2 standard deviation), a weight of 56 kg, the patient is classified G1P1 according to the Tanner classification, and the bone age was 13 years according to the Atlas of Greulich and Pyle. Hormonal assessment reveals a complete GH deficiency (following an insulin hypoglycaemia test), associated with hypogonadotropic hypogonadism. There was no corticotropic or thyrotropic deficit. Hypothalamohypophyseal MRI reveals a pituitary stalk interruption syndrome with ectopic posterior pituitary. Scrotal ultrasound concludes bilateral testicular hypotrophy. The patient is currently undergoing growth hormone replacement and regular monitoring.

Discussion

Pituitary stalk interruption syndrome is defined by morphological abnormalities on MRI: Pituitary stalk not visible, pituitary hypoplasia and ectopic post-pituitary. Stature prognosis remains pejorative if the diagnosis is late, hence the need for early detection of staturo-puberty delay.

Conclusion

Pituitary stalk interruption syndrome is a rare congenital malformation that must be considered in the presence of combined or isolated hypopituitarism. MRI is currently the most effective means of imaging for the diagnosis of this malformation.

Deep vein thrombosis unmasking the diagnosis of Sheehan syndrome

Rada Sparavalo[1], Sanja Borozan[2] & Sanja Vrbica[3]
[1]General Hospital, Internal medicine, Department of Endocrinology, Endocrinology, Nikšić, Montenegro;[2]Clinical Centre of Montenegro, Endocrinology, Podgorica, Montenegro;[3]General Hospital Nikšić, Radiology, Nikšić, Montenegro

Sheehan syndrome (SS) caused by postpartum hemorrhage leads to varying degrees of pituitary insufficiency. With improved obstetrical care, ischemic pituitary necrosis is less common and, as a consequence, most cases of SS are being overlooked and diagnosis is delayed for years due to its nonspecific signs and symptoms. Data regarding the relationship between hypopituitarism and increased risk of venous thrombosis are inconsistent and need to be elucidated further. A 41-years-old woman presented with swollen leg and profound fatigue. Venous doppler revealed left crural deep vein thrombosis and the treatment with anticoagulants was started. Initial laboratory analysis suggested hypothyroidism with TSH 5.76 IU/ml, free T4 <5.15 ng/dl, free T3 <2.30 ng/dl with negative thyroid-specific antibodies so the patient was placed on levothyroxine (100 mg daily) and referred to endocrinologist. Further evaluation was obtained two months after and revealed the presence of iatrogenic hyperthyroidism (TSH 0.10 IU/ml, free T4 19.44 ng/dl) together with secondary adrenal insufficiency and growth hormone deficiency (GH <0.1 ng/ml). Endocrinology review showed a past history of postpartum hemorrhage after third delivery 6 years ago. Pituitary magnetic resonance imaging (MRI) revealed an empty sella. A diagnosis of SS was made and patient placed on oral glucocorticoid therapy together with modified dose of levothyroxine. A typical presentation of SS include a long period of time between the puerperal hemorrhage and the diagnosis of hypopituitarism. A detailed obstetrical history is needed in order to recognize the pattern and avoid the initiation of thyroid hormone replacement before complete evaluation of pituitary function.

Acromegaly and adrenal myelolipoma - Is there a connection?

João Menino[1], Inês Meira[1], Sara Ribeiro[1], Juliana Gonçalves[1], Jorge Pedro[1] & Joana Queirós[1]
[1]São João Universitary Hospital Center, Endocrinology Department, Porto, Portugal

Introduction
Adrenal myelolipomas are rare benign tumors. There has been an association of adrenal myelolipomas with other pathologies with hormonal hypersecretion, such as hypersecretion of adrenocortical hormone (ACTH) in Cushing's Disease and Congenital adrenal hyperplasia. We report a case of acromegaly with co-existent large adrenal myelolipoma.
Case Report
A 48-year-old caucasian male was referred to our Endocrinology consultation for an adrenal incidentaloma. His past medical history was relevant for dyslipidemia, with no medication. He was asymptomatic. On examination, his blood pressure was within normal range and there were no alterations compatible with acromegaly. His previous CT scans revealed a mass in the right adrenal gland that had grown from 40×44 mm to 59×51 mm in 2 years. An adrenal CT scan in our institution described the mass as a myelolipoma with 50×65×69 mm. The analytical studies revealed a negative 1 mg dexamethasone suppression test (0.6 µcg/dl), no elevation in 24 h urinary metanephrines (64.72 µcg/24 h) or normetanephrines (269.98 µcg/24 h), and a normal ionogram (Na 142 mEq/l, K 4.0 mEq/l, Cl 104 mEq/l) with no hypertension history. During the follow-up, the patient suffered a cranial trauma, and a pituitary adenoma was identified in a CT scan. Further analytical studies revealed an elevated IGF-1 (387 ng/ml), normal prolactin levels (4.5ng/ml), and normal thyroid function (TSH 0.92 µUI/ml, fT4 1.03 ng/dl). A pituitary MRI confirmed the presence of an adenoma with 10mm. An Oral glucose tolerance test confirmed the diagnosis of acromegaly, with a nadir of 1.39 ng/ml. The patient is currently awaiting pituitary surgery.
Conclusion
There is evidence that acromegaly is associated with increased incidence of several types of tumors, including colon polyps and thyroid nodules. To our knowledge, there are no reported cases in literature of large adrenal myelolipomas in patients with acromegaly. Our patient presented with a large myelolipoma, with no known etiology, and further studies and case reports are needed to ascertain their correlation.

Acromegaly and multiple myeloma: a case report

Ruxandra Paula Ristea[1], Teodora Puşcaş[1], Claudiu Zaharia[2], Serghei Tutovan[1] & Mihaela Stanciu[1,2]
[1]County Clinical Emergency Hospital of Sibiu, Endocrinology, Sibiu, Romania;[2]Lucian Blaga' University of Sibiu, Faculty of Medicine, Endocrinology

Introduction
Acromegaly is a progressive disorder caused by excess growth hormone (GH), usually due to a GH-secreting pituitary adenoma, associated with an increased risk of cancer-related mortality. Insulin-like growth factor 1 (IGF-1) has been involved in tumor development by promoting cell proliferation and inhibiting apoptosis. Multiple myeloma (MM), a plasma cell neoplasm, has been suggested to have a potential link to IGF-1 in its pathogenesis.
Case report
This paper presents the case of a 51-year-old male diagnosed with acromegaly in 2018, with a pituitary macroadenoma (12/11/10 mm) that was surgically removed via a transsphenoidal approach. Postoperatively, the patient developed adrenal insufficiency and central hypothyroidism, necessitating corticosteroid and thyroid hormone substitution. Octreotide effectively controlled GH and IGF-1 levels until March 2022, when the treatment was switched to Lanreotide. Later, the patient experienced nonspecific thoracic pain, the thoracic radiography revealing a 7.3 cm mass in the right superior lateral-thoracic region. A thoracic MRI confirmed a 9 cm mass, later diagnosed as plasmacytoma following biopsy. Radiotherapy was initiated, and a bone marrow examination performed one month later revealed a cytological profile of a grade III A Durie Salmon multiple myeloma. The patient was treated with lenalidomide, low-dose dexamethasone, and bortezomib (VRd regimen) and was proposed for a bone marrow transplant.
Conclusions
Although acromegaly is associated with malignancy, its association with MM has not been thoroughly investigated. This case highlights the need for increased awareness of the potential association between these two conditions. Long-term surveillance and close monitoring of acromegaly patients are essential to detect and manage the development of secondary malignancies. This enables early intervention and improved patient outcomes, especially given the current lack of consensus on therapeutic guidelines and recommended prognosis for multiple myeloma coexisting with acromegaly.

A rare case of SIAD in unique association with the rare lesion of a pituicytoma

Sonia Kaniuka-Jakubowska[1], Maria Maksymowicz[2], Grzegorz Zielinski[3], Małgorzata Zdrojewska[4], Nicole Kaźmierczak[1], John Wass[4], Federico Roncaroli[5] & Renata Świątkowska-Stodulska[1]
[1]Facult, of Medicine, Medical University of Gdansky Department of Endocrinology and Internal Medicine, Gdansk, Poland; [2]Maria Sklodowska-Curie National Research Institute of Oncology Department of Cancer Pathomorphology Warsaw, Poland; [3]Militar, Institute of Medicine, Department of Neurosurgery Warsaw, Poland; [4]Oxford University Hospitals NHS Foundation Trust, Department of Endocrinology at the Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, United Kingdom; [5]Facult, of Biology Medicine and Health, University of Manchester, Division of Neuroscience, Manchester, United Kingdom

Introduction
AVP secretion disturbances in pituitary lesions usuall, present as AVP deficienc, due to compression of the posterior pituitary lobe. Excessive secretion of AVP (syndrome of inappropriate antidiuresis) (SIAD) is ver, uncommon in patients with pituitary tumor. A few cases of non-functionating adenoma, prolactinoma, and even pituitary apoplex, were described to present with SIAD. Pituicytoma is a rare tumor of the neurohypophysis. The, usuall, present with visual defects, hypopituitarism, headache, and fatigue. Rarel, the, are associated with Cushing's disease or acromegaly. We present a patient with pituicytoma with SIAD.
Case presentation
A 45-year-old female was admitted with hyponatremia. Low sodium levels were first noted six months before knee replacement surgery. There was no hyponatremia 2 years before, in random check. The patient onl, complained with muscle cramps. The Laboratory results were compatible with SIAD: hyponatremia, plasma hypoosmolality urine hyperosmolarity and increased urinar, sodium excretion, without an, features of adrenal, thyroid or renal disturbances. She underwent detailed screening for malignanc, and the onl, finding was pituitary mass. Pituitary MRI revealed a 6x9x13mm lesion in the left-lateral part of the pituitary with involvement of the pituitary stalk. The patient refused fluid restriction and insisted on surgical treatment. After surgery she presented with AVP deficienc, on graduall, decreasing doses of desmopressin. Histopathological results revealed pituicytoma.
Conclusion
To our knowledge, this is the first documented case of pituicytoma presenting with SIAD. SIAD associated with pituitary lesions is ver, uncommon. A common mechanism causing AVP oversecretion irrespective of the type of lesion is possible including AVP secretion b, the pituitary mass.

EP722

Pituitary apoplexy presenting with altered level of consciousness, in a normal pituitary gland

Eni Celo[1], Megi Lekbello[2], Erion Spaho[3], Bariola Duro[4], Marsida Kasa[3], Grisilda Gjana[3] & Eriselda Taulla[3]
[1]Trauma University Hospital, Albania;[2]Mother Theresa University Hospital; [3]Trauma University Hospital; [4]Public Medical Center Paskuqan, Paskuqan, Albania

Introduction
Pituitary apoplexy is a rare, potentially life-threatening syndrome caused by ischemic infarction or hemorrhage, generally into a pituitary tumor. The clinical manifestations of PA usually manifest suddenly and include headache, nausea/vomiting, altered awareness and visual abnormalities. Regarding endocrine deficiencies, signs and symptoms of cortisol deficiency are generally observed in the early stage after apoplexy onset, as occurred in our patient. Hypothyroidism, hypogonadism, and growth hormone deficiency are frequent and may occur progressively during weeks, months, or years. In cases with severe, visual or neurological manifestations, surgical decompression is indicated; patients with mild, stable clinical picture can be managed conservatively.
Case presentation
We describe the case of a 67-year-old man with spondylolisthesis L5-S1 who was admitted to Trauma University Hospital in preparation for a scheduled surgery. His medical history included type 2 Diabetes, arterial hypertension, dyslipidemia. In 2020 he was hospitalized with inferior paraplegia and his head CT was normal. He was dismissed from the hospital with some diagnosis including diabetic polyneuropathy and anxiety disorder. The patient appeared to be recovering well until two days later, when it was noticed that he was lethargic and disoriented. His examination resulted in low blood pressure 86/60 mmHg, regular pulse rate of 113 bpm. During the

neurological examination he was unresponsive of verbal stimulations, but responsive of dolent stimuli. His pupils were equal in size and both had normal direct and consensual responses to light. The neurologist recommended a head MRI in which resulted in pituitary apoplexy. In his blood work resulted glycemia – 68 mg/dl, normal BUN, sodium - 120 mmol/l (136-145), potassium – 4.5 mmol/l (3.5-5.1), TSH -1.6 mUI/ml (0.4-4), prolactin – 8.5 ng/ml (3.5-19.4), LH – 4.1 mUI/ml (1.6–15.2), FSH – 2.9 IU/ml (3- 8.1), ACTH – 5.5 pg/ml (6-50), cortisol – 1.8 mg/dl (3.7-19.4). Management included hemodynamic stabilization, correction of electrolyte disturbances and corticosteroid administration: intravenous hydrocortisone was administered with the dose of 100 mg every 8 hours for 24 hours, then transitioned to oral hydrocortisone 20 mg in the morning (08.00) and 10 mg at noon (16.00). After hydrocortisone admission the patient regained his normal mental status with no further episodes of confusion. On the ophthalmologic examination the patient had no visual deficits so a conservative approach was considered safe. After 6 days he was dismissed from the hospital on glucocorticoids replacement.

Discussion

This case illustrates the prompt and accurate diagnosis of pituitary apoplexy after a major surgery leading to optimal patient outcome.

EP724

Anterior pituitary insufficiency, diagnosis and etiology: about 43 cases

Zaynab Hifdi[1], Saloua Elamari[1], Soukaina Laidi[1] & Marouan Fatima[1]
[1]Cheikh Khalifa Bin Zayed Al Nahyan Hospital, Casablanca, Morocco

Introduction

Pituitary insufficiency results from the failure of the anterior pituitary gland to secrete hormones, and has many causes. Nonspecific clinical manifestations can delay the diagnosis. Our study aims to detail the clinical, biological, radiological, and etiological aspects of pituitary insufficiency, evaluate treatment and identify factors associated with complications.

Material and methods

This retrospective study includes patients over 18 years of age with biologically confirmed pituitary insufficiency. We describe in detail demographic, clinical, paraclinical, etiological and therapeutic aspects. An in-depth analysis identifies factors contributing to diagnostic delays and complications.

Results

The mean age of patients was 59 years, with a sex ratio (M/F) of 0.79. Pituitary insufficiency was often discovered by signs of hyposecretion (27.9%), complications such as pituitary apoplexy, hyponatremia and acute adrenal insufficiency (34.88%), or during a systematic work-up for pituitary adenoma (37.2%). Clinically, 74.4% showed signs of corticotropic insufficiency, 55.8% of gonadotropic insufficiency, and 27.9% of hypothyroidism. Hormonal investigations revealed corticotropic (88.4%), thyrotropic (62.8%), gonadotropic (55.8%), somatotropic (13.95%) and lactotropic (13.95%) deficiencies. Imaging showed abnormalities in 83.72% of cases, including macroadenoma (51.6%), craniopharyngioma (7.1%), inflammatory pathology (11.9%), Sheehan syndrome (7%), empty sella turcica (4.8%), and genetic pathology (9.5%). Iatrogenic, infectious and microadenoma causes have a prevalence of 2.4% each.

Conclusion

Our study highlights an increased prevalence of pituitary insufficiency in women. Vague clinical signs often lead to late diagnosis. A thorough diagnostic approach and individualized therapeutic management are crucial to optimize clinical outcomes in patients with pituitary insufficiency.

Inhabitual presentation of parathyroid adenoma

Amel Elkorbi[1], Nawres Bouaziz[1], Mahdi Ferjaoui[1], Rachida Bouatay[1], Naourez Kolsi[1], Harrathi Khaled[1] & Jamel Koubaa[1]
[1]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Introduction

Spontaneous extracapsular hemorrhage of a parathyroid adenoma causing cervico-mediastinal hematoma is a rare but life-threatening manifestation. Our objective is to present a rare case of cervico-thoracic hematoma secondary to a spontaneous rupture of a parathyroid adenoma and to specify its clinical, radiological, therapeutic and evolutionary features.

Case report

This is a 50-year-old woman with no significant pathological history who presented to the emergency department for cervico-thoracic ecchymotic lesions associated with upper dysphagia. History evoluted for five days. There was no context of trauma or anticoagulant treatment. The patient complained from generalized bone pain. Physical examination find no cervical mass. A cervico-thoracic scan was showed an extended retropharyngeal hematoma extended to the posterior mediastin associated with signs of compression. We noted also an inferior right retro-thyroid nodule. Parathormone levels was elevated PTH, malignant hypercalcemia and hypophosphoremia were also observed. The diagnosis of symptomatic primary hyperparathyroidism was concluded. Cervical ultrasound and MIBI scintigraphy confirmed the parathyroid nature of this nodule. A lower right parathyroidectomy was performed after correction of serum calcium. The evolution was marked by the normalization of the phosphocalcium balance and the absence of recurrence of the hematoma with a follow-up of one year.

Discussion/Conclusion

The parathyroid origin should be evoked in the presence of any spontaneous cervico-thoracic hematoma associated with compressive signs. The association, although rare, is still possible.

Development of transition readiness assessment questionnaire for patients with rare endocrine diseases

Savi Shishkov[1], Janeta Yaneva[1], Radina Dimitrova[1], Maria Zlateva[2], Mira Siderova[1] & Violeta Iotova[2]
[1]Medical University "Prof. Dr. Paraskev Stoyanov ", Second Department of Internal Medicine, Varna, Bulgaria; [2]Medical University "Prof. Dr. Paraskev Stoyanov", Department of Paediatrics, Varna, Bulgaria

Introduction

Transition readiness is important for adolescents with chronic diseases. Health deterioration in this age may have long-lasting negative effects. Concerning rare endocrine disease, proper knowledge of the condition and treatment is required for optimal disease management.

Aim

The aim of the current study was to develop transition readiness assessment questionnaire suitable for use in pediatric patients and young adults with chronic endocrine diseases.

Methods

A 16 item long questionnaire was developed with similar questions in two variants – one for self-assessment and the other for health care professional (HCP) assessment. In the self-assessment scale, the options were no/I don't know/yes respectively valued as 0/1/2 points. Depending on the level of knowledge each item in the HCP variant was marked with 0 to 2 points. In total, 32 points yielded a 100% score.

Results

The pediatric patients scored on average 54% in the HCP assessment scale compared to 65% for the adults. In 2/10 adult patients' the self-assessment and HCP assessment matched. In the rest (8/10) there was a large discrepancy between self and HCP assessment, with higher result in the latter. The two patients with matching results scored 100% indicating that well educated patients are also more self-responsible In all cases the transition readiness questionaries led to discussion with the patient and/or the parent. A second simplified version of the questionaries was developed that reflects the recommendations given by patients and HCPs. After applying corrections to the initial variant, the second version was evaluated as appropriate by the HCPs.

Conclusion

In the majority of patients HCP assessment scored superior compared to self-assessment tool. A second version of the questionnaire was developed for further testing and validation. Transition readiness assessment with tailored tools is useful in initiating discussions with the adult HCP. This facilitates further preparation for the transfer to adult-centered health care.

EP764

Reactional pituitary hyperplasia in a young turnerian girl

Rahal Amel[1]
[1]Bologhine Hospital, Endocrinology, Algiers, Algeria

Introduction

Pituitary hyperplasia, defined as an increase in the size of the pituitary gland, is rare in children; the main etiology is the onset of puberty. We report the case of a

15-year-old girl with Growth retardation and amenorrhea. The exploration of the pituitary region revealed pituitary hyperplasia measuring 18 mm x 13 mm. Karyotype revealed Turner mosaic syndrome.
Discussion
In our patient, the hyperplasia was secondary to thyroid cell proliferation secondary to prolonged poorly controlled peripheral hypothyroidism; however, an autoimmune origin cannot be ruled out. It was the response to treatment with Levothyrox, which led to a net regression of hyperplasia of more than 80% after regular treatment with thyroid hormones, which confirmed our diagnosis.
Conclusion
The prevalence of pituitary hyperplasia secondary to peripheral hypothyroidism varies from 21 to 85% and is 70% in patients with TSH levels exceeding 50µUI/ml. The diagnosis of thyrotropic hyperplasia is certain once the process has regressed after hormone replacement, and if this does not occur, the diagnosis should be reconsidered.

Diagnosis and management of cervical paragangliomas: a report of six cases

Rachida Bouattay[1], nawres bouaziz[1], Emna Bergaoui[1], Mahdi Ferjaoui[1], Amel El Korbi[1], Nawrez Kolsi[1], Khaled Harrathi[1] & Jamel Koubaa[1]
[1]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Introduction
Paragangliomas are rare tumours that arise from paraganglia of neural crest origin. They have an incidence of approximately 1:300,000 and a third arise in the head and neck. A significant number of cervical paragangliomas are relatively asymptomatic, causing little more than a lump in the neck. The rest can cause cranial nerve palsies and infiltrate the skull base. Surgical treatment may cause the same deficits and, in some, risks more serious neurological deficits. The aim of this study is to review our experience in the management of these tumours.
Methods
This is a retrospective study involving cases of cervical paragangliomas, taken care of in our department, over a period of 10 years (2012-2021).
Results
A total of 6 cervical paragangliomas were identified in 5 patients. There were 3 women (60%) and two men (40%) with a mean age of 53.4 years (range: 32-68 years). There was not a family history for paragangliomas. A slow growing, painless neck mass was the main clinical presentation in all cases. There was no evidence of a functional tumor. Physical examination revealed a firm lateral cervical swelling. There were no cervical lymphadenopathy or nerve palsy in all cases. In preoperative imaging, neck ultrasound was performed for all patients. Computed tomography was performed in 4 cases and imagnetic resonance imaging in 3 cases. Of these 5 cases, 4 patients had carotid body paragangliomas, one of which is bilateral. Only one patient had vagal paraganglioma. We did not observe any malignant tumor. Secretory activity was studied in all cases an all patients had normal level of metanephrines. In our study, 3 patients were treated with surgery without postoperative complication in follow-up. One patient was treated with radiotherapy, while there was a patient who was not followed up.
Conclusions
Cervical paragangliomas are slow-growing tumours. Due to its localization near large vascular structures and cranial nerves, the surgical treatment is challenging. The surgery should be as conservative as possible to minimize the complications. In that aspect, preoperative embolization was mainly advised in large and hyper-vascularized tumors. However, in some parts of the world, radiotherapy (whether conventionally fractionated or as a single treatment from the 'gamma knife') or a watchful waiting policy is preferred.

Neuroprotective steroids in patients with multiple sclerosis

Radmila Kančeva[1,1], Martin Hill[1], Marta Velíková[1], Lyudmila Kancheva[1], Josef Včelák[2], Radek Ampapa[3], Michal Židó[4], Ivana Štětkářová[4], Anna Libertinová[5] & Eva Havrdová - Kubala[6]
[1]Institute of Endocrinology, Steroid Hormones and Proteohormones, Prague, Czech Republic;[2]Institute of Endocrinology, Molecular Biology and Genetics, Prague, Czech Republic;[3]Jihlava Hospital, MS center, Jihlava, Czech Republic;[4]3FM CU and UHKV, Neurology, Prague, Czech Republic;[5]Faculty of Medicine, Charles University and University Hospital Motol, Neurology, Prague, Czech Republic;[6]General Faculty Hospital, Clinic of Neurology, Prague, Czech Republic

Multiple sclerosis (MS) is a common inflammatory autoimmune and demyelinating disease of the central nervous system (CNS) that compromises health and leads to disability. Sex differences in the prevalence and progression of MS suggest the involvement of sex steroids in the pathophysiology of MS. In late pregnancy, at the highest levels of progesterone and estradiol, the number of relapses decreases and increases again after delivery due to changes in steroid levels. In addition, dehydroepiandrosterone (DHEA) and its derivatives may also influence the development of MS. Therefore, the correlations between circulating steroid levels in MS patients were evaluated with respect to the pathophysiology of MS. The levels of endogenous steroids ($n=85$) (quantified using the GC-MS/MS platform) in serum samples from 23 fertile-aged follicular menstruating women with multiple sclerosis and 7 premenopausal women ($n=7$) before treatment were simultaneously compared with age-matched controls ($n=16$) using a multivariate regression with dimensionality reduction (orthogonal projection to latent structure, OPLS) including the age of the volunteers. The presence of MS was negatively correlated with serum endogenous steroid levels, with steroid levels explaining 29% of the presence of MS. The analytes included sulphates of Δ^5 pregnanes (glutamate and negative $GABA_A$ receptor modulators) and androstanes, their free analogues, neuroprotective and immunoprotective 7α-hydroxy, 7-oxo-, 7β-hydroxy and 16α-hydroxy-metabolites of Δ^5 androstanes, progestogens (bioactive progesterone, 20α-dihydroprogesterone, 17-hydroxyprogesterone, its free and conjugated 20α-dihydrometabolite, 16α-hydroxyprogesterone) inactive Δ^4 androgen androstenedione, bioactive Δ^4 androgens testosterone and 5α-dihydrotestosterone including its conjugated form, estrogens estrone sulfate and bioactive estradiol, a variety of 5α/β reduced free and conjugated 20-oxo and 20α-dihydropregnanes (including GABAergic positive modulators with hydroxyl in the 3α-position, glutamate receptor modulators). Furthermore, the analytes measured included 5α/β-reduced free and conjugated androgens also including a number of neuroactive steroids and finally the active corticosteroids cortisol and corticosterone as well as the inactive cortisol metabolite cortisone and finally 11β-hydroxy-androstanes. It was found that 28 steroids were significantly negatively correlated with MS. These steroids included a number of bioactive substances including five neuroprotective and immunoprotective 7α-hydroxy, 7-oxo-, 7β-hydroxy-Δ^5 androstanes, a number of GABAergic positive modulators with a hydroxyl at the 3α-position, and two 11β-hydroxy androstanes. Thus, it is likely that lower serum levels of a number of bioactive steroids in MS patients could be related to the pathophysiology of this disease. Grant NU20-04-00450 from the Ministry of Health of the Czech Republic supported the study.

Pituitary stalk interruption syndrome – a rare case of delayed onset adrenal crisis

Huajing Ni[1], Denuka Kankanamge[1], Martina Preda[2], Antonio Di Ieva[1] & Veronica Preda[1]
[1]Faculty of Medicine and Health Sciences, Macquarie University, Macquarie Park, Australia;[2]I-MED Radiology, Sydney, Australia

Background
Pituitary stalk interruption syndrome (PSIS) is a rare congenital condition characterised by the triad of thin or absent pituitary stalk, hypoplasia of the adenohypophysis, and ectopic neurohypophysis. PSIS has multifactorial aetiology with highly heterogenous clinical manifestations, usually diagnosed in early infancy or childhood. There have been previous reports of untreated panhypopituitarism diagnosed in adulthood, indicating preservation of some pituitary function. Nearly all patients had normal posterior pituitary function. It is difficult to predict the onset of hormonal crisis, making routine surveillance of critical importance. We present an unusual case of a 31-year-old male who has been off hormonal supplementation for at least a decade with an acute hypoadrenal crisis. Our case highlights the challenges in transition of care from paediatric to adult services and the importance of long-term follow-up of PSIS patients.
Clinical Case
Our patient presented following an acute episode of collapse in the context of a recent viral infection, with profoundly hyponatremia (98 mmol/l) and seizure. Congenital hypopituitarism was diagnosed at 10 days of age and managed with hydrocortisone, thyroxine and growth hormone replacements under paediatric endocrinology care, reaching predicted height of 170 cm . After a brief period of testosterone therapy at age 18, he was lost to follow-up and had been on no replacement between age 18–30. He was able to maintain a physically demanding job without any significant adrenal crises or hospitalisation until his recent presentation. Physical examination revealed no dysmorphic features. His biochemistry during admission was consistent with central hypothyroidism (TSH 0.81 mIU/l, FT4 7 pmol/l, FT3 $<$ 1.5 pmol/l) with non-detectable growth hormone and gonadotropins. Cortisol was measured post stress doses of hydrocortisone and ACTH was 1.9 pmol/l. Prolactin was 300 mIU/l. MRI pituitary confirmed extremely thin stalk with small residual pituitary gland, an

area of T1 brightness representing probable ectopic pituitary tissue, and posterior bright spot was not present. He was recommenced on glucocorticoid and thyroxine replacement with normalisation of serum sodium, and will continue to follow up with an adult service.

Conclusion

The present case aims to raise awareness of PSIS, a rare condition predominantly diagnosed in the paediatric population with lasting impact into adulthood. It should be emphasised to patients as they enter adolescence the importance of ongoing hormone replacement, and active efforts should be made to facilitate transition of care to an adult service along with medical alerts, sick day management and family awareness of the condition.

Acromegaly complicated with hypercortisolemia

Saori Kitayama[1], Yasufumi Seki[1], Satoshi Morimoto[1], Noriyoshi Takano[1], Kaoru Yamashita[1], Daisuke Watanabe[1], Kanako Bokuda[1], Kosaku Amano[2], Takakazu Kawamata[2], Takashi Komori[3], Tatsuo Sawada[3] & Atsuhiro Ichihara[1]

[1]Tokyo Women's Medical University Hospital, Department of Internal Medicine, Tokyo, Japan;[2]Tokyo Women's Medical University Hospital, Department of Neurosurgery, Tokyo, Japan;[3]Tokyo Women's Medical University Hospital, Department of Pathology, Tokyo, Japan

Introduction

Acromegaly hardly complicates hypercortisolemia due to co-over-secretion of ACTH from the pituitary tumor. Herein, we present a case of acromegaly with hypercortisolemia.

Clinical case

A 68-year-old woman visited a local clinic due to bitemporal visual field defects. A magnetic resonance imaging scan of the pituitary gland showed a 25 mm-sized mass extending from the sellar to the suprasellar region, and she was referred to our hospital for further evaluation. Physical examination revealed combined features of acromegaly and Cushing's disease including cranial ridges, macroglossia, enlargement of the nose and lips, moon face, and central obesity. Her body mass index was 23 kg/m^2. Serum levels of hemoglobin A1c, low-density lipoprotein cholesterol, and triglyceride were 5.3%, 104 mg/dl, and 133 mg/dl, respectively. Serum GH and insulin-like growth factor (IGF)-1 levels were 2.59 ng/ml and 238 ng/ml (+2.2 SD) (reference, 60-180), respectively. Serum GH levels were not suppressed (1.77 ng/ml) during a 75 g oral glucose tolerance test. Morning plasma ACTH and cortisol levels were 55.9 pg/ml (reference, 7.2-63.3) and 13.5 μg/dl (reference, 4.0-18.3), respectively. Plasma cortisol levels were suppressed not by 0.5 mg of dexamethasone but by 8.0 mg of dexamethasone, suggesting a coexistence of acromegaly and Cushing's disease. Transsphenoidal surgery was performed, and the immunostaining of the excised tumor cells was positive for GH but negative for ACTH. GH and IGF-1 levels were normalized just after the surgery. Although the cortisol levels remained unsuppressed by 0.5 mg of dexamethasone 8 years after the surgery, the case had not exhibited metabolic abnormalities associated with Cushing's disease.

Discussion

The co-secretion of GH and ACTH from the pituitary tumor is extremely rare because the expressions of the two hormones are regulated by different transcription factors. However, the endocrinological tests suggested a coexistence of acromegaly and Cushing's disease in our case. Pseudo-Cushing's syndrome, a condition accompanied by physiologic overactivity of the hypothalamic-pituitary-adrenal axis, displays signs of Cushing's disease. The absence of pathological evidence and metabolic impairment of Cushing's disease suggested this case as acromegaly with hypercortisolemia associated with pseudo-Cushing's syndrome.

Conclusion

We present a case of acromegaly with hypercortisolemia associated with pseudo-Cushing's syndrome. The significance of hypercortisolemia might need to be carefully interpreted in patients with acromegaly.

Pituitary microadenoma in children and adolescents: minireview of the literature

Ashraf Soliman[1], Noor Hamed[1], Nada Alaaraj[1], Fawzia Alyafei[1], Shayma Mohamed[1] & Sohair Elsiddig[1]

[1]Department of Pediatrics Hamad Medical Centre, Pediatric Endocrine, Doha, Qatar

Background

Pituitary tumors are uncommon in childhood and adolescence, with a reported prevalence of up to 1 per million children. Only 2 - 6% of surgically treated pituitary tumors occur in this age group. Although these tumors are almost never malignant and hormonal secretion is rare, they can cause significant morbidity. Pituitary microadenomas, though rare, pose unique challenges due to their potential hormonal activity and growth during a critical developmental period. Microadenomas are defined as those smaller than 10 mm, while those larger are classified as macroadenomas.

Methods - Literature Search

We conducted a search of the medical literature using Pubmed, Google Scholar, and Scopus, focusing on research articles about pituitary microadenomas in children and adolescents. A total of 33 articles met our search criteria and were analyzed for this mini review.

Results and discussion

Prevalence: Pituitary adenomas constitute about 3% of all intracranial neoplasms in children and account for 5% of all pituitary adenomas. A 60-year study on pediatric pituitary adenomas revealed a small percentage of microadenomas, underscoring their rarity.

Clinical Presentations

In a study of 20 microadenomas, 75% occurred in girls, with an average age at diagnosis of 14.4 years. Common symptoms included amenorrhea (53.3%) and galactorrhea (42.8%) in girls, and gynecomastia in boys.

Pathological types

Prolactinomas, corticotrope, and somatotroph adenomas are the most common types. Among 42 pituitary adenomas studied, 33% were macroadenomas, and 21% were microadenomas, with prolactin-secreting and ACTH-secreting adenomas being the most prevalent.

Management

Treatment strategies are guided by the tumor's functionality and size. Medical management is typically the first choice for functioning microadenomas that secrete excess hormones. Surgical intervention, primarily transsphenoidal surgery, is reserved for symptomatic or functioning tumors unresponsive to medical therapy. Radiotherapy and radiosurgery are considered in refractory cases or when surgery and medical therapy fail.

Outcomes

The prognosis for children with pituitary microadenomas is generally favorable. For instance, in medically managed prolactinomas, many patients achieve normal prolactin levels and tumor shrinkage. Success rates for surgically treated cases vary based on tumor type and the extent of its removal.

Conclusion

Pediatric pituitary microadenomas, while rare, require a nuanced approach to diagnosis and management. Advances in diagnostic techniques and treatment protocols have improved outcomes. Ongoing research and vigilant long-term follow-up are crucial for optimizing patient care and outcomes, particularly due to the potential for recurrence and long-term endocrine effects.

Sheehan syndrome in a tunisian hospital: a clinical experience of 123 cases

Sawsen Nouira[1], Hamza Elfekih[1], Amel Maaroufi[1], Yosra Hasni[1], Molka Chaieb[1] & Kussay Ach[1]

[1]University Hospital Farhat Hached, Endocrinology, Sousse

Introduction

Sheehan's syndrome (SS) results from severe post-partum hemorrhage leading to necrosis of the pituitary gland. Here we describe the clinical characteristics of patients with Sheehan syndrome.

Methods

We conducted a 44-year cohort study (1977 to 2021) of patients with SS followed at the endocrinology department of Farhat Hached Hospital in Sousse, Tunisia. Medical history, physical examination findings and laboratory investigations were documented.

Results

One hundred and twenty-three patients diagnosed with Sheehan syndrome were included. The mean age at diagnosis was 43 ± 12 years [21-78]. The mean delay between the previous obstetrical event and the diagnosis of SS was 11 years. Thirty-four patients (28%) gave birth at home. All patients had a history of obstetric hemorrhage, 79 cases (64%) had blood transfusion and 16 cases (13%) had undergone peripartum hysterectomy. The most frequent symptoms were asthenia in 108 cases (87%), amenorrhea in 106 cases (86%), agalactia in 102 cases (86%) and loss of pubic and axillary pilosity in 44 cases (36%). At diagnosis, 93% (n = 115) had corticotropic deficiency, 93% (n = 104/112) had gonadotropin deficiency, 91% (n = 113/123) had thyrotropic deficiency, and 86%

($n=112$) had lactotropic deficiency. The somatotropic axis was investigated in 42%($n=51$) of patients, and somatotropic deficiency was found in all of them. Sheehan's syndrome was diagnosed relatively late (>1 year) in 100 patients. We found that the majority of multiparous patients 83%($n=83$) consulted late ($P=10^{-3}$). More than half the patients who consulted early ($n=17/23$) had a history of blood transfusions ($P=10^{-3}$).
Conclusions
Early diagnosis of SS based on our clinical findings is important for proper management of these patients through multidisciplinary collaboration between obstetricians and endocrinologists. In addition, special attention and strict follow-up are required for all women presenting with massive hemorrhage in the last trimester, in order to identify cases of SS.

Silent gonadotroph adenomas and platelet dynamics

Ekin Yiğit Köroğlu[1], Gülsüm Karaahmetli[1], Didem Özdemir[2], Servet Güreşçi[3], Denizhan Divanlıoğlu[4], Fatma Dilek Dellal Kahramanca[1], Oya Topaloğlu[2], Reyhan Ersoy[2] & Bekir Çakır[2]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yıldırım Beyazıt University Faculty Of Medicine, Endocrinology and Metabolism, Ankara; [3]Ankara Bilkent City Hospital, Pathology, Cankaya; [4]Ankara Bilkent City Hospital, Neurosurgery, Cankaya

Objective
Gonadotroph adenomas are the most common subtype of pituitary adenomas. Rarely, clinical findings may occur due to the secretion of high amounts of biologically active gonadotropins. It may affect platelet activity if there is an excessive increase in the release of estrogen and testosterone or if it is used in pharmacological doses. In this study, we aimed to investigate whether platelet activity indices and coagulation parameters were affected in silent gonadotroph adenomas.
Methods
Patients who operated for a pituitary adenoma in our center between March 2019 and July 2023 were recruited for the study. Presence of thromboembolic disease history, preoperative and postoperative (after the first month) follicle-stimulating hormone (FSH), luteinizing hormone (LH), total testosterone, free testosterone, estradiol (E2), platelet count, mean platelet volume (MPV), platelet distribution width (PDW), international normalized ratio (INR) and activated partial thromboplastin time (aPTT) levels of the patients were recorded.
Results
25 female patients and 32 male patients were included in the study. We found no statistically significant difference between FSH, LH, testosterone, and E2 levels in both genders' preoperative and postoperative periods. No statistically significant difference was observed in MPV, PDW, INR, and aPTT in both genders. None of the patients in the study had a history of thromboembolic events. No thromboembolic event was observed in any patient within the first year of the postoperative period.
Conclusion
Silent gonadotroph adenomas do not affect platelet activity in male and female patients.

Overview of pituitary malignancies

Hassan Heshmati[1]
[1]Endocrinology Metabolism Consulting, LLC, Hassan Heshmati and Valerie Shaw Endocrine Research, Anthem, AZ, United States

Introduction
Pituitary malignancies include pituitary carcinomas and pituitary metastases. These malignancies are ver, rare and create important diagnostic and therapeutic challenges. This review presents an update on pituitary malignancies.
Methods
A systematic search of literature was conducted using the search terms pituitary carcinoma, pituitary metastasis, prevalence, management, and survival.
Results
Pituitary carcinomas are tumors of adenohypophyseal origin that have craniospinal and/or systemic metastases. They are denominated metastatic pituitary neuroendocrine tumors and represent around 0.1%-0.2% of all pituitary tumors. The affected patients are mainly males. The diagnosis of pituitary carcinomas is often delayed, and several cases are only diagnosed at autopsy. The clinical and biochemical features of pituitary carcinomas are usually similar to those of benign pituitary tumors. Most pituitary carcinomas are hormone-secreting tumors (mainly prolactin- and adrenocorticotropic hormone-secreting tumors) but some pituitary carcinomas develop in the setting of silent pituitary tumors. There are no well-established histopathologic, molecular, or genetic distinctions between benign pituitary tumors and pituitary carcinomas. The diagnosis of pituitary carcinomas cannot be made until metastases are identified. The metastases can be in the central nervous system (e.g., brain, spinal cord, dura, and leptomeninges) and/or distant organs (e.g., bone, liver, and lungs). The treatment of pituitary carcinomas includes surgery (e.g., gross total or subtotal resection), radiotherapy, and medical therapy (e.g., suppression of excess hormonal secretion, correction of hormonal deficiencies, chemotherapy, and immunotherapy). Although the prognosis is relatively poor, the survival of pituitary carcinomas has significantly improved since the introduction of temozolomide, a drug used as a first-line chemotherapy. Patients with metastases to the central nervous system have also a longer survival than those with distant organs metastases. Pituitary metastases account for approximately 1% of all pituitary tumors. They invade mainly the posterior lobe of the pituitary gland. Breast, lung, kidney, and prostate are the most common primary cancers. In several patients, the primary cancer remains unknown. Most cases are asymptomatic and often diagnosed at autopsy. Symptomatic patients present with diabetes insipidus, hypopituitarism associated with hyperprolactinemia, and visual impairment. The treatment of pituitary metastases includes surgery, radiotherapy, and medical therapy (e.g., correction of hormonal deficiencies, chemotherapy, and immunotherapy). The prognosis is poor. The median overall survival is approximately 1 year.
Conclusions
Pituitary carcinomas and pituitary metastases are rare malignancies that are difficult to diagnose and treat. They have poor prognosis. Most pituitary carcinomas are hormone-secreting tumors. The main cancers metastasizing to the pituitary gland are breast and lung cancers.

A male case of autoimmune hypophysitis

Oumaima Dimassi[1,2], Najwa Lassoued[1,2], Nada Hassairi[2], Maryem Souissi[1,2], Wafa Alaya[1,2] & Habib Sfar[1,2]
[1]Mahdia, Tunisia; [2]Taher Sfar University Hospitaly Endocrinology departement, Mahdia, Tunisia

Background
Hypophysitis is a heterogeneous condition that leads to inflammation of the sella and/or suprasellar region, potentially resulting in hormonal deficiencies and/or mass effects. The overall incidence and prevalence of hypophysitis has dramatically increased over the past decade, mainly due to increased awareness of the condition in the medical community. The clinical presentation varies from an asymptomatic condition to a fatal disease often as a result of electrolyte abnormalities due to glucocorticoid deficiency in the context of adrenal crisis from central adrenal insufficiency. A presumptive diagnosis can be made often without biopsy. Hormone replacement and, in selected cases, careful observation is advised with imaging follow-up.
Case presentation
A 47-year-old male patient with a history of dyslipidemia and smoking habit, presented with muscle cramps, paresthesias, profound fatigue, constipation, and significant weight loss over a year. Initial diagnostic tests revealed primary hypothyroidism due to Hashimoto's thyroiditis. Upon admission, clinical signs included low blood pressure and episodes of hypoglycemia. Laboratory findings indicated corticotropic insufficiency, gonadotropin deficiency, and normal prolactin. Cerebral MRI findings were pivotal in the diagnostic process, revealing no abnormalities in the anterior pituitary, homogeneous enhancement and a normal pituitary stalk. The diagnosis of autoimmune hypophysitis was made due to the association of anterior pituitary insufficiency and Hashimoto's thyroiditis. Treatment was initiated promptly, incorporating levothyroxine, oral hydrocortisone, and testosterone injections. Despite the severity of the initial presentation, significant improvement was observed with no reported functional complaints.
Conclusions
Although the diagnosis of hypophysitis ultimately requires a biopsy, the presumptive diagnosis based on clinical manifestation in conjunction with magnetic resonance imaging (MRI) and laboratory findings is typically made in clinical settings. Milder forms of hypophysitis are treated with replacement of deficient hormones. Timely diagnosis and interventions are keys to prevention of the lethal complications of this disease.

EP889

Cyclic cushing's syndrome: understanding the patterns of a complex endocrine disorder

Beatriz Tavares da Silva[1], Andreia Martins Fernandes[2], Raquel Almeida[3], Maria Teresa Pereira[1] & Cláudia Amaral[1]
[1]Porto, Porto, Portugal; [2]Coimbra, Coimbra, Portugal; [3]Santa Maria da Feira, Santa Maria da Feira, Portugal

Introduction
Cyclic Cushing's Syndrome is an uncommon disorder characterized by recurrent episodes of elevated cortisol levels, alternating with periods of normal cortisol secretion. These cycles of hypercortisolism can occur at regular or irregular intervals, ranging from days to years between episodes.
Case presentation
A 57-year-old woman evaluated at the Endocrinology Outpatient Clinic because of symptoms of hypercortisolism with 18 months of evolution: unexplained weight gain (15 kilograms), worsening blood pressure control, thin arms and legs, a moon face and proximal muscle weakness. On physical examination, the patient presented a cushingoid facies without facial plethora, cervical fat accumulation and centripetal obesity. Her medical history included hypertension since 2019 with optimal control using two antihypertensive drugs. She underwent laboratory investigation to document the presence of hypercortisolism and was diagnosed with ACTH-dependent hypercortisolism, evidenced by elevated midnight salivary cortisol levels (37.9 nmol/l; n <7.6) and 24-hour urinary free cortisol (UFC) (4485.3 nmol/day; NR: 11.8-485.6), as well as elevated ACTH (137.4 pg/mL; n <60). Pituitary MRI confirmed the presence of a microadenoma with 7mm. Although she was proposed for bilateral inferior petrosal sinus sampling (BIPSS), in the days preceding the procedure, she presented significant improvement of her symptoms. Cortisol levels dropped significantly: 0800 hours serum cortisol of 4.5 ug/dl (NR: 6.2-19.3) measured twice and a 24-hour UFC of 18.7 ug/day (NR: 4.3-176). Subsequent MRI failed to definitely demonstrate pituitary apoplexy and there were no clinical evidence suggesting this diagnosis. The diagnosis of Cyclic Cushing's Syndrome was assumed to be the most likely and BIPSS was not performed. One month later, she was evaluated for generalized fatigue and there was again evidence of hypercortisolism with elevated midnight salivary cortisol levels (63.0 nmol/l; n <7.6) and a 24-hour UFC of 2540.6 nmol/day (NR: 11.8-485.6), confirming recurrent cortisol secretion in favour of the diagnosis of Cyclic Cushing's Syndrome. BIPSS is scheduled to be performed later this month, despite the increased probability of Cushing Disease.
Conclusion
Cyclic Cushing's Syndrome poses a unique challenge in the realm of endocrine disorders. Unlike its more predictable counterpart, this syndrome involves intermittent hormone level fluctuations, complicating both diagnosis and treatment. The diagnosis remains a complex task and demands continuous patient follow-up. This case emphasize the importance of optimizing confirmation of hypercortisolism at the time of BIPSS.

EP890

Temozolomide therapy in an aggressive ACTH-producing pituitary tumour

Inês Redondo de Carvalho[1], Gonçalo Fernandes[2] & Francisco Sobral do Rosário[1]
[1]Hospital da Luz Lisboa, Endocrinology Lisbon, Portugal; [2]Hospital da Luz Lisboa, Oncology Lisbon, Portugal

Introduction
Aggressive pituitary tumours are rare (<2% of pituitary macroadenomas) and are characterized by local invasiveness, progressive growth, and multiple recurrences despite conventional treatments. Approximately 30-40% of these tumours are functioning corticotroph adenomas. Diagnosis relies on clinical, imaging evaluation with magnetic resonance imaging (MRI), hormonal, and pathological assessments. Its therapeutic approach is challenging.
Clinical Case
A 53-year-old woman diagnosed in 2015 with Cushing's disease due to a pituitary macroadenoma underwent transsphenoidal resection, with no apparent residual lesion and normalization of ACTH levels. Histology identified a corticotroph pituitary adenoma with a low Ki67 (<3%) and p53+ in more than 50% of cells. One year later, she experienced a significant tumour recurrence, leading to a second surgical intervention where complete tumour resection was impossible. Therapy with cabergoline and gamma-knife radiosurgery was conducted, resulting in residual tumour. Elevated ACTH levels and hypercortisolism persisted, and therefore metyrapone was initiated. The clinical picture of hypercortisolism worsened, leading to the development of diabetes mellitus, vertebral osteoporotic fractures, and retinal detachment. In 2020, she underwent bilateral adrenalectomy. Since then, there has been a gradual rise in ACTH levels with persistent lesions. In 2023, she experienced a sudden episode of ophthalmoplegia and left eyelid ptosis, consistent with homolateral cavernous sinus syndrome. MRI confirmed left cavernous sinus invasion by the pituitary tumour, prompting urgent transsphenoidal surgery with subtotal lesion resection. Histology revealed a corticotroph pituitary tumour with Ki67 15% and an increased number of mitoses. Postoperative imaging control showed residual intra-sellar lesion with bilateral cavernous sinus involvement. Genetic testing (FoundationOne) did not identify any mutation considered a therapeutic target. Following multidisciplinary discussion, chemotherapy with temozolomide was initiated (administered every 3 weeks, with a dose of 150mg/m^2 in the first cycle and 200 mg/m^2 in the following). The treatment was well-tolerated, without hematological complications. An initial reduction in ACTH levels was observed, as well as lesion stability at the end of the 6th cycle.
Conclusion
This case presents an aggressive corticotroph adenoma, illustrating the complexity of its treatment, which requires a multimodal and multidisciplinary approach. Due to tumour progression despite various interventions, temozolomide therapy was initiated.

EP891

Mucocutaneous diathesis in severe cushing disease

Inês Redondo de Carvalho[1], José Carda[2], Carlos Tavares Bello[1], Isabel Esperança[3] & Francisco Sobral do Rosário[1]
[1]Hospital da Luz Lisboa, Endocrinology Lisbon, Portugal; [2]Hospital da Luz Lisboa, Haematology Lisbon, Portugal; [3]Hospital da Luz Lisboa, Intensive Care Medicine, Lisbon, Portugal

Introduction
Cushing syndrome is a complex disease with multisystemic manifestations. It includes skin and connective tissue abnormalities, in which glucocorticoids reduce the synthesis and production of collagen, resulting in skin thinning, subcutaneous vascular tissue frailty and mucocutaneous bleeding.
Case report
A 59-year-old woman with history of hypertension, type 2 diabetes, hypercholesterolemia, and chronic kidney disease, was admitted to the Intensive Care Unit due to severe hypokalaemia. In the past months, she referred muscle weakness, asthenia, weight gain, and more recently elevated blood pressure with headaches. Physical examination at admission revealed a cushingoid phenotype and haemorrhagic diathesis (petechiae on the abdominal girdle and lower limbs). Blood work-up was consistent with ACTH-dependent hypercortisolism and MRI showed a pituitary macroadenoma invading adjacent structures. Unexpectedly, the patient developed subconjunctival haemorrhage, epistaxis, bleeding at puncture sites, and diffuse petechiae. No menorrhagia, haematuria, gastrointestinal bleeding or hemarthrosis occurred. The patient was not taking acetylsalicylic acid, non-steroidal anti-inflammatory drugs, or anticoagulants. Considering the mucocutaneous diathesis, the patient was submitted to an extensive diagnostic study which included grade I thrombocytopenia (100-110$\times$10^9/l) (reference range: 170-430$\times$10^9/l), normal coagulation time (PT, aPTT and TT), increased fibrinogen level, normal platelet aggregation studies by Platelet Function Analyser (PFA-100) and Aggregometry test, increased Von Willebrand factor and activity, and increased VIII factor. Given the absence of platelet or coagulation abnormalities that could justify the haemorrhagic diathesis, it was assumed to be related with vascular and subcutaneous fragility secondary to hypercortisolism. A skin biopsy was not carried out because of the established skin diathesis and since it would not change the therapeutic attitude. The bleeding diathesis did not allow for surgical intervention. Following multidisciplinary discussion, mifepristone was initiated at 200mg/day, leading to significant improvement in the haemorrhagic diathesis. The patient underwent bilateral adrenalectomy due to the risk of a neurosurgical procedure. However, postoperatively, the patient developed multisystem organ failure of unknown origin resulting in the patient's demise.
Conclusion
The authors report on a case of severe Cushing disease, whose main clinical manifestations were the hypokalaemia and haemorrhagic diathesis. Mucocutaneus haemorrhage is not usually severe in Cushing's, often being the thromboembolic events the clinician's major concern from the haematological standpoint. Medical treatment with mifepristone rapidly improved both conditions and can be considered a treatment option in this setting. Clinical heterogeneity in Cushing disease is very wide and a multidisciplinary approach should be undertaken to improve patient care.

Cardiac arrest as a presentation of hypophysitis-induced hypopituitarism developed following a COVID-19 infection

Nino Tedoradze[1], Mariam Pailodze[1], Ann Kobaidze[1], Meri Davitadze[2], Sophio Tsikarishvili[1], Nino Akiashvili[1] & Lika Jajanidze[1]
[1]Caucasus Medical Centre, Endocrinology Tbilisi, Georgia; [2]Universit, of Birmingham, Institute of Applied Health REsearch, Birminghem, United Kingdom

Background
Hypophysitis is a rare inflammatory condition of the pituitary gland, speculated to have autoimmune aetiology. The diverse clinical presentations rely on hormonal deficiencies and the pathophysiological impact on the target organs. This condition may give rise to life-threatening complications. MRI is the best imaging modality for diagnosis and the conclusive diagnosis necessitates a biopsy of the affected tissue. The optimal management approach remains a subject of controversy. Herein, we describe a case of hypophysitis with sudden cardiac arrest.
Case Report
An 18-year-old female was admitted to the hospital due to loss of consciousness during swimming, and involuntary movements. Cardiopulmonary resuscitation was performed successfully with restoration of cardiac function. Further investigation revealed mitral valve abnormalities, systemic inflammatory syndrome, and severe metabolic acidosis. Laboratory tests showed: pH=6.5, PcO2=34, Po2=275, Hco3=2.9 mmol/l, lac=22. Cardiac catheterization ruled out significant coronary stenosis, pinpointing the cause of cardiac arrest to ventricular fibrillation. Four months prior, patient had a Covid-19 infection, and a month later she developed visual disturbances, transient blindness, hearing loss episodes, and menstrual irregularities. laboratory tests showed slightly elevated TSH, and pituitary hyperplasia on brain MRI. Medications were not prescribed. On the 3rd day of hospitalisation, patient developed polyuria and hypernatremia, plasma and urine osmolarity were normal, ACTH=9.0 0 pg/ml, Cortisol=16.320 μg/dl (5.27-22.4), TSH=0.10 μIU/ml (0.35-5.5), FT4=0.59 pg/ml (0.83-1.43), FT3=0.7 pg/ml (3-4.74). Considering the previous MRI findings, hypophysitis was suspected and the diagnosis of hypopituitarism with hypothyroidism and hypocortisolism was established. The patient was commenced on replacement therapy with hydrocortisone and levothyroxine sodium, alongside desmopressin for fluid and electrolyte balance. For cardiac rhythm disturbances, antiarrhythmic medication was started, the patient underwent an implantation of a cardioverter-defibrillator. Currently the patient on levothyroxine sodium 50 mg daily, Hydrocortisone 20mg daily, metoprolol 100mg twice weekly, levetiracetam 500 mg twice daily. Follow-up assessments demonstrated improvement in cardiac function and normalisation of hormone levels. In 6 months, the patient failed short Synacthen test and was continued on replacement.
Conclusion
Making an accurate and timely diagnosis of hypophysitis still remains a challenge. It is possible that Covid-19 was the reason of hypophysitis. Recognizing and addressing early symptoms and signs of hypopituitarism can be potentially life-saving, in particular when it is masked with cardiac disorders. Additionally, detailed history-taking may play a key role in establishing the diagnosis. Addressing hormonal deficiencies early on not only prevents potential life-threatening events but also improves the overall quality of patient care.

Macroprolactinemia and empty sella syndrome

Oumayma Zarrouk[1], Taieb Ach[1], Rihab Kochtali[1], Ghada Saad[1], Asma Ben Abdelkrim[1], Molka Chadli Chaieb[1] & Koussay Ach[1]
[1]University Hospital of Farhat Hached, Endocrinology Departement, Sousse

Introduction
Macroprolactinemia is a polymeric form of prolactin release that leads to clinically paucisymptomatic presentations. It can be isolated or associated with other causes of hyperprolactinemia. We report the case of macroprolactinemia discovered in a patient being treated for an empty sella turcica.
Case report
This concerns a 47-year-old patient, monitored since the age of 31 for moderate idiopathic hyperprolactinemia discovered following bilateral galactorrhea and amenorrhea. There was no associated medication use. Her exploration revealed a prolactin level of 635 mIU/l. Thyroid function tests were normal (T4=10.2 ng/l, TSH=1.76 mIU/l). A brain CT scan showed an empty sella turcica. The patient's evolution under 5 mg/day of dopamine agonists was marked by the occurrence of pregnancy with persistent moderate hyperprolactinemia in the postpartum period. The patient reached menopause at the age of 47, with elevated gonadotropins (FSH=78 mIU/ml, LH=33 mIU/ml, and estradiol: 35 pg/ml). Consequently, the treatment was discontinued, and regular clinical monitoring was initiated. Chromatography revealed a predominance of the macroprolactin form with 4.8% monomeric prolactin, 5% big prolactin, and 83% big big prolactin.
Conclusion
Our observation suggests that macroprolactinemia can be associated with classical etiologies of moderate hyperprolactinemia, such as an empty sella turcica. Detecting it could potentially avoid the need for dopamine agonist treatment.

Delayed puberty due to pituitary tumours (macroprolactinomas) is rare, a case report

Furhana Hussein[1], Gideon Mlawa[2], Zahid Khan[2], Belayet Hossain[2], Muhammad Saleem[2] & Man-Yan Cheung[2]
[1]Queen's Hospital, Endocrinology and Diabetes/Acute Medicine, London, United Kingdom; [2]Queen's Hospital, London, United Kingdom

Introduction
There are multiple causes of delayed puberty including constitutional delay in growth and puberty, chronic diseases, hypothyroidism, and pituitary tumours (e.g. craniopharyngioma). Delayed puberty due to macroprolactinoma is rare.
Case Presentation
A 23-year-old male was reviewed in the Endocrine clinic after presenting with headaches and generally feeling unwell. Blood test showed a high prolactin level of 84637, low FT 7.7, low testosterone level 0.1 with low LH 1.5 and FSH 0.5. IGF-1 was 58. MRI pituitary showed Pituitary Macroadenoma (3.0×2.7×2.2 cm). X-ray of left wrist revealed bone age of 14-15 years old. During his clinic review, he was found to have a high-pitched voice, pre-pubertal hair, pubic hair distribution Tanner stage 2, and micropenis. He was started on cabergoline 250 micrograms twice a week and his prolactin level improved to 15325 after 1 month of therapy then later to 1975. The cabergoline dose was increased/escalated to 500 micrograms twice a week
Discussion
Delayed puberty is diagnosed when there is a lack of secondary sexual characteristics at the age of 14 years in boys and the age of 13 years in girls. Some of the causes of delayed puberty include constitutional delay of growth and puberty, poor nutrition, hypothyroidism, and chronic diseases. The above causes are for patients with intact Hypothalamic-pituitary axis. The causes of delayed puberty may also be due to impaired hypothalamic-pituitary axis. These include tumours such as craniopharyngioma, astrocytoma, and impaired development of hypothalamic-pituitary axis in septo-optic dysplasia. Irradiation, trauma, or surgery to the hypothalamic-pituitary region may contribute to delayed puberty as well. This case demonstrated that the patient most likely developed the pituitary macroprolactinoma before puberty and it has been slow growing. Medical therapy with dopamine agonist has produced improvement in prolactin levels but the patient will need small dose of testosterone 50mg once a month to induce puberty.
Conclusion
Here we present a rare cause of delayed puberty caused by macroprolactinoma. Medical management is first line treatment with dopamine agonist such as cabergoline. It is also important in these cases to consider hereditary macroprolactinomas causes such as multiple endocrine neoplasia type 1 (MEN 1) and Familial isolated pituitary adenoma (FIPA) syndrome especially if two or more cases of pituitary adenomas appear in the same family in the absence of MEN 1 and Carney complex.

Craniopharyngioma in children: a therapeutic challenge! (about 2 cases)

Ahmed Boukhalfa[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Mohamed VI University Hospital Center, Marrakech, Morocco, Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakesh, Morocco

Introduction
Craniopharyngioma (CP) is a rare epithelial tumor of the sellar and suprasellar region, histologically of low grade (WHO grade I). Significant locoregional invasion explains the frequency of recurrence, mainly due to incomplete surgical resection. We report two cases of craniopharyngioma in children, in order to outline the therapeutic difficulties encountered during management.
Case 1
Eleven years-old patient reported frontal headache with asthenia and chills, followed by vomiting. Examination BP 11/6 cmhg, HR 95 bpm, Tanner S2P3. Workup: TSH 3.3 mIU/l, fT4 10 pmol/l, fT3: 3.24 pmol/l, FSH 5.5 IU/l, LH: 2.1 IU/l, PRL 12.58 ng/ml, Cortisolaemia 12.64 ug/dl, Na+ 133, K+ 5.3. MRI: median intra- and suprasellar mass 16*19*20 mm, polymicrocystic. Fundus: no abnormalities. Patient underwent surgery, histology: craniopharyngioma. Post-

operative MRI showed persistent lesional process of 16×17×12 mm, indicating incomplete surgical resection.
Case 2
Patient aged 21, followed for sellar and suprasellar lesional process of 22.4×30×37 mm. Examination BP 126/72 mmHg, HR 76 bpm, Tanner S2P2. Work-up: Cortisol 14.61 µg/dl; TSH 1.71 mIU/l; fT4 17.53 pmol/l, Prolactin 8.8 ng/ml; estradiol <5 ng/l; FSH 4.86 IU/l; LH 0.98 IU/l. Tumour resected, histology showed a craniopharyngioma. At 18 months post-op recurrence with signs of compression of the anterior quadrigeminal tubercles, visual field: OD concentric narrowing and OG temporal superior quadranopsia. Several repeat operations performed (6 times), with installation of bilateral blindness. At last checkup, intra- and suprasellar process with polylobed contours and dual cystic and fleshy components, 49×46×48 mm.
Discussion
The most common symptoms in children prior to CP diagnosis are headache (68%), visual disturbances (55%), growth retardation (36%), nausea (34%), neurological deficits (23%), polydipsia/polyuria (19%) and weight gain (16%). Hypothalamic-pituitary MRI is the gold-standard imaging modality. The type of surgical resection depends on locoregional invasion and determination of the primary origin of the prostate cancer (ventricular, suprasellar, etc.). Over two-thirds of patients treated with surgery and radiotherapy (RTH) in childhood have a satisfactory outcome. Current radiotherapy techniques include 3D fractionated radiotherapy, intensity-modulated HBRT, steriotactic HBRT and, more recently, proton therapy.
Conclusion
Le CP is a locally aggressive, low-grade tumor with high morbidity in children and adults.
Keywords: craniopharyngioma, children, surgery, invasion, recurrence.

Cardiovascular complications of acromegaly: about 76 cases

Alida Mireille Uwimana[1], Nassim Essabah Haraj[2], Siham El Aziz[2] & Asma Chadli[2]
[1]CHU Ibn Rochd, Casablanca, Morocco; [2]CHU Ibn Rochd, Department of Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
Acromegaly is a rare disease with an insidious course characterized by several complications that determine its prognosis. This is a case study to evaluate the cardiovascular impact on 76 patients treated at CHU Ibn Rochd Casablanca.
Material and methods
This is a retrospective study of 76 cases of acromegaly followed in the endocrinology department of Ibn Rochd University Hospital from January 2005 to October 2023. All our patients had an ECG; Heart echo and metabolic assessment. The statistical analysis was carried out using EXCEL software.
Results
The average age was 49 years with a sex ratio F/M of: 0.33. The average BMI rate was 29 kg/m^2 with overweight in 12 patients (20.8%), and obesity in 23 patients (41.6%). The average duration of the disease was 9 and a half years; The average IGF1 level was 2.3 times normal and the etiological diagnosis was a pituitary adenoma in all patients. Hypertension was found in 33%, rhythm and/or conduction disorders were observed in 52 % of patients, hypertensive cardiomyopathy in 16%. Metabolic assessment: pre-diabetes in 10 patients (17.8%) and diabetes in 28 patients (50%). Dyslipidemia was observed in 20 patients (35.7%).
Discussion
Among the cardiovascular complications, hypertension is frequently found; it is more frequent as the disease is older, the GH is higher and the age of the patients is greater. 26 % patients had at least 2 risk factors and 9 % were affected by 4 risk factors These complications are the consequences of the effects of permanent hypersecretion of growth hormone and growth factor (IGF-1) as well as late treatment
Conclusions
Cardiovascular complications of acromegaly are common and must be screened systematically in order to prevent the morbidity and mortality of this disease.

Lower limb kinetics during walking in patient with acromegaly

Yuqi Wang[1], Michaela Title[1], Melanie Posiewko[1], Lisa Tramble[2], Syed Ahmad[2], David Clarke[3], Syed Imran[2] & Michel Ladouceur[1]
[1]Dalhousie University, Kinesiology, Halifax, Canada; [2]Dalhousie University, Endocrinology, Halifax, Canada; [3]Dalhousie University, Neurosurgery, Halifax, Canada

Acromegaly, characterized by growth hormone excess, adversely affects the patients' musculoskeletal and neural systems, consequently impairing physical function. Previous studies have noted walking impairments in patients with acromegaly (PWA). This study aimed to characterize the kinematic and kinetic changes during walking in PWA. Kinematics and kinetics of walking were evaluated in PWA ($n=8$) in biochemical remission and a control group of patients with non-functioning pituitary adenomas (PNA, $n=8$). The groups were of similar age, sex, and BMI and all participants underwent surgery to remove the pituitary adenoma. Self-reported survey data was used to compare joint pain, functional disability scores, and history of joint surgery between groups. PWA reported significantly higher back, hip, and knee pain and greater functional disability of the hip and knee than PNA. However, the history of joint surgery did not significantly differ between groups. Bipedal ground reaction forces and centre of pressure (COP) were measured using two AMTI force plates with one underneath each foot. Lower limb kinematics were measured using a 7-body segment model with anatomical 3D positions recorded using a 14-camera OptiTrack motion capture system. Force plate and motion capture systems were synchronized and sampled at 200 Hz. Lower limb kinematics and kinetics were calculated using Visual 3D. The outcome measures of the study consisted of walking speed, stride length, angular excursion, joint moments and joint power. Group differences were found in lower limb kinematics and kinetics during the stance phase. PWA exhibited increased hip and knee flexion, decreased hip adduction, and decreased ankle plantar flexion at push-off. Hip flexion moments were reduced, and hip abduction, knee extension, and knee abduction moments were elevated in PWA. There were no differences in ankle joint moments between groups. These kinematic and kinetic modifications during the initial stance phase resulted from a higher energy generation by hip extensors but lower energy absorption by hip abductors and knee extensors in PWA compared to PNA. In the midstance phase, PWA demonstrated lower energy absorption by hip flexors compared to PNA. Furthermore, PWA revealed lower energy generation by hip flexors, energy absorption by knee extensors, and energy generation by ankle plantar flexors during push-off. These results show that changes in the mechanics of walking in PWA are similar to those observed in patients with hip and knee osteoarthritis. However, some differences in the energy distribution pattern indicated a potential alteration in muscle activation strategies compared to patients with osteoarthritis.

HTA and hypokalemia: always think of cushing's disease

Talbi Dounia[1], Elmoatamid Kaoutar[1], Sebbar Ghizlane[1], Rifai Kaoutar[1], Iraqi Hinde[1] & Gharbi Mohamed El Hassan[1]
[1]Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Arterial hypertension of endocrine origin remains a rare and curable cause of hypertension. The association of hypertension and hypokalemia should always prompt us to consider cushing's disease.
Case Report
A 39-year-old female patient, followed for 9 years for hypertension on dual therapy. Clinical examination was unremarkable, in whom the diagnosis of ACTH-dependent cushing's syndrome was made on the basis of clinical and biological criteria with elevated ACTH at 52 pg/ml and hypokalemia at 3.2 mEq/l. Hypothalamic-pituitary MRI showed a 6-mm pituitary microadenoma.
Discussion and Conclusion
Hypokalemia is a frequent finding in patients with cushing's disease. In the presence of hypercortisolism, the conversion of cortisol to cortisone may be saturated by a decrease in 11B-hydroxysteroid dehydrogenase (type 2) activity, so cortisol has an affinity for the mineralocorticoid receptor identical to that of aldosterone, leading to stimulation of the mineralocorticoid receptor in the renal tubules, inducing an increase in mineralocorticoid activity, with increased sodium reabsorption and potassium excretion, increased bicarbonate reabsorption and higher blood pressure. Consequently, this combination of hypertension and hypokalemia should suggest cushing's disease in particular, when other causes have been ruled out.

Recurrence and predictive factors of the same in the endogenous cushing syndrome

Raúl Rodríguez Juárez[1], Maria Dolores Aviles Perez[1], Elena Martínez Silla[1], Javier García Sanchez[1], Laura Cánovas Noguera[1] & Juan Luis Delgado Montoya[1]
[1]Granada, Granada, Spain

Objective
Endogenous cushing syndrome (ECS) is a complex and rare disease. After treatment, 50% of cases have recurrence. The objective is to evaluate the prevalence of recurrences in patients diagnosed of ECS and its predictive factors.
Materials and Methods
Analytical retrospective observational study with 19 ECS diagnoses cases followed-up from January 1999 to December 2023. Demographic (sex, age), clinical (cause, face plethora, fragile capillary, reddish-purple stretch marks, high blood pressure, diabetes mellitus, obesity, osteoporosis) and biochemical (plasma cortisol (PC), nocturnal salivary cortisol (NSC), urinary free cortisol (UFC) before treatment) variables were collected, and recurrence frequency and relationship with the previously mentioned variables. The statistical analysis was performed with the IBM SPSS v.25 program (Statistical significance $P < 0.05$).
Results
19 patients were analyzed, 16 females and 3 males. Mean age 41 ± 10.8 years. ECS's cause was 52.6% cushing's disease, 36.8% adrenal cause and 10.5% ectopic cause. The 89.5% of the cases had high blood pressure, 73.7% facial plethora, 57.9% capillary fragility and obesity and 52.6% reddish-purple stretch marks. Diabetes mellitus was observed in 36.8% and osteoporosis in 26.3%.
Conclusions
In our study, there's a recurrence of 42.1% of the cases, most frequently in those of pituitary origin. Despite observing a similar percentage in clinical variables, the means of the biochemical variables before treatment are higher in those patients who presented recurrence, although these differences were not statistically significant, probably related to the presence of a small sample size. This increases the possible usefulness of this variables as predictors of disease recurrence.

Experiences with pasireotide treatment in subjects with acromegaly

Martin Kužma[1,2], Peter Vanuga[1,3], Peter Jackuliak[1,2] & Juraj Payer[1,2]
[1]Faculty of Medicine (University of Comenius), Bratislava, Slovakia; [2]Hospital Bratislava Ružinov, Bratislava, Slovakia; [3]National Institute of Endocrinology and Diabetology, Lubochna, Slovakia

Currently, acromegaly is treatable by 3 groups of drugs available for the treatment of acromegaly: dopamine agonists (DA), somatostatin analogues (SRL) and a growth hormone receptor blocker (GH receptor antagonist GHRA). More recently, pasireotide and pasireotide-LAR were developed as multi-receptor targeted SRLs with higher potency than 1st generation SRLs/octreotide-LAR and lanreotide/and until now were considered second generation SRLs. Pasireotide, unlike first-generation SRLs, has good affinity for both SST2 and SST5. One of the pasireotide monotherapy groups are non-diabetic patients sufficiently controlled for 1st-generation SRL therapy in combination with low-dose pegvisomant. Pasireotide can also be used in combination with pegvisomant, if the combination of drugs does not sufficiently control the biochemical activity or symptoms of the disease. Short-acting pasireotide demonstrated tumor reduction of at least 20% in 56% of patients after 6 months of treatment. Pasireotide-LAR shows a good tolerability profile, like SRL. The worsening of acromegaly symptoms has been reported to be better with pasireotide than with first-generation SRLs. Hyperglycemia is seen as one limiting factor for its use in acromegaly and Cushing's disease, especially in diabetic or prediabetic patients at the beginning of treatment. However, all that is achieved is that glycemic control is achieved with good standard antidiabetic treatment, only a small proportion of patients require interruption of treatment and hyperglycemia is induced after the end of reversible treatment. In this abstract we share our experiences with pasireoitde treatment in 5 acromegaly subjects. Overall, it could be assessed that pasireotide treatment is sufficiently effective in inducing biochemical control and at the same time a safe treatment modality in terms of adverse effects and hyperglycemia.

Secondary amenorrhea revealing a giant hamartoma of the tuber cinereum

Hayfa Farid[1], Taieb ACH[1,2], Sawsen Nouira[1], Hamza Elfekih[1,2], Yosra Hasni[1,2], Amel Maaroufi[1,2] & Molka Chedli Chaieb[1,2]
[1]Farhat-Hached University Hospital, Department of Endocrinology-Diabetology, Sousse, Tunisia; [2]Faculty of Medicine of Sousse, University of Sousse

Introduction
Hamartomas are benign tumors that occur in many different parts of the body. Brain locations of hamartoma are rare but still reported in few cases such as the tuber cinereum (TC) location. Children with hypothalamic hamartomas develop precocious puberty generally associated with gelastic seizures. However, TC hamartomas do not necessarily induce clinical symptoms. Amenorrhea has never been reported as a revealing symptom of TC hamartomas. Here we describe an atypical discovery of a giant hamartoma of the TC in a young woman who presented for a secondary amenorrhea.
Case Presentation
A 23-year-old woman presented to our department for a secondary amenorrhea associated with recurrent headaches. The past history revealed that the patient had her first periods at the age of 19-year-old, and presented one year after a spaniomenorrhea. On examination, there was no hirsutism, no galactorrhea no signs of hypothyroidism or hypogonadism with a normal neurological examination. Her body mass index was 30 kg/m^2. Pelvic exam was normal. Laboratory data revealed a negative Human Chorionic Gonadotropin level, normal thyroid function and normal serum levels of Growth hormone and ACTH. Serial hormone tests including serum concentration of luteinizing hormone, follicle stimulating hormone, estradiol, and progesterone, indicated normal cyclical ovarian activity. A moderate hyperprolactinemia after dilution was identified (=33 ng/ml [3–20 ng/ml]). There were no other medications intakes explaining the hyperprolactinemia. Synacthen testing showed normal adrenal response. A luteinizing hormone-releasing hormone test showed a normal gonadotrophin response excluding the pituitary cause of the secondary amenorrhea. Hyperprolactinemia was the selected diagnosis to secondary amenorrhea. A magnetic resonance imaging revealed a homogeneous suprasellar hamartoma of the TC of 20 mm, with sellar extension. The hyperprolactinemia was explained by the mechanical compression on the pituitary stalk. The patient was started on cabergoline with an improvement of the prolactin levels and had a natural pregnancy 6 months later.
Conclusion
The hamartoma of the TC is a rare, non-neoplastic heterotopic mass of normal nervous tissue. In contrast, during early life, the diagnosis is made of clinical symptoms such as precocious puberty and/or gelastic seizures. Works on clinical manifestations in the adult life are rare. In our case the main symptom was a secondary amenorrhea. More detailed imaging techniques and new molecular methods may, in future, provide further insight into the pathogenesis of either sexual impairment or seizure activity in TC hamartoma.

EP927

A case of inappropiate secretion of thyrotropin-to be or not to be a TSHoma

Cristina Stancu[1], Vlad Radulescu[2], Andreea Cristina Bordeianu[2] & Corin Badiu[2,3]
[1]National Institute of Endocrinology Endocrinology IV, Bucharest; [2]National Institute of Endocrinology Endocrinology IV, Bucuresti; [3]Carol Davila University of Medicine and Pharmacy Endocrinology Bucuresti

A 39 years old pacient presented for the first time in may 2023 with altered vision, dizziness, tachycardia and palpitations with paraclinical investigations suggestive for inappropiate TSH secretion: TSH=5.31 μUI/ml (NR: 0.27-0.42), fT4=56.8 pmol/l (NR: 11.9-21.6), fT3=17.4 ng/dl (NR: 3.1-6.8), ATPO <9 UI/ml, ATG=12.7 UI/ml (NR: 0-115). He has been treated with antithyroid drugs (Thiamazole 10 mg per day). The thyroid ultrasound and ophthalmological exam were normal. Additional laboratory testing showed elevated level of prolactin=919 μUI/ml (NR: 86-324) and SHBG=141 nmol/l (NR: 18.3-54.1), IGF-1=126.5 ng/ml (NR: 83-238). We repeated the thyroid function which revealed: TSH=4.71 μUI/ml (NR: 0.35-4.94), fT4=24.69 pmol/l (NR: 9-19), T3=208.26 ng/dl (NR: 35-193). He never experienced galactorrhea or symptoms of low libido. The MRI exam revealed a sellar gadolinophilic tumor with suprasellar extension, having contact with the optic chiasm and the left optic nerve, extended at the level of the right cavernous sinus measuring approximately 20/28.1/24 mm (AP/lL/CC) concordant with clinical manifestations and laboratory results. The tumor ablation was performed through transsphenoidal approach endoscopic assisted. The histophatological and immuno-histochemistry results proved that it was a plurihormonal macroadenoma prolactin and GH secreting but with negative staining for TSH (repeated twice), ACTH, LH, and FSH. Given all the information, we could not exclude an immature adenoma of PIT1 line which requires additional genetic testing. After surgery, at 3 months apart, the pacient presents central hypothyroidism, central adrenal insufficiency, confirmed with the insulin tolerance test (basal cortisol=0.62 μg/dl, maximum cortisol=8.79 μg/dl) and somatotroph insufficiency (maximum GH=0.16 ng/ml) but with normal pituitary-gonadic axis and prolactin slightly above the upper limit of normal. We substituted the thyroid and the adrenal function. At 5 months post-surgery we obtained optimal thyroid and adrenal substitution, and partial stimulation after 1 μg of Synachten i.v with the highest cortisol level=17.58 μg/dl with normal somatotroph and gonadal axis (we considered optimal stimulation if cortisol >18 μg/dl, partial response 12-18 μg/dl and diagnostic for insufficiency <12 μg/dl). In conclusion, particularity of the case is the initial clinical and biochemical setting of the patient which is in contrast with the histopathological exam of the macroadenoma and also the partial recovery of the adrenal axis, especially after pituitary surgery.

A rare case of transient central hypothyroidism

Zora Lazurova[1], Juraj Semancik[1] & Martin Javorsky[1]
[1]University of PJ Safarik, 4th Department of Internal Medicine, Kosice, Slovakia

We report a case of 48 years old female with history of arterial hypertension and breast cancer in long term remission. She was admitted to the hospital due to strong headache. MRI of the brain revealed spontaneous intracranial hypotension caused by the cerebrospinal fluid (CSF) leak in left fronto-parietal region, thickening of pachymeningeal tissues, distension of sinus transvs and cranial buldging of the pituitary gland with non homogenous structure. Although patient did not present any clinical symptoms suspicious for hypopituitarism, the hormonal profile was performed and the central hypothyroidism was found (TSH less then 0.005 mIU/l; $n=0.3$-4.2 mIU/l, fT3 4.06 pmol/l; $n=$ 3.1-6.8 pmol/l, fT4 11.02 pmol/l; $n=$ 11.9 – 21.6 pmol/l), while all other axes were intact. Thyroid hormones were mildly decreased, therefore no substituion therapy was indicated. Patient underwent the procedure using epidural blood patch, with excellent clinical outcomes, CSF leak disappeared right after procodure. Hormonal tests one month after procedure found mild improvement of central hypothyroidism (TSH 0.03 mIU/l, fT3 4.6 pmol/l, fT4 11.2 pmol/l), other axes remained normal. Three months after procedure the MRI check up revealed complete resolution of the signs of intracranial hypotension, also pituitary gland turned to be homogenous and not enlarged. Laboratory tests shown normalization of thyroidal axis function (TSH 2.1 mIU/l, fT3 4.9 pmol/l, fT4 14.6 pmol/l). This case presents a rare cause of transient central hypothyroidism due to a spontanoues intracranial hypotension. To the best of our knowledge, only few cases of hypopituitarism in patients with this rare condition have been described to the date.

Psychological aftermath of acromegaly: a case report

John Warner-Levy[1] & Adrian Heald[1]
[1]Salford Royal Hospital, Salford, Department of Endocrinology and Diabetes, Salford, United Kingdom

Case

Acromegaly is associated with osteoarthritis due to soft tissue swelling. Our patient was first diagnosed with acromegaly in 2001 at the age of 51, subsequently undergoing a transsphenoidal pituitary adenoma resection in 2002, followed by postoperative radiotherapy in 2003, with subsequent development of anterior hypopituitarism. He has comorbidities of osteoarthritis, (having previously undergone bilateral total hip replacements and a left total knee replacement), bunionectomy with pinning of the right great toe in 2014, well-controlled T2DM, and a colonic polyp. He currently takes Hydrocortisone/levothyroxine/Tostran gel/Pegvisomant(*GH receptor antagonist*)/Omeprazole/Tramadol/Calcichew/Rosuvastatin/Metformin/Naproxen, and Lanreotide(*somatostatin analogue*). Although his acromegaly remains well controlled with a normal IGF-1, he still suffers from significant joint pain and experiences limited mobility as sequelae of his acromegaly. Due to his joint problems as a result of his acromegaly, he unfortunately had to stop working as a warehouse operative in 2011. Since leaving work, he has felt anergia and a lack of motivation. In an attempt to overcome this, between 2011 and 2020, he was volunteering regularly. On days when he was volunteering, he felt engaged and well, but on days when he was not working as a volunteer, he would find himself sleeping excessively with an absence of purpose. All of these activities finished with the Covid-19 pandemic, and since then, he has not been able to perform any voluntary work. His symptoms have since worsened, with a pronounced feeling of 'pointlessness' and continuing weariness. He believes his motivation would return if he regained structure to his life. Frustrations have also arisen due to no longer being able to perform simple 'DIY' household tasks, due to difficulty bending over and balancing on ladders. In January 2024 he was seen by an endocrinologist in a regional chronic fatigue syndrome clinic. It was felt that he did not have chronic fatigue syndrome but rather was experiencing reactive low mood as a result of a major change in his functional level over the last decade or so. On consultation with a clinical psychologist, it was felt that a referral to his local Social Prescribing Team would facilitate some low-intensity cognitive behavioural therapy while also putting him in touch with organisations who could potentially provide him with some structured and meaningful voluntary work. He continues to follow up with his endocrinologist.

Radiation-induced hypopituitarism: a case report

Yelena Aghajanova[1,2] & Sona Maghakyan[1,3]
[1]Yerevan State Medical University after Mkhitar Heratsi, Department of Endocrinology, Yerevan, Armenia; [2]Muratsan University Hospital, Department of Endocrinology; [3]Mikaelyan Institute of Surgery, Department of Endocrinology, Yerevan, Armenia

Introduction

Radiation treatment is used for patients with secreting and non-secreting pituitary adenomas, residual pituitary adenomas, or recurrent pituitary adenomas to achieve long term disease control. The hypothalamic–pituitary unit is a particularly radiosensitive region in the central nervous system and pituitary hormone deficiencies are the commonest late complication of radiotherapy, which usually occur after several years. The development of hormone deficiencies with time varies in the published literature. We report a patient with hypopituitarism who developed clinical manifestations 2 years after radiation therapy.

Case Presentation

A 59-year-old man, who complained of general weakness and shortness of breath for the past 1-month, lost consciousness, had cardiac arrest. Ambulance was called, CPR was performed and the patient was transferred to the ICU of the hospital. There he was treated with infusion therapy, inotropic therapy, water-electrolyte balance treatment (KCl 4%), oxygen, insulin therapy, anticoagulants, gastroprotective therapy. Patient had a history of Lymphoblastic leukemia, which has been diagnosed 5 years ago, he underwent chemotherapy, radiation therapy and has been in remission for the past 2 years. He also had Type 2 Diabetes for 15 years, and was on insulin therapy for past 6 years. He had history of acute respiratory infection 1 month before current admission. On admission, examination revealed Ps=62 bpm, BP=106/65 mmHg, T=36.5^{0}C, SpO_2 95 % (7 liter/min O_2+), SpO2 80% (O_2-), BMI=33.6 kg /m^2. Daily diuresis 8000 ml, urine specific gravity-1005-1002-1004. Fasting glucose -10.4-9.8-6.8 mmol/l. Chest X-Ray, ECG and Echo were normal. Hormonal tests: LH-<0.100 mIU/ml (N 1.7-8.6), FSH- 0.457 mIU/ml (N 1.5-12.4), TSH-<0,009 uIU/ml (N 0.3-4.5), FT4-0,899 pg/ml (N 8.9-17.2), ACTH-2.14 pg/ml (7.2-63.3), Cortisol-21.89 nmol/l (171-586), Prolactin-4.07 ng/ml (4.6-21.4), Testosterone-<0.025 ng/ml (2.8-8), HbA1C -6.6% (4.8-5.9). Brain MRI was without features. He was diagnosed with Panhypopituitarism. Secondary hypocortisolism, Secondary hypothyroidism, Secondary hypogonadism, Central diabetes insipidus. Type 2 diabetes mellitus. The patient was given Oxygen, Infusion therapy, Levothyroxine 25 mg (2 days), then 50 mg (5 days) and 75/50 mg every other day, Hydrocortisone 10/5/10 mg 3 times daily, then 10/10/10 mg and 15/10/15 mg doses, Desmopressin at first 2 drops, then 3 drops daily. Dose adjustments were made with blood pressure, pulse and diuresis monitoring. The patient improved on treatment, he was discharged in good general health condition and was advised to continue hormonal therapy with the same doses and see endocrinologist regularly.

Conclusion

According to literature, clinical evaluation, baseline pituitary hormone assessment, and dynamic testing for growth hormone and adrenocorticotropic hormone (ACTH) deficiency (because they are the most sensitive) should begin one year after radiotherapy to prevent these life-threatening complications.

Endolymphatic sac tumor with von hippel–lindau disease: report of a case

Rachida Bouattay[1], Nawres Bouaziz[1], Mehdi Ferjaoui[1], Elkorbi Amel[1], Naourez Kolsi[1], Harrathi Khaled[1] & Jamel Koubaa[1]
[1]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Introduction

Endolymphatic sac tumors (ELSTs) are very rare and locally aggressive low-grade neoplasm of endolymphatic system origin, which can arise sporadically or in association with von Hippel–Lindau (VHL) disease. It is an autosomal dominant multisystem disorder with a prevalence of 1 in 39 000 people that predisposes the patients to clear cell neoplasms of various organs. Herein, we report a rare case of an ELST in a patient with VHL disease, in order to describe the clinicopathologic features of the case.

Case presentation

A female, 58-year-old patient was referred to our Otolaryngology Department with one-year history of progressive sensorineural hearing loss in the left ear and non-pulsatile tinnitus. The family medical history disclosed the presence of symptoms of von Hippel–Lindau disease. Her mother, brother and three nephews had history of resection of cerebellar hemangioblastomas and evidence of genetic

VHL disease. A complete otorhinolaryngological examination was performed and it was normal. Pure tone audiometry showed left side mild sensorineural hearing loss. Computed tomography (CT) scan done primary without contrast then injected in second time showed a low-density lesion with enhancement on contrast arising from the left side of the cerebellopontine angle region. Erosion of the left petrosal bone and mastoid air cells was observed, extending to the internal auditory meatus. On magnetic resonance imaging (MRI) study, a 3.2×1.8×2.6 cm hyper vascular lesion was detected in the petrous part of the left temporal bone and mastoid air cells. Moreover, a work-up was performed to confirm the VHL syndrome. An ophthalmologic examination done detected multiple hemangioblastomas of the retina and an ultrasonography of the abdomen revealed bilateral renal cysts. Genetic study was not performed on our case. With these findings a provisional diagnosis of ELST associated with VHL disease was made. Therefore, the patient was treated with intensity modulated radiotherapy. She is followed regularly for 36 months with routine MRI surveillance. There were no several complaints and MRI display no radiological signs of progression.

Discussion & Conclusion

Endolymphatic sac tumors are rare neoplasm of the petrous temporal bone that has a slight female predominance. The association between ELST and VHL disease has increased our knowledge of this rare tumor. Approximately 10% of patients with VHL disease have ELSTs. Early surgery resection is the best treatment strategy of this tumour and radiotherapy is used almost exclusively as palliative treatments for tumors that cannot be resected completely.

A rare association of insulinoma in tuberous sclerosis complex patient

Muhammad Tahir Chohan[1], Davis Ogeto[1], Kamal Abouglila[1], Irfan Khan[2], M Shafie Kamaruddin[2], Anna Mitchell[3], Earn Gan[3], Manu Nayar[4] & Wasfi Alrawashdeh[4]

[1]University Hospital of North Durham, United Kingdom; [2]Darlington Memorial Hospital, United Kingdom; [3]Royal Victoria Infirmary, United Kingdom; [4]Freeman Hospital, United Kingdom

Introduction

Tuberous sclerosis complex (TSC) is a multisystem inherited disease associated with neurocutaneous manifestations and multiple hamartomas but rarely associated with neuroendocrine tumours (NETs). The current TSC guidelines do not recommend routine screening for NETs in TSC.

Case report

21 year old male with genetically confirmed tuberous sclerosis (TSC-2 mutation) with intellectual disability, epilepsy with previous episodes of status epilepticus and stable subependymal giant cell astrocytoma. Medications included Sodium valproate, Clobazam, Lamotrigine, Perampanel, Cenobamate and buccal midazolam as needed. His usual seizure frequency was several absence seizures throughout the day but only 1-2 generalised tonic-clonic seizures per month. He was admitted with increased frequency of generalised tonic-clonic seizures over the preceding few weeks and was found to have spontaneous hypoglycaemia (1.9 mmol/l). Subsequent investigations confirmed endogenous hyperinsulinism (fasting laboratory blood glucose 1.9 mmol/l, C-peptide 0.56 (0.34-1.8 nmol/l) insulin 43.7 (12-150 pmol/l)). Short synacthen test, thyroid function tests and antiepileptic drug levels were satisfactory. CT of the chest, abdomen and pelvis did not reveal any concerning abnormalities; neuro-imaging showed a stable astrocytoma. A Tektrotyd scan did not reveal any Tektrotyd avid pancreatic lesion. Given high suspicion of underlying insulinoma clinically, he underwent endoscopic ultrasound which revealed an 18 mm hypoechoic lesion close to the tail of pancreas and splenic hilum. A biopsy confirmed well differentiated pancreatic NET with expression of insulin (Ki-67 $<2\%$)

Management

His blood sugars were managed with a combination of diazoxide, subcutaneous octreotide and intravenous dextrose infusions. After the biopsy confirmed pancreatic insulinoma, he underwent laparoscopic spleen preserving distal pancreatectomy with complete excision of underlying insulinoma. After surgery, his diazoxide, octreotide and dextrose infusions were stopped and he did not have any further hypoglycaemic episodes.

Conclusion/learning points

Insulinoma is an uncommon pancreatic NET. It is rarely associated with TSC but should be considered in people with TSC who have spontaneous hypoglycaemia or increased seizure frequency, as early diagnosis and surgical management results in better treatment outcomes.

Cardiovascular complications in acromegaly

Zahra Ismail[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]

[1]University Hospital Center Mohamed VI, Departement of Endocrinology, Diabetes and Metabolic Disease, Marrakech, Morocco

Introduction

Chronic excess of growth hormone is responsible for numerous cardiovascular, respiratory, metabolic and neoplastic complications, leading to significant morbidity and mortality. The aim of this study is to analyze the different cardiovascular manifestations and cardiovascular risk factors in acromegaly.

Methods

A retrospective descriptive study including 44 patients hospitalized in the endocrinology department of University Hospital Mohamed VI of Marrakech, from October 2006 to February 2022. Data were collected from medical records.

Results

the sex ratio is 1, mean age of 46.7 years [15-68]. GH hypersecretion was related to a pituitary adenoma in all cases. The IGF-1 measured in 32 patients, was elevated in 31 (96.87%), GH was elevated under OGTT in 1 patient, and in 12 patients, the diagnosis was made retrospectively based on pathology results (27.3%). Cardiovascular risk factors: hypertension was present in 27.3% of cases, diabetes in 34% and dyslipidemia in 2.2%. thirty four percent of patients was overweight and 9% obese. None of the patients had a coronary syndrome or stroke. The ECG found electric left ventricular hypertrophy in 34% of cases. Chest X-rays showed cardiomegaly in 27.2% of cases. Echocardiography was performed in 29 patients, and showed abnormality in 4 cases (9%): left ventricular hypertrophy in 2 patients, hypertrophic dilated cardiomyopathy in one patient and stage 3 tricuspid valve disease in 1 patient.

Conclusion

Cardiovascular complications are very common in acromegaly (20-50% of cases), dominated by hypertension and hypertrophic heart disease. Compared with the general population, the risk of death in patients with acromegaly is increased to 61%, The main cause of mortality is cardiovascular complications. The higher the level of GH and the longer the course of the disease, the more serious these complications become. The evolution of cardiovascular complications during acromegaly management appears to vary greatly according to the disease history and the degree of control of GH excess. Some studies have shown that the cardiac structure and function improve significantly after the disease is controlled.

Vagal paraganglioma miming a lymph node metastasis of papillary thyroid cancinoma

Amel Elkorbi[1,2], Nawres Bouaziz[2], Mahdi Ferjaoui[2], Rachida Bouatay[2], Naourez Kolsi[2], Harrathi Khaled[2] & Jamel Koubaa[2]

[1,2]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Introduction

Vagal paragangliomas are rare tumors that developed from paraganglionnar tissue. They are relatively easy to diagnose. They have benefited from advances in diagnostic imaging, particularly angiography and magnetic resonance imaging (MRI). We aim to study the particularities of clinical findings in a vagal paraganglioma miming a lymph node metastases in patient with a history of papillary thyroid carcinoma.

Case report

We report the case of a 66-year-old woman treated for lymph node tuberculosis eight years ago, with a discovery on a cervical ultrasound monitoring of an infracentimetric left thyroid nodule staged EU-TIRADS 4 with lymph node metastases. The patient underwent a total thyroidectomy with bilateral mediastinal lymphadenectomy for multifocal papillary carcinoma associated with lymph node metastases in recurrent chains. The patient was treated by complementary iratherapy with no fixation on technetium scintigraphy. However, thyroglobulin remained at high levels. A cervico-thoracic computed tomography was performed concluding to a vascularized sized 18x30 mm in relation to the left carotid glomus, suggesting lymph node metastases in the context. The patient underwent left functional lymphadenectomy. Per-operatively, we observed a high bleeding lesion closed to the vagal nerve. The extemporaneous examination confirmed the diagnosis of a vagal paraganglioma. Definitive pathology did not show any lymph node metastases. The postoperative period was marked by the

occurrence of a recurrent left paralysis with a good course after speech therapy. There were no recurrence of paraganglioma and thyroid carcinoma after six years of fellow-up.
Discussion/Conclusion
Paragangliomas are usually benign tumors. They are rare and slow in evolution. Management is well codified included imaging for the diagnosis of the tumor and its extensions, surgery as standard treatment and radiotherapy is an alternative in non-operable cases. Nevertheless is not usually the rule, as in our case we misdiagnosed the paraganglioma on the CT scan, as it highly mimed a lymph node metastasis.

Body mass index in patients with prolactinoma
Hind Ouakrim[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Chu Mohamed Vi Marrakesh - Drh, Marrakech, Morocco

Introduction
Hyperprolactinemia may be associated with weight gain, metabolic syndrome, and insulin resistance. Treatment with dopamine agonists (DA) has been shown to reduce body weight and improve metabolic parameters. The objective of our study is to confirm weight gain secondary to hyperprolactinemia and analyze the evolution of weight in patients under dopaminergic antagonists.
Materials and Methods
This is a prospective cross-sectional analytical study conducted over an 8-year period involving 88 patients aged $\geq$18 years, followed for prolactinomas who adhered to medical treatment with DA.
Results
The average age was 35 years, with most females (70.5%). The mean BMI was 28 kg/m^2, and the average abdominal waist circumference was 106 cm. The prevalence of overweight was 36.4%, and obesity was 34.1%. The average treatment duration was 6 years. Weight reduction was observed in 29.5% of patients.
Discussion and Conclusion
Patients with prolactinomas have a higher prevalence of obesity or overweight compared to normal individuals. The mechanism by which hyperprolactinemia induces weight gain is not fully understood, but the blockade of dopaminergic tone may play a significant role. Studies have shown that hyperprolactinemia affects the expression of genes involved in appetite regulation, contributing to increased fat mass in these patients. Normalizing prolactin levels can improve body composition. It is crucial to monitor BMI in patients with hyperprolactinemia and take measures to maintain an ideal weight and reduce the risks of associated diseases.

Unusual revelation of a pheochromocytoma with neurofibromatosis type 1
Souleima Trigui[1], Dhoha Ben Salah[2], Dhieb Nesrine[2], Charfi Hana[2], Frikha Hamdi[2], Fatma Mnif[2], Mouna Mnif[2], Mohamed Abid[2] & Nabila Mejdoub[2]
[1]Chu Hedi Chaker, Endocrinology Sfax, Tunisia; [2]Chu Hedi Chaker, Endocrinology Sfax

Introduction
Pheochromocytoma represents only 5% of adrenal incidentalomas. It is malignant in only 10% of cases. We report a case of pheochrompcytoma with suspucion of double cortico-meullary component or an ectopic secretion of CRH in the context of neurofibromatosis type1
Observation
A26year old woman with a history of unilateral renal lithiasis, colic and breast neoplasia, with no notable personal history, consulted for right lumbar pain. An abdominal CT scan showed a solidocystic right adrenal incidentaloma with a spontaneous density of 40 HU measuring 79$\times$75 mm and a slightly irregular contour. The fleshy portion had an absolute washout of 33%. It displaces the liver above and the upper pole of the kidney below. It displaces the inferior vena cava and the right renal vein medially. The left adrenal gland is unremarkable. Pheochromocytoma was suspected in the presence of paroxysmal malaise with headaches, palpitations, and weight loss. Her BMI was of 25 kg/m^2. ambulatory blood pressure measurement had shown blood pressure paroxysms with concomitant tachycardia In addition, she had café au lait spots, axillary lentigines and cutaneous and subcutaneous neurofibromas. However, she had no signs of hypercorticism or recent virilisation. Hotmonal exploration concluded to a mixed secretion of catecholamin and cortisol. ACTH was 34.8 pg/ml. 17 OH progesterone and SDHEA levels were normal fter confirming the diagnosis of pheochromocytoma, a thoracic-abdominal-pelvic CT scan did not reveal any metastases or secondary locations. Indeed, our patient neurofibromatosis type 1 and Slit lamp examination revealed lish nodules. she had no flush syndrome and Calcitonin was normal. She underwent a right adrenalectomy by right laparotomy The anapatomopathological examination showed a pheochromocytoma of 10 cm with a PASS score of 5 with cystic and haemorrhagic changes without necrosis nor capsule infiltrationThe immunohistochemical study was strongly positive for chromogranin, and negative for ACTH, but not unavailable for CRH. At 2 months postoperatively, normalization of Metanephrine and Normetanephrine levels as well as a positive minute braking were noted. ACTH was normal and The CT scan performed showed postoperative remodelling of the right adrenal gland without signs of recurrence.
Conclusion
Mixed corticomedullary tumour (MCMT) of the adrenal gland is an extremely rare tumour characterised by a mixture of steroidogenic and chromaffin cells in a single tumour mass. It is associated with ectopic adrenocorticotropic hormone in some cases. Current theories regarding the pathogenesis of MCMT should be further investigated by genetic testing

Hypokalemia and neurocognitive impairment in a female patient admitted to the emergency department – case report
Dumitras Teodor[1], Duta-Ion Simona[1], Juganaru Ruxandra[1], Clement Robert[2,3] & Fica Simona[1,2]
[1]Department of Endocrinology, Elias University Emergency Hospital, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [3]Department of NeuroSurgery, Colentina Clinical Hospital

Introduction
Hypokalemia is a dyselectrolytemia which can cause weakness, paralysis, neurological symptoms, cardiovascular complications and sometimes can be fatal. It can be diagnosed in uncontrolled diabetes mellitus, hyperaldosteronism, gastrointestinal or renal pathologies.
Case report
A 67 year old female was admitted to the emergency department with confusion, cognitive impairment and headaches and no other known medical history. She presented discrete ecchymoses, discrete facial hirsutism, hypertension 170/110 mmHg, obesity with a BMI of 32 kg/m^2. Laboratory exams revealed hypokalemia (2.9 mmol/l: normal range 3.6-5.1), metabolic alkalosis and newly diagnosed diabetes mellitus (glycemia 254 mg/dl and Hba1c 10%). She was also diagnosed with severe cognition impairment and depression. Renin and aldosterone levels were normal, but the basal cortisol value was very high (37.3 mg/dl: normal range $<$20 mg/dl) with high ACTH (108 pg/ml: normal range 7.2-63.3 mg/dl) and also high DHEAS (2 times upper limit of normal value). After the 1mg dexamethasone overnight test the cortisol value was 26.5 mg/dl, after 2$\times$2 dexamethasone test 21.9 mg/dl and after 8$\times$2 high dexamethasone supression test 7.8 mg/dl (supression $>$50%, but still $>$1.8 mg/dl). Thorax, abdominal and pelvis computed tomography performed in the ER showed no other tumors. The cerebral and pituitary MRI revealed left sided pituitary microadenoma 5/5/5 mm and a right cerebellopontine angle tumor (neurinoma) of 20/30 mm. After a multidisciplinary team approach we decided to go for transsphenoidal surgery, and in the weeks before the operation she received medical treatment with spironolactone 100mg/day, mifepristone 200mg/day, potassium oral and IV supplementation, antihipertensive medication, antidepressive medication, oral antidiabetics. She performed the surgery, with the pathological exam confirming the diagnosis of pituitary tumor with basophilic ACTH secreting cells. First day after the operation she presented a cortisol level of 1,1 mg/dl and at one week the patient presented low cortisol (3,15 mg/dl) and low ACTH (12,75 pg/ml) with significant improvement of neurocognitive and depressive status, tension and glycemic control. She was discharged with substitutive corticotherapy for secondary adrenal insufficiency (20mg hydrocortisone equivalent to 5mg prednisone per day).
Conclusions
Cushing disease is a very important endocrinological pathology which can present under multiple clinical presentations. It requires an efficient work-up and diagnosis in order to offer the best medical approach available. What is more, the

postoperative periodic follow-up is mandatory due to the known risk of recurrence.

EP1021

Primary pituitary abcess: case report

Aicha Lachkhem[1], Mezaache Ahlam[1], Abdelkader Yahi[1], Lounes Haffaf[1], Bensalah Meriem[1], Abderrahim Derriche[2] & Derradji Hakim[3]

[1]Army Central Hospital, Endocrinology, Algiers, Algeria; [2]Army Central Hospital, Radiology, Algiers, Algeria; [3]Army Central Hospital, Neurosurgery, Algiers, Algeria

Introduction

Pituitary abscess (PA) is a rare accounting for 0,2-1% of all sellar lesions, it is generally classified as primary or secondary according to their etiopathogenesis.

Case

A 20-year-old female with a history of vulvitis a year ago, dental abscesses on multiple dental caries who presented 05 months ago with intracranial hypertension syndrome in a febrile context. One-month later amenorrhea sets in as well as polyuropolydeptic syndrome, hormonal exploration reveals panhypopituitarism and the MRI showed a pituitary abscess measuring 13×14 mm extended to a height of 10 mm presenting in discrete T1 hyposignal, T2 hypersignal and diffusion with clear drop in ADC, enhancing in an annular and peripheral manner after injection of gadolinium salts, the patient was treated with double antibiotics therapy for 21 days without success as well as dental care. The abscess disappears spontaneously after 8 months of evolution.

Discussion

Primary PA represent the most common type, accounting for 67% of all cases so far reported and result from hematogenous bacterial spread to an otherwise normal pituitary gland. On the contrary, secondary PA occur in only 33% of cases and represent a secondary infection of pre-existing sellar lesions. In those cases of secondary PA, factors such as the anatomical distortion and subsequently impaired circulation, as well as the altered immunological status may be considered a pre-existing condition for abscess formation. On the contrary, due to the limited number of cases so far reported and their heterogenous management, little is known about the risk factors and natural history typical of primary PA. PA pathophysiology is still unknown for both primary and secondary PAs, even though several hypotheses have been considered. Atlas *et al*. reported that either primary or secondary PA could be the result of both hematogenous seeding or direct extension from an adjacent infectious process, as in cases of sphenoid sinusitis, meningitis, or contamination from a CSF fistula. Vates *et al*., in their series, reported that 16.7% of patients had a history of sepsis, Charles-Henry Mallereau *et al*. reported only 4 of 84 patients with a medical history of dental granuloma that could potentially be considered as the primary infectious focus. Other risk factors considered included an underlying immune-compromised condition and previous radiotherapy

Conclusion

Despite highly sophisticated clinical and radiological investigations, the preoperative diagnosis of PA remains challenging and recently led to the proposal for a management algorithm for sellar masses suspected for being PA.

Erdheim-chester disease: a case report with pituitary involvement

Tugce Apaydin[1], Shahla Aghamaliyeva[2] & Özlem Üstay[3]

[1]Alanya Alaaddin Keykubat University Training Hospital, Endocrinology and Metabolism, Antalya, Turkey; [2]Marmara University Faculty of Medicine, Internal Medicine, Pendik; [3]Marmara University Faculty of Medicine, Endocrinology and Metabolism, Pendik

Introduction

Erdheim-Chester disease (ECD) is a rare non-Langerhans histiocytic multisystem disorder, which mainly presents with multifocal sclerotic lesions of the long bones, followed less frequently by heart, lung, central nervous system, skin, pituitary, and orbital involvement. Here, we presented a rare case of ECD manifested in a young male subject with pituitary involvement.

Clinical Case

A 19-year-old man was referred to our outpatient clinic with polydipsia and polyuria. He complained of headaches, retro-orbital pain, and swelling in the scalp. Physical examination showed bilateral exophthalmos, and bone swelling on the right frontal and parietal bone. In laboratory examination, urine density, serum sodium, and serum osmolarity were 1005 g/mL, 140 mEq/l, and 285 mOsm/kg; respectively. His FSH, LH, free testosterone, growth hormone, and IGF-1 levels were low, and the remaining anterior pituitary hormones were within normal range. The water deprivation test confirmed the diagnosis of Arginine vasopressin deficiency (AVP-D) and desmopressin nasal spray (10 μg/day) was started. Pituitary magnetic resonance imaging showed 8x6 mm nodular enlargement with diffuse contrast enhancement after intravenous contrast material (IVCM) injection in the middle part of the distal-pituitary gland. Multiple mass developments, enlargement of the diploe distance both in the fronto-occipital and parietal bones were observed after IVCM. A 4×2.5×2.5 cm lesion extending to the cerebellar vermis was observed in the posterior fossa. Radiographic investigation of the long bones determined lytic lesions and positron emission tomography revealed an increased uptake of 18F-FDG in the both proximal humerus, radius, ulna, distal ends of femur, tibiae and all bones in the cranium. Resection of posterior fossa lesion was performed and pathology revealed foamy CD68+, CD163+, S100-, CD1a− histiocytes, sparse giant cells, and fibrosis. This diagnosis of ECD was confirmed both histologically and immunohistochemically. BRAF V600E mutation screening was positive. Vemurafenib 480 mg twice daily was started due to the central nervous system involvement. Bone pain was regressed three months after the treatment, and anterior pituitary hormone deficiency was recovered. However, AVP-D persisted.

Conclusion

Diabetes insipidus is usually the first and most common endocrine manifestation of ECD. Hypopituitarism is rare but in order from most frequent to least; hypogonotrophic hypogonadism, growth hormone deficiency, thyrotropin deficiency, and adrenocorticotropic hormone deficiency can be present. Treatment is warranted for patients with symptoms or those with evidence of central nervous system involvement or organ dysfunction. Pre-existing AVP-D and endocrinopathies typically tend to persist, even after radiographic regression of disease.

EP1025

A low-grade somatotroph adenoma presenting as a giant pituitary macro-adenoma

Yin Yin[1], Rebecca Evans[1], Cynthia Mohandas[1], Itopa Abedo[1] & Arthur Ogunko[1]

[1]Darent Valley Hospital, Dartford and Gravesham NHS Trust, Endocrine and DM, Dartford, United Kingdom

A 31-year-old lady was referred to the outpatient endocrine clinic for subfertility, intermittent galactorrhoea and amenorrhoea since birth of her son 5 year ago. However, she denied visual disturbances and headache. She was struggling to lose weight but she had no clinical features suggestive of corticosteroid or growth hormone excess apart from an increase in her UK shoe size from 5.5 to 6.5 and family members noted her hands were slightly bigger. She was on an antidepressant, Sertraline, which was withheld for two weeks, so that a repeat pituitary profile can be carried out. It showed hypogonadotropic hypogonadism. The results were as follows: FSH 1.2 IU/l (2.5-10.2), LH <0.2 IU/l (1.9-12.5); oestradiol <55 pmol/l (55 - 422), Prolactin 1200 mIU/l (70 - 566) and IGF11 45 mol/l (10.2 to 40.7). But the Cortisol level, TSH and ACTH were within acceptable range. MRI pituitary demonstrated a pituitary/suprasellar mass with a 45mm craniocaudally dimension, which was displacing the optic chiasm superiorly and compressing on it. Formal visual field testing showed bilateral superior temporal quadrantanopia. She underwent Trans-sphenoidal surgery and was initiated on hydrocortisone replacement post-operatively. There was evidence of residual tumour in postoperative MRI scan and histology showed eosinophilic excess with intranuclear inclusions and immunohistochemistry demonstrated PIT 1 lineage pituitary adenoma, variably intense positivity for TSH predominantly, second most frequent was GH with Ki 67 3 %. Post-surgery, the Pituitary multidisciplinary team meeting (MDT), diagnosis was clinically silent and low-grade somatotroph adenoma biochemically. There was subjective improvement in the vision post operatively with normal VF confrontation and normal prolactin 289 mIU/l but persistently raised IGF153.9 mol/l. MDT noted that good debulking surgery but there was still a residual suprasellar part of tumour. Somatostatin analogue (SSA) therapy was recommended and re-do surgery for residual tumour if SSA therapy failed to achieve the therapeutic goal. The plan is to repeat MRI Pituitary and assess pituitary function with insulin tolerance test in 3 months. Learning points: This case highlights the somatotroph adenoma is presenting with a silent pituitary mass for decades and that diagnosis can be delayed until the clinical or biochemical manifestation of acromegaly. We picked up the diagnosis early by chance simply because she was investigated for subfertility. Surgical debulking surgery is main stay of treatment in somatotroph

adenoma as it can lower GH levels and improve the cure rate with subsequent SSAs.

Cushing's vs pseudo-cushing's: neutrophil-lymphocyte ratio assessment

Ekin Yiğit Köroğlu[1], Didem Özdemir[2], Muhammed Saçıkara[1], Hüsniye Başer[2], Oya Topaloğlu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Cankaya; [2]Ankara Yıldırım Beyazıt University Faculty Of Medicine, Endocrinology and Metabolism, Cankaya

Objective
The neutrophil-lymphocyte ratio may increase in Cushing's Syndrome. We aimed to demonstrate the usability of the neutrophil-lymphocyte ratio in the differentiation of Cushing's Syndrome and Pseudo-Cushing's Syndrome, whose differential diagnosis is clinically and laboratory challenging.
Material and Methods
23 patients were included in the study. Patients were divided into Cushing's Syndrome and Pseudo-Cushing's Syndrome groups according to clinical findings and combined Dexamethasone-CRH test results (with cut-offs of 1.4 mg/dl, 3.1 mg/dl, and 3.9 mg/dl). The neutrophil and lymphocyte values and screening tests of Cushing's Syndrome were recorded. The neutrophil-lymphocyte ratio was calculated and compared between Cushing's Syndrome and Pseudo-Cushing's Syndrome groups.
Results
The neutrophil-lymphocyte ratio differed significantly when we grouped patients clinically (2.47 ± 1.38 vs 1.51 ± 0.44, $P=0{,}033$). Since only one patient was evaluated as having Pseudo-Cushing's Syndrome with a cut-off value of 1.4 mg/dl, statistical analysis could not be performed for this value. When grouping was made according to the 3.1 mg/dl cut-off, there was no significant difference in neutrophil-lymphocyte ratio (2.41 ± 1.50 vs 1.63 ± 0.51, $P=0.095$). When patients were grouped according to a cut-off of 3.9 mg/dl, the neutrophil-lymphocyte ratio was significantly higher in those with Cushing's Syndrome (2.68 ± 1.57 vs 1.59 ± 0.49, $P=0{,}021$).
Conclusion
The neutrophil-lymphocyte ratio is significantly higher in Cushing's Syndrome patients than in Pseudo-Cushing's Syndrome patients. However, instead of using this parameter alone for diagnosis, it would be more accurate to use it as a contributor to other tests.

Neurosteroids refer to hormones with a steroid structure and, their synthesis pathways are identical to those of traditional steroids. However, neurosteroids are generated denovo in the central and peripheral nervous systems and utilize cell surface receptors. Few animal studies indicated synthesis of NS in pituitary. Presence of neurosteroids in human pituitary adenomas(PAs) has yet to be assessed. This is preliminary data of an ongoing study. Seventyseven specimens from human PAs were included. Blood samples were obtained preoperatively. Samples were analyzed by using mass spectrometry. Table 1 compares tissue availability and levels of NS between

Panhypopituitarism diagnosed in old age: a case report

Kader Ugur[1,2], Melik Genç[1], Mithat Mızrak[1,2] & Süleyman Aydın[3]
[1]Firat University School of Medicine, Department of Internal Medicine, Turkey; [2]Fırat University School of Medicine, Department of Endocrinology and Metabolism, Elazıg, Turkey; [3]Firat University School of Medicine, Department of Endocrinology and Metabolism, Turkey

Introduction
Hypopituitarism is a clinical syndrome that develops as a result of inadequate production and release of one or more pituitary hormones. The prevalence is 45/100,000 and the incidence is 4/100,000 cases/year. Here, we aimed to present a patient with complete pituitary hormone deficiency.
Case
A 75-year-old woman had been followed up with hypertension for 20 years and osteoporosis for 16 years. She underwent surgery 7 years ago for a femur fracture due to a fall. She was admitted to our clinic because of 11 kg weight loss and anemia for the last 6 months. In her anamnesis, we were informed that she had a long history of fatigue, loss of appetite, slowed movements and depressive appearance. She had 6 birth stories and breastfed all her children. She had her last period at the age of 45. We were informed that the patient had a history of 2 head traumas at the age of 15 and 65 years. Basal pituitary hormones and pituitary MRI were requested from the patient with poor general condition. Whole body CT, endoscopy and colonoscopy were requested because of weight loss and anemia. The hormone results were consistent with those of panhypopituitarism (Table 1). The pituitary MRI revealed that pituitary height decreased by 2.5 mm and this result is compatible with partial empty sella. Age-related changes were detected on the whole body CT. Endoscopy and colonoscopy were normal. The DEXA T score was reported as L1-L4: −3, L2-L4: −3.1 and femoral neck: −2.6. Corticosteroids, levothyroxine replacement and bisphosphonate-calcium were initiated. The patient, whose general condition was better, was followed up.
Discussion
Since most of the signs and symptoms seen in pituitary hormone deficiencies in adult patients are non-specific, we suggest that the most important step to avoid a dela, in diagnosis is to carefull, investigate the cause.

Table 1. Laboratory findings of the patient

Empty sella in a patient with clinical and biochemical diagnosis of acromegaly - a case report

Meryam Alahyane[1], Sana Rafi[1], Sidebatt Ammar[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Mohammed VI University Hospital of Marrakesh, Department of Endocrinology, Diabetes, Metabolic Diseases and Nutrition, Marrakesh, Morocco

Background
Acromegaly is an acquired disorder related to excessive production of growth hormone (GH) and insulin-like growth factor-1 (IGF-1). Empty sella (ES) is an anatomical condition of sella turcica that is partially or completely filled with cerebrospinal fluid mainly due to intrasellar herniation of subarachnoid space. Here, we describe a rare case of a patient who presented with clinical and biochemical features of acromegaly who had an ES on pituitary magnetic resonance imaging (MRI).
Case report
A 51 year old female patient, with a recent prediabetes history, Hypertension well controlled under monotherapy. The patient has no history of pituitary apoplexy and has never noticed morphotype changes. Acromegaly was suspected by an endocrinologist during a consultation for goitre. Serum IGF1=481.4 ng/ml (N: 55-234), An oral glucose tolerance test showed no suppression of GH values. Serum levels of prolactin, cortisol, prolactin, TSH and FT4 were normal. Sella contrast-enhanced MRI was performed for tumor localization: T1 and T2 - weighted images revealed ES with no adenoma. Visual field examination was normal. Due to lack of availability, PET/CT couldn't be performed To rule out an ectopic GH secretion. We have decided to start medical treatment with long-acting Lanreotid 120 mg per 28 days, and reeavaluate clinical, Biological and radiological features in 6 months.
Discussion
Acromegaly stems from GH-secreting pituitary tumors in approximately 95% of all cases, and most tumors are visible on MRI of the sella. In 5% of cases, it is caused by the ectopic secretion of growth hormone-releasing hormone (GHRH), which is responsible for pituitary hyperplasia. Primary ES may occur due to the inherent weakness of the diaphragm sella and/or the increase in intracranial pressure promoting herniation of the arachnoid membrane into the pituitary pit. When ES is seen after surgery, irradiation, or medical treatment of pituitary adenoma, it is defined as secondary. Pituitary hyperfunction is rarely seen in ES and acromegaly is the least common finding. The mechanism underlying the association of acromegaly and ES remains unclear. Apoplexy on existing pituitary adenoma and then formation of necrosis can proceed to ES. Since our patient did not have a history of pituitary apoplexy and we could not find any reason for secondary ES, we considered primary ES.

Diabetes insipidus with dilated cardiomyopathy and premature ventricular contractions: case report

Hemmet Al Haddad[1], Amr El Meligi[1], Merrit Makram[1], Noha Tarek[1], Randa Salam[1], Ahmed Fayed[2], Ahmed Atef[1] & Bishoy Yakoob[3]
[1]Cairo University, Internal medicine, endocrinology, Cairo, Egypt; [2]Cairo University, Internal medicine, nephrology, Cairo, Egypt; [3]Cairo University, Cardiology, Cairo, Egypt

Introduction
Central diabetes insipidus (CDI) results from a deficiency of arginine vasopressin (AVP) secretion. It is treated by replacement therapy with the synthetic AVP analogue desmopressin. With atrial distension there is increased afferent vagal stimulation that decreases renal sympathetic tone and inhibits antidiuretic hormone (ADH) release, which in turn leads to the diuresis response. Additionally, atrial distension leads to atrial natriuretic peptide (ANP) release, which has powerful diuretic and natriuretic properties.
Case presentation
25 year male presenting with polyuria of 5 litres daily for 1.5 years not preceded by head trauma, surgery, convulsions nor drug intake.
Physical examination
BP: 140/90 mmHg, Pulse: 58 b/m with frequent irregular irregularity, BMI: 23.3, normal RR and temperature. Unremarkable abdominal, neurological, chest and cardiological
Investigations
Normal CBC, liver kidney functions., Calcium, potassium, and thyroid function HbA1C: 4.4%, Serum osmolality: 279 mOsm/kg (275 to 295), serum sodium: 144 mmol/l (135-145) Urine specific gravity:1015, urine osmolality: 287 mOsm/kg (500-800), urinary sodium in 24 hours showed heavy saluresis: 593 mmol/day (40-220 mmol/day) According to the results of water deprivation test The patient was diagnosed as partial central diabetes insipidus Urine osmolality 302 mOsm/kg, after desmopressin admistration 699 mOsm/kg The patient started treatment with oral desmopressin 0.2 mg/day
Outcome and follow up
The polyuria did not improve despite increasing doses of desmopressin. Even though the patient did not complain of palpitation, he was referred to cardiac electrophysiological studies for his persistent PVCs. Holter showed episodes of sinus tachycardia, frequent polymorphic PVCs (16%) with numerous couplets and triplets. Echo: dilated right and left ventricular internal dimensions with mildly reduced ejection fraction:41% Cardiac MRI: scattered left ventricular mural myocardial areas of altered bright signals on T2w with delayed myocardial enhancement Suggesting inflammatory myocarditis not ischemic disease. The polyuria improved on anti-arrhythmic drugs (b blockers) in addition to anti-ischemic measures.
Conclusion
Inhibition of ADH occurs in cases of atrial dilatation that leads to the diuresis response. Also, atrial distension leads to ANP release, which has powerful diuretic

and natriuretic properties and usually associated with saluresis and can give false positive results with water deprivation test. We report a case of apparently healthy male presenting with polyuria as sole presentation of dilated cardiomyopathy misdiagnosed as diabetes insipidus (DI) by water deprivation test.

Clinical profile of patients with pituitary tumors in a tertiary endocrine center in Kathmandu, Nepal

Ansumali Joshi[1], Srijana Karmacharya[1], Puspa Dahal[1] & Rama Rana[1]
[1]Kathmandu Diabetes and Thyroid Centre, Endocrine, Lalitpur, Nepal

Pituitary tumors are infrequently seen in an endocrine practice. We collected retrospective data from our clinical records of our patients with pituitary tumors from January 2018 to December 2023. There were a total 31 patients; males 9 (29.03%) and females 22 (70.97%). Mean age was 38.54±12.37 years and average BMI was 26.10±3.91. Headache and visual problem was the most common symptom in 13 (41.9%) patients each followed by menstrual irregularity in 8 (25.80%) patients. Hypertension was seen in 12 (38.70%) patients and diabetes seen in 9 (29.03%) patients. Nonfunctioning pituitary adenoma (NFPA) was seen in 8 (25.80%) patients. Most NFPA were macroadenoma 6 (75%). Functioning pituitary adenoma(FPA) was seen in 23 (74.20%) patients. Somatotroph adenomas were 8 (34.78%), prolactinomas were 7 (30.43%), ACTH secreting tumors were 7 (30.43%), thyrotropinoma was 1(4.35%). Most somatroph adenomas were macroadenomas 6(75%). Most prolactinomas were macroadenomas 4 (57.14%). Most ACTH secreting tumours were microadenomas 6 (85.71%). Optic chiasmal compression was seen among 12 (38.71%) patients and all had macroadenomas and 7(58.33%) had functioning tumors. Cavernous sinus invasion was seen in 12 (38.71%) patients and all had macroadenomas. Treatment of NFPA was surgical in 5 patients (62.5%), conservative in 2 (25%) patients and 1 (12.5%) patient underwent combined procedure (surgery and conventional radiotherapy). Mean follow up period of NFPA who underwent surgery was 29.33 months, and mean decrease in tumor size was 27.26 mm (in greatest dimension). All of the tumor removal was possible in 2(33.33%) patients. Treatment of FPA was surgical in 12 (52.17%)patients. Mean follow-up years of FPAs who underwent surgery was 54.83 months and mean decrease in tumor size was 18.02 mm (in greatest dimension). All of the tumor removal was possible in 4(30.77%) patients. Among 8 patients with acromegaly, 6 patients had surgery, 1 patient had cyberknife surgery and 1 patient lost to follow up. Among 7 patients with prolactinoma, 2 patients had surgery and all patients were treated with cabergoline. One patient with prolactinoma underwent a combined procedure (surgery and radiotherapy). Among 7 patients with ACTH secreting tumors, 4 patients had surgery, 2 had medical treatment with ketoconazole and 1 lost to follow up.

Double pituitary lesions in cushing disease – a case report

Lara Ormanac[1,2], Silvija Canecki-Varžić[1,2], Romana Marušić[2,3], Ema Schonberger[1,2], Kristina Steiner[1] & Ines Bilić-Ćurčić[1,2]
[1]Clinical Medical Center Osijek, Department of Endocrinology, Osijek, Croatia; [2]Medicinski fakultet, Osijek, Croatia; [3]Place of Remembrance - Vukovar Hospital, Vukovar, Croatia

Introduction
Double and multiple pituitary adenomas (PAs) are rare in patients with Cushing's disease. If two PAs are found, MRI cannot assess secretory activity. The claimed diagnostic effectiveness of inferior petrosal sinus sampling (IPSS) ranges from 82 to 100% across various studies. Yet, this procedure has limitations in everyday clinical practice. Thus, more clinical data on these lesions and possible advanced yet simpler diagnostical procedures are needed, as treatment options are dependent on precise clinical diagnoses.
Case report
We present a 27-year-old patient who was referred to the endocrinology clinic for obesity treatment and elevated values of serum cortisol (589 nmol/l (ref. 171-536)) and urine cortisol (687 nmol/dU (ref. 100-379)). He noticed the roundness of his face, an increase in anxiety requiring therapy, purple stretch marks around the navel, and gained about 6-7 kg, despite regular physical activity. Due to excessive body mass (BMI 31.46 kg/m^2), liraglutide was introduced and an endocrinological workup was performed. In the overnight and low-dose dexamethasone suppression test no suppression occurred and ACTH values of 9.8 pmol/l were recorded indicating Cushing disease. The initial MRI of the pituitary gland was performed and showed no abnormalities, as well as the CT of the thorax and pelvis excluding visible ACTH-producing tumors. In addition, mildly increased values of IGF-1 were recorded with no clinical implication since mildly elevated IGF-1 in Cushing's disease does not imply pathological growth hormone (GH) excess. To distinguish between ectopic ACTH and Cushing disease IPSS was performed, revealing the ACTH ratio of the right petrous sinus and periphery significantly greater than 2, while on the left side, it was below 1 confirming the diagnosis of Cushing's disease. To control hypercortisolemia, ketoconazole was introduced into therapy. A control MRI of the pituitary gland was performed after 3 months, now exposing two potential pituitary lesions (in the caudolateral part diameter of 2.5 mm and the posterolateral part a diameter of 3 mm), which could indicate ACTH secreting microadenomas. Therefore; ^{18}F-FET PET is planned to localize corticotroph microadenoma.
Conclusion
The diagnostical challenges in differentiating Cushing syndrome never cease to exist. In this case report we intended to increase awareness of the need to explore the possibility of the presence of two distinct corticotroph tumours. Initial studies using ^{18}F-FET-PET/MR suggest a high predictive value for localizing corticotroph microadenomas posing a promising method in the differentiation of Cushing's disease.

A rare cause of acromegaly due to ectopic secretion of growth hormone

Nassim Ben Hadj Slama[1], Taieb ACH[1], Zeineb Jemni[2], Rihen Meddeb[2], Ghada Saad[1], Kaouthar Chatti[2], Asma Ben Abdelkrim[1], Koussay ACH[1] & Molka Chadli[1]
[1]Farhat Hached University Hospital, Endocrinology Soussa, Tunisia; [2]Sahloul University Hospital, nuclear medicine, Soussa, Tunisia

Introduction
Acromegaly is a rare condition characterized by growth hormone (GH) excess and elevated Insulin-like growth factor 1 (IGF-I) levels attributed in the vast majority of cases to a pituitary adenoma. In rare cases, GH secretion is from an ectopic origin.
Case Presentation
We present the case of a 70-year-old patient complaining of headaches without visual symptoms. The patient had a 15-year history of sleep apnea, hypertension and diabetes. Clinical examination revealed a dysmorphic syndrome characterized by extremity enlargement, prominent forehead wrinkles, widened nasal base, prognathism, and dental arcade enlargement. The rest of the examination was unremarkable. Biochemical investigation showed an elevated IGF-1 level of 757 ng/mL. GH during an oral glucose tolerance test was 3.1 ng/ml, confirming the diagnosis of acromegaly. Pituitary MRI revealed a right temporoparietal expansive process corresponding to a meningioma measuring 28×32×27 mm. The pituitary gland was normal, without a visible adenoma. The GHRH assay returned normal at 40 ng/l. A whole-body CT scan revealed no abnormalities except for a compressive right temporoparietal meningioma. Octreoscan showed intense fixation at the ileo-caecal junction, and the meningioma exhibited moderate fixation. Colonoscopy revealed no abnormalities, and several biopsies of the ileo-caecal junction returned normal. The decision was to put the patient on somatostatin analogs for the treatment of acromegaly and not to operate the meningioma due to the high surgical risk.
Discussion
In cases of biologically confirmed acromegaly where no pituitary adenoma is detected, pituitary MRI is the initial examination. Ectopic acromegaly, comprising less than 1% of cases, typically results from ectopic GHRH secretion. They are often associated with pulmonary or pancreatic neuroendocrine tumors. However, GHRH levels in our patient were normal, indicating a rare case of acromegaly due to ectopic GH secretion, with only 19 cases reported in the literature. Octreoscan identified two fixation sites, with the meningioma's fixation being non-specific due to somatostatin receptors. The second fixation at the ileo-caecal junction suggests ectopic GH secretion by a digestive neuroendocrine tumor. Nevertheless, colonoscopy and biopsy revealed no abnormalities.

Chronic granulomatous mastitis in a patient with microprolactinoma

Mirna Hrabar[1], Anamarija Zrilic Vrkljan[1] & Vlatka Pandzic Jaksic[1]
[1]University Hospital Dubrava, Department of Endocrinology, Diabetes, Metabolism and Clinical Pharmacology, Zagreb, Croatia

Treatment of patients with a microprolactinoma is considered when hypogonadism is present in the form of menstrual cycle dysfunction or infertility. The presence of galactorrhea alone does not require treatment unless it is bothersome to the patient. The exact etiology of granulomatous mastitis is still unclear. Hyperprolactinemia has been identified as a possible factor in the occurrence and development of granulomatous mastitis. A 42-year-old female patient was referred to our clinic because of persistent hyperprolactinemia (3-4 times the upper limit) and MRI finding of a 5 mm microadenoma. This workup had been performed by her gynecologist because of menorrhagia and slightly irregular menstrual cycles. Her gynecological condition was to be treated with a levonorgestrel-releasing intrauterine system. She was not taking any medication. Her medical history was unremarkable, with the exception of a breast abscess that required surgical intervention twice in the last two years. Both times a biopsy of the lesion was performed, which revealed lobulocentric granulomatous inflammation, while the microbiologic analysis was sterile. Autoimmune disorders were excluded. No previous or current galactorrhea was detected. Laboratory tests revealed no other pituitary dysfunction. Only follow-up was recommended. Transient hyperprolactinemia due to recent breast manipulation was considered, but prolactin levels remained consistently elevated. The size of the microadenoma also remained stable. At the age of 44, she developed oligomenorrhea and occasional nipple discharge, that did not correspond to typical galactorrhea. Ultrasonography revealed duct ectasia and an inhomogeneous, hypoechoic, oval lesion in the upper left quadrant of the left breast that probably corresponded to a chronic abscess. FNA of the lesion confirmed persistent inflammation. At this point, we decided to change the approach and introduced a dopamine agonist. This was followed by prolactin level decrease, microadenoma shrinkage, and repeated ultrasound examination confirmed the regression of the long-standing inflammatory breast process. Hyperprolactinemia as a possible etiologic and predisposing factor for the occurrence and development of granulomatous mastitis should not be neglected. It seems that the presence of granulomatous mastitis should be taken into account when deciding on the introduction of a dopamine agonist in a patient with microprolactinoma and no other indication for drug therapy. Further clinical studies are needed to clarify the role of dopamine agonist use in patients with granulomatous mastitis and microprolactinoma.

Predictive factors of a Delayed response during insulin tolerance test

Sahar Abidi[1], Nadia Khessairi[1], Sabrina Ayari[1], Kammoun Elyes[1], Ibtissem Oueslati[1] & Melika Chihaoui[1]
[1]Endocrinology Department, Rabta Hospital, Tunis, Tunisia

Introduction
The insulin tolerance test (ITT) is commonly used for the evaluation of the corticotropic axis. There are different protocols depending on the number and timing of blood samples. The aim of our study was to investigate the predictive factors of a late response during ITT.
Methods
Our study was cross-sectional and descriptive. One hundred patients with suspected adrenal insufficiency (AI) were evaluated. An intravenous rapid insulin bolus of 0.1 to 0.2 units/kg was administrated. Eight blood samples for glucose and cortisol measurements were taken: before the insulin injection, at the time of hypoglycemia and samples every 10 minutes for 60 minutes after hypoglycemia. An adequate response was defined as a serum cortisol level above or equal to 18 µg/dl after a serum glucose level below 40 mg/dl. we considered a late response if it occurred 30 minutes after hypoglycemia.
Results
The mean age was 41.4 ± 15.12 years. The gender ratio (F/H) was 0.2. Forty-two patients (42%) had an adequate response and 58 patients (58%) had an inadequate response. Twenty-six patients (62%) had an early response and 16 patients (38%) had a late response. Mean age was comparable between the two groups (39.5 ± 16.1 years vs 44.8 ± 12.5 years; $P = 0.26$). We didn't find a difference between early and late responders patients regarding weight, BMI, hypoglycemia onset time and fasting blood glucose ($P = 0.48$, $P = 0.60$, $P = 0.24$ and $P = 0.34$ respectively). Basal cortisol level was lower in late responders patients than in early responders patients ($P = 0.001$). A basal cortisol level $\leq$ 11.2 µg/dl had a sensitivity of 62% and a specificity of 82% to predict a late response.
Conclusions
Our study showed that the occurrence of late response is frequent. Therefore, it is necessary to multiply the number of cortisol level samples after hypoglycemia, especially in patients with basal cortisol level below 11.2 µg/dl.

Cabergoline-resistant pituitary prolactin adenoma: a case report

Ghita Khamel[1], Sara Oualhadj[1], Ikram Amira[1], Hind Iraqi[1], Kaoutar Rifai[1] & Mohamed Hassan Gharbi[1]
[1]Chu Ibn Sina, Rabat, Morocco

Introduction
Prolactin adenomas are the most common pituitary tumors. The aim of treatment is to achieve normal prolactin levels in order to reduce tumor mass and restore the gonadotropic axis. Dopaminergic agonists, including cabergoline, are the standard treatment. But some adenomas can be resistant to this treatment and behave like aggressive tumors. We report the case of a macroprolactinoma resistant to cabergoline.
Observation
50-year-old female patient referred from neurosurgery after a surgical management of a 63 mm giant invading macroadenoma complicated by apoplexy, with histological examination of an adenoma expressing prolactin. Postoperative biological workup revealed persistent hyperprolactinemia at 10379/ml, and a pituitary macroadenoma measuring 42 × 35 mm on hypothalamic-pituitary MRI. The visual field revealed a bitemporal hemianopia. The patient was put on cabergoline at a dose of 1 mg per week, gradually increasing to 3 mg per week, with persistent hyperprolactinemia at 6028 ng/ml and a macroadenoma at 38 mm. Transphenoidal revision surgery was indicated, with persistent hyperprolactinemia at 2598 ng/ml at 6 months postoperatively on 4 mg cabergoline.
Discussion
Four histological observations have been made in DARP studies increased angiogenesis, cellular atypia, increased proliferation and invasiveness. Resistance to cabergoline is due to decreased expression of dopamine receptor subtype 2. This resistance could result from the reduced dopaminergic signalling caused by these changes, or may be the result of uncharacterized mutations. As described, invasion of the cavernous sinus is a more frequent finding in DARP management is delicate and requires a multimodal approach, including transphenoidal surgery, alternative medical therapies such as somatostatin analogues and estrogen receptor antagonists.
Conclusion
The notion of resistance to dopaminergic agonists (DAs) remains controversial. Although rare, they constitute pathological entities that require the emergence of new therapies.

Medullary thyroid microcarcinoma revealed by lymph node metastases. about a case

Karimi Meryem[1], Hajar Azagouagh[1], Nawal Moussaid[1], Rifai Kaoutar[1], Iraqi Hind[1] & Mohamed Elhassan Gharbi[1]
[1]Chu Ibn Sina, Endocrinology Rabat, Morocco

Introduction
Micro medullar, thyroid carcinoma is defined as a rare variant of MTC, with a size less than or equal to 1 cm , often incidentall, discovered.
Observation
A 67-year-old patient with no medical history presented with two supraclavicular lymph nodes four years ago. A biopsy revealed metastatic tumor proliferation suggestive of a carcinomatous process. Immunohistochemistry confirmed cervical lymph node metastasis of MTC, and further testing showed a calcitonin level of 10,769 ng/ml. A PET SCAN revealed no anomalies, and a thorough evaluation for multiple endocrine neoplasia (MEN) was normal. Total thyroidectomy with bilateral extensive lymph node dissection was performed, revealing a 5mm intraparenchymal low-grade micro medullary carcinoma.
Discussionl and Conclusion
Contrary to the common perception of micro medullary thyroid carcinoma as having a favorable prognosis, a significant increase in the prevalence of lymph node metastases is observed. Due to the severity of complications associated with recurrences and distant metastases, two approaches are utilized: regular monitoring of serum calcitonin levels, showing a decreasing trend, and genetic screening, particularly in hereditary cases. Biochemical screening programs are crucial for identifying sporadic cases of micro medullary thyroid carcinoma in patients with thyroid nodules.

Acromegaly in humans, cats and dogs: epidemiological, pathophysiological, clinical and management resemblances and differences

Mariana Lopes-Pinto[1], Patrícia Lunet Marques[2,3], Ema Paula Ricca Lacerda Nobre M Caetano[1], Diego Miceli[4], Rodolfo Oliveira Leal[2,3] & Pedro Marques[5,6]
[1]Unidade Local de Saúde de Santa Maria, Hospital de Santa Maria, Endocrinology Department, Lisbon, Portugal; [2]Centre for Interdisciplinary Research in Animal Health, Faculty of Veterinary Medicine, University of Lisbon, Portugal; [3]Associate Laboratory for Animal and Veterinary Sciences (AL4AnimalS); [4]CONICET, Buenos Aires, Argentina, Buenos Aires, Argentina; [5]Pituitary Tumor United, Endocrinology Department, Hospital CUF Descobertas, Lisbon, Portugal; [6]Faculdade de Medicina, Universidade Católica Portuguesa, Lisbon, Portugal

Background
Acromegaly is a rare disorder associated with excessive levels of growth hormone(GH) and insulin-like growth factor-1(IGF-1). GH/IGF-1 excess leads to morphologic craniofacial and acral changes as well as cardiometabolic complications, but the phenotypic changes and presentation differ across species.
Aim
To present the resemblances and distinctive features of acromegaly in humans, cats and dogs.
Methods
A literature review of the epidemiology, pathophysiology, clinical features, diagnosis and management of acromegaly in humans, cats and dogs was performed by doctors and veterinaries specialized in Endocrinology. The key aspects of each species were summarized and compared.
Results and conclusion
Acromegaly is associated with prominent craniofacial changes: frontal bossing, enlarged nose, ears and lips are typical in humans; increased width of the head and skull enlargement are common in cats; dogs may present with exophthalmos. Malocclusion, prognathism, dental diastema and upper airway obstruction may occur in the three species, as well as growth and widening of extremities resulting in osteoarticular compromise. Increase of articular joint cartilage thickness, vertebral fractures and spine malalignment is more evident in humans, while arthropathy and spondylosis deformans may occur in cats. Organomegaly, heart failure, ventricular hypertrophy, and an increased cardiometabolic risk is observed in humans and cats. Diabetes may be present in humans, cats and dogs. In GH-secreting pituitary tumours, local compressive effects and behavioral changes are mostly observed in humans, but may also affect cats. Being particularly rare in dogs, hypersomatotrophism may occur due to GH hypersecretion in mammary glands, primary hypothyroidism or, extremely uncommon in this species, due to a GH-secreting pituitary adenoma. Cutis verticis gyrata and skin tags are exclusively found in humans, palmigrade/plantigrade stance is sometimes observed in acromegalic cats, while dogs can present with excessive skin folds and coat thickening. Serum IGF-1 is used for acromegaly diagnosis in humans, cats and dogs, but oral glucose tolerance test with GH measurement is only useful in humans and dogs. Imaging studies are performed after biochemical diagnosis of acromegaly. Hypophysectomy is the first line treatment in humans and cats, although not always available in veterinary medicine. In dogs, GH-secreting mammary tumours may require surgery, while radiotherapy and pasireotide have been successfully used for pituitary adenomas. In conclusion, GH-secreting pituitary tumours are the main cause of acromegaly in humans and cats, but they rarely occur in dogs. Substantial acromegalic similarities are present across the species, however there are few species-specific features and management particularities can be found.

EP1113

Acromegaly revealed by unstable diabetes

Karimi Meryem[1], Ali Halouache[2], Isswani Jad[2] & Guerboub Ahmed Anas[2]
[1]Ibn Sina Rabat, Endocrinology Rabat, Morocco; [2]Hôpital Militaire D'Instruction Mohammed V, Endocrinology Rabat, Morocco

Introduction
Acromegaly is a rare condition characterized by the hypersecretion of growth hormone (GH), resulting in morphological anomalies, metabolic disturbances, including overt diabetes, and endocrine abnormalities.
Case Report
We present the case of a 54-year-old patient with a history of cervical lumbar sciatica under treatment. The disease history dates back 3 years with the onset of polyuria-polydipsia syndrome and fatigue. On clinical examination, the patient exhibits acrofacial dysmorphic features. The laboratory findings revealed an HbA1c of 8%, IGF1 level twice the normal range. Hypothalamo-hypophysial MRI reveals a 12 mm pituitary macroadenoma without invasion of the cavernous sinuses. The patient was prescribed oral antidiabetic drugs and subsequently referred to a neurosurgeon for surgical intervention.
Discussion and Conclusion
Acromegaly is an insidious and slowly progressive pathology, often leading to a late diagnosis. This prolonged diagnostic delay is responsible for the onset of complications, including diabetes.

Cushing's syndrome complicated with pulmonary embolism: report of three cases and literature review

Nana Hao[1], Sumita Cholekho[2], Huiwen Tan[2,3], Chun Wang[2], Jianwei Li[3] & Yerong Yu[3]
[1]Sichuan University China; [2]Sichuan University Department of Endocrinology and Metabolism, China; [3]

Objective
To summarise and analyze the pathogenesis, clinical risk assessment, and treatment of venous thromboembolic events (VTE) associated with Cushing syndrome (CS), and to improve clinicians' understanding of this complication.
Methods
The clinical diagnosis and treatment of 3 patients with Cushing disease (CD) combined with pulmonary embolism were reviewed, and relevant literature at home and abroad was reviewed.
Results
Three patients, all female, were diagnosed with CD and underwent resection of the saddle region. Three-dimensional reconstruction of pulmonary arterial vessels on the 6th day after the operation indicated pulmonary embolism, and they were treated with low molecular heparin and rivaroxaban anticoagulant therapy successively, and the CTA of the pulmonary artery was reexamined after 3 months without any abnormality. The keywords "Cushing's disease, Cushing's syndrome" and "pulmonary embolism, venous thromboembolism" were searched. A total of 73 articles were retrieved from the Pubmed database, of which 28 were case reports, 10 were reviews, and 35 were clinical studies. The risk of VTE in CS is more than 10 times higher than that in the general population, and the pathogenesis and clinical risk assessment are complex, while the duration of prophylactic anticoagulation and its protocols have not yet reached a consensus.
Conclusion
CS is associated with multisystem complications. The risk of VTE in CS is significantly higher, with a rapid onset of disease and a high mortality rate. Clinical vigilance, avoidance, and screening of CS-related complications are needed for early diagnosis and treatment.

Severe hyponatremia revealing lymphocytic hypophysitis

Abdelkader Yahi[1], Lachekham Aicha[1], Haffaf Lounes[1], Benabdellatif Katia[1], Longo Redoune[1], Derriche Abderrahim[1], Talbi A[1], Derradji Hakim[1], Ould-Kablia Samia[1] & Bendalah Meriem[1]
[1]El Djazair, Endocrinology Bir Mourad Rais

Background
Hypophysitis is a rare pathology its symptoms and radiological signs are non-specificy making its diagnosis difficult
Case Description
A 62-year-old Women, mother of 5 children, with a History of type 2 diabetes mellitus, hypothyroidism. During a period of fasting, the patient presented with profound asthenia, a tendency to hypotension. A severe hyponatremia at 119 mmol/l was diagnosed. The patient received urgent treatment. The hormonal biological assessment revealed a collapsed cortisol level with a normal ACTH level confirming the corticotrope deficiency. The rest of the assessment is in favor of anterior pituitary insufficiency with gonadotrope, somatotrope and lactotrope deficiency. The hypothalamic-pituitary MRI suggests a partially empty sella turcica and a nodular thickening of the pituitary stalk of 5.5 mmy strongl, enhanced in favor of lymphocytic hypophysitis.
Discussion
Lymphocytic hypophysitis is linked to lymphocytic infiltration of the pituitary gland. Its probably autoimmune pathogenesis remains poorly understood. It can be associated with autoimmune thyroiditis or another autoimmune disease in 20% of cases. There

are asymptomatic forms where the diagnosis can be made several years after the initial event. The diagnosis is sometimes made in the presence of anterior pituitary insufficiency with normal imaging or with an empty sella turcica appearance, especially in a multiparous woman. Corticotropic deficiency is the most common, and makes this disease serious due to the risk of acute adrenal insufficiency.
Conclusion
A number of clinical, biological and neuroradiological arguments may suggest the diagnosis of lymphocytic hypophysitis, but the certainty can only be histological.

Hyponatremia secondary to neurohypophysitis in a patient on nivolumab (immune checkpoint inhibitors): a case report

Macarena Dubert *P*érez[1], Miguel-Angel Ruiz-Gines[1], Marina Fernández-Rufete Lozoya[1], María Zurdo López[1], Laura Morell Jurado[1], Mercedes Agudo Macazaga[1] & Juan-Antonio Ruiz-Ginés[2]
[1]Hospital Universitario de Toledo, Análisis Clínicos, Toledo, Spain; [2]Hospital Clinico Universitario Lozano Blesa, Neurocirugía, Zaragoza, Spain

Introduction
Immune checkpoint inhibitors (ICIs) are a type of immunotherapy approved for the treatment of certain tumors. As the use of ICIs increases, the incidence of rare side effects, called immune-related adverse effects (IRAE), is also increasing, and can affect different systems (gastrointestinal, hepatic, and endocrine among others), with hyponatremia being a possible side effect in patients treated with ICIs. Our objective is to describe one of the few clinical cases published in the scientific literature that induce SIADH, secondary to pituititis, in patients with monotherapeutic treatment with Nivolumab.
Case report
A 69-year-old man diagnosed with stage IV melanoma, undergoing chemotherapy treatment with Nivolumab, was referred to the Emergency Department from outpatient Medical Oncology clinics due to severe hyponatremia of 103 mmol/l in a follow-up test (prior to the chemotherapy cycle). The patient presents a history of several days of evolution of fatigue, anorexia and hypotension (107/64mmHg; 120 bpm). No fever.
Discussion and conclusions
The possible etiology of hyponatremia would be SIADH in an oncological patient undergoing immunotherapy treatment with Nivolumab. This involvement would be considered secondary to ICI-induced hypophysitis (IRAE), a well-known complication of Lipilimumab, having ruled out adrenal insufficiency and hypothyroidism leading to euvolemic hyponatremia. Nivolumab is a monoclonal antibody that binds to the PD-1 receptor and blocks interaction with its ligands (PD-L1 and PD-L2) located on a large number of cancer cells, quickly establishing itself as the standard of care for locally advanced or metastatic melanoma. It is a very attractive treatment because it achieves better response rates and long-term survival, but due to the growing number of indications, the set of toxicities, in clinical practice, is increasing dramatically. These drugs have been shown to cause a unique set of toxicities that most clinicians were unaware. Therefore, due to their relative novelty and rarity, it is of vital importance that clinicians in the different medical services (Medical Oncology, Emergency Department, Intensive Care United, Primary Care, among others) receive training on the recognition and treatment of potential complications. The use of these drugs in the treatment of a wide variety of malignancies is being investigated, and as their use spreads, it is inevitable that the number of patients with endocrine side effects, such as neurohypophysitis, will increase.

The aggressiveness of rarity - a case of neuroendocrine tumor of the colon

Sara Loureiro Melo[1,2], Leandro Augusto Silva[1,2], Gonçalo Varela Cunha[1,2], Benilde Barbosa[2], José Moura[2] & Lèlita Santos[2]
[1]Portuguese Institute of Oncology of Coimbra Francisco Gentil; [2]ULS of Coimbra, Portugal

Introduction
Neuroendocrine Tumors of the Colon are often aggressive and metastatic at diagnosis. The diagnosis is histologicaly obtained through immunohistochemical evaluation of biopsy specimens/metastases, with positive staining for Chromogranin A and Synaptophysin.

Case Report
A 54-year-old independent patient with Type 1 Diabetes, leading to diabetic nephropathy, underwent a renal transplant followed by graft failure and is currently on hemodialysis and systemic corticosteroid therapy. She presented to the Emergency with abdominal pain, described as constant, squeezing, located in the left flank, refractory to analgesia, associated with unintentional weight loss of 1.5 kg , night sweats, and constipation, all during the last month. Imaging studies revealed a lombo-aortic and mesenteric lymph node conglomerate, leading to hospitalization for further evaluation and symptomatic control. During the hospitalization, additional studies showed presence of an ulcerative and vegetative tumor in the descending colon, measuring 3 cm in length. Biopsy results were consistent with poorly differentiated colon carcinoma (CK20+ /CK7/CDX2+), with neuroendocrine differentiation. Additional CT-CTAP imaging revealed the presence of supra and infra-diaphragmatic conglomerates. A diagnosis of metastatic Neuroendocrine Tumor of the Colon was made, and immunotherapy with Ipilimumab and Nivolumab was proposed. The patient is currently awaiting the first cycle of treatment.
Conclusion
This case report aims to demonstrate not only the importance of reviewing rare tumors, particularly neuroendocrine tumors, but also to highlight their nonspecificity and aggressiveness.

EP1119

Clinical symptoms of pituitary apoplexy are not the diagnosis itself - a case of pituitary chordoma

Igor Kopczyński[1], Sonia Kaniuka-Jakubowska[1], Dominik Stodulski[2], Tomasz Przewoźny[2] & Renata Świątkowska-Stodulska[1]
[1]Medical University of Gdansk, Department of Endocrinology and Internal Medicine, Gdańsk, Poland; [2]Medical University of Gdansk, Department of Otolaryngology, Gdańsk, Poland

Chordomas of the skull base are rare lesions, which account for less than 0.2% of all intracranial tumours. They arise from embryonic remnants of the primitive notochord. They are described as locally aggressive, rarely metastatic tumours with a tendency to frequent relapses. They usually grow slowly with the destruction of the surrounding tissues. The symptoms are very unspecific which is the cause of the delay of the diagnosis. The most common initial symptoms are headaches and neuro-ophthalmological dysfunctions. Involvement of the suprasellar region may lead to partial or complete destruction of the pituitary gland, causing hypopituitarism and diabetes insipidus. Literature data indicates that the treatment of chordomas should be a combination of maximal surgical resection and adjuvant radiotherapy. A 60-year-old man reported impaired movements of the left eye with ptosis and secondary diplopia over two weeks before the admission to the neurology ward. He also suffered from nasal blockage with bloody discharge on the left side. Physical examination revealed a palsy of the 3rd left cranial nerve. He was transferred to our endocrinology department with clinical suggestion of pituitary apoplexy. In the meantime, brain computed tomography and magnetic resonance imaging were performed showing a large mass (78x54x55mm) in the sphenoid bone and clivus, extending to the sella, elevating upward the pituitary and optic chiasm, infiltrating into the nasopharynx, nasal cavities, bilateral cavernous sinuses, surrounding both internal carotid arteries. There was a suspicion of bleeding into the mass and thrombosis of the superior sagittal sinus and confluence of sinuses. The endocrine assessment revealed hypopituitarism with adrenal and thyroid deficiency with mild hyperprolactinemia. The patient underwent transnasal biopsy of the mass. Histopathology examination revealed a chordoma. The patient underwent cytoreductive endoscopic surgery, awaiting for the proton-beam therapy. The presenting case visualizes that the symptoms typical of pituitary adenomas also apply to the rare non-adenomatous sellar region lesions. It emphasizes the need for a multidisciplinary approach, with apart from endocrinologist and neurosurgeon, dedicated neuroradiologist, otorhinolaryngologist and radiation oncologist and confirms the need for pituitary centres of excellence.

EP1120

Endocrinological features of operated craniopharyngiomas: about 7 cases

Fatimzahra Bentebbaa[1], Imane Ziani[1], Siham Benouda[1], Siham Rouf[1] & Hanane Latrech[1]
[1]Mohamed VI University Hospital center, Oujda, Endocrinology-Diabetology and Nutrition Department, Oujda, Morocco

Introduction
Craniopharyngioma is a rare benign epithelial tumour arising from the pituitary stalk or pituitary gland, developing in the sellar and suprasellar region, it affects both adults and children, The clinical presentation may include endocrine symptoms suggestive of hypopituitarism, ophthalmologic symptoms, signs of intracranial hypertension and focal neurological signs. However, after surgical treatment, hypothalamic-pituitary endocrine damage is common. The aim of our work was to study the pituitary hormone profile of operated craniopharyngiomas.
Material and Methods
Retrospective descriptive study including 7 patients followed at the Endocrinology-Diabetology-Nutrition Department at the Mohammed VI University Hospital of Oujda Morocco, with surgically treated craniopharyngioma, hospitalised in our department for postoperative hormone exploration.
Results
Four women and three men, aged 21.8±12.6 years, referred for endocrine management of a craniopharyngioma, all patients had visual impact, and the craniopharyngioma was intra and suprasellar in all patients, transphenoidal endoscopy was used for 4 patients, frontal approach was used for 3 of our patients. With regard to the postoperative hormonal profile, 6 patients developed a polyuro-polydipsic syndrome (85.7% of cases), 5 patients had a corticotropic deficiency (71.4% of cases), 2 of whom had this deficiency pre-operatively, the thyreotropic deficiency was observed in 3 patients (42,8% of cases), 1 of these patients had this deficiency pre-operatively, gonadotropic deficiency was observed in 6 patients (85.7% of cases), 2 of whom had hypogonadotropic hypogonadism pre-operatively, and finally somatotropic deficiency was present pre-operatively in only 1 patient. For hormone replacement, it involved hydrocortisone supplementation for corticotropic deficiency, levothyroxine for thyroid insufficiency, estrogen and progestin treatment for women with gonadotropic deficiency, and testosterone replacement therapy for men.
Conclusions
Our study confirms that in craniopharyngiomas, antehypophyseal insufficiency and diabetes insipidus are frequent after surgical treatment. Adequate hormone replacement therapy and long-term medical monitoring are therefore necessary.

EP1148

Case report of a young woman with central diabetes insipidus
Nives Gojo Tomić[1,2] & Mirjana Kardum Pejić[2,3]
[1]Clinical Hospital Dubrava, Endocrinology and Diabetes, Zagreb, Croatia; [2]Clinical Hospital Dubrava, Department of Endocrinology and Diabetes, Zagreb; [3]Clinical Hospital Dubrava, Endocrinology and Diabetes, Zagreb

Arginine vasopressin deficiency (or central diabetes insipidus - CDI) is a rare disorder (1 in 25 000 individuals). It is characterised by decreased release of antidiuretic hormone (ADH) which results in polyuria and polydipsia. Majority of cases are acquired and caused by neurosurgery or head trauma, primary or secondary brain tumours, infiltrative diseases or autoimmune neurohypophysitis. Only about 5% of all reported cases are caused by genetic or congenital disorders. It has been suggested that an autoimmune process is involved in many patients with non-traumatic CDI (30-50%). Antibodies to AVP neurons were found in approximately one-third of the patients with 'idiopathic' CDI. We present a nineteen year old female, previously healthy, who presented in January 2022 with polyuria (10-12L daily), polydipsia (10-15L of water daily), nocturia (4-5 times) and nocturnal thirst during the previous 2-3 months. After excluding diabetes mellitus she was admitted to hospital to exclude possible diabetes insipidus. During the water deprivation test, laboratory tests showed low urine osmolality and mild plasma hyperosmolality. After administration of nasal desmopressin, urinary osmolality increased and the patient's symptoms improved. Water deprivation test was positive for central diabetes insipidus. Magnetic resonance showed medially positioned infundibulum with thickened pituitary stalk (about 3.8 mm). There was no hyperintense signal ('bright spot') in the neurohypophysis. According to the radiologist, differential diagnosis of these changes could include lymphocytic hypophysitis. During hospitalization, extensive laboratory tests and imaging were done. Infiltrative diseases, infections including tuberculosis, and autoimmune diseases including sarcoidosis were excluded. Results of imaging (abdominal ultrasound, chest x-ray) were normal. There were no other pituitary deficits, or other hormonal deficits. The baseline hormone test showed slightly elevated prolactin level. Other laboratory tests showed high thyroid peroxidase antibodies. Ultrasound changes which indicate Hashimoto thyroiditis were found. After starting therapy with intranasal desmopressin, there was significant clinical improvement. Control MR imaging 9 months and 18 months after diagnosis showed no change in comparison with the first one. Desmopressin therapy was continued with excellent clinical and laboratory results.
Conclusion
The aetiologic diagnosis of central diabetes insipidus is difficult. The underlying cause remains unknown in many cases. This case did not show exact aetiology of central diabetes insipidus. We cannot determine vasopressin secretory cells antibodies, so possible autoimmune aetiology could not be confirmed. Although aetiology of the disease was not proved, proper treatment led to symptom control, clinical improvement and normalization of pathologic laboratory tests during 2 years after diagnosis.

EP1149

Silent mixed growth hormone and prolactin pituitary adenoma, a case report
Zahra Ismail[1], Sidiebatt Amar[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]University Hospital Center Mohamed VI, Departement of Endocrinology, Diabetes and Metabolic Disease, Marrakech, Morocco

Introduction
Silent somatotroph pituitary adenomas are defined as pituitary adenomas with positive immunostaining for GH without signs of clinical or biochemical acromegaly. Silent somatotroph adenomas are rare and diagnosis is made post-operatively. Almost two-thirds are mixed GH-prolactin tumors. We report the case of a non-functioning macroadenoma coexpressing prolactin and GH.
Observation
A 37-year-old man presented with headache and progressive vision loss. Clinical examination revealed no gynecomastia, galactorrhea or signs of acromegaly. A cerebral MRI revealed a heterogeneous tumor in the sellar region invading the ethmoid and sphenoid sinus and containing calcifications, measuring 56×55×54 mm, suggestive of a chondroma sphenoid sinus. The hormonal profile: prolactin=206 ng/ml, thyrotropin and corticotropin deficiency. Visual field was restricted. The patient underwent trans-sphenoid surgery. Pathology and immunohistochemistry showed a mixed pituitary adenoma positive for prolactin and GH antibodies with a Ki67=3%. The IGF1 performed post operatively was normal at 107.6 ng/ml. The follow-up MRI showed tumor residue. We started treatment with dopaminergic agonists (Cabergoline) and proposed radiotherapy and somatostatin analogue (Lanreotide).
Discussion
Somatotroph adenomas are often identified in the setting of acromegaly. Occasional cases of silent adenomas have been described in the literature, mainly in young females. The cause of tumor silence is still unknown. Preoperative biochemical work-up should include an IGF-1 measurement and if clinical suspicion for GH excess, GH measurement. Management of this type of adenomas is initially based on surgery. Because of the potential of phenotype change to clinical acromegaly and recurrence, the need for radiation is higher than other non-functioning tumors and close follow-up is recommended.

EP1150

Pituitary apoplexy- a case report
Jona Troshani[1], Olta Zeneli[1], Bruno Teme[1], Sindi Bushati[1] & Agron Ylli[1]
[1]Mother Teresa Hospital, Tirana, Endocrinology Tirana, Albania

Background
Pituitary apoplexy is a rare but potentially life-threatening condition in which the pituitary gland undergoes infarction or haemorrhage, most commonly in the setting of an underlying tumour. We report on apoplexy of a diagnosed pituitary adenoma who presented with a sudden onset of headache, vomiting, ophthalmoplegia and vision loss. Neuroimaging revealed hemorrhagic pituitary mass. Trans-sphenoidal surgery was performed, which resulted in moderate neurological recovery.
Case presentation
A 36 years old patient presented in our emergency unit with a sudden onset of headache, vomiting, ophthalmoplegia, visual disturbance –vision loss. Medical history: Patient was diagnosed with pituitary macroadenoma since he was 31-years-old. He was not taking medication for this pathology. In the objective examination the patient was agitated but had a clear consciousness. His skin and mucous membranes were pale. There were no pathological sounds in the auscultation of the heart and lungs. There were not peripheral edema. Laboratory analysis: the most important data is the low value of cortisol - 1.00 mg/dl [2.9-17.3], his thyroid hormone levels, TSH, gonadotropins, prolactin and progesterone

were within range. He had a low testosterone level 0.49 ng/ml [2.4-8.7]. CT Scan revealed a lesion with sellar and suprasellar extension with hyperdensity inside and around, measuring 42x38x47 mm, which modifies the sella turcica, suggestive of macroadenoma. The patient was hospitalized in Neurosurgery where intravenous fluids and hydrocortisone was immediately started. Transsphenoidal surgery was performed the next day which resulted in moderate neurological recovery.
Conclusion
Enlargement of the pituitary gland may precipitate haemorrhage. Pituitary apoplexy has a widely varied symptomatology—it should be considered as a differential diagnosis for headache or visual disturbance. Although the treatment of pituitary apoplexy is still a matter of debate with regard to surgery, the results of early sphenoidal procedure within 1 week after pituitary apoplexy are satisfactory than patients operated later.

Sarcoidosis presenting as cranial diabetes insipidus- a case report
Ishara Ranathunga[1], Chandima Idampitiya[1] & Fathima Pambinezhut[1]
[1]Cumberland Infirmary United Kingdom

Background
Sarcoidosis is an immune-mediated condition characterized by the presence of non-caseating granulomas, primarily impacting the respiratory system, lymphatic system and heart. The involvement of the central nervous system, especially hypothalamic- pituitary involvement is a rare occurrence. We report a patient initially presenting with Cranial Diabetes Insipidus who was later diagnosed to have sarcoidosis.
Case presentation
A-67-year old male presented with progressive polydipsia, polyuria and nocturia for 7 months duration without any other systemic symptoms. He had no headaches or constitutional symptoms such as poor appetite, weight loss or night sweats. His physical examination had been unremarkable. He was noted to have a high serum osmolality of 307 mmol/kg and a relatively dilute urine osmolality of 143 mmol/kg. His serum co-peptin after an overnight fast came back relatively low at 1.9 pmol/l in the presence of a serum sodium of 148 mmol/l suggestive of Cranial Diabetes Insipidus. The rest of the pituitary hormones were within the normal range and the MRI pituitary showed thickening and enlargement of the pituitary stalk with absent posterior pituitary bright spot. The anterior pituitary appeared normal in size, signal intensity and enhancement pattern. He was successfully treated with Oral Desmopressin 50 mg in the morning and 100 mg at night which completely resolved his symptoms. Fifteen months after developing the initial symptoms of cranial diabetes insipidus, he presented with general lethargy, weight loss, chronic cough and multiple large joint pains. Further investigations revealed a marginally raised ACE level (74 U/l) and CT chest showed irregular septal thickening in left upper and lower lobe, scarring in left apex, multiple mediastinal and hilar nodes, suggestive of sarcoidosis with central nervous system involvement.
Conclusions
The occurrence of central nervous system manifestations in sarcoidosis is rare and individuals might display these symptoms without accompanying systemic manifestations. Recognizing this unusual presentation holds significance in guiding investigations and initiating early treatment to prevent the disease from advancing further.

An incidental pituitary finding on an 18FDG PET scan
Sawsen Nouira[1], Hamza Elfekih[1], Fatma Ben Abdessalem[1], Amel Maaroufi[1], Yosra Hasni[1] & Molka Chaieb[1]
[1]University Hospital Farhat Hached, Endocrinology, Sousse

Introduction
Pituitary adenomas stand as the most prevalent form of tumorous pathology impacting the pituitary gland in adults. Their discovery might arise from either hypersecretion in functional adenomas or the manifestation of compression symptoms on neighboring structures. Detection of a pituitary adenoma can occur incidentally during various imaging modalities, encompassing both structural and functional assessments. This study documents a case involving the incidental detection of a pituitary macroadenoma during a PET-CT scan.
Observation
We report the case of a 61-year-old patient with a history of large B-cell gastric lymphoma evolving over four years, managed with chemotherapy. A post-chemotherapy evaluation was conducted through an 18FDG PET-CT scan. The scan revealed a significantly increased metabolic activity in the sellar region associated with tissue infiltration. A hypothalamic lymphomatous localization was deemed unlikely as there was no pathological metabolic activity observed in lymph nodes or in the gastric region. Clinical examination and laboratory tests showed no signs of hormonal overproduction or pituitary deficiency. An MRI of the pituitary gland confirmed the presence of an expansive intra-sellar process, demonstrating heterogeneous enhancement after gadolinium injection, measuring 17×15×14 mm, exerting a mass effect on the optic chiasm. Visual field examination revealed no abnormalities. The diagnosis of a non-secreting pituitary macroadenoma with suprasellar extension was established. The patient was referred to neurosurgery for further management.
Discussion et conclusion
The discovery of an incidental pituitary adenoma through an 18FDG PET scan is exceedingly rare. This rarity in discovery and the lack of definitive correlation between FDG uptake and functional status raise questions about the metabolic behavior of these tumors. Understanding the mechanism of uptake in non-secreting adenomas could potentially unveil novel insights into their biology and pathogenesis. This aspect of our research highlights the complexity of pituitary adenomas and emphasizes the need for further investigations into their metabolic characteristics to elucidate their clinical significance and management.

Gemelli IRCCS, UOC Endocrinologia e Diabetologia, Rome, Italy; [3]Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Scienze Biotecnologiche di Base, cliniche intensivologiche e perioperatorie, Rome, Italy; [4]Fondazione Policlinico Universitario A. Gemelli, IRCCS, Dipartimento di Scienze delle emergenze, Anestesiologiche e della rianimazione, Rome, Italy

Introduction
The pseudo-Cushing's encompass several disorders that can occur in high-stress situations, such as the sepsis, and that show biochemical features like those of Cushing's syndrome. We present a case with difficult differential diagnosis, for overlapping laboratory findings.
Case description
A 74-year-old man was admitted to our hospital for worsening dyspnoea since a month, 15 kilograms weight loss in the previous months, asthenia, hypotonia and muscle hypotrophy. In past medical history: glucose intolerance in treatment with metformin, depression in treatment with mirtazapine and vortioxetine and pancreatic intraductal papillary mucinous neoplasm (IPMN). Due to the onset of acute hypoxic-hypercapnic respiratory failure, the patient was treated with not-invasive ventilation and then admitted to the intensive care united, for pneumonia and respiratory failure due to Meticillin-sensitive Staphylococcus aureus (MMSA) and Klebsiella Aerogenes. Antibiotic therapy was started according to the results of the antibiograms and sepsis. The neurological assessment showed a severe strength deficiency of the neck flexors and four limbs and hypophonia, reflexes were not revocable. No abnormalities in ocular motility, palpebral ptosis and muscular or lingual fasciculations were detected. Electromyography of deltoid muscles, brachial biceps and right rectus femur documented a method of recruitment of the myopathic type, suggestive for a sporadic late onset nemaline myopathy (SLONM). During the treatment in ICU, the patient underwent endotracheal intubation for the worsening of respiratory function and inotropic drug therapy was introduced for the development of septic shock. According to patient's clinical condition, hormones were tested showing an ACTH-dependent hypercortisolism. The results of Nugent, Liddle and the dexamethasone suppressed CRH stimulation tests suggested a not-neoplastic ACTH-dependent hypercortisolism. The pituitary contrasted magnetic resonance image showed a gland hypertrophy and the abdominal computed tomography (CT) ruled out adrenal lesions. Unfortunately, the patient developed a multi-organ failure, and at least died. The autopsy finding confirmed the absence of pituitary and other neuroendocrine tumours and showed a bilateral adrenal hypotrophy.

Conclusions
Our clinical case described a patient with pseudo-Cushing's syndrome during sepsis and pre-agonist phase, with difficult differential diagnosis, in which the combination of the low-dose dexamethasone suppression test and the CRH test allowed a conclusive and correct diagnostic orientation.

Rheumatological complications during cushing's disease: about 51 cases

Bassiratou Hamza Maliki[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]CHU Ibn Rochd - Casablanca, Morocco, Endocrinology and Metabolic Disease Service, Casablanca, Morocco

Introduction
Rheumatological manifestations are frequent in Cushing's disease with impact on quality of life.
Objective
The aim of our study is to describe rheumatological manifestations in Cushing's disease
Material and methods
Retrospective study of 51 patients diagnosed for Cushing's disease followed in the Endocrinology of CHU IBN Rochd from Casablanca from 2012 to 2023. Osteo-articular complications were detected either at diagnosis or during monitoring. The statistical analysis was done by the SPSS version 25 software.
Results
We included 51 patients including 45 women and 6 men, the average age of patients was 36.20 years (17-69). The average seniority of the disease was 2.5 years. The average Clu was 657 UG/24 hours (116.8 - 2196). To pituitary MRI: macroadenoma in 27 patients, microadenoma in 21 patients and normal in 5 patients. On the clinical level: gonalgia 49% ($n=25$), lumbar dorso rachialies 58.82% ($n=30$), diffuse arthralgia 11.76% ($n=6$), shoulder arthralgia 7.84% ($n=4$), arthralgia of the elbow 7.84% ($n=4$). Biologically: moderate hypocalcemia in 4 patients, hypophosphoremia in 2 patients, hypovitaminose D in 58.82% ($n=30$). To osteodensitometry: osteopenia of the femur 17.65% ($n=9$), wrist osteopenia 27.45% ($n=14$), osteopenia of spine 11.76% ($n=6$), osteoporosis of the 31.37% ($n=16$), osteoporosis of the femur 7.84% ($n=4$) and normal 27.45% ($n=14$).
Conclusion
Rheumatological complications are frequent in Cushing's disease dominated by lumbar dorso rachialgia, hypovitaminose D and spine osteoporosis.

Hyperprolactinemia: a rare association between primary hypothyroidism and macroprolactinoma

Eya Sassi[1], Sondes Chermiti[2], Bochra Zitoun[2], Hajer Marzouk[2], Issam Kharrat[2], Yosra Hasni[3] & Wided Debbabi[2,2]
[1]Ibn Aljazzar Hospital, Endocrinology, Kairouan, Tunisia; [2]Ibn Aljazzar Hospital, Endocrinology, Kairouan, Tunisia; [3]Farhat Hached Hospital, Sousse, Tunisia

Introduction
Primary hypothyroidism is a common cause of hyperprolactinemia. TSH measurement is part of the first-line investigation of hyperprolactinemia wich usually disappear after L-thyroxine therapy. the presence of pituitary hyperplasia mimicking a pituitary macroadenoma has been reported by several authors, but coexistence oh primary hypothyroidism and prolactinoma is rarely reported.
Case
We report a rare case of hyperprolactinemia revealing the association of primary hypothyroidism with a pituitary microprolactinoma. was 29 years old referred to endocrinology consultation for hyperprolactinemia (Prolactin level: 120 ng/ml) discovered in the context of infertility and secondary amenorrhea. Hyperprolactinemia was confirmed, and the first-line investigation concluded to peripheral hypothyroidism (TSH > 60 mUI/l) secondary to autoimmune thyroiditis (antiTPO antibodies: 453 mUI/l). Management consisted in hormone replacement therapy with thyroxine. Clinical evolution was marked with hormonal normalization 3 months later but persisting amenorrhea and hyperprolactinemia justifying pituitary MRI leading to the diagnosis of macroprolactinoma. Anti-dopaminergic treatment was prescribed with prolactin levels normalization, pituitary microadenoma size reduction and recovery of menstrual cycles.
Conclusion
Hyperprolactinemia is common in primary hypothyroidism, due to compensatory increase in the discharge of central hypothalamic TRH as a result of low thyroxine. Association of primary hypothyroidism and prolactinoma as cause of hyperprolactinemia is a rare condition which requires long-term follow-up to avoid missing the diagnosis and preserve the gonadal function and fertility.

Role of tolvaptan as a cost-cutter in hospitalized SIADH patients

Kirtanya Ramachandran[1,2], Bashir Mahamud[2] & Gideon Mlawa[2]
[1]Redcliffe hospital, Redcliffe, Australia; [2]Queens Hospital, London, United Kingdom

Background
SIADH is a condition characterized by excessive ADH secretion from the posterior pituitary in the absence of triggers like high plasma osmolality and low blood volume or low blood pressure. This leads to excessive and unwanted water retention and increase in the total body water content, though the plasma sodium levels are normal.
Case
An 89 y/o gentleman was admitted after he sustained a fall at his home and was diagnosed with right neck of femur fracture by the orthopaedic team. He had a background of atrial fibrillation, COPD, BPH, HTN, CKD, hypercholesterolemia, GORD for which he was on edoxaban 30mg OD, alfuzosin hydrochloride 10mg OD, atorvastatin 20 mg OD, salbutamol 100 mg, indapamide and omeprazole. He underwent right hip hemiarthoplasty and was making good progress clinically. However his renal functions started deteriorating mild AKI The patient was immediately started on IV fluids for the AKI and it resolved subsequently. However, his bloods showed his sodium levels to be quite low at 122. Therefore, the indapamide he was taking was stopped as well as the omeprazole he was on, was changed to famotidine. He was started on Fluid fluid restriction upto 750 ml. He was started started on oral Tolvaptan as sodium did not improve with fluid restriction. Sodium level improved remarkably to 130 with tolvaptan. His bilateral leg swelling also improved and he was clinically and biochemically stable. He was discharged and followed up a week later in the clinic to ensure his renal function was stable.
Discussion
SIADH alone contributes to nearly one third of the hyponatremia cases seen. Tolvaptan, is most effective treatment in euvolaemic hyponatramia and is given orally given. It is V2 receptor antagonist and leads to aquaresis. One of the remarkable features of this drug is, how quick it is at correcting the hyponatremia as well as the added advantage of not having to keep the patient in fluid restriction.
Conclusion
Hyponatremia when profound, is independently associated with a higher risk of death, with increased length of stay and in turn the cost of care for hospitalized patients. The vaptans represent a revolutionary step forward in the treatment strategy for patients with SIADH. They no longer need fluid restriction, the correction of hyponatremia occurs efficiently and quickly, and duration of hospitalization is shorter than with fluid restriction or demeclocycline.

Ocular manifestations of pituitary adenoma

Rekik Mona[1], Kammoun Sonda[1,2], Jallouli Aida[1,1], Ben Mrad Aymen[1], Nabila Mejdoub[3] & Trigui Amira[1]
[1]Habib Bourguiba Hospital; [2]; [3]Hedi Chaker Hospital

Introduction
Pituitary adenomas are common, and their impact on visual function is often significant, given the intimate relationship between the anterior pituitary and the optic pathways. Ocular symptoms may be indicative. Compressive optic neuropathy and oculomotor paralysis present a diagnostic challenge. This report details four cases where ocular manifestations played an essential role in establishing the diagnosis of pituitary macroadenomas.
Observation
Observation 1: A 63-year-old man with no significant medical history, presented with sudden-onset ptosis and diplopia. Ophthalmological examination revealed a complete paralysis of the third cranial nerve, and cerebral magnetic resonance imaging (MRI) showed a partially hemorrhagic macroadenoma. Observation 2: A 56-year-old man with no significant medical history, presented with complains of

bilateral progressive visual loss. Visual acuity was reduced to 1/20 in the right eye and negative light perceptions in the left eye. The pupillary light reflex in the right eye was normal, but a positive Marcus Gunn sign was observed in the left eye. Fundoscopy revealed bilateral optic atrophy. Brain MRI identified a sellar and suprasellar macroadenoma. Observations 3 and 4: The other two patients were women aged 25 and 33, who presented with complain of persistent headaches and vomiting. Ophthalmological examination indicated preserved visual acuity and bilateral stage II papilledema on fundoscopy. Brain MRI revealed a macroadenoma with a mass effect on the optic chiasm. The endocrine investigations have concluded to a non-secreting pituitary macroadenoma in cases 2,3 and 4.

Conclusion

Pituitary adenomas can manifest as a tumor syndrome, an endocrine syndrome or an acute intrasellar syndrome. The tumor syndrome primarily involves ophthalmological signs related to compressive optic neuropathy. This is most often associated with non-functional pituitary adenomas. Consequently, their discovery is often delayed until the tumor syndrome stage. When the macroadenoma extends supra-sellar with compression of the optic chiasm and/or pituitary stalk, it results in stasis papilledema, most commonly bilateral, causing visual field deficits. It can manifest as oculomotor paralysis, primarily affecting the third cranial nerve. Brain MRI allows for the diagnosis of pituitary macroadenomas and provides a precise assessment of their extension. These clinical cases highlight the diverse clinical manifestations of pituitary macroadenomas, underscoring the importance of brain imaging and ophthalmological evaluation in the diagnosis and management of these conditions.

Insulinoma: diagnostic difficulties of a rare tumor

Marwa El Arem[1], Bilel Ben Amor[2], Ekram Hajji[1], sana abid[1], Ines Bayar[1], Héla Marmouch[1], Hanene Sayadi[1] & Inès Khochteli[1]
[1]Hospital Fatouma Bourguiba, endocrinology; [2]Hospital Fatouma Bourguiba

Introduction

Insulinoma is a rare neuroendocrine tumor. Its diagnosis is clinico-biological. Preoperative topographical diagnosis is necessary to guide the therapeutic procedure.

Observation

We report the case of a 37-year-old patient, without notable pathological history, who was admitted for exploration of severe hypoglycemia, not felt, evolving for 2 years and complicated by convulsive attacks. The initial etiological investigation revealed corticotropic insufficiency and thyrotropic insufficiency. Despite substitution with hydrocortisone and L-thyroxine, hypoglycemia persisted. The dosage of insulinemia and C-peptide, carried out at the time of hypoglycemia, were inappropriate, thus confirming the presence of associated endogenous hyperinsulinism. The concomitant dosage of sulphonylureas was negative. Pancreatic MRI and CT angiography were normal. Likewise, the octreoscanner did not show any pathological uptake in the pancreas. Endoscopy ultrasound showed a small cystic lesion measuring 8x9 mm at the level of the pancreatic uncus. The cytopathological examination after cytopuncture showed an immunocytochemical appearance compatible with a neuroendocrine tumor. A second CT angiography, guided by the endoscopic ultrasound results, confirmed the presence of a cystic tumor at the level of the uncus. The patient underwent enucleation with disappearance of the hypoglycemia.

Conclusion

The cystic form of insulinoma is exceptional. In our case, only endoscopic ultrasound allowed the localization of this particular form.

Isolated ophthalmoplegia should we think about pituitary apoplexy?

Abdelkader Yahi[1], Haffaf Lounes[1], Lachekham Aicha[1], Benabdellatif Katia[1], Longo Redoune[1], Derriche Abderrahim[1], Talbi A[1], Derradji Hakim[1], Ould-Kablia Samia[1] & Bensalah Meriem[1]
[1]Algeria, Endocrinology Bir Mourad Rais

Background

Pituitary apoplexy (PA) is a rare neuroendocrine emergency due to acute ischemic infarction or hemorrhage of the pituitary gland. We report a case of apoplexy manifesting with isolated ophtalmoplégia.

Case description

We report the case of a 48-year-old man with a history of hypertension, type 2 diabetes mellitus, and dyslipidemia. Consult a private ophthalmologist following the sudden appearance of double vision and sagging of the right upper eyelid. The ophthalmological examination revealed paralysis of the right common oculomotor nerve (3rd cranial nerve). The patient was placed on symptomatic treatment. A week later, given the worsening of the ptosis, a brain CT scan was requested, which revealed a tumor process in the sellar region with hemorrhagic changes. Hypothalamic-pituitary MRI revealed a hemorrhagic pituitary macroadenoma measuring 30 mm long axis. The diagnosis of pituitary apoplexy was made. Since the patient was scored 2 according to the Pituitary Apoplexy Score (PAS), he benefited from conservative treatment (corticotherapy) with complete recovery of the visual impairment. The morphological evaluation carried out at 3 months found a clear regression of the tumor volume with the persistence of a remainder of 11 mm.

Discussion

PA is an atypical condition. The incidence ranges from 2 to 10% of all pituitary adenomas (PITNET). Despite the best diagnostic and treatment conditions, morbidity and mortality remain high at 15.3%. Therapeutic management, particularly medical or surgical management, is still debated and remains at the discretion of the practitioner. The interest in the PituitaryApoplexy Score (PAS), rated from 0 to 10, was reported in the 2011 British consensus, without threshold established to guide management.

Conclusion

The study of this observation underlines the variable clinical presentation of pituitary apoplexy whose evolution is conditioned by early diagnosis and treatment making it possible to first preserve the vital prognosis, as well as the visual prognosis and prevent irreversible damage.

Challenges in treatment of cortikotroph pituitary macroadenoma

Tamara Dojcinovic[1], Aleksandra Markovic[2] & Jelena Malinovic Pancic[3]
[1]University Clinic centre of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina; [2]University Clinical Centre of the Republic of Srpska; [3]University Clinical Centre of the Republic of Srpska

Cushing's syndrome is a condition characterized by hypercortisolism (endogenous and exogenous) regardless of its etiology. Hypercortisolism caused by an adrenocorticotropin secreting pituitary adenoma is defined as Cushing's disease. These tumors represent 10-12% of all pituitary adenomas. ACTH-secreting macroadenomas occur in only 4-23% of all patients with Cushing's disease. We present the case of 56-year-old female patient with hypercortisolism and stigmata of Cushing's syndrome. On physical examination we registered "buffalo hump", "facies lunata", hematomas on the skin and central obesity. Laboratory findings verified a disturbed diurnal cortisol rhythm with elevated ACTH values, as well as high cortisol values in low-dose dexamethasone test and partially suppressible values of cortisol in the high-dose dexamethasone test. An NMR of the pituitary gland was performed, verifying a 1.2 cm pituitary macroadenoma. The patient was further referred to a neurosurgeon and neurosurgical treatment was performed (PH: pituitary neuroendocrine tumor PiTNET type of corticotroph tumor, densely granulated subtype). Due to the persistent complaints of the patient, hypokalemia, unregulated hypertension and diabetes, the testing was repeated 3 months following surgery. Along with a disturbed diurnal cortisol rhythm, elevated ACTH values were also maintained. The patient has been referred to a higher reference center and treatment with the steroidogenesis inhibitor metyrapone had been initiated. In the further course, a control pituitary NMR was performed 6 months after the first one, and the rest of the 18 mm adenoma was verified. ACTH values were persistently increasing, and the diurnal rhythm of cortisol was still significantly impaired despite metyrapone therapy. The patient was reoperated on, and immediately postoperatively, elevated ACTH values were registered. The patient was advised to continue therapy with newer generation steroidogenesis inhibitors (osilodrostat), which is not registered in our country, and at this moment she is unable to obtain metyrapone, so cabergoline as only option was introduced. In later course, patient received gamma knife radiosurgery, and reevaluation in order to assess effects will be made. As already stated, Cushing's disease is a rare condition with many challenges in treatment because in a certain number of cases surgical resection does not provide complete remission. Additionally, the treatment of such a patient in our region is hard due to impossibility of obtaining and prescribing steroidogenesis inhibitors, so the only therapeutic option here in case of failure of cabergoline and radiotherapy is ultimately bilateral adrenalectomy.

Pediatric pituitary microadenomas: a case series and review of diagnostic challenges and treatment outcomes

Ashraf Soliman[1], Noor Hamed[1], Nada Alaaraj[1], Fawzia Alyafei[1] & Shayma Ahmed[1]
[1]Hamad Medical Centre, Department of Pediatrics, DOHA, Qatar

Background
Pituitary microadenomas in pediatric populations, though infrequent, present diagnostic and therapeutic challenges.
Methods
We retrospectively reviewed six pediatric cases of pituitary microadenomas diagnosed and treated at our institution. The cases were analyzed for presenting symptoms, hormonal profiles, and treatment responses.
Results
Case 1: A 12-year-old with growth hormone deficiency showed significant height improvement with somatropin treatment, without change in microadenoma size. Case 2: Central hypothyroidism was managed with levothyroxine, resulting in the resolution of headaches and fatigue, though growth deceleration persisted. Case 3: Precocious puberty was treated with a GnRH analogue, with ongoing monitoring. Case 4: The patient awaits further evaluation for recurrent headaches and elevated IGF1. Case 5: Early puberty signs were managed with triptorelin, with ongoing monitoring for microadenoma. Case 6: Treatment for precocious puberty and GH hypersecretion involved a GnRH analogue, with abnormal growth patterns under investigation.
Conclusions
The six cases exhibited a spectrum of growth anomalies ranging from short stature with slow growth velocity to precocious puberty with accelerated growth. Hormonal disturbances included growth hormone deficiency, central hypothyroidism, and central precocious puberty.

Therapeutic challenges in the treatment of acromegaly

Aleksandra Markovic[1,2], Mirjana Bojic[1], Tamara Dojcinovic[1,2], Danijel Djekic[1], Bojana Caric[1,2] & Jelena Malinovic-Pancic[1,2]
[1]University Clinical Centre of the Republic of Srpska, Internal Medicine, Banja Luka, Bosnia and Herzegovina; [2]University of Banja Luka, Faculty of Medicine, Banja Luka, Bosnia and Herzegovina

Introduction
Acromegaly is a chronic disease that occurs as a result of excessive growth hormone secretion, caused by somatotropin-secreting tumors of the pituitary gland in 98% of cases. The first line of treatment for these patients is operative via transsphenoidal approach, however, absolute remission is not achieved in 50% of patients and pharmacological therapy is indicated.
Case report
We will present the case of a 43-year-old patient who was hospitalized at the endocrinology department in 2016 due to enlargement of the hands, feet and nose, galactorrhoea as well as secondary amenorrhea. Elevated basal growth hormone (GH) values were verified: 79.05 ng/ml, there was no suppression in the oral glucose tolerance test, which established the diagnosis of acromegaly. NMR of the pituitary gland was performed, and described a macroadenoma of size 31×31×20 mm (LL×KK×AP) with expansion into the suprasellar cistern and cavernous sinuses on both sides. Operative treatment was indicated by the neurosurgeon, and conducted via transsphenoidal approach. After that, she was examined on several occasions by an endocrinologist from a lower reference center with persistently high IGF1 values but never came to our institution. She came to our centre in 2023 because of headaches, poorly regulated diabetes and hypertension. Again she had elevated basal GH values with the absence of suppression in the oral glucose tolerance test (GH 0 30, 60, 90, 120 min: 210 - 245 - 216 - 193 - 210 ng/ml), as well as high IGF1 443, 9. NMR of the pituitary gland was obtained and it showed deformed sella turcica, with a macroadenoma that spreaded parasellarly on both sides, invading both cavernous sinuses, compressing the optic nerves and the optic chiasm. Octreotide LAR 30 mg was introduced into the therapy immediatelly. A neurosurgeon was consulted again and a reoperation was indicated and performed. Postoperatively, elevated values of IGF1 persisted - 760 ng/ml, and the application of octreotide LAR was continued. Since she continuously had elevated levels of IGF1, we planned on introducing pasireotide or pegvisomant into the therapy, but that was not possible at this moment, given that these drugs are not available in our country.
Conclusion
As already mentioned in the introduction, the treatment of acromegaly is complicated and in most cases requires a combination of therapeutic modalities since transsphenoidal surgery does not lead to complete remission. We will also consider other therapeutic modalities (such as radiation).

Hyponatremia after surgery of subdural hematoma and oxcarbasepine therapy

Mubina Hodzic[1], Davorka Dautbegović- Stevanović[1,2], Alma Badnjević-Cengić[1] & Amila Čerim-Aldobašić[1]
[1]Cantonal hospital, Of Internal diseases, Zenica; [2]

Introduction
Hyponatremia is the most common electrolyte disorder that occurs in 15-30% of hospitalized patients. It is manifested by a wide range of clinical changes, from very mild to life-threatening conditions. Hyponatremia in the elderly is mainly caused by drugs (thiazides and antidepressants), SIADH or endocrinopathies. The paper presents a patient with severe hyponatremia after surgery of subdural hematoma and oxcarbazepine therapy.
Case report
A 77-year-old female was admitted to the Department of internal diseases in 2023, September due to slow speech, disorientation, inability of walking, occasionally abdominal pain. At the end of August 2023. she had a surgery of subdural hematoma due to nausea, headache, walking instability with preoperative normal mineral status. Her cousin denies vomiting, diarrhea, head injuries. The patient was taking enalapril hydrochlorothiazide, rosuvastatin in therapy. She was conscious, oriented, bradipsychic, lightly dehydrated, normotensive on admission but later was hypotensive in Intensive care Unit. Also oxcarbasepine therapy mentioned in a Neurosurgery discharge letter due epilepsy but denied taking it. Low values of sodium were noticed at biochemical findings. Other parameters were normal including glucose, renal, hepatic. Urine culture was positive in Escherichia coli. Serum sodium was corrected with small volume of hyperosmolar sodium chloride at admission due acute hyponatremia and later with isotonic sodium chloride. Due epilepsy attack during hospitalization neurologist consulted and oxcarbasepine started. Sodium diminished and the medication discontinued with the consecutively rising of serum sodium. The patient was conscious, oriented, communicative but not able to walk by herself during the hospitalization.
Conclusion
Evaluation of hyponatremia in the elderly is a challenge for the physician. A female patient had anamnesis and symptoms (hypotension, head surgery, improving with

(Abstract EP1193).

Case	Age at Presentation	Presenting Complaints	Main Findings	Hormonal Abnormalities	Treatment/Follow-up
1	12 years	Short stature	WtSDS = -2.22, HtSDS = -2.6, GV = 4 cm/year, MPHSDS = -1.28, IGF1 SDS = -1.81, GH peak 5.2 mg/l	GH deficiency	Started somatropin, no significant change in microadenoma size
2	12.4 years	Headaches and fatigability	HtSDS = -0.5, MPHSDS = 0, GV = 2.6 cm/year, IGF1 SDS = -1.28, GH peak 6.7 mg/l, low FT4, advanced bone age	Central hypothyroidism, GH deficiency	Started on levothyroxine, slow GV, continued levothyroxine after stopping
3	7 years 10 months	Premature thelarche, accelerated growth, premature pubarche	GV = 12.2 cm/year, HtSDS = +1.72, MPHSDS = -0.82, advanced bone age, high basal LH and FSH	Central precocious puberty	Started on GnRH analogue, will be reevaluated
4	12 years	Recurrent headaches, secondary amenorrhea	BMISDS = 2.5, HtSDS = +0.8, GV = 2.2 cm/year, high morning ACTH, normal cortisol, prolactin, LH and FSH	ACTH hypersecretion, central precocious puberty	Planned for GH suppression test, pelvic US, and salivary cortisol
5	2.8 years	Premature thelarche, family concern about accelerated growth	HtSDS = 2.4, BMISD = 0.44, high basal and stimulated LH and FSH, high estradiol, IGF1SDS = +3.1	Central precocious puberty	Started on triptorelin, will be followed for growth and MRI
6	7 years 5 months	Excessive body hair, symptoms of precocious puberty	Advanced bone age, high IGF1, paradoxical increase in GH during suppression test	Central precocious puberty GH and ACTH hypersecretion	Treatment with GnRH analogue, reassessment indicated abnormal growth

isotonic saline) which could favour a cerebral Salt wasting syndrome. On the other side there are uncertain data on using an oxcarbasepine after head surgery as a cause of SIADH which also developed during second hospitalization. These two entities are overlapping with different treatment options.

Challenges in the diagnosis and management of psychogenic polydipsia

Zineb Ait Si Ali[1], Manar Bari[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]

[1]Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Endocrinology Diabetology Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction

Psychogenic polydipsia occurs in both psychiatric and somatic contexts. Clinically, it presents with a wide range of symptoms, both neurological and psychiatric, and can evolve into acute somatic complications, of which water intoxication is the most severe, with a high mortality rate.

Case report

A 35 years-old male patient, treated for mental retardation since the age of 9 following a tonsillectomy, the post-op effects of which were marked by a coma lasting one month, also treated for epilepsy since the age of 18 on levetiracetam. The patient had presented 5years ago with behavioral problems such as psychomotor agitation, self-aggressivity and suicide attempts, and was put on amisulpride and risperidone. He was referred to us to investigate a Polyuria-polydipsia syndrome that had been evolving for 4 months, with abundant drinking (7l/pd) and abundant polyuria (5l/pd) with a single nocturnal awakening. Clinical examination revealed a conscious patient; normal blood pressure and cardiac rate, eupneic, moderate obesity BMI 33.2 kg /m^2. Input/output fluide balance was 3.9L/4L per day. Paraclinical tests showed: Natremia 137.93mmol/l, Kalemia 3.96mmol/l, renal function normal, urinary osmolarity: On admission (1pm urine): 225.99mosmol/l, Morning urine (1st micturition): Concentrated appearance, Osmolarity: 378.46mosmol/l. Hypothalamo-pituitary MRI: diffuse supratentorial and subtentorial cortico-subcortical atrophy associated with sequellar gliosis lesions, pituitary gland of normal size and morphology, presence of physiological hypersignal of the postpituitary gland. Water deprivation test was not performed, given the context of epilepsy and the appearance of concentrated urine and urinary osmolarity greater than 300mosmol/l. Psychogenic polydipsia was considered, given the psychiatric involvement, the concentrated appearance of urine, urinary osmolarity $>$300mosmol/l and normal MRI. Polyuria secondary to the use of levetiracetam was discussed, but the patient had been on this treatment for at least 5 years.

Conclusions

Psychogenic polydipsia is characterized by a disturbance in the control of thirst that is not due to a disorder of antidiuretic hormone production. Although most often seen in patients with chronic schizophrenia, psychogenic polydipsia is also associated with other mental illnesses such as affective disorders, childhood-onset psychoses, mental retardation, personality disorders and anxiety. Treatment options are limited, if, for psychiatric reasons, a choice of antipsychotic medication has to be made, preference will be given to risperidone, olanzapine and clozapine. Short-term cognitive-behavioral therapies have produced interesting results, based on self-monitoring of fluid intake, behavioral control of stimuli through the use of reduced-capacity bottles, learning coping strategies and the use of reinforcement and gratification mechanisms.

«Diagnostic difficulties of central insipidus diabetes associated with stalk thickening»

Hassiba Khaldi[1,1]

[1]military central hospital, algies, Algeria

Introduction

CID in children is a rare pathology, the diagnosis is generally easy as it manifestes itself by a polyuro_polydipsic syndrome (PPS) of variable severity secondary to an ADH deficiency. The discovery of a thick pituitary stalk in this context must encourage us to look for the etiology with the fear of tumoral causes

Observation

We report the case of a young patient, of 16 years old, with no particular history, hospitalised for sudden polyuroplydipsic syndrome with no precipitating factors. The clinical examination was normal except for a low BMI of 15 kglm^2 and delayed puberty classified G1P2 TANNER.PPS was about 2,3 liters Biological investigation showed a low urinary density $<$ 1005 and Urinary osmolality of **65** mosm/l. Plasmatic osmolarity was about **298** mosmo/l Anterior pituitary investigation after Desmopressine supplementation showed corticotropin deficiency (cortisol: **117,9** nmol/l, ACTH: 5 pg/ml), the othor anterior pituitary functions were normals Pituitary MIR showed a thick pituitary stalk corresponding to a likely infundibulo-neurohypophysitis after eliminating tumoral, infiltrative and infectious pathologies. The patient was put on replacement therapy (DESMOPRESSINE) and underwent clinical and morphological monitoring every 3 to 6 months.

Conclusion

It is advisable to repeat the etiological investigation several years after the so-called idiopathic forms of CID in search of a tumoral or infiltrative pathology, but also to evaluate the progress of the thickening stalk.

Crooke cell corticotrop adenoma: case series

Ekin Yiğit Köroğlu[1], Çağlar Keskin[1], Servet Güreşçi[2], Denizhan Divanlıoğlu[3], Cevdet Aydın[4], Oya Topaloğlu[4], Reyhan Ersoy[4] & Bekir Çakır[4]

[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara; [2]Ankara Bilkent City Hospital, Pathology, Ankara; [3]Ankara Bilkent City Hospital, Neurosurgery, Ankara; [4]Ankara Yıldırım Beyazıt University Faculty Of Medicine, Endocrinology and Metabolism, Ankara

Crooke cell corticotroph adenomas are a rare subtype of corticotroph adenomas. It can be detected in less than 1% of all pituitary adenomas. They are usually noticed as invasive macroadenomas on preoperative imaging. They are expected to have a more aggressive course and more frequent recurrences during their clinical course. We present a case series of 11 patients who were followed up with Cushing's Disease in our clinic and were diagnosed with Crooke cell adenoma after surgery. Nine patients were female(81.8%), and 2(18.2%) were male. The average age of the patients was 41.0(19.0-71.0) years. There were macroadenomas in 6 patients(54.5%) and microadenomas in 5 patients(45.5%). The average largest tumor diameter was 14.00 (4.50-35.00) mm. Pituitary adenoma invaded surrounding tissues in 3 patients(27.3%). Optic chiasm compression was observed in 2 patients(18.2%). Preoperative hypopituitarism was present in 6 patients(54.5%). In this group of patients, macroadenoma was detected in 5 patients, and microadenoma was detected in 1. The patients' preoperative laboratory parameters and clinical findings are given in Table 1 and Table 2, respectively. A 1-milligram dexamethasone suppression test was performed in all patients in the preoperative period, and it was found to be high in all patients. 24-hour urinary cortisol was measured in 8 patients and was high in 5. In the postoperative period, two patients could not be evaluated for remission because they continued their follow-up in another center. Biochemical remission was achieved in 4 of the other nine patients(44.4%), and biochemical remission was not achieved in 5(55.6%). Postoperative follow-up periods of patients in biochemical remission have been 33, 39, 56, and 62 months; no recurrence was observed in any patient during this period.

Table 1. Laboratory parameters of patients with Crooke cell corticotroph adenoma

Test	n	Minimum	Maximum	Mean
ACTH($<$46 pg/ml)	11	13,50	443,00	108,8455
Cortisol(5.2-22.4 μg/dl)	11	11,10	60,00	31,0273
1 mg dexamethasone suppression test($<$1.8 μg/dl)	9	3,90	43,56	21,1956
24-hour urinary cortisol(3.5-45 μg/day)	8	24,66	2279,63	547,9125
Midnight salivary cortisol($<$0.69 μg/dl)	4	,64	2,28	1,6100

Table 2. Clinical findings of patients with Crooke cell corticotroph adenoma

Clinical finding	Present	Absent
Central Obesity	9(81.8%)	2(18.2%)
Proximal myopathy	3(27.3%)	8(72.7%)
Moon face	4(36.4%)	7(63.6%)
Abdominal purple striae	3(27.3%)	8(72.7%)
Buffalo hump	6(54.5%)	5(45.5%)
Hirsutism	5(62.5%)	3(27.3%)
type 2 Diabetes Mellitus	5(45.5%)	6(54.5%)
Hypertension	5(45.5%)	6(54.5%)
Hyperlipidemia	6(54.5%)	5(45.5%)
Osteoporosis	1(9.1%)	10(90.9%)
History of thrombosis	1(9.1%)	10(90.9%)
Hypokalemia	3(27.3%)	8(72.7%)

EP1217

Evaluation of macroprolactinoma in a cohort of 48 patients

Rahal Amel[1]
[1]Bologhine hospital, endocrinology algiers, Algeria

Introduction
Prolactinoma is the most common pituitary tumour; in the majority of cases it is a microadenoma.
Materials and methods
Through a retrospective study of 46 patients followed for macro prolactin adenomas we evaluate the response to medical treatment of macroprolactinoma. In our series, macroprolactinomas are more frequent in men (59%), more often diagnosed between the ages of 25 and 45. As expected, cranial tumour syndrome remains the main reason for consultation in both sexes in 65%. Biologically, the correlation between tumour volume and prolactin is clear, with levels slightly higher in men. Among the macroprolactinomas we recruit 37% of giant adenomas; more common in men. In terms of treatment, medical treatment is the first choice in 83% of cases. Surgery was used in 33% of cases, most often for compression of the optic tracts. Among our patients, 43% were resistant to medical treatment, more frequently in men.
Discussion
The aim of our work was to evaluate the therapeutic response of prolactin macroadenomas. As expected, our results are consistent with the data in the literature; macroadenomas adenomas are more frequent in men with a more striking clinical, biological and morphological presentation. The therapeutic management of macroprolactinoma also revealed a morphological resistance which is more frequent in men, because of a higher tumour volume. Despite this resistance, two thirds of our patients responded to medical treatment.

Evaluation des pratiques de commande des tests de prolactine

Dhouha Zouari[1], Rim Marrakchi[1], Charfi Ameni[1], Mohamed Ccaher Rabah[1], Mariem Boudaya[1], Kamel Jamoussi[1], Mohamed Abid[2] & Mouna Turki1[2]
[1]Laboratory of Biochemistry, Hédi-Chaker Hospital, Sfax, Tunisia, [2]Endocrinology departement, Hedi Chaker Sfax Tunisie

Introduction
Hyperprolactinaemia can be caused by physiological changes, medications, pathological conditions, or can be idiopathic. The aim of this study was to evaluate clinicians's practice in ordering prolactin (PRL) test.
Methods
A retrospective study concerning 75 prolactin requests data collected by the laboratory computer system (Health Lab) during January 2024. We collected age, sex and ordering's origins. PRL tests were performed based on electro-chemiluminescence immunoassay (eCLIA) by Dxi600Û Beckman Coulter. Hyperprolactinaemia was defined by PRL levels above 25ng/ml and 15ng/ml respectively for women and for men.
Results
The mean age of patients was 37 years, with extremes ranging from 13 to 85 years with a male/female sex ratio of 0.3. The majority of PRL requests were from the endocrinology department (58.7%), followed by the gynecology department (18.7%) and the psychiatry department (13.3%). Reasons for prescription PRL were mainly as follows: 22% for gynecological reasons (primary and secondary amenorrhea, irregular cycle, galactorrhoea, metrorrhagia, spaniomenorrhea, infertility), 19% for suspecting pituitary tumour, 17% for monitoring hyperprolactinemia, 10% for investigating polycystic ovary syndrome, 8% for monitoring subjects receiving neuroleptics. We observed 37.3% of the requests without clinical indications. The mean of PRL levels was 27 ng/ml, with extreme values ranging from 1.8ng/ml to 196.15 ng/ml. Among requests with clinical indications of having hyperprolactinaemia and requests without clinical indications,?only 29.4%, and 28.6% had respectively hyperprolactinaemia.?
Conclusion
There was an over-ordering for prolactin in our hospital practice. Further evaluation is needed to determine strategies that can reduce excessive prolactin testing.

Hypoaccousia revealing acromegaly: a case report

Hajar Azagouagh[1], Karimi Meryem[1], Nawal Moussaid[1], Rifai Kaoutar[1], Iraqi Hind[1], Mohamed Elhassan Gharbi[1]
[1]Chu Ibn Sina, Endocrinology, Rabat

Introduction
Acromegaly is a rare disease defined by the clinical expression of hyperfunction of the somatotropic axis with unchecked secretion of growth hormone. It has many complications, which is why early diagnosis is essential.
Observation
We report the case of a 47-year-old patient , with a history of chronic smoking and renal lithiasis operated on in 2018. His history of illness goes back 3 months to the onset of hypoacusis, which prompted the patient to consult an ENT specialist, He then referred the patient to the endocrinology department, where the diagnosis of acromegaly was made in view of the dysmorphic acrofacial syndrome with elevated IGF1 levels, and we completed it with a hypothalamic-pituitary MRI scan showing a pituitary micro-adenoma measuring 7*8*8 mm. Resection surgery was proposed to our patient.
Discussion and conclusion
Because of its insidious nature, acromegaly is often diagnosed late, exposing the patient to the risk of morbidity and mortality, but it may be preceded by abnormalities such as hypoacusis. Complications account for the full severity of the disease, notably cardiovascular, metabolic and neoplastic complications. Thinking about the secondary origin of hypoacusis could lead to earlier diagnosis and better management of acromegaly.

Microadenoma of prolactin revealed by galactorrhea in a man

Karimi Meryem[1], Hajar Azagouagh[1], Hasna Ouirar[1], Mariam Hmaichat[2], Diehah Isselmou[1], Isswani Jad[2] & Guerboub Ahmed Anas[2]
[1]Chu Ibn Sina, Endocrinology, Rabat, [2]Hopital Militaire Mohamed V Rabat, Endocrinology, Rabat

Introduction
Galactorrhea is defined as the secretion and flow of milk from the mammary gland in a man or a woman who is not breastfeeding. It is generally due to a pituitary adenoma secreting prolactin. The etiological diagnosis is based on prolactin levels and imaging.
Case report
We report the case of a 42-year-old patient with no notable medical history. His symptoms date back 17 years, marked by the onset of bilateral gynecomastia, spontaneous galactorrhea, and decreased libido. Biological assessment reveals hyperprolactinemia more than 20 times the normal level, with a significantly reduced testosterone level. Hypothalamo-hypophysial MRI reveals a 5mm microadenoma lateralized to the left. The patient is treated with dopamine agonists, resulting in good clinical and biological improvement.
Discussion and conclusion
Galactorrhea represents a pathognomonic and rare sign of hyperprolactinemia in men, usually secondary to a prolactin-secreting pituitary adenoma. The frequency of microadenomas is much lower in men, possibly due to later diagnosis in this population.

Use of selective adrenal and ovarian venous sampling in postmenopausal women with severe hyperandrogenism: Report of 3 cases

Valeria Arsentales Montalva[1], Olga Giménez-Palop[2], Ismael Capel[2], David Subías[2], Ana Romero[1], Alba Hernández[1], Andreea Muntean[1], Judith Jover[1], Laura Costa[3], Juan Perendreu[4], Carlos García[5] & Mercedes Rigla[2]

[1] Endocrinology and Nutrition Department, Parc Taulí University Hospital, Sabadell, Barcelona, Spain; [2]Endocrinology and Nutrition Department, Parc Taulí University Hospital, Autonomous University of Barcelona (UAB), Sabadell, Barcelona, Spain; [3]Obstetrics and Ginecology Department, Parc Taulí University Hospital, Sabadell, Barcelona, Spain; [4]Interventional Radiology Department, Parc Taulí University Hospital, Sabadell, Barcelona, Spain; [5]UDIAT Laboratory Department, Parc Taulí University Hospital, Sabadell, Barcelona, Spain

Background
Although the majority of cases of hyperandrogenism in postmenopausal women are due to functional causes, the sudden appearance of a severe and rapidly progressive condition, especially if associated with signs of virilization and defeminization, requires always ruling out the existence of an androgen-producing tumor at both the adrenal and ovarian levels. Etiological diagnosis can be difficult because ovarian tumors are not easily demonstrable by imaging.
Case Reports
Three postmenopausal women (mean age: 69 years) referred to our center for hirsutism and elevated testosterone levels. As relevant associated diseases: obesity, dyslipidemia and type 2 diabetes. They reported growth of facial hair, upper chest and back for the last 3-4 years, acne, seborrhea, androgenic alopecia and weight gain between 5-8 Kg. Two of them, with a history of oligomenorrhea in the reproductive age. The average Ferriman-Gallwey score was 21, without clitoromegaly. High total testosterone levels stood out in all cases, with an average figure of 1.73 ng/ml (reference value 0.03-0.41 ng/ml) and a mean free testosterone of 3.04 ng/ml (reference value 0-0.1 ng/ml). The determinations of dehydroepiandrosterone sulfate (DHEAS), 17-hydroxyprogesterone, prolactin, thyroid function, 24-hour urinary free cortisol excretion and low-dose dexamethasone suppression test were within normal limits. The transvaginal ultrasound and the pelvic MRI did not show any remarkable findings. A CT Scan of the adrenal glands showed a non-functioning left adrenal nodule (measured 25x22 mm) already known and studied, with normal (DHEAS) levels in one of the three cases, without signs of growth or formation of new lesions in any of the glands. In the absence of conclusive radiological localization of androgen hyperproduction, selective catheterization of ovarian and adrenal veins was performed under stimulation of 250 ug of ACTH. In all cases, the high gradient existing between the ovarian vein/peripheral venous blood, sustained the suspicion of excessive production of androgens of ovarian origin, laparoscopic bilateral oophorectomy being performed in all patients. The pathology showed ovarian stromal hyperplasia with bilateral hyperthecosis, as well as foci of Leydig cell hyperplasia in one case. After the surgery, there was a significant improvement in hirsutism, with normalization of testosterone levels in all cases.
Conclusion
Selective venous catheterization and hormone sampling in postmenopausal women with severe hyperandrogenism could be useful to determine the source of androgenic hyperproduction in the absence of conclusive localization with standard imaging modalities, being bilateral oophorectomy as the standard surgical technique after reproductive age.

Endocrine and reproductive consequences of pubertal stress in rats

Oksana Faliush[1], Olga Sachynska[1], Anna Lymareva[1], Inna Perchyk[1] & Alexander Reznikov[1]
[1] VP Komisarenko Institute of Endocrinology and Metabolism, National Academy of Medical Sciences of Ukraine, of Endocrinology of Reproduction and Adaptation, Kyiv, Ukraine

Adolescence is one of the most dynamic periods of development, which is highly sensitive to changes induced by stressors. Disruption in hormonal balance associated with stress have a negative impact on puberty and reproductive function. The aim of the work was to study the long-term endocrine effects of chronic pubertal stress in rats. On the 22 postnatal day (PND), the Wistar rats were separated from their mothers and sorted by sex into individual cages, so that animals from different litters were in both the control and experimental groups. The animals were subjected to stress daily in the morning hours from 30 to 45 PND by placing them in cylinders with a diameter of 4.5 cm and a length of 10 cm, equipped with breathing holes. During the stress period and upon its completion, the onset of sexual maturation was recorded in both the control and experimental animals, while observing somatic development. After the stress period ended, the animals were housed in cages in groups of five individuals each. All investigations were conducted on sexually mature rats at the age of 6 months. The weights of gonads and the adrenal glands, and the morphology of the reproductive organs were studied. The quantitative and qualitative indices of the spermatozoa in epididymal washes were determined. The plasma corticosterone levels were measured both at baseline and after one hour of tight restriction. The pubertal chronic stress significantly delayed the sexual maturation of females and adversely affected weight gain in males. In adult animals, pubertal stress did not change the weight and morphology of the gonads, except for slight vacuolation of the spermatogenic epithelium compared to intact ones. The index of spermatogenesis in the experimental group was significantly lower than in the control, due to a decrease in the number of late spermatids, which indicates inhibition of spermatogenesis. Pubertal stress resulted in a 25.9% decrease in sperm count and a 2.4-fold slowing of oxidative-reductive processes in spermatozoa. These animals showed an increase in the number of pathological forms of spermatozoa. A significant decrease in adrenal weight in females and a tendency to a decrease in males were observed. The basal corticosterone levels reduced by 1.7 times in males. Stress reactivity in females and males did not differ from the control. Thus, chronic pubertal stress, under the selected experimental conditions, resulted in adverse long-term sex-specific effects on the reproductive and adaptive systems of adult animals.

Orexin A is a new marker of insulin resistance in polycystic ovary syndrome

Yulia Absatarova[1], Yulia Evseeva[1], Elena Andreeva[1] & Margarita Samsonova[1,2]
[1]Endocrinology Research Centre, Gynecology, Moscow, Russian Federation; [2]

Dysregulation of the neuroendocrine system is a key element in the pathogenesis of polycystic ovary syndrome (PCOS). Orexins (hypocretins) are a new class of hypothalamic neuropeptides that influence sleep-wake rhythms and the state of energy metabolism. In addition, their receptors expresses in peripheral tissues, including the endocrine system. Data have emerged on the role of orexins in the regulation of the reproductive system and, in particular, ovulation, through a direct effect on the hypothalamic-pituitary-ovarian axis, and their stimulating effect on GnRH neurons has been described.
Objective
To study orexin status in women with PCOS and its role in the pathogenesis of the disease.
Methods
The study involved women 18-39 years old: 20 patients with PCOS with a body mass index (BMI) ≥ 25 kg/m^2 (group 1), and 20 women with PCOS and BMI $<$ 25 kg/m^2 (group 2). The diagnosis of PCOS based on the Rotterdam criteria (2003). The control group consisted of 20 healthy women with a regular menstrual cycle and BMI <25 kg/m^2. We determined the levels of orexin A, LH, FSH, testosterone, insulin in the blood serum in all three groups in the 1st phase of the menstrual cycle (3-7 days of cycle) or against the background of a menstruation delay for more than 2 months (in patients with PCOS).
Results
All three groups were age-matched. In group 1, the median BMI was 30.8 kg/m^2 [26.6; 34.6], in group 2 - 21.4 kg/m^2 [19.2; 22.4], in the control group - 20.9 kg/m^2 [20.0; 22.8]. The median level of orexin A was significantly lower in the group of patients with PCOS and BMI ≥ 25 kg/m^2, compared with the group of PCOS with normal BMI and healthy women: 1.32 ng/ml [0.29;3.56], 5.77 ng/ml [3.34;9.87] and 11.06 ng/ml [8.41;17.49], respectively ($P<0.05$). In the overweight PCOS group, insulin level was significantly higher compared to patients with normal weight and healthy participants: 13.7 [8.3; 23.7] mIU/l; 7.2 [5.2; 9.1] mIU/l and 6.2 [5.0; 8.6] mIU/l, respectively ($P<0.05$). We found a negative correlation between the level of orexin A and BMI, orexin A and insulin: the higher was the BMI and the insulin level; the lower was the level of the neuropeptide orexin, respectively.
Conclusion
Orexin A is a potential marker of ovarian hyperandrogenism. It also reflects the severity of insulin resistance, which is one of the main triggers in pathogenesis of PCOS.

Sex-specific effects of perinatal exposure to tetrabromobisphenol a, an endocrine disrupting chemical on brain development and behavior in mice

Eui-Bae Jeung[1], YongIn Kim[1], Sun Kim[1] & Inho Hwang[1]
[1]Chungbuk National University, Laboratory of Veterinary Biochemistry and Molecular Biology, College of Veterinary Medicine, Cheongju, Korea, Republic of South

Tetrabromobisphenol A (TBBPA) is a brominated flame retardant and is widely used in electronic goods, plastics, and furniture. TBBPA is frequently detected in water, soil, organisms and even in human breast milk. Though some regulatory agencies have asserted that consumer exposures to TBBPA are unlikely to have adverse implications for human health, the reported evidence of endocrine-disruption of TBBPA has raised concerns regarding its effects on neurodevelopment and behavioral functions. The present study examined the effects of exposure to TBBPA on neurodevelopment. The Developmental Neurotoxicity Test (DNT) was performed to determine whether TBBPA is a developmental neurotoxicant. Additionally, maternal mice were administered 0, 0.24 and 2.4 mg/kg TBBPA. Mice offspring underwent behavioral tests for assessment of locomotor, depressive, cognitive, and social behaviors. Gene expression pattern change at transcriptional level in the brain was investigated with real-time PCR. As a result, TBBPA was classified as a developmental neurotoxicant from the DNT. In addition, the behavioral experiments revealed gender-specific effects. In females, only a deterioration of the motor ability was observed. In contrast, deteriorations in motor function, memory, and social interaction were noted in males. Aberrant expression of several genes, such as Na+/Ca2+ exchanger 2 (NCX2), acetylcholinesterase (AChE) and oxytocin (OXT), were found in the brains of TBBPA-treated mice offspring. To summarize, these findings suggest that perinatal exposure to TBBPA interferes with brain development and behavioral functions in mice. Therefore, it is necessary to pay more attention to the potential effects of TBBPA in the early development of brain.

The relevance of endocrine disruptors, obesity, and cytokines for polycystic ovary syndrome

Michaela Duskova[1,2], Jana Vítků[3], Lucie Kolatorova[4], Jana Vrbikova[4], Michala Vosátková[3], Josef Včelák[5] & Markéta Šimková[5]
[1]Institute of Endocrinology, Department of Steroids and Proteofactors, Praha 1, Czech Republic; [2]General Teaching Hospital Prague, 4th department of internal medicine, Praha, Czech Republic; [3]Institute of Endocrinology, Department of Clinical Biochemistry, Praha 1, Czech Republic; [4]Institute of Endocrinology, Department of Clinical Endocrinology, Praha 1, Czech Republic; [5]Institute of Endocrinology, Department of Molecular Endocrinology, Praha 1, Czech Republic

As genetic and environmental components contribute to the PCOS expression, we compared levels of endocrine disruptors, steroid hormones, cytokines, and metabolic parameters in twenty healthy, nine normal-weight PCOS women, and ten obese PCOS women. Steroid hormones, bisphenols (BPA, BPS, BPF, BPAF) and parabens (methyl-, ethyl-, propyl-, butyl-, benzyl-parabens) were measured by liquid chromatography-tandem mass spectrometry. Differences between the groups were assessed using the Mann-Whitney U test. Spearman correlation coefficients were calculated for the individual parameters relationship. Significantly higher levels of BPA, Anti-Müllerain hormone, lutropine, lutropine/folitropine ratio, testosterone, androstenedione, 7β-OH-epiandrosterone, and cytokines (IL-6, VEGF, PDGF-bb), were found in normal-weight PCOS women compared to controls. In PCOS women concerning the weight, there were no differences in hormonal, but in metabolic levels. Obese PCOS women had significantly higher insulin resistance, fatty-liver index, triglycerides, cytokines (IL-2, IL-13, IFN-γ). In healthy, but not in PCOS, women, there was a positive correlation of BPA with testosterone, SHBG with lutropine, and folitropine, while testosterone negatively correlated with SHBG. In obese women with PCOS, insulin resistance negatively correlated with SHBG and estradiol. No differences were observed in the paraben exposure. Levels of BPA were higher in PCOS women, indicating its role in the etiology. Obesity significantly worsens the symptoms.

Vitamin D levels in pregnant women, vitd-supplementation and its association with pregnancy outcomes

Dimitra Pappa[1], Eleftheria Barmpa[1], Stefanos Tamouridis[1], Aikaterini Evagelopoulou[2], Alexander Daponte[2] & Alexandra Bargiota[1]
[1]University Hospital of Larissa, Department of Endocrinology and Metabolic Diseases, Larissa, Greece; [2]University Hospital of Larissa, Department of Obstetrics and Gynecology, Larissa, Greece

Introduction
Data on the desirable Vitamin D (VitD) levels and VitD-supplementation during pregnancy are very controversial and thus everyday practice varies a lot. In our study the aim is to record VitD levels, as well as the VitD-supplementation and their association with pregnancy outcomes in women referred to our center in the second and third trimester of pregnancy.
Methods
We studied 193 pregnant women mean age 30.34±7.07 years old. In each patient we measured 25(OH) Vitamin D3 levels at the second and third trimester of pregnancy (reference range for 25(OH) Vitamin D3 is 20-32 ng/ml, and VitD deficiency is <20 ng/ml). We also recorded the VitD-supplementation, gestational age at delivery (GAd), childbirth type and offspring birthweight (ofBW).
Results
Baseline mean gestational age (GA) was 27.18±6.78 weeks and mean 25(OH) Vitamin D3 levels were 20.64±11.80 ng/ml. 133 out of 193 (68.91%) women had normal 25(OH) Vitamin D3 (ND3, mean levels 23.35±13.19 ng/ml), and 60 out of 193 (31.08%) had 25(OH) Vitamin D3 deficiency (DD3, mean levels 14.76±3.79 ng/ml.) ND3 women had mean age 30.24±7.28 years old, mean GA 27.84±6.23 weeks, 34/ND3 (25.56%) were not on VitD-supplementation, 67/ND3 (50.37%) were on 200-800 IU VitD-supplementation daily, 19/ND3 (14.28%) on 1000-1800 IU/daily and 13/ND3 (9.77%) on 2000-4000 IU/daily. 35 of ND3 (26.21%) were on calcium-supplementation (500 mg/daily). In ND3 the mean GAd was 37.98±1.32 weeks, mean ofBW was 3034.34±587.44 gr and 53/ND3 (39.84%) had a caesarean section. DD3 women had mean age 30.56±6.55 years old, mean GA 25.73±7.70 weeks, 6/DD3 (10%) had VitD-supplementation >4000 IU/daily, 21/DD3 (35%) were on 2000-4000 IU/daily, 9/DD3 (15%) on 1000-1800 IU/daily, 18/DD3 (30%) on 200-800 IU/daily and 6/DD3 (10%) were not on VitD-supplementation. 14 of DD3 (23.33%) were on calcium-supplementation (500 mg/daily). In DD3 the mean GAd was 37.57±1.83 weeks, mean ofBW was 3094.76±587.22gr and 25/DD3 (41.66%) had a caesarean section.
Conclusion
VitD-supplementation doses during pregnancy defer - despite the existing guidelines - depending on the Obstetrician. Current recommendation suggest that women with normal VitD levels require VitD-supplementation with 400-600 IU/daily, whereas women with VitD deficiency a higher dose of 1000-4000 IU/daily. In our study pregnant women who referred to us at the second and third trimester with normal VitD levels were on no or on the minimum daily dose of VitD-supplementation (200-800 IU) and those with VitD deficiency were on the maximum daily dose (2000-4000 IU) - more or less complying with the recommendation. No significant differences on pregnancy outcomes were reported between the two groups.

Immunological role of progesterone and cortisol during pregnancy

Atsushi Yasuda[1], Toshiro Seki[1], Hirofumi Kashiwagi[1], Natsumi Kitajima[1], Masami Seki[1] & Yoshie Kametani[1]
[1]

During pregnancy, levels of pregnancy-related proteins and hormones such as progesterone (P4), estrogen, and glucocorticoids (GC) increase. Although the regulatory mechanisms of P4 production in the placenta are not completely understood, studies using mouse models have demonstrated that P4 induces immunosuppression using a GC receptor-dependent pathway, suggesting that both it has been suggested that steroid hormones have a similar effect. Understanding the orchestrated role of P4 and cortisol (COR) is important for understanding the mechanisms of immune regulation during human pregnancy. Based on previous experiments showing that P4-treated T and B cells remained in the spleen, we hypothesized that P4-treated cells could produce functional IgG antibodies. Therefore, we immunized humanized mice and examined antigen-specific antibody production. However, the titer of antiserum in humanized mice varied among individuals and was not significantly different, and the percentage of plasmablasts did not differ between mice treated with P4 and COR. For this, we analyzed the production of antigen-specific B cell clones in mice by preparing hybridomas, treating them with P4 and COR, and analyzing cross-reactivity of

whole antibodies to immunizing antigens and third-party antigens. Results showed that spleen cell numbers were lower in COR-treated mice, the entire IgG-secreting clone was maintained in P4-treated mice, and B-cell clones in COR-treated mice were also observed to secrete IgG. In contrast, P4-treated mice produced antigen-specific IgG-secreting clones, slightly fewer than control mice, whereas COR-treated mice did not produce high-titer antigen-specific B cell clones. These results suggest that transient treatment of lymphocytes with high concentrations of P4 preserves the function of humanized murine B cells, whereas treatment of COR significantly reduces function. Few antigen-specific clones per spleen cell were detected in COR-treated mice. The reason may be the low proportion of B cells among CD45+ cells in the spleen. Defects in antigen-specific plasmablast formation may be caused by defects in functional B cell engraftment due to COR pretreatment. Irreversible and systemic humoral immunosuppression has no benefit for immunity during pregnancy. Therefore, to maintain pregnancy, it may be necessary to neutralize the effects of COR with large amounts of P4. Further analysis of the role of P4 and COR during pregnancy would be necessary to understand the immunomodulatory mechanism.

Assessment of non-invasive NAFDL indices in patients with PCOS

Valentina Elezovic Kovacevic[1], Sanja Ognjanovic[1], Bojana Popovic[1], Dusan Ilic[1], Milica Opalic Palibrk[1], Lena Radic[1], Katarina Krstic[1], Jelica Bjekic Macut[2], Danijela Vojnovic Milutinovic[3], Olivera Stanojlović[4] & Djuro P. Macut[1]

[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Department for Enocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia; [2]Clinical Hospital Centre Bezanijska Kosa, Belgrade, Serbia; [3]IBISS, University of Belgrade, Belgrade, Serbia, Belgrade, Serbia; [4]Institute of Physiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Introduction
Polycystic ovary syndrome (PCOS) is one of the most common endocrine disorders in reproductive-age women. This highly complex reproductive metabolic disorder is independently associated with high prevalence of non-alcoholic fatty liver disease (NAFLD). While the gold standard of NAFLD diagnosis is liver biopsy or MRI, it is costly and hard to perform in large population. Recently, simple and convenient markers, such as liver fat score (LFS), fatty liver index (FLI), and hepatic steatosis index (HSI) have been demonstrated to exhibit comparable coefficient values to standard diagnosis. The aim of this study was to analyse these non-invasive parameters in women with PCOS.
Subjects and Methods
PCOS was diagnosed using ESHRE/ASRM criteria. PCOS group was divided into four phenotypes: PCOS-A (anovulation (ANOV), hyperandrogenism (HA), polycystic ovary morphology (PCOM)), PCOS-B (ANOV, HA), PCOS-C (HA, PCOM) and PCOS-D (ANOV, PCOM). Fatty liver index (FLI), liver fat score (LFS), and hepatic steatosis index (HSI) were used to assess NAFLD. They were calculated according to the previously defined formulas. Values of LFS > -0.640, FLI >60 and HSI >36 was considered as having NAFDL.
Results
We analysed 165 women with PCOS, mean age at diagnosis 25.2 ± 5.1 years and mean BMI 24.1 ± 6.0 kg/m^2. Most of the group were patients with phenotype A (48.5%), phenotype D (20%), then phenotype B (18.2%) and phenotype C was present in 13.3%. The mean FLI was 21.1 ± 29.2, mean LFS -0.504 ± 2.05 and mean HSI 36.2 ± 5.7. The prevalence of NAFLD in PCOS women evaluated by FLI, LFS and HSI were 14.01%, 36.6 % and 46.4%, respectively. Among phenotypes there were differences in FLI (P-0.0001) and HSI (P-0.036), but not in LFS (P-0.051). Phenotype PCOS-A and PCOS-D shown significant difference in both FLI (P-0.001) and HSI (0.043) as well as PCOS-C vs PCOS-D (FSI P-0.0001; HSI P-0.009); phenotype PCOS-B vs PCOS-C shown difference only in FLI (P-0.01).
Conclusion
In our group, the prevalence of NAFLD varied widely depending on the specific index even though our population is younger and non-obese. Further studies are needed to validate the capacity of NAFLD indices to predict NAFLD in different phenotypes of PCOS.

Study on quality of life, self-esteem, anxiety and depression among transgender people in a healthcare area

Irene Zayas Aguilar[1], Almudena Lara Barea[1], Laura Larrán Escandón[1], Daniel Medina Rivero[1] & Isabel María Mateo Gavira[1]

[1]Hospital Universitario Puerta del Mar, Endocrinology and Nutrition Department, Cádiz, Spain

Introduction
Transgender people are a population affected by a variety of negative health indicators. Studies report, among other conditions, a high prevalence of mental health problems, however, long-term longitudinal follow-up studies are scarce.
Objective
The aim of this study is to assess the quality of life (WHOWOL-BREF scale), self-esteem (RSES scale), levels of anxiety (GAD-7 scale) and depression (PHQ-9 scale) of transgender people attended at the Provincial Gender Unit of the Hospital Puerta del Mar (Cádiz).
Materials and methods
This is a descriptive cross-sectional study based on the electronic medical records and the answers obtained in the questionnaires administered to the people attended at the Gender Identity Unit of Hospital Puerta del Mar (Cadiz), between October of 2022 and May of 2023.
Results
Of the 150 people included in this study, 62% were transmen and 32.7% transwomen and 4.7% non-binary gender. The mean age was 19.9 ± 4.9 years. The majority of people (58%) had a previous mental health history and 32.7% visited clinical psychologist during the follow-up. 45.6% declared bullying in the social field. The people analyzed had moderate levels of anxiety and depression, with no significant differences found between groups. The mean score in the self-esteem scale was 13.77 ± 3 indicating low self-esteem. Transwomen had better perception of their health ($3,35 \pm 0.9$) than transmen (2.97 ± 0.96), ($P = 0.03$). Transgender people, who visited the unit's psychological consultation, had a lowed score in the physical domain of the WHOQOL-BREF scale (77.48 ± 15.54 vs 85.22 ± 16.54), ($P < 0.01$).
Conclusions
In our cohort, most transgender people have a previous history of mental health and almost half declared bullying in the social field. People who visit clinical psychologist have less physical wellbeing. It is essential that the Gender Identity Unit team has available mental health professionals to provide psychological support.

Audit of the clinical utility of androstenedione

Ruth Byrne[1], Rachel Crowley[1,2] & Patrick Twomey[1,2]

[1]St. Vincent's University Hospital, Dublin, Ireland; [2]University College Dublin, Ireland

Introduction
Hyperandrogenism is a diagnostic feature for polycystic ovarian syndrome (PCOS). Androstenedione is a testosterone precursor that has been shown to be useful in diagnosis of PCOS especially in the setting of normal testosterone. During 2022, our laboratory in St Vincent's University Hospital in Dublin, Ireland, changed from using a radioimmunoassay to an electrochemiluminescence immunoassay, which requires a non-gel tube in line with manufacturers requirements. In the endocrinology department we noticed that many samples were not being processed in the lab due to incorrect tube use. We audited the androstenedione levels processed in St. Vincent's University Hospital over a four-month period at the start of 2023 and analysed results in conjunction with the other serum androgens, testosterone and dehydroepiandrosterone sulfate (DHEAS).
Results
145/319 androstenedione samples were analysed. 41/145 samples were above the upper limit of normal (>4.6 nmol/l), all in female patients. 17/41 had normal testosterone levels (0.4-1.7 nmol/l). This is significant as elevated androstenedione confirmed biochemical hyperandrogenism and a diagnosis of PCOS in 8/17 despite normal testosterone.
Conclusion
The findings support the 2023 International Evidence based guideline for PCOS, which recommend doing androstenedione and DHEAS in patients with normal testosterone.
Recommendations
This audit identifies a need to educate users of sample tube requirements and encourages communication with clinical biochemistry; androstenedione remains part of the biochemical workup of PCOS, as it can identify more subtle hyperandrogenism; reflective or reflex laboratory testing could be an option for adding androstenedione levels, in cases with normal testosterone.

Low reproducibility of plasma testosterone concentrations in male patients with hypogonadism treated with transdermal testosterone gel

Valeria Lanzi[1,2], Rita Indirli[1,2], Beatrice Mantovani[1], Iulia Petria[1,2], Eriselda Profka[1], Giovanna Mantovani[1,2] & Emanuele Ferrante[1]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

Introduction
Testosterone replacement therapy (TRT) in male hypogonadism aims at restoring physiological plasma testosterone (T) levels. According to current guidelines, gel formulations should resemble better the circadian T secretion and offer physiological and consistent T concentrations. However, only a few real-life studies have assessed intra-individual reproducibility of T levels in patients treated with gel formulations.
Methods
Thirty patients treated with Tostrex gel 2%® were included (group A, mean age 59 [SD 10] years, median dosage 30 [IQR 20-40] mg). As a comparator group, 14 patients treated with Testavan® gel 2% were recruited (group B, age 54 [13] years, $P=0.19$; dosage 34.5 [23-46] mg, $P=0.05$). All patients maintained the prescribed dosage over 3 months prior to the first sampling. Blood samples were drawn at two time points one week apart (T1 and T2), two hours after gel's application on the same site (medial thigh for Tostrex, shoulders for Testavan). T (CLIA, Roche Elecsys), hemoglobin (Hb) and hematocrit (Htc) were assessed.
Results
The lowest and highest T levels between the two samplings were compared in each group. In group A, the median lowest TT concentrations were 3.8 [2.6-5.5] ng/ml, the highest were 4.9 [3.9-7.8] ng/ml (absolute-Δ 1.1 [0.4-1.9] ng/ml, percent-Δ 25%, $P<0.001$). The discrepancy between T1 and T2 was clinically-significant in 9 patients (30%): in 7, T was below normal in one sampling (which would have prompted Tostrex dosage increase), while it was within normal range in the other sampling (leading to no dosage change); in 2, T was above normal in one sampling (which would have prompted dosage reduction), while it was within normal range in the other sampling (leading to no dosage change). In group B, lowest T levels were 3.4 [2.0-4.2] ng/ml and highest were 4.6 [3.4-5.6] ng/ml (absolute-Δ 1.0 [0.4-1.9] ng/ml, percent-Δ 25%, $P<0.001$). T difference was clinically-significant in 5 patients (36%). As expected, Hb and Htc were comparable between T1 and T2 in both groups. Average TT concentrations, Δ TT, Hb, Htc, and the frequency of patients with clinically-significant T1-T2 difference, were comparable in groups A and B. No correlation was observed between TT and Hb or Htc at either time-point.
Conclusion
TRT with gel formulations is affected by intra-individual variability, which makes it difficult to establish the appropriate dosage. Therefore, therapeutic monitoring should rely not solely on plasma T levels but also on symptomatic response, as well as safety data such as haematocrit.

Chitosan/Alginate-loaded astragalus hamosus shows ameliorating effects on lipid profile, inflammatory and hormonal parameters, and reduces mirna-222 expression in polycystic ovary syndrome rats

Maryam Parvini Kohnehshahri[1]
[1]Department of Biology, Urmia Branch, Islamic Azad University, Urmia, Iran

Background
Polycystic ovary syndrome (PCOS) is a common endocrine and metabolic disorder in women of childbearing age. This study aimed to investigate the effects of Chitosan/Alginate-loaded *Astragalus hamosus* extract (Chn/Al-AH) on the histology of Ovaries and uterus, miRNA-222, *ESR1*, and *IRS1* genes expression, pro-inflammatory cytokines, lipid profiles, sex hormone levels in rats with PCOS induced by estradiol valerate (EV).
Methods
25 female Wistar rats, with an average weight of 180 g, were divided into control and PCOS groups. The PCOS model was induced by a single intramuscular injection of EV (4 mg/kg). After 28 days of PCOS induction, the rats were orally administered Chn/Al-AH at doses of 5, 10, and 15 mg/kg. Following four weeks of treatment, histological changes in ovaries and uterus, serum sex hormone levels, lipid profile, pro-inflammatory cytokines, body weight, and the expression of miRNA-222, *ESR1*, and *IRS1* genes were evaluated.
Results
Chn/Al-AH hydrogels were successfully synthesized, and physicochemical properties confirmed their properties. Healthy follicles with normal morphologies at different stages of development were observed in the control group. EV-induced PCOS rats exhibited an increase in cystic follicles and endometrial hyperplasia, a decrease in follicular clusters and corpus luteum, a significant increase in body weight, abnormal lipid profiles, elevated pro-inflammatory cytokine levels, altered sex hormone levels, upregulation of miRNA-222 expression, and downregulation of *ESR1* and *IRS1* genes expression. Treatment with Chn/Al-AH at all doses showed a decrease in cystic follicles, LH/FSH ratio, estrogen, testosterone, insulin, TNF-α, IL-6, LDL, VLDL, triglyceride, cholesterol, and *miRNA-222* expression and an increase in corpus luteum, progesterone, HDL, and *ESR1* and *IRS1* expression in comparison with the PCOS group. LH, FSH, and IL-18 levels were not altered significantly after treatment.
Discussion
Applying Chn/Al-AH exhibited ameliorative effects on the PCOS rats, restoring both endocrine and metabolic abnormalities to normal levels and attenuating complications in EV-induced PCOS rats. Notably, it significantly reduced miRNA-222 expression and promoted follicular development at various stages while reducing cystic follicles and increasing corpus luteum formation.
Conclusions
Chn/Al-AH was found to have beneficial effects in attenuating and improving certain complications in the PCOS rat models.

Body composition influences on serum anti-müllerian hormone (AMH) levels in adult males imply hemodilution

Veronika Tandl[1], Christoph Haudum[1], Katharina Eberhard[2], Barbara Hutz[1], Ines Foessl[1], Ewald Kolesnik[3], Andreas Zirlik[3], Dirk von Lewinski[3], Daniel Scherr[3], Nicolas Verheyen[3], Thomas Pieber[1] & Barbara Obermayer-Pietsch[1]
[1]Medical University of Graz, Division of Endocrinology and Diabetology, Department of Internal Medicine, Graz, Austria; [2]Medical University of Graz, Core Facility Computational Bioanalytics, Graz, Austria; [3]Medical University of Graz, Department of Internal Medicine and University Heart Center Graz, Graz, Austria

Background
A negative relationship between body mass index (BMI) and serum Anti-Müllerian hormone (AMH) levels has been previously reported. Whether this is because of an adverse effect of adiposity on AMH production or the hormone's dilution in a higher blood volume that accompanies larger body size ('hemodilution') is not yet clear. Blood volume can be estimated by body weight, body surface area (BSA) or lean mass (LM). Of note, adipose tissue is poorly perfused and adds relatively little to the overall blood volume.
Objectives
To investigate a possible hemodilution effect, we analyzed the relationships between serum AMH levels and different body size and composition parameters in adult males.
Methods
We used data of 382 adult, male participants of the ongoing, prospective BioPersMed study cohort. Body parameters used include height, weight, waist circumference, BMI, waist-to-hip ratio, body surface area (BSA) and estimated lean mass (eLM). Of 278 participants, dual energy X-ray absorptiometry (DXA)-derived body composition data, including fat mass (FM) and LM, were additionally available. We performed univariate and multivariate regression models with potential confounders (age, follicle-stimulating hormone, and estradiol) included as additional predictors.
Results
In the fully adjusted models, weight ($R2=0.201$; $\beta=-0.002$; $P=0.0022$), BSA ($R2=0.206$; $\beta=-0.231$; $P=0.0006$) eLM ($R2=0.206$; $\beta=-0.006$; $P=0.0006$) and LM ($R2=0.197$; $\beta=-0.006$; $P=0.003$) significantly predicted AMH. In an age adjusted model that challenged FM and LM against each other by including them both as predictors, only LM remained significant ($R2=0.061$; $\beta=-0.007$; $P=0.0035$).
Conclusions
In adult males, weight, BSA, eLM and LM (proxies of blood volume) better predicted serum AMH levels than measures of adiposity – suggesting hemodilution is at least partly responsible for the observed inverse relationship between AMH concentrations and BMI. Thus, hemodilution should be considered for normalization in future studies.

Unveiling the uncommon nexus: kallmann syndrome and cardiomyopathy - a singular case study

Ahmed Hussien[1] & Maha Nasreldin[2]
[1]University Hospital of Hairmyres, Cardiology, Glasgow, United Kingdom; [2]Egyptian ministry of health, Cairo, Egypt

This case report delves into the intriguing connection between Kallmann syndrome and cardiomyopathy in a 62-year-old male who presented with new atrial fibrillation (AF) with rapid ventricular response and signs of fluid overload. Despite being a known case of Kallmann syndrome, the emergence of severe impaired left ventricular systolic dysfunction (LVSD) added a distinctive layer to the clinical scenario. Cardiomyopathy screenings for common causes like sarcoidosis, amyloidosis, and hemochromatosis proved negative. The patient's management involved a combination of diuretics, direct oral anticoagulants (DOAC), bisoprolol, digoxin, eplerenone, and dapagliflozin. Notably, the rate control of the underlying atrial fibrillation and improvement in overload symptoms paved the way for outpatient direct current cardioversion (DCCV). This case highlights the rarity of the association between Kallmann syndrome and cardiologic diseases, shedding light on the complexity of endocrinological and cardiovascular interplay.

Introduction

Kallmann syndrome with cardiopathy is a rare genetic disorder affecting the reproductive and olfactory systems, characterised by hypogonadotropic hypogonadism associated with gonadotropin-releasing hormone (GnRH) deficiency, anosmia or hyposmia (with hypoplasia or aplasia of the olfactory bulbs) and complex congenital cardiac malformations (double-outlet right ventricle, dilated cardiomyopathy, right aortic arch). It represents a distinct clinical entity from Kallmann syndrome. This case challenges conventional expectations by revealing a noteworthy connection between Kallmann syndrome and severe LVSD.

Clinical Presentation

The patient's presentation included fast AF and signs of fluid overload, necessitating diuretic therapy. Echocardiography unveiled a dilated left ventricle with an alarming ejection fraction (EF) of 25%, signifying severe LVSD.

Investigations

Blood tests were unremarkable. NT-pro BNP was raised. Chest X-ray showed pulmonary congestion. Thorough screening for common etiologies of cardiomyopathy such as sarcoidosis, amyloidosis, and hemochromatosis yielded negative results, emphasizing the atypical nature of this case.

Management

The multidisciplinary approach involved diuretics and the initiation of DOAC, bisoprolol, digoxin, eplerenone, ramipril and dapagliflozin. This regimen not only stabilized the patient's heart rate but also led to a significant improvement in symptoms of fluid overload.

Outcome

With successful medical management, the patient's heart rate was controlled, and symptoms of fluid overload resolved. Plans for outpatient DCCV were made to address the underlying rhythm disturbance.

Conclusion

This case serves as a unique exploration of the intersection between Kallmann syndrome and cardiomyopathy. The absence of common cardiologic culprits underscores the need for heightened awareness and further research into the intricate interplay between endocrinological disorders and cardiovascular manifestations.

Characterization of liver abnormalities in a population of adult turner women: results from an observational study

Carolina Cecchetti[1], Laura Rotolo[1], Paola Dionese[1], Elisabetta Belardinelli[1], Beatrice Solmi[1], Amanda Vestito[2], Elton Dajti[2], Antonio Colecchia[3], Uberto Pagotto[1] & Alessandra Gambineri[1]
[1]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum, University of Bologna, Italy, Bologna, Italy; [2]Department of Digestive Diseases, Gastroenterology Unit, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum, University of Bologna, Italy, Bologna, Italy; [3]Gastroenterology Unit University Hospital, Modena, Italy, Baggiovara, Italy

Introduction

Liver function test abnormalities (LFA) are common in patients with Turner syndrome (TS). The etiopathogenesis of this complication remains unclear, probably being multifaceted. Metabolic syndrome, generalized vasculopathy, and autoimmunity have been proposed as possible causal mechanisms.

Objectives

- To describe the prevalence and possible related factors of morpho-functional liver abnormalities in TS adult patients.
- To evaluate the utility of hepatic elastometry in optimizing the diagnostic work-up of TS patients with LFA.

Materials and Methods

98 adult TS patients, regularly followed up at our Unit, underwent liver elastometry (FibroScan: Echosens, Paris, France) and hepato-splenic ultrasound. Blood samples were obtained to analyze liver enzymes and other metabolic parameters. Alanino-aminotransferase(ALT), aspartate-aminotransferase(AST), gamma-glutamyil-transferase(GGT), and alkaline-phosphatase(ALP) were considered abnormal(LFA) when above 1xULN. Data were retrospectively collected regarding metabolic complications, autoimmune diseases, menstrual history, and hormonal replacement therapies (GH and estrogen-progestin therapy). The presence of structural cardiovascular anomalies and the diameter of the first aortic tract were assessed by retrieving the latest cardiac examination (cardiac MRI and/or transthoracic echocardiography).

Results

61 patients (62,2%) had at least one LFA, GGT being the most frequent (60,2%). No cases of cirrhosis were observed; the prevalence of fibrosis was 8,1% ($n=8$). Patients with LFA (LFA-TS) showed significantly higher BMI, waist circumference, and waist-to-height ratio than patients with normal liver enzymes (NLE-TS) ($P=0.042$, $P=0.008$, $P=0.004$ respectively). Liver stiffness measurements (LSM) and liver fibrosis prevalence did not differ between the two groups; steatosis was the only morphological parameter significantly more prevalent in LFA-TS ($P=0.035$). LFA-TS showed significantly higher fasting glucose ($P=0.010$) and HbA1c levels ($P<0.001$) and more frequently had a diagnosis of hypertriglyceridemia ($P=0.041$). In LFA-TS, the diameter of the Valsalva sinuses was significantly wider than in NLE-TS ($P=0.034$), whereas there was a similar tendency in ascending aortic diameter, without reaching significance ($P=0.068$). No significant difference was detected regarding structural cardiovascular abnormalities, autoimmunity, menstrual cycle history, type of EP therapy, estrogen dosage, and history of GH therapy between the two groups.

Conclusions

LFA are highly prevalent in adult TS women; this complication seems particularly related to metabolic abnormalities, making its management pivotal in this rare disease. A relation with aortic dilation seems plausible, in the context of a possible generalized vasculopathy: further studies are needed to investigate this finding. Finally, given the presence of liver fibrosis also in NLE-TS, the sole presence of LFAs is not able to discriminate whether liver elastometry should be performed in TS patients.

Impact of drospirenone-only-pill on sexual function: experience of our'pcos and female endocrinology outpatient clinic'

Alessandra Tomaselli[1], Marianna Minnetti[1], Elena Rosato[1], Chiara Tarantino[1], Dario De Alcubierre[1], Davide Ferrari[1], Flavio Rizzo[1], Francesca Sciarra[1], Riccardo Pofi[2], Andrea Isidori[1] & Carlotta Pozza[1]
[1]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [2]Oxford Centre for Diabetes, Endocrinology and Metabolism and NIHR Oxford Biomedical Research Centre, Department of Endocrinology, Oxford, United Kingdom

Introduction and Objectives of the Study

Combined oral contraceptives (COCs) are frequently prescribed for fertility control, however sexual dysfunction has been reported as a common side effect. In 2020, a novel progestin-only pill containing Drospirenone (DRSP) was approved as an oral contraceptive. To date, here is a notable dearth of data on the impact of DRSP on sexual function and impact on hormones, particularly regarding steroids. This study aims to investigate the potential effects of DRSP on sexual function and hormonal profiles, with a focus on steroids, in a cohort of women referred to our 'female endocrinology' outpatient clinic.

Subjects and Methods

Prospective evaluations were conducted on women taking DRSP at baseline (T0), and at 3 (T1), 6 (T2), and 12 months of follow-up (T3). Blood samples were collected to obtain a comprehensive hormonal profile, and the Female Sexual Function Index (FSFI) questionnaire was administered to assess sexual function. At each timepoint, Ferriman-Gallwey (FG) and GAGS scores were evaluated along with anthropometrics, vital signs, menstrual patterns, and adverse events.

Results

The study population comprised 26 women taking DRSP, including 12 of them with an active sexual life through all the timepoints. The median age was 24 [IQR 21-26] years. Most women (73%) exhibited clinical and/or biochemical

hyperandrogenism, with a baseline FG mean score of 9.0±7.0 points and a GAGS median score of 3.5 [IQR 0-11]. While no significant changes were observed in FSFI total scores at any timepoint, a noteworthy improvement in the satisfaction domain score was identified at T2 and T3 ($P=0.01$ and $P<0.001$, respectively). Regarding hormonal profile, there was a significant reduction in Δ-4-androstenedione levels at T2 ($P=0.01$), persisting at T3 ($P=0.006$), and a notable decrease in total testosterone levels at T2 ($P<0.001$). Conversely, no significant alterations were found in 17-β-oestradiol, gonadotropins, and SHBG levels during follow-up. Also, no significant alterations were found on hypothalamus-pituitary-adrenal axis hormones, thyroid hormones, and prolactin levels. Clinically, improvements in FG score were recorded at T3 ($P=0.006$) and in the GAGS score at T2 ($P=0.008$). No adverse events were reported, although 5 dropouts occurred due to abnormal menstrual profiles.
Conclusions
Preliminary data indicate that after 12 months of DRSP use, there was no worsening in sexual function, whereas there was a significant enhancement in sexual satisfaction. Furthermore, improvements were observed in clinical and biochemical markers of hyperandrogenism. Further assesments are warranted to validate these preliminary findings.

Growing up with an endocrine disease: assessing transitional features in a cohort of young patients moving from pediatric to adult clinic

Valeria Citterio[1], Giulia Rodari[1,2], Alessia Gaglio[2], Valentina Collini[1], Alessandro Risio[1], Eriselda Profka[2], Federico Giacchetti[2], Emanuela Orsi[2], Giovanna Mantovani[1,2] & Claudia Giavoli[1,2]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milano, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milano, Italy

Introduction
Transition from childhood to adulthood represents a time-period in which adolescents/young adults (AYAs) with chronic illnesses start coping with self-managing their disease, often resulting in poor compliance to follow-up. Indeed, up to 50% of AYAs with common endocrine disorders is lost during the referral to an adult clinic. Transition in Endocrinology is poorly investigated yet, in terms of transition readiness, compliance to therapy, adherence to nutritional advice and quality of life (QoL). According to studies performed in other medical fields, these aspects can represent important determinants of a successful transitional program, thus predicting better disease outcomes.
Methods
In the present cross-sectional study, we consecutively enrolled 37 outpatients referring to a tertiary center with a transition-specific endocrine clinic in the presence of at least one chronic endocrine condition. Epidemiological and clinical data were collected. Moreover, transitional features were investigated through four specific questionnaires analyzing transition readiness (TRAQ), quality of life (KINDL-r), medications' adherence (MARS-5) and diet habits (KIDMED).
Results
Thirty-seven patients (F/M 23/14, 62%) were consecutively enrolled (age 18.4± 2.0 years, min-max 15.3-23.5). Among them, 8/37 were affected by childhood-onset growth hormone deficiency, 3/37 ACTH deficiency, 10/37 hypogonadism, 14/37 hypothyroidism, 28/37 vitamin-D deficiency, 1/37 polycystic ovary syndrome and 1/37 hyperprolactinemia (median disease duration 7 years, IQR 2.7-11). In 19/37 patients was found at least one non-endocrine comorbidity and 4/37 two or more. As far as questionnaires were concerned, median MARS score was 24 (IQR 23-24), KIDMED was 4±3, TRAQ score was 3.7±0.6, and QoL was 0.77±0.15, 0.61±0.15, 0.83±0.13, 0.85 (IQR 0.75-0.95), 0.64±0.11 and 0.85± 0.12 for physical, psychological, self-worth, family, friends, functioning and disease-related aspects, respectively. Transition readiness and physical well-being were positively associated with age ($P=0.003$ and $P=0.031$, respectively). Moreover, physical, psychological and self-worth QoL were positively associated with male gender ($P=0.004$, $P=0.008$ and $P=0.002$, respectively) while disease-related QoL was negatively associated with the number of endocrine consultations ($P=0.012$) and positively with the presence of nutritional follow-up ($P=0.016$).
Conclusions
This represents the first study assessing transition aspects in endocrine conditions. According to our results, transition readiness seems to be age-related. Moreover, males show less concern about the underlying disease, with higher levels of physical and psychosocial well-being and more self-esteem. Attendance at the clinic negatively affects diseases-related QoL, though this could be related to disease severity. Interestingly, nutritional support seems to improve disease burden and perception. Further longitudinal studies are needed in order to identify predictors and determinants of adherence during transition in endocrine diseases.

Early embryonic testicular regression syndrome: a rare case of primary amenorrhea

Mădălina Elena Iftimie[1], Ramona Dobre[1,2], Burcea Iulia-Florentina[1,2], Larisa Budulucă[1], Emanuela Braha[1] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background
Normal sex development is warranted by a complex and coordinated interaction between mutually antagonistic activating and repressing genetic and hormonal factors that act in a strict spatio-temporal sequence. Deviations from this established pattern can result in heterogenous chromosomal, gonadal or phenotypic congenital abnormalities named disorders of sexual development (DSD). We present a rare case of early testicular regression syndrome.
Case report
A 15 years and 11 months old female adolescent presented in our clinic with primary amenorrhea and delayed puberty. At physical examination she had normal female external genitalia, secondary sex characteristics consistent with the pre-adolescent stage (Tanner B1P2), low stature, dextroscoliosis, subtle cranio-facial dysmorphism and a slight psycho-emotional immaturity. Laboratory studies showed elevated gonadotropins with undetectable levels of estradiol and testosterone and abdominal and pelvic magnetic resonance imaging revealed no uterus or gonads, only the presence of a short lower vaginal tract. Her karyotype was found to be 46, XY and fluorescence *in situ* hybridization confirmed the presence of the SRY gene. Laparoscopic exploration of the abdomen and pelvis discovered 2 oblong pelvic masses consistent with rudimentary fallopian tubes with fibrous scarring and paramesonephric remnants on the pathology report. She was started on a gradual estrogen replacement therapy to simulate puberty along with psychotherapy. She now has normal stature and a significant improvement in secondary sexual characteristics (Tanner B3P3) and socio-psycho-emotional features at the age of 19 years and 10 months old.
Conclusion
The true prevalence of testicular regression syndrome remains unknown as the phenotype is highly variable depending on when gonadal regression occurs in utero. A thorough comprehension of embryonic sexual development and differentiation is key in accurately evaluating and managing these rare cases of XY DSD. Providing psychological support resources for patients and their families is also an essential point.

Klinefelter syndrome (KS) prevalence at invasive prenatal diagnosis (ipd) procedures: a systematic review of the literature

Francesco Costantino[1,2], Sara De Vincentis[1,2], Maria Chiara Decaroli[1,2] & Vincenzo Rochira[1,2]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena (Italy); [2]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria of Modena (Italy)

Introduction
KS prevalence is estimated to range from 0.1-0.2 % in men and actually the estimated frequency is of about 1:500 to 1:1000 men[1]. However, the real prevalence remains unknown due also to the fact that the disease is often overlooked and undermanaged[1].
Aim and methods
We performed a systematic literature search including studies published between 1971 and January 2024 to investigate the real prenatal prevalence of KS (including both pure and mosaic karyotypes) among chromosome abnormalities (CAs) and sex CAs (SCAs) diagnosed by different IPDs procedures (i.e. chorionic villus sampling, amniocentesis, and cordocentesis). The primary endpoint was the prevalence of KS. No specific criteria for study populations were provided.
Results
Among the 1826 studies detected by the literature search, 59 matched our inclusion criteria, considering so far 776912 IPD procedures, most of them performed for medical indication (88%). A total of 24094 CAs (3.10%) diagnosis were reported, of which 3729, (15.48%), was due to SCAs (i.e. 45,X0; 47,XXY; 47,XXX; 47,XYY). KS was diagnosed in 1074 out of 776912 fetuses, and as expected was the most prevalent SCA in males (median 0.13%, range 0-9.28%), with 46,XY/47,XXY accounting for 8.41% of all KS. Despite a high heterogeneity between studies, KS was mainly reported when genetic tests were performed in the presence of any gynecological indication (median of 0.13% vs 0.01%) ($P<0.0001$). Moreover, KS cases among CAs were more common

when IPD procedures were performed due to any medical indication than without (3.32% vs 0%). A significant association between KS and mother's age at birth was confirmed, hence the median >35/<35 y/o ratio was 1.07 (range 0-3.07).
Conclusions
This study confirms that around 1.3 of 1000 men (0.65/500) may be affected by KS, which is in line with data suggested by the literature. As the vast majority of KS diagnosis have been done after a gynecological indication, it is possible that this prevalence overestimates the prevalence rate in general population. Further studies are needed to analyze the prevalence of KS in the overall population. To our knowledge this is the widest systematic synthesis and confirms the association reported between KS and CAs' risk factors (e.g. advanced mother age, abnormal US).

Beta thalassemia major, hypogonadism and cardiovascular risk

Francesca Allosso[1], Lucia Digitale Selvaggio[1], Martina Errico[1], Graziella Grande[1], Claudia Di Ludovico[1], Raffaele Navarra[1], Maddalena Casale[2], Silverio Perrotta[2] & Daniela Pasquali[1]
[1]University of Campania L. Vanvitelli, Department of Advanced Medical and Surgical Sciences, Naples, Italy; [2]University of Campania L. Vanvitelli, Department of General and Specialized Surgery for Women and Children, Naples, Italy

Beta thalassemia major (betaTM) is an inherited hematological disorder characterized by reduced or absent synthesis of beta-globin chains and anemia. Chronic transfusion treatment is necessary, exposing patients to iron overload comorbidities such as hypogonadism. It is due to iron accumulation in the pituitary gland and, more rarely, in testis and ovaries. HPG axis dysfunction can manifest as low estradiol or testosterone with low to normal serum LH and FSH, as commonly seen in hypogonadotropic hypogonadism (HH). The aim of our study was to verify the prevalence of hypogonadism in beta-TM patients (HH-betaTM), to evaluate the differences compared to a non-thalassemic hypogonadal population (HH), to assess the difference in cardiovascular risk (CVR) between beta-TM patients with and without hypogonadism. 47 patients (30 females, 17 males) with betaTM (22-60 years on average) were studied. Associated endocrinopathies included GH deficiency, thyroid nodules, osteoporosis. The control group consisted of 27 HH-nonthalassemic patients (8 women, 21 men), aged 19-73 years. Levels of testosterone, estradiol, LH and FSH were evaluated in both groups. CVR was assessed in betaTM patients using risk score calculators. In the total of 30 women betaTM patients 15 had HH, only six were receiving replacement therapy, while nine were refusing treatment. In the population of 17 male beta-TM patients, 6 had HH with a mean pre-therapy testosterone level of $204 \pm 22{,}118$ ng/dl, FSH level of $4{,}167 \pm 2{,}073$ IU/l and LH level of $3{,}55 \pm 3.92$ IU/l. All were on replacement therapy with testosterone. In male HH-nonthalassemic controls, mean of FSH was $1{,}428 \pm 1{,}528$ IU/l, of LH was $0.928 \pm 1{,}189$ IU/l and of testosterone was $194 \pm 88{,}427$ ng/dl. The difference between levels of FSH and LH in HH-betaTM and HH controls was significant only in the male population ($P < 0.01$). No differences were found in CVR in 15 females with HH-betaTM compared to 15 female non-hypogonadal betaTM. CVR was significantly different in male with HH-betaTM compared to non-hypogonadal betaTM male (1.467% vs 0.633%)($P < 0.05$). Our data confirm the high incidence of hypogonadism in thalassemia, but in the male betaTM population there are higher gonadotropin levels compared to patients with HH, due to the mixed nature of the systemic damage. This characterizes HH in thalassemia as an intermediate clinical entity that deserves differentiated attention in terms of diagnosis, type of replacement therapy and follow-up. In the thalassemic male population, hypogonadism significantly worsens cardiovascular risk and highlights the importance of replacement therapy.

Delayed puberty and ataxia – important clinical manifestations of polr3b-related leukodystrophy

Simon Mifsud[1] & Miguel Debono[1,2]
[1]The University of Sheffield, United Kingdom; [2]Sheffield Teaching Hospitals NHS Foundation Trust, United Kingdom

Background
POLR3-related leukodystrophy is an autosomal recessive hypo-myelinating leukodystrophy characterized by specific features on MRI and varying combinations of four major clinical findings[1]. The latter include neurological dysfunction, abnormal dentition, endocrine dysfunction, and myopia[1]. Endocrine dysfunction in POLR3-related leukodystrophy includes hypogonadotropic-hypogonadism (HH), short stature, growth hormone deficiency, and less commonly thyroid dysfunction.
Case report
A 27-year-old lady recently diagnosed with POLR3B-related leukodystrophy was referred to endocrinology to screen for endocrine dysfunction. She gave a longstanding history of ataxia, myopia, and delayed puberty. During childhood and adolescence, she had a short stature compared to her peers. She had very minimal breast development and never had spontaneous menstrual bleeding. She was reviewed by several healthcare professionals and was prescribed the combined oral contraceptive pill (COCP). This led to a growth spurt but had to be discontinued because of worsening mental state. At the time of review, she had been off the COCP for four years. She complained of frequent episodes of hot flushes and sweating. She also sustained nontraumatic vertebral fractures. She denied hyposmia or anosmia. She had a stable weight and appetite. She denied galactorrhoea and was on no medications. On physical examination, she was at Tanner Stage 2. She had grossly normal visual fields to confrontation. Laboratory investigations revealed FSH of 4.5IU/l and LH of 2.9IU/l with an oestradiol of < 91.8 pmol/l, indicating HH. The rest of her pituitary profile including IGF-1 level was unremarkable. A DEXA scan revealed normal bone density. An MRI head showed atrophic cerebellar hemispheres and a low-volume pituitary gland. Transvaginal ultrasound had previously shown no abnormal anatomic disorders of the genital outflow tract. DNA sequencing performed previously revealed that she is a compound heterozygote for POLR3B mutations, specifically c.1244T>C (p. Met415Thr) and c.1263+2T>C. The patient was prescribed low-dose transdermal oestradiol (escalating dose) and progesterone soon after, to enhance the development of secondary sexual characteristics.
Discussion
The differential diagnosis of patients presenting with a combination of neurodegenerative disorders and HH is extensive. This case highlights the importance of maintaining a high level of clinical suspicion for the diagnosis of POLR3–related leukodystrophy in patients presenting with delayed/arrested puberty, particularly in the presence of concurrent cerebellar manifestations. Early diagnosis and timely management can improve the patient's quality of life and avoid complications of untreated hypogonadism.

Steroid secreting ovarian tumour causing extreme hyperandrogenism, virilisation and polycythaemia in a post-menopausal female

Ruth Byrne[1], Carla Moran[1,2,3], Catherine Foley[2], Kamal Fadalla[1], Michael Jeffers[2] & Waseem Kamran[2]
[1]St. Vincent's University Hospital, Ireland; [2]Beacon Hospital, Ireland; [3]University College Dublin, Ireland

Introduction
Hyperandrogenism causing virilisation in postmenopausal females is rare. It is caused by abnormal ovarian or adrenal androgen production, but establishing the source of androgen excess can be challenging. Testosterone levels >5 nmol/l can be associated with virilization (Hirschberg, 2022).
Case
A 75-year-old post-menopausal woman, with a 3-year history of androgenic alopecia (Ludwig scale 3/3) and hirsutism (Ferrimen Gallwey Score 32/36) was investigated. She had known, but previously unexplained, polycythaemia (Hgb 17.6 g/dl). Laboratory testing showed extremely elevated Testosterone (30.6 nmol/l, RR 0.4-1.4), moderately elevated Androstenedione (4.29 nmol/l, RR 0.5-2.8) but normal DHEAS levels (1.1umol/l, RR 0.3-4.2). Estradiol (321 pmol/l), LH and FSH levels (both <1 IU/l, <1 IU/l) were inappropriate for her post-menopausal status. There was no evidence of congenital adrenal hyperplasia (17 OHP 1.36 nmol/l) or Cushing's syndrome (cortisol level post dexamethasone administration 36 nmol/l). MRI revealed bilateral mildly enlarged ovaries with multiple small follicles and a thickened endometrium. Adrenal imaging was normal. GnRH was not administered given already suppressed gonadotropins. Hysterectomy and bilateral salpingo-oophorectomy were performed. The left

ovary contained a well circumscribed, non-capsulated tumour which expressed inhibin, Calretinin and Melan-A, indicating a steroid cell tumour. Two months following surgery, biochemistry showed undetectable Testosterone (<0.4 nmol/l). Estradiol (<92 nmol/l), LH (19 IU/l) and FSH (28 IU/l) were physiological for age and polycythaemia had resolved (Hgb 15.8 g/dl). At 6 months postoperatively, her hirsutism and alopecia were persistent, but improved (Ferrimen Gallwey Score 17/36, Ludwig scale 2/3).

Conclusion

This case offers insight into the workup of post-menopausal virilisation, which is rare and always requires further investigation. This patient presented with extreme biochemical hyperandrogenism and virilisation due to an ovarian tumour, and exhibited resolution of endocrine abnormalities and polycythaemia following successful surgery. Her case also highlights the importance of checking a testosterone level in females with unexplained polycythaemia.

Low dose estradiol gender-affirming hormone therapy (GAHT) generates rapid feminizing body changes in transgender women: a dual energy x-ray absorptiometry-based prospective study

Iris Yaish[1], Guy Gindis[1,2], Asaf Buch[1,3], Yael Sofer[1,2], Yona Greenman[1,2], Mira Arbiv[1], Yaffa Moshe[1] & Karen Tordjman[1,2]

[1]Tel Aviv Sourasky Medical Center, Institute of Endocrinology and Metabolism, Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv, Israel; [2]Faculty of Medicine, Tel Aviv University, Internal Medicine, Tel Aviv, Israel; [3]Ariel University, Department of Nutrition Sciences, Ariel

Background and Aim

We previously demonstrated that low-dose estradiol (E2) administered sublingually alone for 6 months in treatment-naïve trans women (TW), suppressed testosterone to the same degree, but generated higher serum E2 levels as the same oral dose combined with cyproterone acetate. We now sought to assess the possible differential impact of these approaches on anthropometric and body composition measurements, sex-dependent indicators with proven metabolic prognostic value.

Methods

22 treatment-naïve TW, 23.2±1.1 y, opted non-randomly, in a 1:1, ratio to receive sublingual E2 (2 mg divided into 4 daily doses), or oral 2 mg E2+10 mg cyproterone acetate for 6 months (6M). Anthropometric, hormonal, and body composition by DXA (Lunar Prodigy-GE) measurements were obtained at baseline, and after 6M of GAHT.

Results

Anthropometric, body composition measurements, and testosterone at baseline and 6M did not differ between the groups. In a first step, all subjects were analyzed together for assessment of the general impact of GAHT. By paired comparisons, neither weight nor BMI had changed at 6M. Hip circumference remained unchanged, however, waist circumference decreased by 2.7±1.19 cm ($P=0.047$), resulting in a significant reduction in waist-to-hip-ratio ($P=0.018$). The total regional fat percentage increased from 23.4±2.3% to 27.8±1.8% ($P<0.001$). This increase was significant for all fat depots (gynecoid, arms, legs, trunk) except for the android area. Total body fat mass increased by 2.6 kg, from 18.4±2.4 to 21.0±2.4 kg ($P=0.008$). In contrast, subjects lost lean mass in all compartments. The whole body lean mass loss was 3.4±0.3 kg (a 21.6% decrease, $P<0.001$), leading to a decrease in the lean/fat mass ratio from 4.7 to 2.9, ($P=0.0002$). Analyzed separately, some changes appeared to be influenced by the treatment route, particularly the increases in fat depots that were significantly milder in the sublingual group. The lean body mass decrease, however, was similar with both treatments. After age-adjustment, none of the variables at 6M correlated with hormone levels. However, decreases in total body, legs, and arms lean mass were inversely correlated with testosterone at 6M ($r=-0.41$, $P=0.045$; $r=-0.476$, $P=0.033$; and $r=-0.563$, $P=0.01$, respectively).

Conclusions

A relatively short GAHT period with a low dose of E2 generated significant body feminization in TW. Subjects in the sublingual group were surprisingly spared from body fat accumulation. The reason for this differential effect of sublingual E2 is still unknown. Sublingual E2 could offer some protection from fat accumulation but not from lean body mass loss in TW.

Lipid profile in turnerian patients treated with growth hormone

Khawla Rhouzali[1], Hamdane Chaymae[1], Moussa Baraya[1], Siham Rouf[2] & Hanane Latrech[2]

[1]Department of Endocrinology-Diabetology and nutrition, Mohammed VI University Hospital Center. Faculty of Medicine and Pharmacy, Mohammed First University, Oujda, Morocco., Oujda, Morocco; [2]Department of Endocrinology-Diabetology and nutrition, Mohammed VI University Hospital Center. Faculty of Medicine and Pharmacy, Mohammed First University, Oujda, Morocco., Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy, Mohammed First University Oujda, Morocco, Oujda, Morocco

Introduction

Turner syndrome (TS) is a rare genetic disorder characterized by an aberration of the X chromosome, most commonly associated with various comorbidities, such as metabolic disorders, particularly dyslipidemias. The aim of this study is to determine the frequency of dyslipidemias associated with TS and to evaluate the impact of growth hormone (GH) treatment on lipid metabolism.

Methods

This is a descriptive and retrospective study of 22 patients diagnosed with Turner syndrome at the Endocrinology-Diabetology and Nutrition Department of the University Hospital of Oujda-Morocco, including 11 patients treated with growth hormone (GH) over a period of 6 years. All patients underwent pre-treatment assessments, including lipid profile during evolution.

Results-Discussion

The mean age of our population was 13.91±6.93 years. Five patients (45.5%) had dyslipidaemia prior to initiation of GH treatment; elevated LDL cholesterol levels was observed in 60% of patients, hypertriglyceridaemia in 20% and mixed dyslipidaemia in 20%. After initiation of GH treatment, the evolution was marked by an improvement in the lipid profile in 60% of cases, while 40% maintained dyslipidaemia for up to one year. In contrast, six patients (55.5%) did not have dyslipidaemia on the initial metabolic test, of whom 66.6% did not develop dyslipidaemia during the GH treatment period, whereas two patients (33.3%) developed dyslipidaemia one year after GH treatment. In our serie, GH treatment significantly confirmed its positive effect on lipid metabolism by reducing serum LDL levels.

Conclusion

GH treatment has a positive effect not only on statural gain but also on the metabolic profile of patients with Turner syndrome, which ties in with the conclusions of the literature on the innocuity of GH treatment of patients with TS.

Time-dependent progression of metabolic dysfunction in a mouse model of polycystic ovary syndrome

Jelina Basnet[1], Samar Rezq[1], Alexandra M Huffman[1], Licy L Yanes Cardozo[1] & Damian Romero[1]

[1]University of Mississippi Medical Center, Jackson, United States

Background

Polycystic ovary syndrome (PCOS) is the most common endocrine disorder in reproductive-age women. PCOS is associated with metabolic disorders such as obesity, dyslipidemia, systemic insulin resistance (IR), and adipose IR. Hyperandrogenism is prevalent in PCOS and is linked to metabolic dysfunction in multiple tissues, including WAT. However, data on the disease onset and progression of WAT mediated metabolic derangements in PCOS women are lacking. Therefore, we aim to test the hypothesis that the androgen dihydrotestosterone (DHT) induces time-dependent progression of WAT and metabolic dysfunction on both the molecular and functional levels in PCOS. This hypothesis was tested using a well-characterized DHT-induced PCOS mouse model after 2, 4, 8 and 12 wks of DHT administration.

Methods

Three-week old female mice (C57BL/6N) were implanted with Silastic tubes filled with DHT (8 mg, s.c.) or vehicle ($n=6$/grp) for 2, 4, 8 and 12 weeks. Weekly body weight (BW, gravimetry), body composition (EchoMRI), subcutaneous fat (SCF)- a WAT depot mass (gravimetry) were assessed. Serum leptin, adiponectin, and insulin were measured by ELISA, while non-esterified free fatty acid (NEFA) and cholesterol by using a clinical chemistry analyzer. Adipose IR (insulin×NEFA) was calculated. SCF androgen receptor (AR), lipolytic marker adipose triglyceride lipase (ATGL), and adipogenesis marker peroxisome proliferator-activated receptor-γ (PPAR-γ) protein levels were assessed by Western blot.

Results

DHT mice showed significant ($P<0.05$) increases in BW (1.15-fold) and lean mass (1.14-fold) starting 2 weeks following DHT-exposure where higher

cholesterol (1.3-fold), insulin (2.3-fold) and adipose IR (2.5-fold) as well as lower insulin-sensitizing adipokine adiponectin levels (50%) were also observed compared to vehicle. The increases in SCF mass (1.5-fold) and total fat mass (2.2-fold) were only significant starting at 8 weeks. DHT significantly increased NEFA (1.3- and 1.2-fold, 8- and 12-weeks post-DHT, respectively) and leptin (1.5-fold, 12 weeks post-DHT). On the molecular level, DHT mice had an upregulation in SCF AR expression (1.5-fold) at 2 weeks and an upregulation of ATGL and PPARγ expression by 50% and 40% at 4 weeks post-DHT.
Conclusion and significance
Our findings suggest that some of the associated metabolic traits such as serum adiponectin, insulin, cholesterol and adipo-IR, occur very early following the induction of hyperandrogenemia that may be drivers of disease progression. Therefore, actively screening and managing risk factors for metabolic derangements from early on in PCOS is critical for disease management.

Variations in the assessment and education of polycystic ovary syndrome (PCOS) during initial consultations across europe: a multinational study

Anisah Ali[1], Harshal Deshmukh[2], Alexander Wilde[3], Ashwin Joshi[3], Elena Armeni[4], Isin Yesilkaya Baylan[5], Erkut Attar[5], Fahrettin Kelestimur[5], Meri Davitadze[6,7], Punith Kempegowda[6] & PCOS SEva Working Group[6]
[1]University of Birmingham Medical School, Birmingham, United Kingdom; [2]Hull University teaching hospital NHS trust, Hull, United Kingdom; [3]South Tyneside and Sunderland NHS Foundation Trust, Sunderland, United Kingdom; [4]Royal Free Hospital London, London, United Kingdom; [5]PCOS and hirsutism clinic, Yeditepe University hospital, Istanbul, Turkey; [6]Institute of Applied Health Research, University of Birmingham, Birmingham, United Kingdom; [7]Clinic NeoLab, Tbilisi, Georgia

Objective
To explore the differences in various assessments recommended by the International PCOS guidelines during the initial consultation for women with PCOS across Europe.
Methods
This retrospective multi-centre study was conducted from June 2023 to January 2024. All women over age 18 who attended their first consultation in a dedicated PCOS clinic from 1st January 2020 to 31st December 2023 in the UK ($n=359$), Turkey ($n=239$), Greece ($n=92$) and Georgia ($n=10$) were included. Those undergoing follow-up or without PCOS were excluded. Data were collected on sociodemographic variables and assessments, including diagnosis based on guidelines, cardiometabolic risk, dermatological assessment, emotional well-being, long-term risk education, lifestyle management, and reproductive screening. Descriptive statistics were analysed using SPSS 28.0.
Results
The most common reasons for referral across all countries were irregular periods (65.7%), excess hair growth (61.1%), and acne (38.9%). Irregular periods were the most common reason for referral in the UK (59.6%), Greece (82.6%), and Georgia (100.0%), followed by excess hair growth (UK: 53.2%, Greece: 65.2%, and Georgia: 90.0%). However, in Turkey, excess hair growth was the most common reason for referral (70.3%), followed by irregular periods (67.0%). The most common co-morbidities across all countries were anxiety (9.7%), hypothyroidism (9.0%), and depression (6.7%). Anxiety was the most common co-morbidity in the UK (14.2%) and Georgia (20.0%), whereas hypothyroidism was most common in Turkey (10.9%) and Greece (10.9%). During consultation, the most common parameters assessed across all countries, as per international PCOS guidelines, were dermatological concerns (92.4%), reproductive screening (83.0%), and lifestyle management (80.4%). Similar trends were found in Turkey, Greece, and Georgia, where dermatological concerns and lifestyle management were assessed in 100.0% of women. In Turkey, diagnosis based on guidelines (99.2%), cardiometabolic risk (99.2%), emotional well-being (99.6%), long-term risk education (99.6%), and reproductive screening (99.6%) were assessed in almost all women and in all women from Greece and Georgia. In the UK, dermatological concerns (85.2%), reproductive screening (67.1%), lifestyle management (61.8%), and cardiometabolic risk (60.0%) were mostly assessed for, whereas emotional well-being (20.3%) and long-term risk education (14.8%) were the least followed recommendations.
Conclusion
The findings highlight a significant difference in the assessment and education provided during PCOS consultations across countries in Europe, specifically in emotional-wellbeing and long-term risk education. Developing new models of care which prioritise emotional well-being screening and long-term risk education is crucial to address these gaps and improve patient outcomes.

PCOS-like syndrome in the young woman with cortisone reductase deficiency type 1

Katarina Krstic[1], Sanja Ognjanovic[1], Bojana Popovic[1], Dusan Ilic[1], Valentina Elezovic Kovacevic[1], Jelica Bjekić Macut[1,2], Milica Opalic Palibrk[1], Lena Radic[1], Olivera Stanojlović[3], Aleksandra Rasic Markovic[3], Danijela Vojnovic Milutinovic[4] & Djuro Macut[1]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Department for Endocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia; [2]University Medical Centre Bezanijska Kosa, Belgrade, Serbia; [3]Institute of Physiology, Faculty of Medicine, Belgrade, Serbia; [4]IBISS, University of Belgrade, Belgrade, Serbia

Introduction
11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1) is a dimeric enzyme that catalyzes the reduction of cortisone to cortisol within the endoplasmic reticulum. Loss of this activity results in a disorder termed cortisone reductase deficiency type 1 (CRD). Only mutations in H6PD gene, which encodes an enzyme supplying cofactor for the reaction, have been identified as the cause of disease. Biochemical features of CRD are increased cortisol clearance and ACTH-mediated androgen excess. There are close phenotypic similarities between CRD and polycystic ovary syndrome (PCOS): hirsutism, oligo-amenorrhea, central fat distribution, infertility. We present the case of a 21-year old woman with mutations in H6PD gene who presented with secondary amenorrhea, hirsutism and obesity.
Case
After menarche at the age of 12, there were no spontaneous periods. A pediatric endocrinologist diagnosed PCOS (Rotterdam phenotype A). Menstrual cycles (MC) were established with a combined oral contraceptive pill with antiandrogen properties. The breaks in taking the medicine was followed by absence of MC. The patient's dominant complaints are hirsutism (mFG score - 10), obesity (BMI 33 kg/m^2) and secondary amenorrhea.
Results
Investigations showed elevated basal values of androgens (testosterone 6.8 and 8.0 nmol/l [1.2-3.8 nmol/l], androstenedione 6.2 and 6.0 ng/ml [0.24-3.44 ng/ml] and 17-OH progesterone 7.2 and 7.1 nmol/l [0.4-5.0nml/l]), FAI 29.8, AMH 9.45 ng/ml; DHEAS, serum cortisol, IGF-1, prolactin and thyroid function were normal. The results obtained in 2h-OGTT indicate insulin resistance (HOMA-IR 10.5). In low-dose dexamethasone tests, including prolonged DEX I, androgen suppression was absent. Androgen suppression was occurred after administration of GnRH agonist (Diphereline 3.75 mg). Congenital adrenal hyperplasia (CAH) was biochemically excluded by the Synachten test (maximal 17-OHP 7.0 nmol/l and cortisol 685.4 nmol/l). Selective ovarian and adrenal venous sampling were inconclusive indicating abnormal androgen production from the left adrenal gland and right ovary. Genetic analyzes confirmed mutations in H6PD gene: c.455A>G (p. Tyr152Cys) and c.1123G>A (p. Glu375Lys). The result of cortisol clearance is pending. The enlarged ovaries (diameter 5 cm, volume 28 ml) with polycystic morphology were confirmed by ultrasound. Adrenal glands are described as normal (MRI).
Conclusion
The genetic analysis on H6PD gene should be done if there are inexplicably high levels of androgens in a woman with PCO-like phenotype. Peculiar functional testing is needed including specific genetic testing for rare adrenal enzymatic deficiencies.

Clinical and biological aspects of isolated hypogonadotropic hypogonadism

Hager Khiari[1,2], Imen Rojbi[1], Sawsen Essayeh[1], Sabrine Mekni[1], Bennacef Ibtissem[1], Youssef Lakhoua[1], Nadia Mchirgui[1] & Karima Khiari[1]
[1]Charles nicolle hospital, Endocrinology; [2]Charles nicolle hospital, Endocrinology, Tunis, Tunisia

Introduction
Isolated hypogonadotropic hypogonadism is a heterogeneous group of genetic abnormalities affecting the hypothalamic pituitary gonadal axis. The main mechanism consists of an impairment of the production or the action of gonadotropin releasing hormone (GnRH). While several mutations have been identified, the majority of cases remain without etiology. The objective of our study was to describe the clinical and biological profiles of these diseases.

Methods
This was a retrospective study that included patients followed in our department between 2009 and 2023 for idiopathic hypogonadotropic hypogonadism with normal pituitary imaging. Patients with Kallmann syndrome were not included.
Results
We included 15 patients in our study. Twelve patients were males and three were females with a male/female sex ratio (M/F) of 4. The mean age at the initial diagnosis was 26.5 ± 14.5 years with extremes ranging from 14 to 57 years old. The chief complaint was different depending on gender. For males, delayed puberty was the most common ($n=4$). Three patients complained of gynecomastia, two of micropenis, one patient consulted for infertility and another for adrenal insufficiency. For females, reasons for consultation were primary amenorrhea ($n=1$), secondary amenorrhea ($n=1$) and adrenal insufficiency ($n=1$). All patients reported a history of irregular menses. Most patients did not have a family history of hypogonadism ($n=13$), cryptorchidism and infertility were reported in first-degree relatives in two patients. Only one patient had first-degree parental consanguinity. No patient had a congenital malformation. The mean serum testosterone level was 0.99 ± 0.9 ng/ml for men and the mean serum estradiol level was 9 pg/ml for women. The mean (FSH/lH) ratio was 3.8 ± 3.6. An associated pituitary deficiency was observed in six patients. Corticotropic deficiency was the most frequent ($n=5$). Six patients were married, three of them had offspring: one couple had a spontaneous pregnancy and two couples needed treatment with gonadotropins to have children.
Conclusion
Isolated hypogonadotropic hypogonadism is characterized by heterogeneous genetic, clinical and evolutive aspects. The identification of the mutations involved in its genesis is crucial to improve its management and prognosis.

Body composition changes and satisfaction associated with gender-affirming hormone therapy in transgender men

Emilia Gomez Hoyos[1], David Primo Martin[1], Esther Delgado Garcia[1], Lucia Estevez Asensio[1], Ana Ortolá Buigues[1], Juan Jose Lopez Gomez[1], Maria Antonia Maniega Rubio[2], Carmen Rodriguez Fernandez[2], Maria Jose Bartolome Albistegui[3] & Daniel De Luis Roman[1]
[1]Hospital Clínico Valladolid, Endocrinology and Nutrition, Valladolid, Spain; [2]University Clinical Hospital of Valladolid, Mental Health, Valladolid, Spain; [3]University Clinical Hospital of Valladolid, Pediatrics, Valladolid, Spain

Introduction
Gender affirming hormone therapy (GAHT) in transgender men favors their virilization. Aims: To determine its impact on body composition measured by electrical impedance and the satisfaction perceived by the subject (CRES-4 questionnaire).
Material and Methods
Prospective study in transgender men with GAHT (>2 years), attended at the Transgender Medicine Unit of the Hospital Clinico of Valladolid from January 2014 to January 2023. Recording of clinical, analytical, body composition and CRES-4 questionnaire data after giving their consent. Statistical analysis of the data by the SPSS-V17 program.
Results
32 transgender males aged 23 [22-32] years and onset of GAHT at 18 [17-25] years with long-acting testosterone ester 2 (6.3%), short-acting 26 (81.3%) and testosterone gel 4 (12.5%). The initial BMI was 21.9 [19.6-24.7] kg/m^2, fat-free mass (FFM) 43.9 [40.8-47.4] kg, fat mass (FM) 15.6 [10.6-22.9] kg and estimated muscle mass (EMM) 29 [24.7-31.9] kg. At 2 years with testosterone, there was 0.82 [0.1-1.9] kg/m^2 increase in BMI, 3.4[2-5] kg in FFM and 3.8 [1.7-8.1] kg in EMM. FM decreased -1.7[-3.3 to 1] kg. 21/22 subjects were satisfied with GAHT, with 255 [242-265] points on CRES-4. Serum testosterone (near the end of the dose interval) was 391 [264-817] ng/dl with 17 (53%) in the low range (</=400 ng/dl) and 15 (47%) subjects in the mid-high range of normal (>400 ng/dl). In both groups, changes in BMI ($P=0.723$), in FFM ($P=0.288$) and in FM ($P=0.288$) were similar. However, the increase in EMM was 4.9[2.8-10] kg in the low range and 3.3[1.2-7.1] kg in the mid-high range ($P=0.077$). CRES-4 score in the low range was 262 [250-275] and in the mid- high range 255 [242-262] points (p 0.273).
Conclusion
GAHT-induced body composition changes in transgender males were satisfactory. Even with testosterone levels near the end of the dosing interval in the low normal range.

Knowledge and practices among georgian physicians regarding diagnosis and management of polycystic ovary syndrome: experiences from a middle-income country

Meri Davitadze[1,2], Giorgi Kanchelashvili[2,3], Ann Kobaidze[4], Nino Tedoradze[4], Nino Chikhladze[1] & Giorgi Chakhunashvili[5]
[1]Tbilisi State University, Tbilisi, Georgia; [2]Clinic NeoLab, Tbilisi, Georgia; [3]Health Research Union, Tbilisi, Georgia; [4]Caucasus Medical Center, Tbilisi, Georgia; [5]Georgian National Center for Disease Control and Public Health, One Health Division, Tbilisi, Georgia

Introduction
Polycystic ovary syndrome (PCOS) affects 10-15% of women worldwide, depending on the population and the diagnostic criteria used. The diagnostic criteria include clinical and/or biochemical hyperandrogenism, oligo/anovulation, and polycystic morphologic appearance of the ovaries. PCOS is associated with high risk of obesity, diabetes, cardiovascular diseases, and a wide spectrum of mental health disorders. Despite international recommendations, there is still lack of awareness regarding the diagnostic and management approaches with studies being reported mostly from high-income countries. Herein, we aimed to investigate healthcare professionals' knowledge and practices regarding PCOS in a middle-income country.
Methods
A survey-based study was conducted among Georgian physicians, namely endocrinologist, gynaecologists, and family doctors, in March 2022. The survey consisted of questions regarding participants' general information and their knowledge and experience regarding various aspects of PCOS. T-test and chi-square test were performed. Statistical significance was set at $P<0.05$.
Results
Out of the 133 physicians, 77 (57.9%) were endocrinologists, 21 (15.8%) gynaecologists, and 35 (26.3%) family doctors. 93.5% ($n=72/77$) of endocrinologists, 70.0% ($n=14/20$) of gynaecologists, and 84.8% ($n=28/33$) of family doctors perceived PCOS as an endocrine condition ($P=0.015$). however, 51.9% ($n=40/77$) of endocrinologists referred patients to gynaecologists, and 33.3% ($n=7/21$) of gynaecologists referred patients to endocrinologists ($P<0.001$). Less than half of both specialists (49.4% [$n=38/77$] of endocrinologists and 47.6% [$n=10/21$] of gynaecologists) used Rotterdam criteria, while 14.3% ($n=11/77$) of endocrinologists and 4.8% ($n=1/21$) of gynaecologists responded with 'don't know' ($P=0.474$). For initial evaluation, more endocrinologists used metabolic parameters, compared with gynaecologists ($P<0.05$). Only 12.0% ($n=9/75$) of endocrinologists and 19.0% ($n=4/21$) of gynaecologists offered lifestyle modifications for PCOS on a regular basis. 5.7% ($n=38/75$) and 36.0% ($n=27/75$) of endocrinologists most frequently offered metformin and oral contraceptives for PCOS, as opposed to 4.8% ($n=1/21$) and 66.7% ($n=14/21$) of gynaecologists for the same treatment options, respectively ($P=0.001$). Lastly, 61.0% ($n=47/77$) of endocrinologists and 85.7% ($n=18/21$) of gynaecologists disagreed with the statement 'name 'polycystic ovary syndrome' is confusing and should be changed' ($P=.034$).
Conclusions
The knowledge and practical approaches with regards to PCOS differ across specialities and are inconsistent with the current international recommendations. Future studies are warranted to propose relevant improvements and evaluate the effectiveness of implemented mechanisms in Georgia to promote better patient care. Further perspective would be to explore the perceptions and attitudes towards PCOS among women with this condition to better understand their needs.

Beyond the surface: endocrinological implications of thoracic endometriosis syndrome

Aleksandra Czapla-Iskrzycka[1], Katarzyna Pietrzak[2], Renata Świątkowska-Stodulska[1] & Tomasz Marjański[3]
[1]Medical University of Gdansk, Department of Endocrinology and Internal Diseases, Gdansk, Poland; [2]Medical University of Gdansk, Division of Nursing Management, Gdansk, Poland; [3]Medical University of Gdansk, Department of Thoracic Surgery, Gdansk, Poland

Introduction
Thoracic Endometriosis Syndrome (TES) is characterized by clinical symptoms associated with menstruation (eg, catamenial pneumothorax (CP), chest pain, and others) not obligatorily requiring histological confirmation. The treatment is

burdened with frequent recurrences. This study aimed to characterize the treatment of women with TES and assess the concomitant diseases.
Methods
A developed online survey was published in patients' support group. It consisted of sections regarding demographics, symptoms, various treatment strategies, infertility, vitamin D supplementation and diet.
Results
In this descriptive study 40 women with mean age of 37 (22-44y) were included, 85% had confirmed pelvic endometriosis. Eleven patients were diagnosed pathologically with thoracic endometriosis, while the rest (72.5%) experienced the symptoms of TES. 22.5% had a family history of endometriosis, and 1 of them confirmed that a family member had TES. 34 women (85%) were treated with hormonal therapy. 40% of women had comorbidities – the most prevalent were hypothyroidism (50%), insulin resistance(31.3%), asthma (25%), and nodular goitre (18.3%). Progestogens and combined oral contraceptives were the most commonly used, 74.5% and 35.3% respectively. GnRH agonists and among progestogens – dienogest were the most effective in control of recurrent CP (40% of 5 and 30.8% of 26 women). All hormonal drugs alleviated pain. 62.5% of women supplemented vitamin D, 12 of which had previously confirmed insufficiency. Those with insufficiency understandably had higher mean vitamin D dosage (3273 IU vs 2354 IU). Due to hormonal treatment, it was difficult to determine the independent influence of supplementation on symptoms, however, those without hormonal treatment did not notice any changes. 27 women had been pregnant, 7 of whom had miscarriages, but only 2 had not been able to become pregnant again. 35% of all women had been treated due to infertility. 57.5% changed their diet after the diagnosis – the most common changes were an anti-inflammatory diet, sugar withdrawal, and red meat withdrawal. 6 patients had not used hormonal therapy when they changed their diet – most of them did not notice any changes or symptoms appeared more often.
Conclusions
The most prevalent comorbidity with TES is hypothyroidism. The most effective treatment strategies are GnRH agonists and progestogens. All hormonal drugs alleviate pain in TES. Vitamin D supplementation did not change the course of the disease. Infertility is common among TES patients.

Premature ovarian failure after cancer treatment: surveillance and management

Mariana Lopes-Pinto[1], Raquel Calheiros[2], Sara Santos[2], Isabel Inácio[2], Pedro Souteiro[2], Joana Oliveira[2], Ana P Santos[2] & Isabel Torres[2]
[1]Unidade Local de Saúde de Santa Maria, Hospital de Santa Maria, Endocrinology Department, Lisbon, Portugal; [2]Instituto Português de Oncologia do Porto Francisco Gentil, Endocrinology Department, Porto, Portugal

Introduction
Cancer treatment including oophorectomy, radiotherapy and chemotherapy with gonadotoxic agents may induce premature ovarian failure. Early diagnosis and treatment of ovarian failure avoids cardiovascular disorders, osteoporosis and compromised sexual health due to estrogen deficiency and also ensures growth and pubertal development in children.
Aim
Raise awareness for early assessment and management of premature ovarian failure after cancer treatment.
Methods
A retrospective longitudinal study was performed by analysis of medical records of patients with premature ovarian failure due to cancer treatment followed at our centre. Demographics, primary tumour clinicopathological data, cancer treatment details, clinical and biochemical features of hypogonadism, puberty induction requirement and hypogonadism treatment were analysed.
Results
Twenty-one women with previously diagnosed ovarian failure due to cancer treatment were included. Median age at cancer diagnosis was 8 years (minimum: 6 months, maximum: 39 years); at last follow-up median age was 17 years (minimum: 9 years, maximum: 44 years) and one was deceased. Hematological and solid malignancies were documented as primary tumours, the former being more frequent: acute lymphocytic leukemia ($n=6$), acute myeloid leukemia ($n=2$), non-Hodgkin lymphoma ($n=2$) and chronic myeloid lymphoma ($n=2$). All patients underwent chemotherapy, four were also submitted to abdominal or pelvic radiotherapy and one underwent additional unilateral oophorectomy due to small cell carcinoma of the ovary. The mean dose of radiotherapy used was 39.5 Gy $\pm$ 10.3 (SD). Eighteen cases underwent chemotherapy in context of conditioning regimens for hematopoietic stem cell transplant. Gonadotoxic drugs were used in 19 patients, the most common agents were cyclophosphamide ($n=15$), busulfan ($n=13$), cisplatin ($n=3$), melphalan ($n=2$) and carboplatin ($n=2$). Primary or secondary amenorrhea had been described in 11 and 7 cases respectively. Mean FSH at diagnosis of premature ovarian failure after cancer treatment was 74.7 $\pm$ 8.5 (SD) mUI/ml. At last follow-up, 3 patients had completed puberty induction and 5 patients were under therapy for puberty induction with estrogen patch. Vigilance of spontaneous pubertal development was described in 3 girls under 14 years with gonadotrophin levels suggestive of primary ovarian insufficiency. Regarding maintenance hormone therapy, 2 patients were treated with estrogen patch and oral progestin, 2 were treated with oral estradiol/progesterone replacement therapy regimens, and 7 were under oral combined contraceptive pill.
Conclusion
Assessment of ovarian function must be performed after cancer treatments with potential risk of inducing ovarian insufficiency. Sex hormones replacement strategies vary according to pubertal development and prevent estrogen deficiency effects.

PCOS phenotypes and their relationship to aldosterone levels

Chiara Sabbadin[1], Luciana Bordin[2], Loris Marin[2], Alessandra Andrisani[2] & Decio Armanini[1]
[1]University Hospital of Padua, Endocrine Unit, Padua, Italy; [2]University Hospital of Padua, Department of Women's and Children's Health, Padua, Italy

Objective
Polycystic ovary syndrome (PCOS) phenotypes, generated by the possible combinations of the three Rotterdam diagnostic criteria, show a different scale of metabolic risk among PCOS women, being greatest in the classic subgroup, followed by the ovulatory and normoandrogenic phenotype. Aldosterone is an important cardiovascular risk factor. Previous studies reported increased levels of aldosterone in PCOS women, suggesting a possible role in the development of some cardiometabolic alterations.
Aim of the study
To evaluate the possible differences of aldosterone levels among the three PCOS phenotypes.
Protocol and Methods
100 women with PCOS meeting Rotterdam criteria underwent the following hormonal and metabolic evaluations in the early follicular phase: FSH, LH, testosterone, androstenedione, DHEAS, orthostatic aldosterone and renin, total cholesterol, high density lipoprotein cholesterol, triglycerides, glucose and insulin response to oral glucose tolerance test. 17 healthy women, matched for age and BMI, were considered as the control group.
Results
Women belonging to the classic phenotype (40%) show the worst clinical-metabolic picture, being more obese, insulin-resistant, and hirsute and presenting dyslipidemia. Patients with the ovulatory phenotype (37%) show metabolic alterations similar to the classic subgroup, but have lower systolic blood pressure, waist circumference, and triglycerides levels. Patients with normoandrogenic phenotype (23%) have a metabolic profile similar to controls. Aldosterone levels follow this trend, being significantly increased only in classic and ovulatory subgroups.
Conclusions
Classic and ovulatory PCOS phenotypes show more metabolic alterations and higher aldosterone levels compared to normoandrogenic phenotype. Aldosterone could play a certain role in the increased cardiometabolic risk associated to these PCOS phenotypes.

Short and long-term efficacy of minoxidil on beard growth in a group of assigned female at birth transgender people on gender affirming hormone therapy

Lorenzo Marinelli[1], Andreina Bichiri[1], Ezio Ghigo[1] & Giovanna Motta[1]
[1]University of Turin, Department of Medical Sciences, Turin, Italy

Introduction
Minoxidil is a vasodilator drug used as topical treatment of androgenetic alopecia; however, its efficacy for beard enhancement is reported in cisgender men and in a case-report of a transgender assigned female at birth (t-AFAB) adolescent. This study aims to evaluate the short- and long-term efficacy of topical minoxidil in a group of *t*-AFAB people on gender affirming hormone therapy (GAHT) with testosterone.
Materials and methods
Sixteen *t*-AFAB clients with an uncomplete beard development, on GAHT for at least for 6 months, were enrolled at CIDIGEM gender team, Turin. They used Minoxidil 2% 2 ml/day on the interested facial areas for at least 3 consecutive months. Before starting (T0), after 3 (T3) 6 (T6) and 12 months (T12) we evaluated facial hair growth using Ferriman-Gallwey modified score (FGm). Hair gowth pattern and side effects were subjectively reported.
Results
At T0, recruited clients were 26 (2.7) years old, and they were on GAHT for 18,5 [15-54] months; we observed a FGm of 2 [1-2] at the prolabium and 2 [1-2] at the chin. Compared to T0, we observed a statistically significant difference on the pair matched evaluation at T3 (median prolabium FGm 3 [2.25-4] and chin 3.5 [3-4]; $P < 0.05$) and at T6 (FGm 3.5 [3-4] - prolabium and 4 [3.25-4] - chin; $P \leq 0.002$). No major side effects were reported. At T6 73% of the sample stopped minoxidil. At T12 we observed substantial stability of the obtained results (chin FGm 4 [3.75-4] and prolabium FGm 4 [3-4]; $P > 0.05$), even if 2 people reported a slower hair growth since suspension. The other 27% kept using minoxidil due to unsatisfaction of the results or fear of regression.
Conclusion
The use of Minoxidil 2% in a group of t-AFAB people on GAHT showed at 3 and 6 months of use a significative beard growth enhancement. Stopping the therapy at 6 months seemed to maintain the obtained improvements during the subsequent months even if the beard speed growth may be impaired.

EP576

Combined klinefelter and down syndrome – challenges of testosterone replacement therapy

Kristina Groti Antonic[1,2], Mojca Jensterle[1,2] & Andrej Janez[1,2]
[1]University Medical Center Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]Faculty of Medicine, Ljubljana, Slovenia

Introduction
Double aneuploidies are extremely rare. Klinefelter syndrome is a chromosomal disorder characterized by an extra X chromosome in male cells - approximately 80% are 47,XXY; the remaining 20% are mosaic 47,XXY/46,XY. Down syndrome is caused by trisomy of chromosome 21. The prevalence of Klinefelter syndrome is approximately 1 to 2.5 per 1000 boys and men (0.1 to 0.25 percent). The incidence of Down syndrome is approximately 1 in every 990 live births across Europe (10.1 per 10,000 live births). Both chromosomal abnormalities rarely occur together; calculated incidence is 0.4-0.9 per 10000 male newborn. Patients with Down syndrome exhibit characteristic features at birth, while features of Klinefelter syndrome might not be apparent until puberty. Typical Klinefelter syndrome clinical features are tall stature with long extremities, small testes, and learning disabilities. Patients with Klinefelter syndrome have impaired gonadal function resulting in testicular atrophy and hypergonadotropic hypogonadism and azoospermia.
Case presentation
The phenotypic characteristics of a 28-year old man showed the presence of features of Down syndrome. The family had no known history of chromosomal abnormalities or other syndromes. At first visit to pediatrician he presented with midfacial hypoplasia and dermatologic disorders (folliculitis), but without accompanying congenital heart defects, hypothyroidism, diabetes or renal disease. During follow-up, he presented decreased bone mineral density, normal body weight and height, and gastroesophageal reflux disease. He had a global developmental delay, small testes by age 12. At the age of 13 he started testosterone treatment with 1000 mg testosterone undecanoate/3 months and supplementation with vitamin D and calcium. Five years later testosterone dose was decreased to 750 mg/3 months because of the worsening skin inflammation. At the age of 25 he was transitioned to adult endocrinologist. Following the altered behavior as a side effect of testosterone therapy in spite of normal serum testosterone concentrations, his therapy was switched to transdermal testosterone. Examinations within the last 12 months show that the patient has not developed diabetes, cardiovascular or autoimmune complications. Thyroid function is normal, abdominal ultrasoud showed hepatic steatosis, cardiologist reported no abnormalities.
Conclusions
Double aneuploidy with Down-Klinefelter syndrome, as seen in our case, usually presents in the neonatal period with the clinical features of Down syndrome, while features characteristic of Klinefelter syndrome appear later. Both aneuploidies have a potential to weaken or enhance each other. In the presence of typical features of Down syndrome, we highly recommend proceeding with chromosomal analysis.

Low dose sublingual estradiol decreases protein s, generating a potentially pro-thrombotic state: interim results of a controlled prospective pilot study of treatment-naïve trans women

Shelly Bar On[1,2], Iris Yaish[1], Merav Barzilai[2,3], Yona Greenman[1,2], Guy Gindis[1,2], Yaffa Moshe[1] & Karen Tordjman[1,2]
[1]Tel Aviv Sourasky Medical Center Institute of Endocrinology and Metabolism, Institute of Endocrinology, Metabolism, and Hypertension, Tel Aviv, Israel; [2]Tel Aviv University, Faculty of Medicine, Internal Medicine, Tel Aviv, Israel; [3]Rabin Medical Center, Campus Beilinson, Institute of Hematology, Petha Tikva, Israel

Background
Sublingual estradiol (E) for gender-affirming hormone therapy (GAHT) of transgender women (TW) might obviate the need for an anti-androgen, and mitigate pro-coagulant changes. We recently showed that 2 mg E, divided into 4 daily SL doses (SLE), offers no clinical advantage over the same dose given orally in combination with cyproterone acetate (CPA). Furthermore, we showed that after each sublingual administration, serum E2 (sE2) peaked to levels, the likes of which are achieved only during induction of ovulation with gonadotrophins.
Hypothesis and Aim
Given the exceedingly high peak sE2 measured under SLE-GAHT, we hypothesized it could lead to partial acquired Protein S deficiency, a recognized pro-thrombotic state and risk factor for venous thromboembolic events (VTE). Our aim was to assess the hemostatic system under SLE in comparison with the standard combined oral (CO) approach.
Design and Methods
In this ongoing open label study, treatment-naïve TW are assigned in a 1:1 ratio (15 in each arm) to either standard CO (2 mg E2 with 10 mg CPA once daily), or to 2 mg sublingual E divided into 4 daily doses for 6 months (6M). An extensive battery of hemostatic biomarkers, including free Protein S antigen (fPS), are assessed at baseline (BL) and at 6M.
Results
We herein report on 27 subjects (15 CO/12 SLE) who initiated treatment, 17 of whom have already completed it. The median age of the cohort is 20 y (IQR 19-27; range 18-42]. There were no BL differences between the groups. At 6M, none of the hemostatic markers differed between the groups except for fPS, which was significantly lower in the SL group $79.7 \pm 11.6\%$ vs $104.6 \pm 5.6\%$, $P = 0.039$. By paired comparisons for the entire group, fPS decreased from $104.2 \pm 5.2\%$ at BL to $95.8 \pm 5.9\%$ at 6M, $P = 0.003$. This was entirely accounted for by the change in the SLE group, in which fPS went down from $95.7 \pm 10.3\%$ to $79.7 \pm 11.6\%$, $P < 0.001$; with some values reaching the fPS deficiency range. In contrast, fPS, remained unchanged under CO $108.9 \pm 5.7\%$ and $104.5 \pm 5.2\%$, at BL and 6M respectively, $P = 0.153$.
Conclusions
The most notable interim finding was a clinically significant decrease in fPS under low dose SLE. Given the extreme peaks of sE2 we previously reported with this protocol, an acquired deficiency of this natural anti-coagulant was expected. These preliminary findings support our hypothesis and raise the concern that GAHT of TW with chronic SLE might carry an increased long-term risk for VTE.

Statural and weight delay revealing pituitary stalk interruption syndrome: a study of 6 cases

Nora Boutatss[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy- University Hassan II, Endocrinology, Diabetology, Nutrition and Metabolic Diseases, Casablanca, Morocco

Introduction
Pituitary stalk interruption syndrome (PSIS) is a rare disease. It is defined by congenital anomalies of the pituitary leading to isolated or combined anterior pituitary deficiency. Its pathophysiology is unknown. Radiologically, it is characterized by an MRI showing the association of a thin or absent pituitary stalk, ectopic and/or absent posterior pituitary, and hypoplastic anterior pituitary. Symptoms of PSIS during the neonatal and early childhood period are often overlooked, leading to delayed diagnosis.
Objective
To describe the clinical, hormonal, and radiological manifestations of PSIS.
Patients and Methods
A retrospective descriptive study, including 6 patients hospitalized in the Department of Endocrinology and Metabolic Diseases at Ibn Rochd University Hospital in Casablanca for statural and weight delay.
Results
SIX cases of PSIS were collected, consisting of 5 boys and 1 girl. The average age at the first consultation was 14.5 years, ranging from 13 to 16 years. The reason for consultation was statural and weight delay in all patients. Pubertal delay was observed in 3 patients. None of them were born of consanguineous marriage. No history of neonatal incidents, obstetric, or cranial trauma was reported. Physical examination found a micropenis in 2 boys, and bone age was delayed by 2 to 4 years. The hypophyseogram showed isolated growth hormone deficiency (3 cases), combined deficiency (3 cases), and no manifestation of diabetes insipidus. Pituitary MRI revealed a hypoplastic anterior pituitary (4 cases), interrupted pituitary stalk (5 cases), and ectopic posterior pituitary (2 cases). Appropriate hormonal replacement therapy is the only effective means, but the timing of treatment is crucial.
Conclusion
PSIS exhibits significant clinical heterogeneity. The clinical presentation can range from predominantly somatotropic anterior pituitary deficiency to combined deficiencies. Pituitary MRI is crucial for diagnosis. Somatotropic deficiency can be isolated or combined from the outset. Management involves regular monitoring due to the evolving nature of the disease.

Association of celiac disease and growth hormone deficiency: a report on 4 cases

Nora Boutatss[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy- University Hassan II, Endocrinology, Diabetology, Nutrition and Metabolic Diseases, Casablanca, Morocco

Introduction
Celiac disease and growth hormone deficiency can sometimes coexist, presenting a unique clinical challenge. Celiac disease, an autoimmune condition triggered by gluten consumption in genetically predisposed individuals, can lead to malabsorption and various complications. Growth hormone deficiency (GHD) refers to inadequate production of growth hormone, affecting normal growth and development.
Objective
To explore the association between celiac disease and growth hormone deficiency.
Patients and Methods
This is a retrospective descriptive study based on the records of patients followed in our department for growth retardation (GR), where the diagnoses of growth hormone (GH) deficiency and celiac disease (CD) were established.
Results
Our study focused on 4 patients with an average age of 15.5 years, predominantly male (3 boys and 1 girl). All patients were monitored for celiac disease, with initial positive anti-transglutaminase antibody titers. In the absence of growth despite 3 years of a gluten-free diet, GH deficiency was suspected and confirmed by low IGF-1 levels in all cases. Pituitary MRI was normal in all cases. Management involved initiating substitutive growth hormone therapy, resulting in an average height gain of 1.1 SD±2 SD in the first year.
Conclusion
The coexistence of celiac disease and growth hormone deficiency requires a comprehensive and multidisciplinary approach. Timely diagnosis and appropriate management, including a gluten-free diet and growth hormone replacement therapy, can significantly impact the overall well-being and growth trajectory of affected individuals. Regular monitoring and collaboration between gastroenterologists and endocrinologists are essential for optimal outcomes in such case.

Pregnancy planning strategy in a patient with mccune-albright syndrome

Margarita Samsonova[1], Yulia Absatarova[1], Tatiana Kokorina[1] & Natalya Sviridenko[1]
[1]Endocrinology Research Centre, Moskva, Russian Federation

Background
McCune-Albright Syndrome (MAS) is a rare genetic disorder characterized by polyostotic fibrous dysplasia of the skeleton, "café-au-lait" skin hyperpigmentation, and hyperfunction of endocrine glands. A distinctive feature of the syndrome is the autonomous activation of the ovaries leading to the formation of unilateral, recurring estrogen-producing cysts. Hyperestrogenism in turn causes precocious puberty in girls and anovulation in women with MAS. This work describes a clinical case of MAS in a young female patient with a recurring estrogen-producing ovarian cyst who is planning pregnancy, and discusses the possibility of spontaneous conception against the background of ovulation stimulation using clomiphene citrate and hCG.
Case Presentation
A 21-year-old patient diagnosed with MAS at the age of 3 due to hyperestrogenism, a cyst in the right ovary, and signs of bone fibrous dysplasia. Following diagnosis, she underwent regular examinations to assess disease severity and screen for potential syndrome components. At 6, she started fulvestrant therapy, which was discontinued at 10 due to a fracture of the right femoral neck. At 14, didrogesterone therapy was initiated, leading to a regular menstrual cycle. Currently, the patient is planning pregnancy. The last examination in 2021 at 19 years old showed signs of polyostotic fibrous dysplasia, recurring right ovarian cyst, and hyperestrogenism. Hormonal investigation on the 3rd day of the menstrual cycle showed elevated estradiol levels (1401.6 pmol/l) and reduced gonadotropin levels (FSH - 1.39 IU/l, LH - 0.84 IU/l). Progesterone was 5.2 nmol/l, AMH - 3 ng/ml. Pelvic ultrasound confirmed cystic changes in the ovary with increased volume to 118.5 cm^3. During a consultation with a gynecologist, various pregnancy preparation methods were discussed, including the possibility of natural conception. In case of failure, controlled ovulation induction using clomiphene citrate and hCG, or if necessary, IVF or adnexectomy of the affected ovary, was considered.
Conclusion
Currently, adnexectomy of the affected ovary is a well-known and documented method for achieving pregnancy, and there are reports of successful In vitro fertilization in patients with MAS. Given the rarity of the condition, specialists must choose the most appropriate and safe treatment approach in each individual case, sometimes resorting to unconventional methods. For instance, the use of clomiphene citrate followed by hCG as an ovulation trigger could be a potential strategy to overcome anovulation and achieve pregnancy in women with MAS suffering from infertility due to unilateral recurring estrogen-producing cysts.

Superman-a case report of hyperandrogenemia

Tereza Grimmichova[1,2]
[1]Institute of Endocrinology, Praha 1; [2]Faculty hospital Kralovske Vinohrady and 3rd Faculty of Mediciny of Charles University, Internal Medicine, Praha 10

Introduction
SARMs (Selective Androgen Receptor Modulators) are non-steroidal anabolics and should improve body strength, muscle building and aid in burning excess fat. There have been ongoing clinical trials regarding positive effects of SARMs in patients with cancer cachexia, hypogonadism, benign prostatic hyperplasia, breast cancer, Alzheimeŕs disease, osteoporosis etc. with conflicting results. Liver injury and cardiovascular disease are possible severe side-effects. For these reasons,

SARMs have not been officially approved. Nevertheless, SARMs can be freely purchased on the market as supplements.
Case report
A 29-year-old male was examined due to gynecomastia, which has persisted since puberty. The patient wished to undergo surgical treatment. Medical history: negative. Occupation: croupier in a casino. No history of smoking, alcohol, or drugs. On physical examination: 179 cm, 89 kg, BMI 27.8 kg/m^2, muscular constitution, gynecomastia negative. Breast ultrasound described chronic signs of gynecomastia. Laboratory results: Cholesterol 2.78 (2.90-5.00 mmol/l), HDL cholesterol 0.46 (1.00-2.10 mmol/l), LDL cholesterol 2.12 (1.20-3.00 mmol/l), triglycerides 0.53 (0.45-1.70 mmol/l). Liver enzymes: Bilirubin total 9.4 (2.5-21.0 µmol/l), ALT 4.55 (0.17-0.83 µkat/l), AST 1.40 (0.17-0.85 µkat/l), GGT 0.24 (0.17-1.19 µkat/l). Hormonal profile: LH $<$0.1 (1.7–8.6 IU/l), FSH 0.1 (1.5–12.4 IU/l), testosterone (TST)$>$ 100.00 (10-34 nmol/l), free TST (calculated using TST, SHBG, albumin) 3507.5 (168-735 pmol/l), Free Androgen Index (FAI) (TST/SHBG) 4347.83 (30-150%), dihydrotestosterone 7.96 (0.90-3.60 nmol/l), estradiol 0.579 (0.0948–0.223 nmol/l), androstendion 87.80 (2.16-10.90 nmol/l), progesterone 0.862 (0.00–0.474 nmol/l), and SHBG 2.3 (7.9-38.2 nmol/l). The patient admitted using SARMs for body-building purposes. Laboratory results after stopping SARMs: normalization of the liver enzymes. Hormonal profile: LH $<$0.1 IU/l, FSH $<$0.1 IU/l, TST 47.04 nmol/l, free TST 1613.7 pmol/l, FAI 855.27%, SHBG 5.5 nmol/l. The patient conceded using also TST i.m. weekly and discontinued his follow-ups.
Conclusion
SARMs should have more selective effects (more anabolic and less androgenic) with less side-effects when compared to testosterone. Clear evidence is lacking, and persons, especially the male population should be advised of the potential for harm.

Identification of hCG- and LH-dependent ovarian luteoma resulting in marked androgen production during pregnancy states as well as after menopause: characterization *in vivo* and in a human ex vivo model

Mads Jorsal[1], Sam Kafai Yahyavi[1,2], Christine Hjorth Andreassen[1], Hanne Frederiksen[2,3], Anders Juul[2,3,4] & Martin Blomberg Jensen[1]
[1]Copenhagen University Hospital - Herlev and Gentofte, Division of Translational Endocrinology Department of Endocrinology and Internal Medicine, Herlev, Denmark; [2]Copenhagen University Hospital – Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [3]Copenhagen University Hospital – Rigshospitalet, International Centre for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen, Denmark; [4]University of Copenhagen, Copenhagen, Department of Clinical Medicine, Denmark

Context
Steroid hormone-producing tumors account for 0.1% of all primary ovarian tumors. According to the cellular origin they are classified into stromal luteomas, Leydig cell tumors and steroid tumors not otherwise specified. Symptoms and phenotype depend on the specific hormones and concentrations released from the tumor. In this report, we present a postmenopausal woman with virilization during two pregnancies and in menopause caused by an androgen producing ovarian tumor. LH and hCG dependency were demonstrated by treatment with a GnRH agonist prior to surgery and following bilateral salpingo-oophorectomy treatment with FSH, LH and hCG in an ex vivo tissue culture model.
Case description
A 61-year-old postmenopausal woman was referred to our clinic with progression of symptoms including hirsutism, hair loss, deepening of voice, depression, clitoromegaly and android muscle appearance throughout 18-months. Interestingly, during her two successful pregnancies, she developed hirsutism and deepening of the voice. The hirsutism regressed postpartum, while the deepened voice frequency sustained. Blood tests in our clinic revealed normal serum levels of estrogen and gonadotrophins compatible with her postmenopausal status, but elevated serum concentrations of androgens with testosterone levels around 15 nM. A CT scan of thorax and abdomen showed no sign of tumors. However, vaginal ultrasound revealed a process in the right ovary. To further evaluate the tumor, the patient was treated with a GnRH agonist, resulting in androgens being suppressed to levels appropriate for postmenopausal women, thus indicating that the hormone production was dependent on gonadotrophins. To alleviate her condition, she underwent bilateral salpingo-oophorectomy. One tumor was found in each ovary. Histological examination concluded that the most likely diagnosis was stromal luteoma. Tissue cultures from the right ovary showed a several fold increase in testosterone, 17-OHP and androstenedione production upon stimulation with hCG or LH. These findings are consistent with the serum levels and phenotypic changes occurring from elevated hCG levels during pregnancy as well as increased LH levels after menopause. Following the operation, the patient experienced improvements in all prior symptoms consistent with the normalization of androgen serum levels.
Conclusion
Stromal luteomas are a rare finding constituting only 20-25% of steroid cell tumors. Of these, only 12% present with androgenic symptoms making this case a rare finding. Identifying these tumors are difficult since symptoms may only occur in situations where gonadotrophins are elevated i.e., pregnancies and menopause. Our data suggest that androgen producing stromal luteomas can be treated with surgery or GnRH agonist.

Is the deficiency in secondary sex characteristics a potential manifestation of SPENCD (Spondyloenchondrodysplasia)?

İrem Yıldız İçli[1], Alperen Onur İşler[2], Nur Evşan Boyraz[1], Deniz Cagdas[3], Levent Kılıç[4] & Alper Gürlek[2]
[1]Hacettepe University School of Medicine, Department of Internal Medicine, Ankara, Turkey; [2]Hacettepe University School of Medicine, Division of Endocrinology and Metabolism, Department of Internal Medicine, Ankara, Turkey; [3]Hacettepe University School of Medicine, Department of Pediatric Immunology, Ankara, Turkey; [4]Hacettepe University School of Medicine, Division of Rheumatology, Department of Internal Medicine, Ankara, Turkey

Background
Spondyloenchondrodysplasia (SPENCD) is a rare autosomal recessive skeletal dysplasia characterized by radiolucent spondylar and metaphyseal lesions, representing the persistence of chondroid tissue islands within the bone. Besides skeletal abnormalities and short stature, autoimmune disorders, including systemic lupus erythematosus, Sjögren's syndrome, hemolytic anemia, thrombocytopenia, hypothyroidism, inflammatory myositis, Raynaud's disease, and vitiligo, have been reported to occur in this disease. In here, we present a patient with insufficient secondary sex characteristics, despite having normal testosterone levels.
Case
A 21-year-old patient, born at term to healthy parents from same town after an uncomplicated pregnancy, presented with complaints of paleness, arthritis in his right first metacarpophalangeal joint, and arthralgia involving his left knee, both ankles, elbows, and neck at the age of 4. Laboratory examination revealed anemia, hypocomplementemia, hematuria, and proteinuria. ANA, anti-dsDNA antibody, and lupus anticoagulant were positive. Renal biopsy confirmed class IV lupus nephritis. The endocrine work-up was normal. Homozygous mutation in the ACP5 gene led to the diagnosis of SPENCD. Treatment with various immunosuppressive protocols, including hydroxychloroquine, methylprednisolone, cyclophosphamide, and mycophenolate mofetil, resulted in improvement over a 17-year follow-up. When the patient presented to our clinic at the age of 21, clinical and laboratory findings were consistent with activation of lupus, prompting renewed immunosuppressive treatment. During hospitalization, clinical examination suggested hypogonadism. The patient reported a history of erectile dysfunction, decreased libido, absence of morning erections, loss of body hair, and reduced shaving frequency. His height was 146 cm, arm span length was 148 cm, apex-pubis length was 65 cm, and pubis-heel length was 81 cm. Testicular volume was 12 ml for both testes, and penile length measured 7.5 cm. Pubic hair was at Tanner stage 4. Laboratory examination showed a testosterone level of 515 ng/dl (197-669), with FSH, LH, IGF-1, and other anterior pituitary hormones within normal range. Short stature was considered a manifestation of the primary disease. TSH and free T4 values were normal, but anti-TPO and anti-TG values were elevated. Thyroid ultrasound revealed findings consistent with thyroiditis.
Conclusion
Despite normal testosterone levels, inadequate development of secondary sex characteristics and sexual dysfunction may be newly identified features of SPENCD syndrome. ACP5 defect may lead to immune dysregulation. As the patient was under immunosuppressive therapy, lymphopenia and hypogammaglobulinemia were attributed to secondary immunodeficiency. Although FSH and LH levels were normal, autoimmune orchitis will be further evaluated. Resistance at the receptor level by receptor specific autoantibodies may contibute to the pathophysiology.

Rensselaer, New York, USA 12144

Background
Hirsutism, characterized by the male pattern distribution of terminal hair in females due to elevated androgen levels, is a diagnostic feature for polycystic ovary syndrome (PCOS), assessed by the modified Ferriman-Gallwey (mFG) score. The 2023 international PCOS guideline suggests an mFG score of 4-6 for hirsutism detection. However, the lack of universally applicable cut-offs in diverse populations necessitates further research. Therefore, this study aimed to define ethnicity-specific normative cut-offs employing the unsupervised clustering methods (K means clustering) in unselected populations.
Methods
The study utilized data from 12,192 participants aged 12 to 80 years. Data were obtained from community-based studies that were conducted in different countries including China, Iran, Italy, Nigeria, Russia, South Korea, Turkey, and the United States of America. K means cluster analysis ($k=2$) and the receiver operating characteristics curve were used to determine the normative cut-offs for the mFG score. The 75th, 85th, 90th, and 95th percentiles were identified and compared between ethnicities.
Results
The mean ($\pm$SD) age of the total population was 32.7 ± 10.7 years and the mean BMI was 24.1 ± 5.5 kg/m^2. The median (IQR) mFG score of the total population was 1 (0-3). The mFG cut-off scores vary widely across different ethnic groups, ranging from 3 to 9, with the highest scores observed among people of the Persian ethnicity (cut-off = 9), followed by White Italians and Black Africans (cut-off = 7), and Asian Chinese/Han and White Turkish (cut-off = 5). Within the hirsute cluster, the median values for various PCOS-related parameters including mFG score, total testosterone, free testosterone, free androgen index, left ovarian volume, right ovarian volume, and menstrual cycle days (length) were significantly higher compared to the non-hirsute cluster. The finding revealed a highly statistically significant difference ($P<0.001$) when comparing the median mFG score, percentiles (75th, 85th, 90th, and 95th), and the mFG cut-off for each ethnic group.
Conclusions
This finding underscores the notable variation in both the distribution and the normal cut-off values for hirsutism, as determined by the mFG score, across diverse ethnicities. Notably, the highest cut-off values were observed in the Persian population, White Italians and Black Africans. The finding suggested a nuanced picture, urging clinicians to move beyond a similar mFG cut-off point and consider the unique ethnic context for optimal diagnostic accuracy in detecting clinical hyperandrogenism.

Impact of polycystic ovary syndrome on health related quality of life in correlation with marital status: a multinational cross-sectional study

Elleuch Mouna[1], Elloumi Yesmine[1], Ben Salah Dhoha[1], Boujelben Khouloud[1], Krichen Zeineb[1], Ellouze Roua[1], Mnif Fatma[1], Mnif Mouna[1], Charfi Nadia[1], Hadj Kacem Faten[1], Abid Mohamed[1] & Mejdoub Nabila[1]
[1]Hospital of Hedi Chaker

Background and Aims
The Rotterdam criteria are the most accepted criteria for the diagnosis of polycystic ovary syndrome (PCOS). The aim of this research work is to study the quality of life of Tunisian and French women with PCOS according to their marital status.
Methods
A cross-sectional study involved 172 women with PCOS. Data collection was based on telephone interviews with tunisian patients who were diagnosed with PCOS based on rotterdam criteria and french patients via Google Forms over an international group specifically for women with PCOS. A quality-of-life questionnaire specific to polycystic ovary syndrome that exists in two forms. PCOSQ-42 for single women and PCOSQ-47 for married women. Both of them have 5 domains. The responses are rank-transformed and presented as scores.
Results
The mean age of tunisian patients was 28 ± 5.9 years while the mean age of french patients was 26.39 ± 4.3 years. 44 tunisian patients were married and 44 french patients were married. The study of HRQoL by domain had shown that the domain of menstrual disorders and fertility was the most affected in single women indicating a low mean score ($2.84\pm0,8$). Whereas the adaptation domain reported the highest mean score (3.38 ± 0.8). Married women's quality of life was more impaired than single women's: 48.31% had marked impairment of HRQoL and 39.33% had marginal or moderate impairment of HRQoL. The lowest mean score was in the psychological and emotional state domain (2.86 ± 0.7). The highest mean score was in the fertility and sex life domain (3.26 ± 0.9). So this was the domain with the least impairment.
Conclusions
PCOS contributes to an overall diminished HRQo. These results may have implications for the clinical practice and suggest the need for specific interventions in women with PCOS.

Eating disorders in patients with polycystic ovary syndrome: in correlation with marital status

Elleuch Mouna[1], Yesmine Elloumi[1], Ben Salah Dhoha[1], Boujelben khouloud[1], Krichen Zeineb[1], Ellouze Roua[1], Fatma Mnif[1], Mouna Mnif[1], Faten Haj Kacem Akid[1], Nadia Charfi[1], Mohamed Abid[1] & Nabila Rekik Majdoub[1]
[1]Hospital of Hedi Chaker

Background and Aims
Polycystic ovary syndrome (PCOS) may be the most common endocrine disorder in women of reproductive age. Most research findings suggest that PCOS is associated with eating disorders (ED). The aim of this research work is to study the eating disorders in women with PCOS.
Methods
A cross-sectional study involved 172 women, 101 of them are Tunisian and 71 are French. Data collection was based on telephone interviews with Tunisian patients who were diagnosed with PCOS based on Rotterdam criteria and French patients via Google Forms over an international group specifically for women with PCOS. The study was based on a Sick control one stone fat food (SCOFF) questionnaire. It is available in two forms for married and unmarried patients. The responses are rank-transformed and presented as scores. It is based on two parts. The first part consisted of questions on socio-demographic data. The second part consists of a questionnaire for assessing the quality of life of PCOS patients.
Results
The results showed that the average age of the participants was 27.34, with extremes ranging from 14 to 49. More than half were Tunisian (58.72%) and married (51.74%). The majority of women (70.93%) had an eating disorder like anorexia nervosa or bulimia nervosa type. 79.52% of single women had an ED. 62.92% of married women had an ED. ED was more frequent in single women than in married women ($P=0.01$).
Conclusions
This study indicates that the prevalence of eating disorders is increased among women with PCOS compared to healthy women These findings suggest that it should be necessary to pay attention to the screening of eating disorders.

Ethnic disparities in PCOS consultations: findings from a multinational study highlighting variances in assessment and education

Raghavendar Palani[1], Anisah Ali[2], Alexander Wilde[3], Lucy Murphy[3], Ashwin Joshi[3], Isin Yesim Yesilkaya Baylan[4], Erkut Attar[4], Fahrettin Kelestimur[4], Meri Davitadze[5,6], Punith Kempegowda[6,7], Eleni Armeni[1] & PCOS Seva Working group[7]
[1]Royal Free Hospital, United Kingdom; [2]University of Birmingham Medical School, United Kingdom; [3]South Tyneside NHS Foundation Trust, United Kingdom; [4]Yeditepe university, Turkey; [5]Clinic NeoLab • კლინიკა ნეოლაბი, T'bilisi, Georgia; [6]Institute of Applied Health Research, United Kingdom; [7]Queen Elizabeth Hospital Birmingham, United Kingdom

Objective
To explore whether assessments recommended by the International PCOS guidelines during the initial consultation for PCOS varied by ethnicity.
Methods
This retrospective multi-centre study was conducted from June 2023 to January 2024. All women aged >18 who attended their first consultation in a dedicated PCOS clinic from January 2020 to December 2023 in the UK ($n=359$), Turkey ($n=239$), Greece ($n=92$), and Georgia ($n=10$) were included. Those undergoing follow-up or without PCOS were excluded. Data was collected on socio-demographic variables including ethnicity, and assessments, including diagnosis based on guidelines, cardiometabolic risk, dermatological assessment, emotional well-being, long-term risk education, lifestyle management, and reproductive screening. Descriptive statistics were analysed using SPSS 28.0.
Results
75.5% were White, 4.3% were Asian, 10.3% were Black, mixed, or other groups, and 9.7% preferred not to disclose their ethnicity. The most common reasons for referral were irregular periods (65.7%), excess hair growth (61.1%), and acne (38.9%). Irregular periods, excess hair growth and acne were all higher in the White group (prevalence rates, 67.9%, 63.6% and 45.7%, respectively) compared to the Asian group (53.3%, 53.3%, and 13.3%, respectively) and the group of Black, mixed or other ethnic background (66.7%, 54.2%, 15.3%; respectively). The most common co-morbidities were anxiety (9.7%), hypothyroidism (9.0%), and depression (6.7%). The prevalence of anxiety was similar across White (9.81%), Asian (10.0%), and Black, mixed and other (6.9%) groups. Depression was higher in the Asian group (13.3%) compared to White (5.5%) and Black, mixed or other (5.6%) groups. Dermatological concerns and reproductive screening were more commonly assessed in the White group (93.8% and 91.3%, respectively) compared to the Asian and Black, mixed or other groups. Screening for emotional well-being was particularly lower in the Asian (30.0%) and Black, mixed or other groups (22.2%), compared to the White group (70.0%). Similar trends were seen with long-term risk education, which was higher in the White group (56.1%) compared to Asian (23.3%) and Black, mixed or other (9.7%) groups.
Conclusion
There is a significant gap in the parameters assessed according to ethnicity, as recommended by international PCOS guidelines. Specifically, emotional well-being screening and long-term risk education are lower in minority ethnic groups, highlighting the need for a standardised approach to the assessment of PCOS to provide equal patient care.

An international multi-centre study highlights a significant gap in the assessment and education provided during PCOS consultations

Amynta Arshad[1], Sahrish Khan[2], Harshal Deshmukh[3], Agatha Chu[3], Angharad James[4], Kyranna Lafara[5], Gesthimani Mintziori[5], Dimitrios Goulis[5], Elmira Abdullayeva[6] & PCOS Seva Working Group[7]
[1]University of Birmingham Medical School, Birmingham, United Kingdom; [2]Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; [3]Hull University Teaching Hospital, NHS Trust, Kingston upon Hull, United Kingdom; [4]South Tyneside and Sunderland NHS Foundation Trust, Sunderland, United Kingdom; [5]Medical School, Aristotle University of Thessaloniki, Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynaecology, Greece; [6]PCOS and Hirsutism Clinic, Yeditepe University Hospital, Istanbul, Turkey; [7]Institute of Applied Health Research, University of Birmingham, Birmingham, United Kingdom

Objective
To explore the trends over time in several assessments recommended by the International PCOS guidelines during the initial consultation for women with PCOS.
Methods
This retrospective multi-centre study was conducted from July 2023 to January 2024. All women over the age of 18 who attended their first consultation in a dedicated PCOS clinic from 1st January 2020 to 31st December 2023 in the UK ($n=359$), Turkey ($n=239$), Greece ($n=92$) and Georgia ($n=10$) were included. Those undergoing follow-up or without PCOS were excluded. Data was collected on sociodemographics and assessments, including diagnosis based on guidelines, cardiometabolic risk, dermatological assessment, emotional well-being, long-term risk education, lifestyle management, and reproductive screening. Patients were categorised into four groups based on their first consultation date: A (January to December 2020), B (January to December 2021), C (January to December 2022) and D (January to December 2023). Descriptive statistics were analysed using SPSS 28.0.
Results
The most common reasons for referral across all years and centres were irregular menses (65.7%), excess hair growth (61.1%) and acne (38.9%). While irregular menses were the most common reason for referral during the pandemic (B(70.0%), C (65.1%)), women were most referred for hirsutism pre and post-pandemic (A (62.73%), D (68.31%)). The most common comorbidities across all years and centres were anxiety (9.7%), hypothyroidism (9.0%) and depression (6.7%). The most common comorbidity pre- and post-pandemic were depression (12.7%) and anxiety (11.3%), respectively. Interestingly, anxiety and depression were not among the common co-morbidities during the pandemic. During the consultation, the most common parameters assessed across all years and centres were dermatological concerns (92.4%), reproductive screening (83.0%) and lifestyle management (80.4%). Similar trends were screened across all years. Long-term risk management was the least performed recommendation per international PCOS guidelines across all years and centres (56.1%), followed by screening for emotional well-being (59.0%). There were no alterations in the trend for these parameters over time (emotional well-being: A-23.6%, B-61.4%, C-60.1%, D-81%, long-term risk management: A-26.4%, B-59.5%, C-56.3%, D-73.9%).
Conclusion
There is a gap in the assessment and education provided during PCOS consultations, specifically in emotional well-being and long-term risk management. The study emphasises the need for a standardised approach to ensure consistent and comprehensive care. Developing new models of care that prioritise emotional well-being screening and long-term risk education is crucial to addressing these gaps and improving patient outcomes.

Beyond the chromosomal tale: hyperandrogenism in turner syndrome patients

Ingrid-Ioana Stafie[1,2], Stefana Bilha[1,2], Otilia-Andreea Tarcau[1], Anca Matei[1,2], Letitia Leustean[1,2] & Cristina Preda[1,2]
[1]Saint Spiridon County Hospital, Iasi, Romania; [2]''Grigore T. Popa'' University of Medicine and Pharmacy, Iasi, Romania

Introduction
Turner syndrome (TS) is a chromosomal disorder that arises due to the complete or partial loss of one sex chromosome, impacting approximately 1 in every 2500 to 3000 female births. The phenotype is attributed to haploinsufficiency of genes on the X chromosome, which are resistant to inactivation. Virilizing symptoms appearing in a patient with TS advocates for an endocrine assessment and karyotyping to ascertain the virilization's etiology, enabling prompt intervention and prevention of further manifestations.
Case report
We present the case of a 22-year-old patient, diagnosed with Turner syndrome at the age of 1 (partial monosomoy of the short arm of the X chromosome, caused by the deletion of a Xp fragment, which included the whole SHOX gene) with short stature, cardiac malformations (operated VSD at 8-years-old) and renal abnormalities (left renal hypoplasia, neurogenic bladder, recurrent urinary tract infections). She was lost to follow-up from the age of 13 until 20 years old, when she returned for hirsutism and hyperandrogenism. The patient exhibited significant hirsutism (Ferriman score 17), mild acne, and shortened fourth metacarpal. Menarche occurred at 14 years of age with regular menstrual cycles of 30-40 days. Additionally, an abnormal upper-to-lower body segment ratio and macrocephaly were noted. Hormonal evaluation showed elevated baseline testosterone at 1.88 nmol/l, with a repeated measurement of 1.65 nmol/l, DHEAS of 534.9 μg/dl, and 17OHP at 1.28 ng/ml. The patient had a normal HOMA index of 1.4, euthyroid status, and negative ATPO antibodies.

Dexamethasone suppression resulted in an 87% decrease in testosterone and an 80% reduction in DHEAS, ruling out a tumor. Synacthen test revealed 17OHP of 2.15 ng/ml and cortisol of 24.1 µg/dl at 60 minutes, excluding congenital adrenal hyperplasia as a hyperandrogenism source. The CT scan revealed no expansive pelvic masses, excluding the presence of gonadoblastoma. MLPA technique revealed no Y chromosome fragment, but conducting FISH test is mandatory for confirmation - ongoing.

Discussions

In Turner syndrome patients with hyperandrogenism, comprehensive investigations, including genetic testing, are vital to exclude malignancies like gonadoblastoma. The presence of Y chromosome material necessitates a multidisciplinary approach involving endocrinology, genetics, and oncology for optimal management and long-term patient care.

Keywords: Turner Syndrome, hyperandrogenism, SHOX gene

Micropenis diagnosed in adolescence: etiology and treatement

Fatima Zahra Najioui[1], Ossama Achach[1], Hanae Rachedi[1], Boutaybi Latifa[1], Siham Rouf[2] & Hanane Latrech[2]

[1]Department of Endocrinology-Diabetology and Nutrition, Mohammed VI University Hospital Center, Faculty of Medecine and Pharmacy, University of Mohammed 1st, Oujda, Morocco, oujda, Morocco; [2]Department of Endocrinology-Diabetology and Nutrition, Mohammed VI University Hospital Center, Faculty of Medecine and Pharmacy, University of Mohammed 1st, Oujda, Morocco, Laboratory of Epidemiology, Clinical Research and Public Health, Mohammed VI University Hospital Center, Faculty of Medecine and Pharmacy, University of Mohammed 1st, Oujda, Morocco, Oujda, Morocco

Introduction

Micropenis represents a diagnostic and therapeutic challenge. The Diagnosis is based on the measurement of penile length. Defined by normal structure, abnormal size: -2 standard deviation (SD) below of average of age. The aim of our study is to evaluate the etiological profile and therapeutic efficacy.

Patients and methods

It's a retrospective and descriptive study including 55 childrens and adolescents with micropenis, treated with hormonal therapy followed up in the Department of Endocrinology-Diabetology and Nutrition of Mohammed VI University, Hospital Center, Oujda, in Morrocco, between 2014 and 2023. All patients in our series were received a clinical examination including measurement of penis size, biological evaluation and bone age. The statistical analysis was done by SPSS version 21.

Results

The average age of our study group was 13 ± 7 years. Forty-eights percent of the patients were the adolescents. The most frequent reasons for consultation were the Growth retardation (55%) then testicular abnormality (22%). The mean penile size is -2.40 ± 0.41 SD. Nine percent of the patients have penis anomaly and 25% have testicule anomaly. The luteinizing hormone-releasing hormone (LHRH) test was performed in 38% of the patients. The exploration revealed that idiopathic micropenis is the most frequent etiology (29%), followed by growth hormone deficiency (21%). All patients of our group were put on hormonal treatment. The transdermal dihydrotestosterone was administred at 60% of the patients and 40% at the intramuscular injection of testoterone enanthate. The post treatement evaluation revealed that the mean penile size is -1.39 ± 0.75 SD. Therapeutic efficacy was observed in 70% of patients ($P < 0.05$).

Discussion and conclusion

The Early diagnosis of micropenis is based on a thorough clinical examination of all newborns and infants, for early and appropriate management. The most etiology of Micropenis is idiopathic but it is a diagnosis of elimination. The hormonal treatment is not always effective in the puberty, hence the importance of psychological support.

Key words: Micropenis -Growth Hormone- Testosterone Enanthate.

The effectiveness of cognitive behavioral therapy on insomnia severity among menopausal women: a scoping review

Anastasia Ntikoudi[1], Dimitra Owens[2], Athanasios Tsartsalis[3], Alketa Spyrou[1], Eleni Evangelou[1], George Mastorakos[2] & Eugenia Vlachou[1]

[1]University of West Attica, Nursing, Athens, Greece; [2]National and Kapodistrian University of Athens, Athens, Greece; [3]University of West Attica, Athens, Greece

Introduction

Sleep disorders, including insomnia disorder, can affect all aspects of personal life and often occur during perimenopause, menopause, and postmenopause. Data on the number of women who suffer from sleep disorders during menopause range from 28% to 63%. Cognitive behavioral therapy for insomnia (CBT-I) is a multicomponent, drug-free treatment approach that targets behavioral and cognitive factors that contribute to chronic sleep disorders. The aim of this scope review was to evaluate the effectiveness of CBT-I on insomnia severity among menopausal women.

Methods

An extensive literature search was conducted of the Pubmed, Scopus, Cinahl and Medline electronic databases. The search yielded 459 studies, of which 8 eventually met the entry requirements for RCTs.

Results

The majority of the studies included in the current review demonstrated the benefits of CBT-I intervention in the amelioration of insomnia in menopausal women. CBT-I intervention was found to be an efficacious option for the treatment of menopausal women with insomnia with its effect to be sustained over time.

Conclusion

Further studies in larger populations are needed to confirm the effectiveness of CBT-I programs for treating menopausal insomnia.

EP752

Mixed gonadal dysgenesis; about 5 cases

Brahimi Hanane[1], Iabassen Malek[1] & Bensalah Meriem[1]

[1]Central army hospital, Algiers, Algeria

Introduction

Mixed gonadal dysgenesis is an anomaly of sexual development, it is a rare pathology, associated with a numerical anomaly of the sex chromosomes resulting from mosaicism of the Y or X chromosome and leading to abnormal development of the gonads. The most common chromosomal formulas are 45X/46 XX, 45X/46XY, 46XX/47XXX, and 46XY/47XXY. The phenotype is variable, ranging from a completely feminine appearance of the external genitalia to masculine or ambiguous. The diagnosis is made by the study of the karyotype. Management is based on the search for associated anomalies, the evaluation of gonadal function on which the choice of sex is sometimes based. Long-term monitoring is necessary to look for malignant degeneration and replace hormonal deficiencies.

Reported cases

We report 5 cases presenting mosaicism whose clinical, biological and radiological characteristics are described in the table below:

	Age	Phenotype	Karyotype	HCG stimulation test	Assigned sex
Case 1	2 months	Male with ambiguity	46XX/46XY	Negatif	FEMALE
Case 2	14 months	Female with ambiguity	46XX/47XXY	Negatif	FEMALE
Case 3	19 months	Male with ambiguity	46XX/47XXY	Negatif	FEMALE
Case 4	5 years	Female with ambiguity	45X/ 46XY	Negatif	FEMALE
Case 5	2 months	Female with ambiguity	45X/46XX	Negatif	FEMALE

Conclusion

Mixed gonadal dysgenesis is a rare pathology; in our serie, this condition represents 5% of desorders of sex development (DSD). The diagnosis is made during early childhood by the ambiguous appearance of the external genitalia and the small size in Turner syndrome, confirmed by the study of the karyotype. All cases were assigned to the female gender. The search for comorbidities is mandatory, and the risk of degeneration is not negligible, requiring regular monitoring and rigorous monitoring of tumor markers

A zebra among horses – testotoxicosis as a rare cause of peripheral precocious puberty

Viviana Popa[1], Alexandru Florescu[1,2], Andra Berigoi[1], Irina Puscasu[1], Mihaela Florea[1], Stefana Bilha[1,2] & Cristina Preda[1,2]
[1]Saint Spiridon County Hospital, Iaşi, Romania; [2]Universitatea de Medicină şi Farmacie 'Grigore T. Popa' din Iaşi, Iaşi, Romania

Introduction
Testotoxicosis, also known as familial male limited precocious puberty, is a rare cause of peripheral precious puberty caused by an activating mutation of the gene encoding for the LH receptor on Leydig cells (LHCGR gene, cr2p21). This causes autonomous testosterone production irrespective of prepubertal LH values. Ultimately, this can cause psychosocial complications; advanced bone age and low adult height; as well as central precocious puberty.
Case report
We present the case of a 5 year, 8 month old boy that was directed to the Endocrinology Clinic because of increased testicular volume, penile enlargement, and the presence of scrotal, pubic and upper lip hair. Family history was negative for precocious puberty. Clinical examination revealead a height of 119 cm (-0.42 SD) and weight of 20 kg, BMI 14.2 kg/m^2 (normal), Tanner stage 2; and wrist X-ray showed a bone age of 5 years and 6 months. Hormonal evaluation revealead a testosterone level more than 10 times the upper limit of normal for age and sex (7.22 nmol/l), with low FSH and LH levels (0.411 mIU/ml and 0.146 mIU/ml, respectively), even after Triptorelin stimulation (2.33 mIU/ml and 2.68 mIU/ml, respectively). Low 17OH-progesterone levels ruled out congenital adrenal hyperplasia. Testicular or adrenal tumors were excluded based on negative tumor markers and imaging studies; while McCune Albright syndrome and iatrogenic PPP were excluded based on history and physical examination. Therefore, testotoxicosis was diagnosed by exclusion, and treatment with aromatase inhibitors (anastrozole, 0.1 mg/day) and bicalutamide (25 mg/day) was initiated. At 3 month follow-up, no side effects were reported except for mild headache occasionally, and there was regression of pubertal signs. Gonadotropin levels remained low, while elevated testosterone persisted; and bone X-ray didn't demonstrate advancement of bone age. At the moment, genetic studies are underway to identify the causing mutation.
Conclusion
Testotoxicosis is a rare form of PPP, and the limited studies available suggest optimal treatment is with a combination of aromatase inhibitors and antiandrogen medications. Testosterone levels shouldn't be used as a marker for treatment efficacy, as elevated levels can persist; but rather focus should be on gonadotropin levels and decreasing the bone age to chronological age ratio, if advanced at diagnosis. Finally, genetic studies of the child and both parents should be carried out whenever possible, as the causing mutation is usually inherited in an autosomal dominant manner, and females can be asymptomatic carries, but de novo mutations can also occur in previously unaffected families.

EP771

An unusual case of arrested puberty and management of puberty induction in the adult endocrine clinic

Lee Si Min[1], Fernando Loo Jia Jing[2] & Brenda Lim Su Ping[2]
[1]Changi General Hospital, Singapore, Singapore; [2]Tan Tock Seng Hospital, Singapore, Singapore

Introduction
Puberty is the process of transition from childhood to adult reproductive capability, body composition, and adult height. In males, the lack of Tanner stage progression after achieving a testicular size of at least 4 cubic cm (cc) suggests pubertal arrest. While delayed puberty could be a normal variant, arrested puberty is usually pathological, and points towards an acquired pathology rather than a congenital disorder. We describe an unusual case of arrested puberty from subclinical pituitary apoplexy.
Case report
An 18-year-old male was referred to our adult endocrine clinic with arrested puberty. Initial examination revealed short stature (height 163 cm), eunuchoid body habitus, a high-pitched voice and minimal secondary sexual characteristics (Tanner Stage 1 for pubic hair). Bilateral testes were descended with testicular volumes of 8cc (Tanner Stage 2 for external genitalia). Initial investigations revealed central hypothyroidism (FT4 8.0 pmol/l, TSH 1.54 mIU/l), hypogonadotropic hypogonadism (total testosterone <1 nmol/l, FSH 2 IU/l, LH 2 IU/l) and growth hormone deficiency (GHD) (IGF-1 43 mg/l). The bone age was delayed at 15 years old when the patient's chronological age was 18 years old and 9 months. MRI brain showed a 2.6 cm T1- hyperintense sellar-suprasellar mass with chiasmal compression, suggestive of pituitary apoplexy. Endonasal transsphenoidal marsupialisation was performed and histology revealed necrotic tissue. His post-operative course was complicated by pituitary abscess, requiring surgical drainage. He developed panhypopituitarism and central diabetes insipidus and was treated with thyroxine, hydrocortisone and intranasal desmopressin. Glucagon stimulation test confirmed persistent GHD (peak GH 0.06 mg/l). SC somatropin 1.2 mg daily was initiated to optimise adult height. The patient was counselled regarding options for puberty induction including testosterone replacement or gonadotrophin therapy. He opted for testosterone replacement and was initiated on IM testosterone 50 mg every 4 weeks. Whilst on concurrent growth hormone replacement and puberty induction, he grew 8 cm over 11 months with increase in penile length and progression to Tanner stage 2.
Conclusion
Pubertal arrest is usually pathological. In this case, pubertal arrest was an atypical presentation of subclinical pituitary apoplexy. Puberty induction in an adolescent with delayed presentation of pubertal arrest and hypopituitarism is challenging. It requires careful titration of multiple hormonal regimens to optimise the final adult height, secondary sexual characteristics and bone health.

Influence of aromatase inhibitors on metabolic parameters in obese male patient

Shota Janjgava[1], Revazi Jamburia[1], Ana Davitashvili[1], Tekle Bakhtadze[1], Medea Zhgenti[1] & Natia Goletiani[1]
[1]National Institute of Endocrinology, Endocrinology, Georgia

Overview
Numerous epidemiological studies have demonstrated that low testosterone levels are linked to poor life quality and sexual quality, and that hypoestrogenic hypogonadism in obese male patients is connected with and predicts the development of metabolic syndrome and type 2 diabetes in the future. The purpose of the study was to demonstrate how aromatase inhibitors affected anthropometric traits, HOMA-IR, blood pressure, glycosylated hemoglobin level, and dyslipidemia in individuals with hyperechogenic and metabolic syndrome.
Resources and Techniques
85 males with a BMI of 35.83 ± 3.65 kg/m^2 and an age of 35 ± 6.74 were randomly selected among 125 male patients with hypoestrogenism and obesity for a placebo-controlled trial. Patients were split up into three groups: 1) The first group received standard treatment. 2) The second group received standard aromatase inhibitor medication. 3) The third placebo group received standard care along with a placebo. We incorporated life style modification to all groups.
Results
We retook the diagnostic evaluations six months after starting treatment; lipid profile and free testosterone levels improved in all groups, but it was statistically significant in group II. All groups saw a drop in HbA1c, although group II saw the greatest improvement. All groups experienced a decrease in blood pressure, with comparable outcomes.
Conclusion
In obese male patients with hypoestrogenic hypogonadism, our study showed that increasing testosterone and adjusted estrogens can manage blood pressure, lipid profile, HbA1c, and HOMA.

EP873

Complications of hysteroscopic surgery in gynecology: analysis of frequency and risk factors following 2,650 operations at a single institution

Hee Dong Chae[1]
[1]ASAN Medical Center, Department of Obstetrics and Gynecology, Seoul, Korea, Republic of South

Objective
To determine the frequency of complications after hysteroscopic surgery and to analyze the risk factors associated with these complications.
Materials and Methods
We retrospectively analyzed outcomes in 2,650 patients who underwent hysteroscopic surgery at Asan Medical Center between January 1996 and September 2023.

Results
Indications for hysteroscopic surgery included submucosal myoma on ultrasonography in 910 patients, space-occupying lesion in the endometrial cavity on ultrasonography in 1,392, abnormal uterine bleeding in 57, uterine synechiae in 221, uterine septum in 25, and removal of intrauterine device in 30. Mean patient age was 40 years (range, 12-74 years). One hundred forty eight patients had a previous history of uterine surgery (cesarean section in 128 and myomectomy in 20). Operative complications occurred in 80 patients (3.02%), including 30 with uterine perforations, 38 with excessive bleeding, and 12 with postoperative infections. In univariable analysis, age $\geq$40 years ($P=0.002$), nulliparity ($P=0.008$), and body mass index $<$20 kg/m^2, and distension media volume $\geq$2,040 ml ($P=0.008$) were significantly associated with a higher risk of complications, but menopause, previous history of uterine surgery, use of Laminaria or misoprostol, type of distension media, postoperative compression of the endometrial cavity, and operating time were not. In multivariable analysis, body mass index $<$20 kg/m^2 (OR, 2.97; 95% CI, 1.41-6.22; $P=0.004$) and distension media volume $\geq$2,010 ml (OR, 2.56; 95% CI, 1.22-5.36; $P=0.013$) were significantly associated with increased risk of complications. Of several types of surgical procedures, hysteroscopic polypectomy was associated with significantly lower (odds ratio, 0.367; 95% CI, 0.161-0.835; $P=0.017$) and hysteroscopic adhesiolysis with significantly higher (odds ratio, 3.521; 95% CI, 1.525-8.127; $P=0.003$) risks of complications.
Conclusion
Hysteroscopic surgery is a safe procedure, with a very low (3.02%) complication rate. Body mass index $<$20 kg/m^2 and distension media volume $\geq$2,040 ml, and hysteroscopic adhesiolysis were associated with higher risks of complications, but hysteroscopic polypectomy was associated with a lower risk of complications.
Keywords: hysteroscopy; hysteroscopic surgery; complication; frequency; risk factor

The effect of hyperprolactinemia on the hormonal profile of women with recurrent miscarriage

Diyora Mukhammedaminova[1], Sevara Sadrieva[1] & Khurshidakhon Nasirova[1]
[1]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

Introduction
Hyperprolactinemia is characterized by persistently elevated levels of prolactin in the blood serum, with its most common manifestation being a disruption of the reproductive system. Hyperprolactinemia contributes to inadequate endometrial preparation for pregnancy, insufficient implantation of the fertilized egg, and may also exert pathological effects on the production of gonadotropin hormones.
Objective
To investigate the hormonal status of patients with recurrent miscarriage (RM) in the first trimester with hyperprolactinemia.
Materials and methods
A total of 54 women in the first trimester of pregnancy were selected for this study. Among them, 34 pregnant women experienced RM in the first trimester with hyperprolactinemia, while 20 had a normal course of pregnancy. The average age in the hyperprolactinemia group was 30 ($\pm$4.8) years, and in the control group, it was 28 ($\pm$4.1) years. The main diagnostic materials included the concentration of prolactin, inhibin A, FSH, and LH in the blood.
Results
Analysis of hormonal indicators revealed the following: prolactin concentration in the first trimester in women with RM was significantly higher than normal (4075.7$\pm$1103.2 ng/ml), while in patients with a normal course of pregnancy, it was 1015$\pm$332.4 ng/ml. Patients with RM and hyperprolactinemia showed an increase in the concentration of FSH and LH, which was 16.3$\pm$2.1 mIU/ml and 1.14$\pm$0.54 mIU/ml, respectively, compared to the control group with values of 0.19$\pm$0.19 mIU/ml and 0.66$\pm$0.34 mIU/ml. The level of inhibin A decreased almost twofold (133.9$\pm$13.4 pg/ml) in women with RPL, while in the control group, inhibin A concentration remained within the normal range (617.3$\pm$252.8 pg/ml).
Conclusion
1. Hormonal analysis among women with hyperprolactinemia indicates that an increase in prolactin significantly elevates levels of FSH and LH compared to patients with reference values.
2. Our study revealed that a decrease of inhibin A levels is associated with hyperprolactinemia, indicating a risk of pregnancy loss.

Prevalence of polycystic ovary syndrome and infertility in hidradenitis suppurativa

Malek Cherif[1], Rim Chaabouni[1], Fatma Hammami[1], Abdel Mouhaymen Missaoui[2], Khadija Sellami[1], Nabila Rekik[2] & Hamida Turki[1]
[1]Hedi Chaker University Hospital, Dermatology, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Endocrinology, Sfax, Tunisia

Introduction & Objective
Hidradenitis suppurativa (HS) is an inflammatory skin condition which predominantly affects women of childbearing age. Various metabolic and endocrine comorbidities can be associated with HS. The aim of this study was to evaluate the association of HS with male and female infertility.
Materials and Methods
We conducted a retrospective study between January 2012 and December 2022 enrolling all cases of HS in our dermatology department. The diagnosis of polycystic ovary syndrome (PCOS) was made in accordance with the revised Rotterdam criteria from 2003.
Results
We identified a total of 77 cases, with an average age of 39 years and a male-to-female sex ratio equal to 4,1. Among 15 women, four (26,7%) experienced fertility issues. The average age was 27,5 years (20-45 years), and in three cases (75%), HS occurred at a pediatric age (below 18 years). The diagnosis of PCOS was confirmed in two patients (13,3%) presenting with moderate to severe obesity (average BMI$=$35 kg/m^2). Clinical presentations included irregular menstrual cycles and late-onset acne, indicative of clinical hyperandrogenism. Besides, hirsutism with an elevated blood testosterone level (3,99 nmol/l) was observed in one other young patient. The fertility assessment conducted in a reproductive-aged patient revealed hyperprolactinemia associated with a pituitary adenoma. HS manifested in these patients with either axillo-mammary (LC1) or follicular (LC2) phenotype (50% each), and classified as Hurley I or II. A treatment plan involving metformin and a dietary supplement containing myo-inositol and folic acid was prescribed for a single patient diagnosed with PCOS and prediabetes (fasting blood glucose level of 1.21 g/l). Finally, five married men (8,1%) reported unexplored infertility and/or sexual impotence.
Conclusions
Based on previous data, patients with HS face an elevated risk of infertility, particularly among females and individuals aged 36 to 45. Both HS and PCOS affect similar demographics, may be complicated by obesity and metabolic syndrome, and respond to antiandrogen agents. Our data align with those of other previous studies, such as the one by Garg *et al*., where the prevalence of PCOS in patients with HS was 9%. According to the adjusted analysis, the risk of PCOS would be twice as high in women with HS, independent of the influence of obesity and diabetes. In addition, because HS involves the inframammary folds, groin, genitals, and buttocks, patients with HS may be at risk for sexual dysfunction, including abnormal sexual function, impairment, and distress.

EP876

Correlating adiposity with metabolic disturbances in PCOS patients: a single-centre retrospective study

Puja Thadani[1], Bianca Leca[1], Uzma Khan[1], Danielle Bate[1], Allan Davasgaium[2,3], Rajan Mattu[1] & Harpal S. Randeva[1]
[1]University Hospitals Coventry and Warwickshire NHS Trust, Diabetes and Endocrinology, Coventry, United Kingdom; [2]University Hospital Coventry & Warwickshire, WISDEM, United Kingdom; [3]University Hospital Coventry & Warwickshire, WISDEM, Coventry, United Kingdom

Introduction
Polycystic Ovary Syndrome (PCOS) affects 5-10% of childbearing females and, up to 20% in specific ethnic populations (i.e. South Asians and Hispanics). It is linked with a higher prevalence of obesity and metabolic dysfunction, resulting in increased risk for dyslipidaemia, impaired glucose tolerance, type 2 diabetes mellitus (T2DM) and cardiovascular diseases.
Methods
This is a retrospective study of patients diagnosed with PCOS ($n=142$) based on the European Society of Human Reproduction and Embryology (ESHRE) criteria. Data was collected from case notes and electronic records for patients diagnosed from January to December 2019. Medical history, anthropometric and bioimpedance data, including fat percentage (fat%), total fat mass and total fat-free mass, were recorded. Biochemical assessments were carried out in the early follicular phase of the menstrual cycle to assess biochemical androgen excess (Free Androgen Index – FAI) and screen for metabolic co-morbidities. Patients were grouped based on phenotype: A - anovulatory cycles (ANOV), clinical

and/or biochemical hyperandrogenism (HA), and polycystic ovarian morphology (PCO), B (ANOV + HA), C (HA + PCO) and D (ANOV + PCO). Statistical analysis was performed using SPSS statistics version 29.0, considering $P < 0.05$ statistically significant.

Results

The mean age was 29.08 ± 5.95 years. Most women had BMI greater than 40 kg/m^2 (40.6%). Hyperandrogenic PCOS phenotypes were most common: Phenotype A in 51.7%, Phenotype B in 25.2% and Phenotype C in 11.9%. The analysis revealed significant correlations for Fat% in PCOS patients. There was a positive correlation between fat% and age ($r = 0.227$, $P < 0.05$), and a strong positive correlation with the Free Androgen Index (FAI) ($r = 0.292$, $P < 0.01$), indicating higher fat mass is associated with older age and increased androgen levels. Additionally, fat% was positively correlated with total cholesterol (TC) ($r = 0.234$, $P < 0.05$), the TC to high-density lipoprotein ratio (TC: Hdl) ($r = 0.379$, $P < 0.001$), triglycerides ($r = 0.327$, $P < 0.01$) and Haemoglobin A1c (HbA1c) ($r = 0.312$, $P < 0.01$). These correlations suggest that higher body fat percentage may be related to a greater risk of dyslipidaemia and impaired glucose metabolism.

Conclusion

This study showed that adiposity is significantly linked to key metabolic markers such as TC, TC:HDL ratio, triglycerides, and HbA1c, all of which are known risk factors for cardiovascular diseases. It highlights that body fat%, as measured by bioimpedance, is an important variable in the metabolic profile of women with PCOS, with implications for cardiovascular risk and impaired glucose metabolism. These results suggest that monitoring and managing adiposity is essential to reduce cardiovascular and metabolic risk in women with PCOS.

Successful testicular descent induced by gonadotropin replacement therapy in young men with congenital hypogonadotropic hypogonadism

Du Soon Swee[1] & Jielin Yew[2]
[1]Singapore General Hospital, Endocrinology, Singapore; [2]Changi General Hospital, Endocrinology, Singapore

Congenital hypogonadotropic hypogonadism is a rare reproductive disorder characterised by isolated deficiency in the secretion or action of gonadotropin-releasing hormone (GnRH). Diminished GnRH activity in the immediate postnatal months, a period known as minipuberty, has severe consequences on the ontogenesis of male reproductive tract. Affected infant boys may present with micropenis and cryptorchidism. Rarely, adolescents with CHH present with delayed puberty in association with cryptorchidism. While the use of gonadotropins to treat CHH-associated cryptorchidism in infancy is increasingly recognised as a safe and effective therapy, there is scarce data on its utility in adolescents or young adults. Indeed, if such treatment is shown to be efficacious beyond childhood, patients could potentially be spared from surgical orchidopexy. We report two young men who had successful hormonal induction of testicular descent. The first case was a 19-year-old male referred for pubertal failure. He had childhood history of micropenis as well as surgery for undescended testes at 5 years old. Testes were, however, not palpable during examination. Penile length was 4 cm, and there was no sign of any secondary sexual characteristics. Ultrasound scan demonstrated undescended testes (Right: 0.6×0.7×0.8 cm, Left: 0.7×0.8×1.3 cm) in the inguinal canal bilaterally. Kallmann syndrome was subsequently diagnosed based on anosmia and hypogonadotropic hypogonadism (FSH 0.4 U/l, LH <0.1 U/l, testosterone 0.78 nmol/l). Sequential gonadotropin therapy was started with hMG (75 IU daily for 4 weeks) followed by combined hMG and hCG therapy, which were up-titrated to 150 IU 3×/week and 1,500 IU 3×/week respectively. Ultrasound repeated 12 months later showed descent of testes into scrotum bilaterally (Right: 0.9×1.1×1.7 cm, Left: 1.0×1.4×2.4 cm). The second case was a young man who was referred at age 22 years for undervirilisation. Both testes were non-palpable. Biochemistry showed FSH 2.3 U/l, LH 0.8 U/l and testosterone 1.4 nmol/l. Ultrasound confirmed bilateral undescended testes in the upper part of the groin area, on either side of the base of penis (Right: 1.4×1.0×0.8 cm, Left: 1.5×1.1×0.7 cm). Patient was first given FSH monotherapy (75 IU, 3×/week) for 4 months, after which hCG was added and up-titrated to 1,500 IU 2×/week. Ultrasound was repeated 8 months later to reassess testicular position, which showed that the descent of testes into the mid-scrotum, along with a threefold increase in the testicular volume. In concordance, serum inhibin B level rose from baseline 21 pg/ml to 61 pg/ml.

Reference ranges of total testosterone in eastern algerian men

Sara Kendri[1,2], Sarra Zouai[1,2], Anis Amara Korba[1,2] & Farida Djabi[1,2]
[1]Faculty of Medicine, Ferhat Abbas University, Sétif, Algeria; [2]Central Laboratory, University Hospital of Sétif, Sétif, Algeria

Reference ranges are the most common decision support tool used for results interpretation and so a very relevant part of the laboratory report. Their use has become increasingly prevalent in clinical practice. A low serum testosterone (T) level in combination with clinical signs and symptoms are required for hypogonadism diagnosis. The goal of this research was to establish the reference intervals of total testosterone (TT) from healthy adult males. The study sample consisted of 179 adult males aged 18 – 63 years and stratified into three age groups: 18-33, 34-42, and 43-63 years, with measured serum concentrations of TT by electrochemiluminescence immunoassay (Cobas e411®, Roche diagnostics). The 2.5th to 97.5th percentiles of subjects for TT were used as the normative range with parametric method. The mean serum TT level for the three age groups: 18-33, 34-42 and 43-63 years were 419 ± 139, 387 ± 135 and 379 ± 134 ng/dl respectively. We found a statistically significant age-related decrease for serum concentrations of TT ($P < 0.001$). The population mean TT was 394 ± 136 ng/dl. The 95% reference interval (with 90% confidence interval) of serum TT from all participants ranged from 126 (97-155) to 662 (633-691) ng/dl. We generated reference ranges for total testosterone specific for our population using data from apparently healthy men, that could be used for results interpretation in our laboratory because population-specific reference ranges are needed to understand normal vs abnormal TT levels. This study can be helpful in broader research to calculate age-specific reference ranges and cutoffs of TT for the diagnosis of male hypogonadism.

Two sides of the same coin: infertile couple

Elena Moravcikova[1], Helena Urbankova[1], Peter Vanuga[1] & Michal Kulich[1]
[1]National endocrinology and diabetology institute, Endocrinology department, Ľubochňa, Slovakia

Introduction

Our case is a young couple, both endocrinologically monitored from childhood. Woman with diagnosis of oligomenorrhea – secondary amenorrhea. Man with delayed puberty. After complex endocrinological screening both diagnoses was changed to: woman diagnosed with prolactinoma and man with isolated idiopathic central hypogonadism (IICH). They were trying to concieve for 10 years with no succes.

Case

Woman: At 17 years of age diagnosed cystic degenerative pituitary adenoma with compression of the optic chiasm, producing prolactin. Surgery was carried out. After surgery hyperprolactinomia persisted. Treatment with dopamine agonists was introduced. Treatment with bromocriptine was not tolerated with gastrointestine tract. Quinagolide and cabergoline produced insufficient decline of prolactine levels even at maximum dosing. Residuum of tumor showed little growth progress. Primary infertility, persisting secondary amenorrhea and growth of tumor residuum led to second surgery at 30 years of age. Before that she underwent several unsucessful IVF treatment rounds. After surgery MRI scan showed that pituitary tumor was resected completely. Levels of prolactine reached normal values and other pituitary hormones remained functional. Normal menstrual cycle was regained with succesful spontaneous gravidity within one month after surgery. After 3 years second spontaneous gravidity followed. *Man:* Diagnosed with IICH. At 16 years of age diagnosed with delayed puberty with genital hypoplasia. Anosmia was not present. MRI of hypothalamo pituitary area showed no deposit. Cythogenethic survey confirmend normal male karyotype. Also oligoteratozoospermia and spermiogram surveys were carried out. Treatment with chorione gonadotropine with slow enhancement of clinical picture. Treatment of central hypogonadism continued also in adult age.

Conclusion

Woman with pituitary adenoma caused hyperprolactinemia underwent repeated change of medical treatment and two surgeries with complete remission. Man diagnosed with IICH, at first treated with chorionic gonadotropin injection. After second succesful gravidity treatment was changed to DEPO testosterone injection. Two sucesfully treated endocriopathies led to spontaneous gravidity.

Implications of x-linked adrenoleukodystrophy in different family members

Luciana Tonkic[1], Tanja Miličević Milardović[1] & Anela Novak[1]
[1]University Hospital of Split, Internal Medicine Department, Endocrinology, Diabetology, and Metabolism Division, Split, Croatia

Adrenoleukodystrophy (ALD) is a monogenic, X-linked hereditary disorder. Mutation in the ABCD1 gene results in the adrenoleukodystrophy protein (ALDP) deficiency which is involved in the intracellular transport and metabolism of very long-chain fatty acids (VLCFAs). Consequently, VLCFAs accumulate in the central and peripheral nervous systems and adrenal glands leading to the destruction of affected tissues and specific symptoms and signs. There are four distinct types of ALD with adrenomyeloneuropathy being an adult variant. We present a male patient who was hospitalized at the age of 47 with a clinical picture of adrenal insufficiency and progressive paraparesis that made him reliant on a wheelchair. The adrenomyeloneuropathy was suspected. Laboratory results showed low serum cortisol level and normal levels of renin and potassium. The VLCFAs analysis showed the elevated concentration of cerotic acid (C26:0) as well as the elevation of cerotic and lignoceric (C24:0) to behenic (C22:0) fatty acids ratios which confirmed the clinical diagnosis. Genetic testing revealed the hemizygous variant of uncertain meaning in the ABCD1 gene [c.251C > T (p.Pro84Leu)]. Replacement therapy with hydrocortisone was started and since renin, potassium, and blood pressure values were normal, there was no need for mineralocorticoid substitution. At the very beginning of the treatment, the patient took smaller doses of glucocorticoids, which did not lead to the neurological improvement. Because of the above, the total daily hydrocortisone dose was gradually increased to 40 mg and he was able to walk with the help of a cane. As our patient had two daughters, genetic counselling and testing were arranged. Both daughters were healthy but heterozygous carriers of the ABCD1 gene mutation. For heterozygous female carriers, the probability for transmission of the affected gene is 50% for both sons and daughters. It should be taken into account that all affected sons develop disease while daughters are mostly mutation carriers. Therefore, planned pregnancy with the preimplantation genetic testing (PGT) and gender selection is a valuable option. PGT involves in vitro fertilization (IVF), biopsy of the blastocyst, and the transfer of the selected embryo into the uterus. PGT is an option for couples who want to avoid gender-related disorders in offsprings and is mostly allowed for medical reasons in different European countries. In our case, despite genetic counselling, the older daughter had an unplanned pregnancy and gave birth to a clinically healthy son (results of genetic testing are awaited). The younger daughter is going to Belgium for a planned pregnancy.

Unusual PCOS presentation and/or functional amenorrhea

Tea Shehu[1]
[1]Salus Hospital, Endocrinology department, Internal medicine department., Tirane, Albania

Introduction
Polycystic ovary syndrome (PCOS) is a multifaceted endocrine disorder traditionally classified into four phenotypes. A recently proposed hyper-/hypoandrogenic phenotype (HH-PCOS) falling under the D phenotype introduces additional complexity, emphasizing the spectrum of androgenic manifestations within this heterogeneous syndrome. This case report focuses on the complexities associated with PCOS diagnosis, particularly in the context of unconventional presentations especially when androgen levels are low.
Case Presentation
A 24 years old lady, with a history of Hashimoto thyroiditis and positive anti-TPO antibodies, presented with irregular menstrual cycles (five per year), a low BMI, Tanner 2 breast development, and halted puberty breast development. Laboratory findings revealed normal TSH, prolactin, follicular phase estradiol, an LH/FSH ratio of 1.46, elevated anti-Müllerian hormone (AMH), low testosterone, and high sex hormone-binding globulin (SHBG). Imaging showed a polycystic ovary appearance. A progesterone withdrawal test led to withdrawal bleeding, supporting presence of PCOS in contrary to functional component. The patient has a short history of living abroad with higher BMI, which was related to occurrence of acne in her face.
Discussion
While fulfilling Rotterdam criteria for PCOS, the case presented challenges due to conflicting hormonal indicators. Notably, the patient's low testosterone and high SHBG levels deviated from the typical PCOS profile. Features resembling hyper-/hypoandrogenic PCOS (HH-PCOS), such as autoimmune markers and a lean BMI, were present. However, considering the patient's low BMI and age, functional amenorrhea was also considered.
Conclusion
This case underscores the complexity of diagnosing PCOS, particularly in patients with atypical hormonal profiles and low BMI. The coexistence of lean PCOS and functional amenorrhea, or a unique PCOS variant, poses diagnostic challenges. The patient's history of living abroad with a higher BMI and the occurrence of acne further complicate the clinical picture. Clinicians should be aware of nuanced presentations and consider alternative diagnoses when faced with conflicting hormonal evidence, such as low testosterone levels. This case highlights the need for individualized approaches in diagnosing and managing PCOS, especially when fertility is desired.

Male hypogonadism: an often overlooked consequence of substance use

Ilona-Beatrice Blesneac[1], Diana Nita[1], Otilia-Andreea Tarcau[1], Robu Larisa[1], Andreea Rosu[1], Anca Matei[1,2], Alexandru Florescu[1,2] & Cristina Preda[1,2]
[1]"Sf. Spiridon" Clinical Emergency County Hospital, Endocrinology, Isai, Romania; [2]Grigore T. Popa' University of Medicine and Pharmacy, Medicine, Isai, Romania

Introduction
Western countries present a gradual decline in male reproductive function. The decline in testosterone levels and sperm production witnessed over the past five decades, has been ascribed to environmental factors and unhealthy behaviors. Substance and drug usage is recognized as a detrimental lifestyle choice, that can interfere with the processes of steroidogenesis and spermatogenesis. Hypogonadism due to substance and drug abuse can be reversible.
Case report
A 40-year-old male patient was admitted to the endocrinology department 7 years ago, for general fatigue, low libido, and erectile dysfunction. He had no known medical history and physical examination revealed no significant findings. The biochemical analysis was normal, and hormonal tests shown hypogonadotropic hypogonadism with slightly low testosterone levels on two measurements, while the other axes - thyroid, somatotropic, corticotropic, lactotropic, and thyroid - were within normal limits. In the first two years after initial presentation, the patient underwent multiple investigations for an organic cause. Hypothalamic-pituitary MRI, testicular ultrasound, and abdominal-pelvic ultrasound were normal. DXA scan reveals decreased bone mineral density with mild vitamin D deficiency, so vitamin D treatment was initiated. During this time, his wife becomes pregnant. Two years after the initial presentation, hormonal evaluation reveals severe hypogonadotropic hypogonadism with very low testosterone, leading to the initiation of injectable testosterone treatment. Two years later, a semen analysis shows azoospermia, and testosterone treatment is discontinued. After stopping testosterone treatment, the patient continues to show hypogonadotropic hypogonadism with slightly low testosterone, and semen analysis reveals asthenozoospermia. His wife becomes pregnant again. Currently, the patient returns to our endocrinology department for reevaluation, where a complete pituitary assessment shows normal results, with no hypogonadotropic hypogonadism, but testosterone levels at the lower limit. In his medical history, the patient admits for the first time to consuming illicit substances (cocaine, codeine, amphetamine, synthetic drugs) and alcohol over the past years, with a reduction in frequency after the onset of the COVID-19 pandemic.
Conclusions
The widespread production and consumption of drugs poses a significant threat to public health. Concurrent abuse of more than one substance can have unpredictable effects, but they are often additive. When assessing a patient for hypogonadism, it is essential to inquire about the use of illegal drugs and other substances like tobacco and alcohol, particularly important in younger men, when no underlying organic causes of hypogonadism can be identified. Substance discontinuation typically results in the resolution of hypogonadism and should be strongly advised.

Genetics of the y chromosome in male infertility

Hamdi Frikha[1], Nesrine Dhieb[1], Souhir Maalej[1], Khouloud Boujelben[1], Dhoha Ben Salah[1], Faten Haj Kacem Akid[1], Fatma Mnif[1], Nadia Charfi[1], Mouna Mnif[1], Mouna Elleuch[1], Mohamed Abid[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Tunisia

Introduction
Couple's infertility is a major public health problem. Its prevalence is estimated at 15%. In half of the cases, this infertility is of male origin. Different etiologies may

be involved, among which genetic abnormalities of the Y chromosome. In this context, we report the cases of two patients with a structural abnormality of the Y chromosome responsible for the abnormalities of spermatogenesis
Case Description
The first 26-year-old case presents for hyper gonadotropic hypogonadism and short stature with biologically a Testosterone level of 2.83 ng/ml contrasting with an increased level of FSH at 20.6 mIU/ml, and a LH level of 5.17 mIU/ml. The testicular ultrasound showed bilateral testicular hypotrophy with a left testis measuring 4.7 cc and a right testicle measuring 4.8 cc. The spermogram showed a reduced ejaculatory volume to 1.3 ml with azoospermia. The genetic study concluded in an isodicentry of the short arm of the Y chromosome with a marked breakpoint in the Yq11.22 region, found in 85% of cells. This chromosomal abnormality is responsible for a total deletion of the Azoospermia factor b (AZFb) and Azoospermia factor c (AZFC) regions, which could explain azoospermia in our patient. The second cell population is monosomy X. The latter is responsible for a single copy of the SHOX gene, involved in height development. The second 29-year-old case presents for morbid obesity and hypergonadotropic hypogonadism with a biology of testosterone at 1.47 ng/ml, FSH at 16.4 mIU/ml, and LH at 5.17 mIU/ml. The testicular ultrasound showed reduced testicles. The spermogram revealed extreme oligoasthenospermia. The genetic study objected to a deletion in the long arm of the Y chromosome carrying the spermatogenesis regulatory genes, involving the Azoospermia factor (AZF) region
Discussion
The study of structural abnormalities of the Y chromosome has made it possible to assign certain regions of this chromosome a major role in spermatogenesis and whose detailed characterization makes it possible to offer the patient an adapted treatment in terms of genetic counseling, preventive self-preservation, and hope of fatherhood

Diagnosis of hyperandrogenism-insulin resistance-acanthosis nigricans syndrome during transition: a case report

Najoua Lassoued[1], Elloumi Yassmine[1], Zantour Baha[1], Alaya Wafa[1] & Sfar Habib[1]
[1]Taher Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia

Background
HAIR-AN, a syndrome of hyperandrogenism (HA), insulin resistance (IR) and acanthosis nigricans (AN), is a specific subphenotype of polycystic ovary syndrome, and it is seen in almost 5% of all women with hyperandrogenism. We report the case of a HAIR-AN which posed a diagnostic challenge in a 16-year-old girl.
Case Presentation
A 16-year-old girl was referred by her pediatrician to the Endocrinology Department for exploration of primary amenorrhea. The patient was followed in pediatrics since the age of 6 for primary hypothyroidism with progressive onset of morbid obesity. On physical examination, the BMI was 30 kg/m^2. She had a Tanner stage 5. She had moderate hirsutism with a Ferriman-Gallwey score of 20. Acne was visible over her face and back. She had severe acanthosis nigricans on both axillae and neck. Lab tests revealed testosterone level at 1.13 ng/ml, SDHEA level at 611 µg/dl and delta 4 androstenedione at 4.1ng/ml with E2 at 52 pmol/l, FSH at 2.04 IU/l and LH at 5.3 IU/l. Fasting insulin levels were elevated at 35 µIU/ml with high HOMA-IR at 6.16. We ruled out the diagnosis of congenital adrenal hyperplasia, hyperprolactinemia, Cushing's Syndrome and virilizing tumor of the adrenals or ovaries. Given the above features, the diagnosis of HAIR-AN syndrome was made. The patient was started in metformin along with lifestyle modifications. Four months later, she reported that a decrease in hirsutism starting the treatment and she lost two pounds.
Conclusions
In the presence of hirsutism and signs of insulin resistance in an adolescent consulting for primary amenorrhea, the diagnosis of HAIR-AN syndrome should be considered. This diagnosis could be difficult in the peripuberty period and the collaboration between pediatrician and endocrinologist is important to eliminate all the other differential diagnoses at this age.

Predictors of quality of life according to nationality in patients with polycystic ovary syndrome: a multinational cross-sectional study

Elleuch Mouna[1], Elloumi Yesmine[1], Ben Salah Dhoha[1], Boujelben Khouloud[1], Krichen Zeineb[1], Ellouze Roua[1], Mnif Fatma[1], Mnif Mouna[1], Hadj Kacem Faten[1], Charfi Nadia[1], Abid Mohamed[1] & Rekik Majdoub Nabila[1]
[1]Hospital of Hedi Chaker

Background and Aims
Polycystic ovary syndrome (PCOS) may be the most common endocrine disorder in women of reproductive age. The Rotterdam criteria are the most accepted criteria for its diagnosis. The aim of this study is to study the predictors of quality of life in patients with PCOS according to nationality.
Methods
A cross-sectional study involved 172 women, 101 of them Tunisian and 71 French. Data collection was based on telephone interviews with tunisian subjects who were diagnosed with PCOS based on rotterdam criteria and french patients via Google Forms over an international group specifically for women with PCOS.
Results
The mean age of the patients was 27.34 years, with extremes ranging from 14 to 49 years. More than half of the patients were Tunisian (58.72%) and 51.74% of the patients were married. The comparative study between the two groups of patients showed that the French women were more professionally active ($P=0.05$) and were more frequently married (63.38%) vs (43.56%). However, the level of education was higher among Tunisian women who had more university degrees ($P=0.003$). The statistical study showed that menstrual irregularity was more frequent in French women (84.51%) than in Tunisian women (70.3%). However, hypofertility was more frequently reported by married French women. There was no difference between the two groups in terms of pregnancy. Obesity was reported in 32.6% of Tunisian women. Similarly, fatigue and hirsutism were more frequently observed in French women. Acne, however, was more frequent in Tunisian women. A climatic explanation may be proposed. In terms of treatment, 50.70% of French women had a treatment strategy indicated for them, compared with 25.74% of Tunisian women. Physical activity and diet were also applied in both groups, with no significant difference.
Conclusion
These results may have implications for the clinical practice and suggest the need for specific interventions in women with PCOS.

Impact of PCOS phenotypes on quality of life: insights from a serbian pilot study

Milica Opalic Palibrk[1], Sanja Ognjanovic[1], Bojana Popovic[1], Dusan Ilic[1], Jelica Bjekic Macut[2], Valentina Elezovic Kovacevic[1], Lena Radic[1], Katarina Krstic[1], Sarantis Livadas[3], George Mastorakos[4] & Djuro Macut[1]
[1]University Clinical Centre of Serbia, Clinic of Endocrinology, Diabetes and Metabolic Diseases, Beograd, Serbia; [2]University Hospital Medical Center Bezanijska Kosa, Department for endocrinology, Belgrade, Serbia; [3]Athens Medical Centre, Endocrine Unit, Athens, Greece; [4]Unit of Endocrine Diseases, Aretaieion Hospital, National and Kapodistrian University of Athens, Athens, Greece

Introduction
Polycystic Ovary Syndrome (PCOS) stands out as the most prevalent endocrine disorder affecting women during their reproductive years. Diagnosis typically relies on the ESHRE/ASRM criteria, necessitating the presence of at least two of three criteria: anovulatory dysfunction (ANOV), hyperandrogenism (HA), and morphologically polycystic ovaries visualized through ultrasound (PCOM). Using these criteria, patients can be classified into four phenotypes: PCOS-A (HA + ANOV + PCOM), PCOS-B (HA + ANOV), PCOS-C (HA + PCOM), and PCOS-D (ANOV + PCOM). Our pilot study aimed to evaluate the quality of life in various PCOS phenotypes within the Serbian population, using the Serbian version of the Health-related Quality of Life Questionnaire for Polycystic Ovary Syndrome (PCOSQ-50).
Subjects and methods
We analyzed 46 women with PCOS divided into phenotypes PCOS-A ($n=17$, BMI-26.5 $\pm$ 6.1 kg/m^2), PCOS-B ($n=10$, BMI 28.4 $\pm$ 6.2 kg/m^2), PCOS-C ($n=12$, BMI 23.5 $\pm$ 4.6 kg/m^2), and PCOS-D ($n=7$, BMI 22.2 $\pm$ 2.5 kg/m^2), alongside 31 age-matched healthy controls (BMI 22.6 $\pm$ 3.7 kg/m^2). There was no difference in BMI except between the controls and the PCOS-B group ($P=0.011$).
Results
Compared to healthy controls, PCOS-C exhibited lower scores in coping, obesity and menstrual disorders, and total PCOSQ-50 score (2.99 $\pm$ 0.38 vs 3.56 $\pm$ 0.60, $P=0.043$; 3.00 $\pm$ 0.5 vs 3.78 $\pm$ 0.89, $P=0.004$; 3.60 $\pm$ 0.34 vs 3.92 $\pm$ 0.50, $P=0.003$, respectively). PCOS-D displayed significantly lower scores in sexual

function, obesity and menstrual disorders, and coping scale (3.32±1.02 vs 4.37±0.51, $P=0.006$; 2.79±1.23 vs 3.78±0.89, $P=0.004$; 2.35±0.71 vs 3.56±0.60, $P<0.001$, respectively). PCOS-B exhibited a lower total PCOSQ-50 score compared to controls, indicating a lower quality of life (3.37±0.49 vs 3.92±0.50, $P=0.035$). Within the PCOS groups, our study revealed that PCOS-C had a lower score in the obesity and menstrual disorder scale compared to PCOS-A (3.00±0.53 vs 3.80±0.84, $P=0.015$). PCOS-D had lower scores for sexual function and coping scale compared to PCOS-A (3.32±1.02 vs 4.31±0.49, $P=0.021$; 2.35±0.71 vs 3.55±0.59, $P<0.001$, respectively). Fertility and hirsutism scales showed no significant differences within the groups, and compared to controls. While no intra-group differences were observed in psychosocial and emotional scales, these scores exhibited a negative correlation with BMI in PCOS-B ($r=$-0.647, $P=0.004$) and with Free Androgen Index (FAI) in the PCOS-D group ($r=0.924$, $P=0.023$). Higher BMI correlated with a worse Total PCOSQ-50 score in PCOS-B ($r=$-0.522, $P=0.026$). Age showed a positive correlation with sexual function and coping scale in the PCOS-B group ($r=0.567$, $P=0.009$; $r=0.509$, $P=0.22$). However, as expected, coping worsened with higher FAI ($r=$-0.490, $P=0.033$).

Conclusion

These findings underscore the necessity for a more extensive investigation involving a larger participant cohort.

Introduction

Polycystic ovary syndrome (PCOS) is one of the most common endocrine diseases among women of reproductive age and is associated with many metabolic manifestations, such as obesity, insulin resistance, dyslipidaemia and hyperandrogenism. The aim of the research was to analyse lipid profile in women with PCOS and their phenotypes.

Subjects and methods

We evaluated 159 women with PCOS diagnosed using ESHRE/ASRM criteria (PCOS: age: 25.85±5.14 years, BMI 23.75±5.54 kg/m^2) and 51 BMI-matched healthy women (Controls: age: 28.02±5.35 years, BMI 23.17±4.98 kg/m^2). PCOS group was divided into four phenotypes: A (anovulation (ANOV), hyperandrogenism (HA), polycystic ovary morphology (PCOM)), B (ANOV, HA), C (HA, PCOM), D (ANOV, PCOM). We measured levels of lipid indices, total testosterone, SHBG and androstenedione, while values of free androgen index (FAI) were calculated.

Results

Our analysis showed that there were significantly higher triglyceride levels in PCOS group in comparison to controls (PCOS:Controls: 0.95±0.49 vs 0.812±0.49, $P=0.014$), while the levels of total cholesterol, LDL and HDL cholesterol were similar in both groups ($P>0.05$). There were significantly higher levels of total testosterone, FAI and androstenedione ($P<0.001$), as well as significantly lower levels of SHBG ($P<0.001$) in women with PCOS. Comparison of lipid profile between PCOS phenotypes showed that phenotypes B and C differ in triglyceride levels, which were significantly higher in phenotype B (PCOS B:PCOS C: 1.10±0.51 vs 0.84±0.35, $P=0.049$), while the concentration of other lipid parameters between groups was similar ($P>0.05$ in all comparisons). Triglyceride levels showed positive correlation with FAI in PCOS phenotype B ($r=0.551$, $P=0.018$).

Conclusion

In our study we showed that there is a difference in triglyceride levels between metabolic and reproductive phenotypes of PCOS. Positive correlation between triglycerides and FAI in phenotype B represents a direct influence of the PCOS phenotype on metabolic consequences and relevant cardiometabolic outcomes during life.

Female sexual function in pregnancy: impact of gluco-metabolic profile, vitamin D status and chronotype

Roberta Scairati[1], Renata Simona Auriemma[1], Chiara Graziadio[1], Guendalina Del Vecchio[1], Nunzia Verde[1], Giovanna Muscogiuri[1], Attilio Di Spiezio[2], Annamaria Colao[1,3] & Rosario Pivonello[1,3,4]

[1]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy; [2]Dipartimento di Sanità Pubblica, Unità di Ginecologia, Università Federico II di Napoli, Naples, Italy; [3]UNESCO Chair for Health Education and Sustainable Development, Federico II University, Naples, Italy; [4]Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia ed Andrologia, Unità di Andrologia e Medicina della Riproduzione e della Sessualità Maschile e Femminile (FERTISEXCARES), Università Federico II di Napoli, Naples, Italy

Rationale

The gluco-metabolic changes during pregnancy significantly impact women's sexual behavior. This study aimed to define the relationship between metabolic health and sexual function, along with human circadian rhythms and sleep quality during pregnancy.

Methods

This study included 57 pregnant women (14 evaluated at first trimester, G1; 18 at second trimester, G2, and 25 at third trimester, G3). Among groups, no difference between age, gestational hypertension, number of pregnancies obtained by ART, glucocorticoid treatment and BMI before pregnancy (pre-BMI) was detected. In G2 former smokers ($P<0.001$) and physically active women ($P<0.001$) were lower than G1 and G3. All women exhibited vitamin D insufficiency. The entire cohort completed the following questionnaires: 1) FSFI and FSD, to assess female sexuality; 2) PREDIMED, to test adherence to the Mediterranean diet; 3) Pittsburgh Sleep Quality index (PSQI), to assess quality of sleep; 4) Morningness-eveningness (ME), to determine chronotype.

Results

In G1, HbA1c directly correlated with age ($P=0.019$;$r=$-0.98) and inversely with desire score ($P=0.038$;$r=$-0.96). In G2, 4/18 (22%) were diagnosed with gestational diabetes (GDM). Pre-BMI correlated with higher blood glucose (GL) 60 minutes after the OGTT ($P=0.002$; $r=0.9$), while the lubrication score inversely correlated with fasting GL ($P=0.039$; $r=$-0.6), insulin ($P=0.041$; $r=$-0.59), and HOMA-index ($P=0.037$; $r=$-0.60). HOMA index emerged as the best predictor of lubrication score ($\tau=$-2.4; $P=0.037$). In G3, 11/25 (44%) had well-controlled GDM, and the entire group showed lower GL ($P=0.04$) but higher insulin ($P=0.009$) and HOMA-Index ($P=0.03$) than G2. Prolactin levels were significantly higher than G1 ($P=0.02$) and correlated with insulin levels of third trimester ($P=0.002$;$r=0.9$). Vitamin D significantly correlated with sexual satisfaction score ($P=0.007$;$r=0.81$), also confirmed in pregnancy complicated by GDM ($P=0.02$; $r=0.93$). Low adherence to Mediterranean diet (G1, 21.4%; G2, 16.7%, G3, 30.7%) was more prevalent in G3 than other groups ($P=0.03$). In the entire cohort, PSQI indicated sleep disturbances in 91.2% and the ME questionnaire revealed only intermediate and moderate morning chronotype, the latter being more represented in G3 ($P=0.0013$). FSFI score confirmed sexual dysfunction in 57.1% of patients in G1, in 72.2% of G2, and in 64% of G3, with no difference based on chronotype, or between healthy and diabetic women.

Conclusions

Metabolic parameters negatively influence sexual function during pregnancy. Gluco-insulinemic metabolism predicted a worse lubrication score during the second trimester while the lower Vitamin D levels were, the lower satisfaction score was at third trimester. Chronotype did not interfere with sexual function or with metabolic parameters in pregnancy, suggesting that sexual health during pregnancy is independent of circadian rhythms.

Autoimmune Hashimoto's thyroiditis in polycystic ovary syndrome

Ifigenia Kostoglou-Athanassiou[1], Eleni Ziambara[2] & Charilaos Samaras[2]

[1]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece; [2]Asclepeion Hospital, Voula, 1st Department of Medicine, Athens, Greece

In patients with polycystic ovary syndrome (PCOS) a high prevalence of autoimmune Hashimoto's thyroiditis has been consistently observed. Young

female patients present with menstrual and reproductive disorders as well as weight gain. The aim was to present a cohort of patients with PCOS who underwent thyroid function tests and in some of whom autoimmune Hashimoto's thyroiditis was diagnosed. A cohort of 20 female patients aged 17-34 years is described. Patients presented with menstrual irregularity. They were diagnosed with PCOS. All patients underwent thyroid function tests and a thyroid ultrasonogram. In 12 patients autoimmune Hashimoto's thyroiditis was diagnosed, as anti-Tg antibodies were positive in 8 patients and anti-TPO antibodies were positive in 10 patients. In 2 patients clinical hypothyroidism was diagnosed as high TSH levels and low FT_4 levels were observed. In 5 patients subclinical hypothyroidism was diagnosed as they had high TSH and normal FT_4 levels. In patients with clinical and subclinical hypothyroidism thyroxine was administered. The thyroid ultrasonogram revealed micro nodularity and a nonhomogeneous parenchyma. Autoimmune Hashimoto's thyroiditis may be observed in patients with PCOS. Thyroid autoantibodies are detected in serum and thyroid function may be compromised. Oxidative stress and metabolic dysfunction may lead to immune dysfunction and the appearance of autoimmune Hashimoto's thyroiditis in PCOS. Genetic factors may also play a role, however this role has to be further studied and delineated.

A case of missing testicles in a transgender woman - assessment, diagnostic and treatment opportunities

Ioana Madalina Cristian[1], Bianca Andreea Balint[1], Catalina Petrescu[1] & Adina Mazilu[1]
[1]Central Military Universitary Emergency Hospital "Carol Davila", Endocrinology, Bucureşti, Romania

Introduction
Transgender – a common widely spread term that describes people whose gender identity does not match the sex they were assigned at birth. Transgender subjects may undergo various interventions, such as hormone therapy or gender-affirming surgeries to align their physical appearance with their gender identity.
Case report
A 49 year old biologicaly male who declaratively feels like a woman since childhood, who underwent all mandatory psychological examination to legaly change their sex from male to female comes for endocrinological examination. Patient recieved empirical hormonal terapy in the last two years but the feminizing characters are discordant in relation to the dose of hormone replacement administered. At the clinical exam patient presents with bilateral gynecomastia, higher voice, reduced facial hair, hypoplasic penis (2 cm lenght buried in the suprapubic fat pad), right testicle excision for ectopic testicles in childhood no left testicle palpable in scrotum. We raised the suspicion of ovotestis or ectopic testicle, for which an MRI examination is recommended. MRI - hypoplastic penis, the left testicle located in the pelvic subcutaneous fat, anteriorly, left paramedian, with the outline of the scrotum at this level; right testicle not visible, left kidney not visible (surgically removed in childhood). The patient's karyotype was performed with the result was 46, XY. The good result of the patient's feminization with hormone therapy is also generated by the testicular hypofunction. Although the patient's karyotype is confirmed to be 46, XY, further histopathological evaluation is necessary to exclude other causes of cryptorchidism. A different result of the karyotype would have prevented the continuation of the legal transformation of the sex. In the presented case, the resection of the remaining testicle is necessary not only for the gender affirming surgery reason, but also for the risk of malignancy that the restant testicle carries.

Mental state dynamics during perimenopause in women undergone IVF procedures

Desimira Mironova[1] & Violeta Azis[2]
[1]Lozenetz University Hospital, Sofia, Bulgaria; [2]Sofia University St. Kliment Ohridski, Sofia, Bulgaria

This poster delves into the nuanced realm of mental state dynamics during the perimenopausal phase in women who have undergone In Vitro Fertilization (IVF). Recognizing the perimenopausal period as a time marked by diverse emotional and physiological changes, our study places a primary focus on understanding the psychoemotional experiences in this specific cohort.
Methods
A comprehensive examination of mental state dynamics was conducted, utilizing survey-based assessments. Additionally, we measured Follicle-Stimulating Hormone (FSH) levels in perimenopausal women with a history of IVF, providing an additional layer to explore the correlation between FSH and emotional and physiological mood changes.
Results
Our findings illuminate the multifaceted nature of mental state dynamics during perimenopause, emphasizing the unique experiences of women post-IVF. Subsequent analysis revealed a significant correlation between FSH levels and certain aspects of emotional and physiological mood changes, offering an intriguing dimension to the primary focus.
Conclusion
This research underscores the complexity of mental state dynamics during perimenopause in women with a history of IVF. While the primary focus remains on psychoemotional experiences, the correlation with FSH levels adds a valuable layer to our understanding, opening avenues for future exploration.
Significance
Understanding mental state dynamics during perimenopause is crucial for tailored healthcare strategies. The additional exploration of FSH correlation, supported by survey-based assessments, enriches our perspective, paving the way for more targeted approaches that consider both hormonal and psychological aspects.
Keywords: Perimenopause, Mental Health, In Vitro Fertilization, Emotional Fluctuations, Follicle-Stimulating Hormone (FSH), Women's Health.

Induced lactation in an adoptive mother: a case report

Meriem Adel[1], Marwa Chiboub[1], Bel Hadj Sliman Chayma[1], Hajer Kandara[1], Manel Jemel[1] & Ines Kammoun[1]
[1]National Institute of Nutrition and Food Technology, Endocrinology, Tunis

Introduction
Over the last twenty years, infertility has continued to rise. According to the WHO, the global incidence of infertility is 17.5%. Adoption is the legal process of achieving parenthood without birth. Since breastfeeding has many nutritional and psychological benefits, induced lactation, the initiation of lactation in a person who has not given birth, may be of interest to some families. We report a case of nonpuerperal induced lactation in a woman.
Observation
A healthy 33-year-old nulliparous woman consulted the endocrinology department for help in inducing lactation before adopting a child. She was prescribed ethinyl estradiol/Drospirenone 0.03 mg/3 mg daily. After 4 weeks, the patient was matched with a child. Therefore, we have decided to use the accelerated protocol. We continued ethinyl estradiol/ Drospirenone and started taking 20 mg of domperidone four times daily. Domperidone is a dopamine antagonist that stimulates prolactin secretion. After 2 months, significant changes in the breasts, including size and the sensation of being heavy and full, were noted, so the pill was stopped and the 80 mg of domperidone per day was continued. Our patient then started expressing milk with an electric double-pump every 3 hours and at least once a night. The adoptive mother initially expressed 10 ml of milk per day. After increasing water intake and adding galactogenic foods (fenugreek seeds, oat bran, fennel, sesame) she expressed 30 ml/day.
Conclusion
Breastfeeding has immunological, metabolic and psychosocial advantages for both mother and infant. In addition, in Muslim countries, breastfeeding establishes religious milk kinship. Despite the growing interest in induced lactation, many health professionals lack detailed knowledge. Prioritising the provision of adequate support and guidance to all women who wish to breastfeed should be a key focus for health professionals. This approach would improve the overall health of both woman and child and lead to increased rates of breastfeeding.

The effects of supplementing myo-inositol plus α-lactalbumin on reproductive and metabolic abnormalities in PCOS

Zelija Velija Asimi[1,2] & Aida Zujovic Ajanovic[1]
[1]UniMed - Polyclinic of SSST University, Endocrinology, Sarajevo, Bosnia and Herzegovina; [2]Sarajevo School of Science and Technology University, Medical School, Sarajevo, Bosnia and Herzegovina

Objective
The open-label clinical study aimed to evaluate the effects of myo-inositol plus alpha-lactalbumin in PCOS women. Alpha-lactalbumin was used being effective in increasing myo-inositol intestinal absorption. This effect is very useful in greatly reducing the therapeutic failure of myo-inositol in some patients (inositol resistant subjects).
Patients and methods
The study involved 36 normal weight, overweight or obese patients aged 18 to 40 years, with anovulation and infertility >1 year and insulin resistance diagnosed by HOMA-Index. Patients were administered orally with 2 g myo-inositol, 50 mg alpha-lactalbumin, and 200 μg of folic acid twice a day for 6 months. Controls were the same patients at t0 (baseline). The primary outcome was HOMA-index decrease after 3 and 6 months of treatment. Other parameters monitored were BMI, progesterone, LH, FSH, total testosterone, androstenedione, lipids.
Results
Recovery was general. The most important results were obtained with insulin, HOMA-index, LH, and androstenedione. The body weight was significantly reduced, the improvement of hyperandrogenism was prominent, the ovulation rate and the duration of the menstrual cycle were also improved.
Conclusions
The combination of myo-inositol and alpha-lactalbumin improve important parameters in PCOS patients characterized by different metabolic profiles. The benefits of combining myo-inositol and α-lactalbumin clearly make this combination a real advantage in the treatment of PCOS.
Keywords: polycystic ovary syndrome; myo-inositol; α-lactalbumin.

Bardet-Biedl syndrome with hypokalaemia paralysis: case report

Hemmet El Haddad[1], Manal Abou Farha[2], Ihab Sameh[2], Ahmed Fayed[2], Asma Ezzat[1], Randa Salam[1], Alaa Abdalla[2], Sara Ihab[2], Haader Essam[2] & Rodina Khaled[2]
[1]Cairo University, Internal medicine, endocrinology, Cairo, Egypt; [2]Cairo University, Internal medicine, Cairo, Egypt

Introduction
Bardet–Biedl syndrome is a rare autosomal recessive disorder with a wide range of clinical features. The primary clinical features include rod-cone dystrophy, postaxial polydactyly, central obesity, cognitive impairment, male hypogonadism and renal dysfunction.
Case report
22 Year old male, mentaly retarded with Bardet Biedle syndrome presented to our ER with vomiting and generalized weakness for 1 week. There was no history of fever, trauma, sensory disturbances, urinary or stool incontinence, no cranial nerve dysfunction. History of orchiopexy for RT sided undesended testes at the age of 5 years, cataract surgery on left eye at the age of 15 His sister is a known case of bardet biedel syndrome. Physical examination: BP: 110/80., normal temperature and respiratory rate. Weight: 75 kg, Height: 160 cm, BMI: 29 kg/m^2, central obesity, Cataract on Rt eye, Squint, High arched palate, Oral monaliasis Polydactyly in both lower limb and left upper limb, Brachydactyly in both feet. Cardiac and chest examination were normal Fundus examination showed the features of retinitis pigmentosa neurological examination: incomprehensive speech, bilateral Lower and upper limb hypotonia, and hyporeflexia, power, Sensory Coordination and gait: could not be examined Tanner stage 3: Left testis 4 cm, Rt testis 3 cm, Penile length 5 cm, Hypospadias Investigations Normal complete blood picture, urea, creatinine, blood gases Normal bilirubin, albumin, ALT: 27 (16-63 U/l), AST:56 (0-50 U/l) ALP: 240 (35-104 U/l) A1c: 5.8%, Na:140 (136-145 mmol/l), k: 2.3 (3.5-5.1 mmol/l), ca:6.3 (8.6-10.2 mg/dl) phosphrous: 1.6 (2.5-4.5 mg/dl), mg:1.1 (1.7-2.5 mg/dl) PTH:411 (15-65 pg/ml), Vitamin D: <3 (20-40 ng/ml) Normal lipid profile, normal thyroid function Abdominal ultrasonography showed: calcular cholecystitis Lt kidney marked back pressure dilated pelvis with upper 1/3 of the ureter (hydronephrosis), rt 112x 48 lt 102x45mm Tone and power of patient improved after correction of k, mg, ca, ph and vitamin d replacement.
Conclusion
Bardet–Biedl syndrome is worthy of special diagnostic effort for starting timely treatment of the various components and associated complications of the syndrome.

EP1178

Ovarian hyperthecosis vs androgen producing tumour: A challenging and unusual case

Elaf Al-Samaraaie[1], Navya Basavaraju[1], Cherrylene Mari[1] & Probal Moulik[1]
[1]Royal Shrewsbury Hospital, United Kingdom

Introduction
Nearly 10% of all women have experienced hirsutism with hyperandrogenism at some stage in their life. Endogenous sources of androgen excess include ovarian tumours, ovarian hyperthecosis, and adrenal tumors. We present a case highlighting the work-up of hyperandrogenism.
Case report
A 47-year-old female, with background of type 2 diabetes, hypertension, polycystic ovarian syndrome (PCOS), obesity, was noted to have significant androgenisation incidentally in diabetes foot clinic. She had a long history of hirsutism from her 20's but developed deepening of voice, worsening of hirsutism with whole body shaving on alternate days, and androgenic hair loss for two years. She had menarche at 12 years and became hypomenorrhea from her 20's and amenorrhoea for the last few years. She is sexually active but never had confirmed pregnancy without any contraception. There was no significant family history of hirsutism. On examination, male pattern body habitus and male pattern baldness, BMI 42 kg/m^2, modified Ferriman-Gallwey score was 29/36, and clitoromegaly. She was obese but not Cushingoid. Her regular medications included metformin, insulin, dapagliflozin, dulaglutide, amlodipine, ramipril and aspirin. Blood investigations were done in 12years ago during the diagnosis of PCOS and during this referral and results are as tabulated below. CT adrenals was unremarkable with normal appearance of adrenals. Ultrasound of the ovaries showed normal endometrial thickness, enlarged left ovary but right ovary not visualized. Urgent MRI of pelvis has been organised. She was started on flutamide, non-steroidal anti-androgen, along with desogestrel, contraceptive, as sexually active and tolerated well without any side-effects.
Discussion
High testosterone in women may be due to polycystic ovary syndrome, congenital adrenal hyperplasia, ovarian tumours, ovarian hyperthecosis, and adrenal tumors. Ovarian hyperthecosis is associated with high testosterone levels, affecting less than 1% of women in the child-bearing age. In our case, there was partial suppression after overnight dexamethasone along with reassuring radiology pointing towards ovarian hyperthecosis as underlying etiology as initial significantly high testosterone should make the clinician suspicious towards malignancy.

Precocious puberty: etiology and treatement

Fatima Zahra Najioui[1], Rami Imane[1], Fatima Zahra Zerrouki[1], Latifa Yagoubi[1], Siham Rouf[2] & Hanane Latrech[2]
[1]Department of Endocrinology-Diabetology and Nutrition, Mohammed VI University Hospital Center, Faculty of Medecine and Pharmacy, University of Mohammed 1st, Oujda, Morocco, oujda, Morocco; [2]Department of Endocrinology-Diabetology and Nutrition, Mohammed VI University Hospital Center, Faculty of Medecine and Pharmacy, University of Mohammed 1st, Oujda, Morocco, Laboratory of Epidemiology, Clinical Research and Public Health, Mohammed VI University Hospital Center, Faculty of Medecine and Pharmacy, University of Mohammed 1st, Oujda, Morocco, Oujda, Morocco

Introduction
Precocious puberty results from the premature activation of the gonadal axis. It mimics physiological pubertal development, although at an inappropriate chronological age (before 8 years in girls and 9 years in boys). It is a serious challenge with repercussions on physical and psychosocial development. We aimed to evaluate the different etiology of Precocious puberty and the effectiveness of the Gonadotropin-releasing hormone (GnRH) agonists.
Patients and methods
This is a retrospective, descriptive study including a total of thirty-four children with precocious puberty follow-up in the Department of Endocrinology-Diabetology and Nutrition, Mohammed VI University Hospital, Oujda, Morocco. A clinical examination, statural evaluatiol and hormonal settings were performed in all cases. Statistical analysis was performed using SPSS version 21.
Results
The average age of our study group in the first consultation was $5,77 \pm 2,28$ years. Thirty one girls and 3 boys. Sixty-five percent of the patients were consulted in the first year of evoluation. The most common consultation reason was breast development (35%), followed by pubic hair develpement (27%). Statural advancement was found in 47%, with a bone age differance more than 2 years in 35%. LHRH testing was carried out in 83% of patients. Central precocious puberty was predominant with 24%. Fourty-four percent of our patients were treated with agonists GnRH. Post-treatment evaluation revealed that 73% of des patients presented stability or regression of signs.
Discussion and conclusion
Early diagnosis of precocius puberty can prevent short stature in adulthood. LHRH testing is the key test to. Treatment by GnRH agonists has demonstrated efficacy in central precocious puberty.

Recurrent subacute thyroiditis - a genetic disease or a still not well-undestood one?

Cristina Ene[1]
[1] "Dr. Victor Babes" Foundation, Endocrinology, Bucharest, Romania

Background
Subacute thyroiditis is considered a rare form of inflammatory thyroid disease, triggered by a viral infection. The prevalence is higher in women and in the middle-aged groups. The rate of subacute thyroiditis recurrence is between 1.4% and 20%, with wide discrepancies between different studies; the relapse may occur soon after de treatment or even years after, and recent studies show an HLA-dependence.
Methods
We present a case report of recurrent subacute thyroiditis in a patient with co-presence of 2 high-risk HLA haplotypes.
Case report
The patient, a Caucasian 70-year-old woman, presented in the clinic with symptoms consistent with subacute thyroiditis - neck pain, shivers, mild fever, fatigue, malaise, and insomnia – which occurred 2 weeks after a viral throat infection. She also had gastrointestinal (gastroesophageal reflux disease, gastritis with recurrent helicobacter infection) and cardiovascular complications (high blood pressure, dyslipidemia) that needed to be considered. The thyroid ultrasound sustained the diagnosis: painful goiter with ill-defined heterogeneously hypoechoic areas and diminished vascularity. The lab confirmed the subacute thyroiditis with mild elevated inflammatory markers (ESR, CRP) and subclinical hyperthyroidism with negative autoimmune profile. Considering the mild form of the disease and the associated personal risk factors, the treatment was started with 25 mg oral prednisolone, with gastric protection, tapering the dose to 5 mg every week. The patient had a complete resolution of the thyroiditis after 6 weeks of treatment, however, she had elevated blood pressure requiring higher doses of her antihypertensive drugs, and the gastroesophageal reflux worsened, causing gastric discomfort. Unfortunately, our lady came back with milder symptoms after 2 months, with a similar ultrasound and lab profile. After the steroid treatment with the same doses, she had a recurring complete resolution. The disease relapsed once again after one month. Other immunosuppressive diseases were excluded and a genetic test was performed. The PCR test revealed the presence of HLA-DRB1×01, 14 and HLA-B×35:01. Higher doses of prednisolone and pantoprazole were needed.
Conclusion
The presence of HLA-B*35 is a well-known risk factor for recurrent subacute thyroiditis. Recently it has been demonstrated that other haplotypes (HLA-DRB1*01, HLA-B*18:01, HLA-C*04:01) are independent risk factors. A short period of steroid therapy may result in the recurrence of the disease, but known high-risk HLA haplotypes, as an initial diagnostic tool, could lead to a more effective approach to the case. However, its widespread implementation is limited by its costs. Further research is needed to explore more cost-effective strategies.

Long-term observation of nodular goiter in japanese – association with thyroid hormones

Hiroshi Yoshida[1] & Takao Kunori[2]
[1]Iwaki-city Medical Center, Surgery, Iwaki-city, Japan; [2]Iwaki-city Medical Center, Surgery, Iwaki, Japan

Background
Nodular goiter (NOD) is one of the most common disease, which does not always need surgery. Long-term outcomes and relation with thyroid hormones, however, are not clear. We analyzed in Japanese patients who take iodine enriched food.
Patients and methods
3, 781 patients with NOD (solid type 37%, cystic 16%; 2007-2022); mean age, 57 (female, 80%) and 66 (man, 20%) entered in this study. Observation period was 5.1 years (mean; 1-21 years). Single solid nodules ($n=1$, 115; sNOD) were examined at year of 1, 2, 4, and 8 from the first visit. Serology was performed for thyroid peroxidase antibody (TPO), anti-thyroglobulin antibody (TgAb), thyroid stimulating hormone receptor antibody (TSH-RAb) and, in some patients, thyroid stimulating hormone antibody (TSAb). Hormonal assay was performed for free thyroxine (FT4), free triiodo-thyronine (F-T3), thyroid stimulating hormone (TSH) and thyroglobulin (Tg). Nodules were examined by ultrasonogram (US) and aspiration cytology. Enlargement rates (size%) of nodules were calculated by current size/ initial size (diameter in US). Statistical significance was determined by probability ($P<0.05$) in student-t or Kai-2 test.
Results
1. Size%: sNOD with the rates (>110%) increased as observed years, 4%(year zero), 26% (1 year), 35% (2 year), 43%(4 year) and 56% (8 year and more). While sNOD with the rate (<90%) also increased 4% (year zero), 22% (1 year), 23% (2 year), 30% (4 year) and 17% (8 year and more). 26% of sNOD was unchanged after 8 years. 2. Initial size and size% at year 4-6: Size% was highest in small size (<1 mm, median 197%), then 150% (10=<<1 mm), 95% (20=<<1 mm) and 106% (1 mm=<)($P<0.05$). 3. Changes of TSH: Patients with Low TSH (< 0.05μIU/ml) increased as observed years; from 21% to 75%. TSH decreased from 1.30IU/ml (sd=1.67) to 0.79 IU/ml in 10 years ($P<0.05$). TSH decreased from 1.46 IU/ml (mean) to 0.74 IU/ml in 8 years ($P<0.05$). 4. Changes of FT4: Patients with FT4>1.1 ng/dl (normal 0.70-1.48), increased as observed years; from 17% to 49%. FT4 increased from 1.12 ng/dl (sd=0.27) to 1.24 IU/ml(sd=0.24) in 8 years ($P<0.05$). 5. Changes of Tg: Tg increased from 74 ng/dl (median) to 439 ng/dl in 8 years.
Conclusions
2/3 of sNOD remained no growth. sNOD appeared to be associated with TSH and thyroid hormones.

Neoadjuvant lenvatinib in invasive differentiated thyroid cancer

Virginia Soria Utrilla[1], Viyey Kishore Doulatram Gamgaram[1], Marta Iturregui Guevara[1] & Stella González Romero[1]
[1]Hospital Regional de Málaga, Endocrinology and Nutrition

We present the case of a 41-year-old man with a history of testicular seminoma treated with surgery and chemotherapy, and post-chemotherapy chronic kidney disease. He was initially referred to Otolaryngology for a 1-month history of neck mass sensation, with associated dysphonia, dysphagia and dyspnea. On examination, thyroid gland was enlarged. Fibroscopy was performed in consultation, revealing paralysis of the left vocal cord. The patient was referred to Endocrinology and Surgery departments. A cervicothoracic CT and ultrasound were requested. The CT showed a thyroid neoformative lesion with decreased tracheal lumen and pathological lymph nodes in levels III, IV, V, and VI bilaterally. The ultrasound showed a TIRADS-5 thyroid nodule in the left lobe, in which fine-needle aspiration (FNA) was performed, being insufficient for diagnosis. FNA was also performed on a pathological lymph node at right level III, with thyroglobulin 4729.62 ng/ml and TTF-1 positive, indicating thyroid origin, but unable to determine whether it was a follicular neoplasm or a follicular variant of papillary neoplasm. Biopsy-assisted guided (BAG) was requested, which could not confirm the diagnosis either. A blood test revealed normal calcitonine (5.23 pg/ml). At the same time, upper gastrointestinal endoscopy (UGE) and bronchoscopy were requested to assess resectability. UGE showed doubtful esophageal infiltration. Bronchoscopy revealed lesions in left tracheal wall, from which biopsies were taken. Histological study revealed positive immunoreactivity for thyroglobulin and TTF-1, confirming thyroid origin, but unable to state whether it was metastasis of thyroid carcinoma or ectopic thyroid tumor. The case was presented to a multidisciplinary committee, and neoadjuvant treatment with Lenvatinib was decided. After 1.5 months, a cervicothoracic CT showed partial response to treatment, so Lenvatinib was continued. After another 1.5 months, a new CT showed no significant changes and a new bronchoscopy continued visualizing neoplastic-appearing tracheal lesions, with a biopsy compatible with papillary neoplasia. Likewise, a new thyroid BAG was performed, also compatible with papillary carcinoma. With all this, surgical treatment was decided, being necessary total thyroidectomy, bilateral central and lateral lymph node dissection, resection of second to fourth tracheal rings with reconstruction, and temporary tracheostomy. This case aims to highlight the importance of individualized management of invasive differentiated thyroid cancer despite the difficulty in reaching an accurate diagnosis. Invasion of surrounding structures can lead to aggressive procedures such as tracheal resection, so there is a potential role for neoadjuvant therapy with tyrosine-kinase inhibitors in these patients, although it does not always avoid these procedures.

Dysthyroidism in a hypothyroidism patient due to heterophilic antibody interference

Rossana Manzanares Cordova[1], Rocio Dominguez Rabadan[1] & Pilar Rodriguez[1]
[1]Hospital Juan Ramón Jiménez, Endocrinology, Huelva, Spain

Background
heterophilic antibodies are antibodies in patients' sample that can cause false results by binding to the assay antibodies. Interference due to heterophilic antibodies may lead to falsely low or high analytic concentrations. In some settings, the relationship between TSH and thyroid hormones does not fit with the expected feedback mechanisms. This may be due to a pathophysiological process, laboratory error or assay interference.
Case report
A 37-year-old female patient diagnosed with primary autoimmune hypothyroidism since she was 16 years old, well controlled until 2016 when, in relation to a traffic accident with traumatic brain injury, she began with a discordant thyroid hormonal pattern consisting of high TSH levels with normal FT4 or TSH inadequately normal with high FT4, accompanied by symptoms of hyperthyroidism, especially tachycardia, fatigue and weight loss (Table 1) After several check-ups and verifying an abnormal pattern in thyroid function, requiring multiple changes in dose and presentation of levothyroxine, a study of secondary hyperthyroidism and poor absorption was decided; both results were negative. Given the lack of improvement, analysis without interference from heterophilic antibodies was finally performed in an external laboratory since it was not available in our center, the results demonstrates that presence of heterophilic antibodies, presenting adequate levels of TSH and FT4 after their neutralization (Table 2) Currently, the patient maintains follow-up in our clinic with dose adjustment according to analysis carried out without interference from heterophilic antibodies, presenting a significant symptomatic improvement after stabilization of the levothyroxine dose.

Table 1: Summary of Analytical Results

Hormones	08/25/16	10/05/16	10/30/17	01/03/18	04/09/19
TSH (0.27-4.20 UI/ml)	100	3.16	5.83	39.67	1.90
FT4 (0.93-1.70 ng/dl)	1.18	2.29	1.81	1.37	2.14

Table 2: Analyzes without interference from heterophilic antibodies

Hormones	Baseline analysis	After neutralization of heterophilic Ac
TSH (0.27-4.20 UI/ml)	13.08	12.07
FT4 (0.93-1.70 ng/dl)	1.58	0.47

Conclusions
Interference in immunoassays is an important clinical problem that is underestimated and can have important clinical consequences. It is important to recognize the possibility of such interferences early in the diagnostic process and to implement protocols to identify these whenever possible, in a timely fashion, to prevent untoward consequences.

A severe case of ophthalmopathy in a primary hypothyroid patient

Diana Vladica[1], Nicoleta Dumitru[1], Daniela Alexandrescu[1] & Adina Mariana Ghemigian[1]
[1]National Endocrinology Institute "C.I. Parhon", Bucharest, Romania

Introduction
Thyroid-associated ophthalmopathy (TAO) represents a common extrathyroidal manifestation of Graves' disease, however 2-7.5% of primary hypothyroid patients can experience a form of TAO as well. This condition is a rare autoimmune disease, where auto-antibodies (anti-TSH receptor antibodies or TRAb) target antigens shared by the thyroid and the orbit. This results in the inflammation, swelling and bulging of the eyes and surrounding orbital tissues. There are no clear guidelines on how to treat TAO in hypothyroid patients, making it a challenging case to manage. However, based on the current Graves' disease associated ophthalmopathy guidelines, there are several treatments available.
Case presentation
We present a case of a 41 year old female patient, who was admitted to our hospital in March 2023 after experiencing an acute episode of periorbital swelling of both eyes, lagophthalmos, pain, decreased ocular mobility, epiphora and chemosis. The patient, who is also suffering from a severe mental disability and is a non-smoker, was diagnosed with primary hypothyroidism one month prior, and was started on levothyroxine. The patient had no previous hyperthyroid state or radioactive iodine therapy. Laboratory investigations confirmed the primary hypothyroidism with positive thyroid peroxidase antibodies (ATPO) and anti-TSH receptor antibodies (TRAb). The orbital CT scan showed bilateral exophthalmos and some signs of optic nerves degeneration. The examination describes asymmetric involvement (left eye being more affected), chemosis, periorbital edema, exposure keratopathy.
Discussions
The ophthalmologist started the patient on an IV steroid course. After the symptoms have significantly improved, the steroid course was paused, however the condition persists even under euthyroid state. The constant high TRAb values from our patient and a lack of clear guidelines on how to treat TAO in hypothyroid patients, can explain the delay in achieving a remission. Other immunosuppressants such as the addition of oral mycophenolate to the regimen, were not taken into consideration due to the side-effects of the substances and the pre-existing anemia and altered liver function diagnoses our patient had.
Conclusion
TAO in hypothyroid patients is a rare condition, therefore early detection and treatment can help prevent sight-threatening complications. Such cases can be successfully treated with steroids, however in rare cases like this, the addition of other immunomodulatory therapy may be indicated. This step requires a close collaboration between endocrinologists and ophthalmologists.

Multiple metastases from follicular thyroid carcinoma initially misdiagnosed as benign lesion: a case report

Ben Fekih Nawres[1], El Ajmi Wassim[2], Sellem Ali[2] & Hammami Hatem[2]

[1]Faculty of Medicine of Monastir, Nuclear Medicine, Tunisia; [2]Military Hospital, Nuclear Medicine, Tunisia

Introduction
Follicular thyroid carcinoma typically spreads through the hematogenous route, causing distant metastases, with bone and lung being the most frequent sites, while metastases to the liver and skin are less common. We report a case of reassessing the diagnosis of follicular thyroid carcinoma due to the identification of flesh-colored skin nodules, later confirmed as cutaneous metastases.
Case presentation
An otherwise healthy 60-year-old man underwent subtotal right thyroidectomy due to clinical suspicion of malignancy in 2016, but the histopathological examination of the resected tissue did not confirm the diagnosis, and the patient chose not to persue follow-ups. Six years later, our patient presented with cutaneous, asymptomatic nodules in the digastric region and in the occipito-parietal and fronto-parietal scalp. Histopathological examination confirmed metastatic follicular thyroid carcinoma. The remaining thyroid tissue was resected, and subsequent histopathological examination revealed no signs of malignancy. A second examination of the previously resected thyroid tissue (in 2016) was conducted, reclassifying the lesion as malignant and confirming it as follicular carcinoma. Further radiological investigations were then performed, detected multiple hepatic, pulmonary, and bone metastases. The patient was then referred to our department for radioactive iodine therapy (RAI), recieved a dose of 100 mCi. A postoperative radionuclide thyroid uptake scan revealed findings consistent with a metastatic lesion in the crane, right scapula, chest, liver, the whole pelvis, both humeri, the proximal-third of the right femur and multiple staged lesions in the bone spine.
Conclusion
This case underscores the diagnostic challenges and harmful consequences of misdiagnosing follicular thyroid carcinoma. It also highlights the well-established role of radioactive iodine therapy in managing high and intermediate recurrence risk FTCs, both therapeutically and diagnostically, as well as the importance of post-thyroidectomy follow-up care.

Pediatric thyroid surgery: indications and outcomes through the analysis of 25 cases

Houas Jihene[1], Heyfa Belhadj-Miled[1], Monia Ghammam[1], El Ghali Wassim[2], Malika El Omri[1], Abir Meherzi[1], Mouna Bellakhdhar[1], Yosra Hasni El Abed[3], Wassim Kermani[1] & Mohamed Abdelkafi[1]
[1]Farhat Hached Hospital, ENT Department, Sousse, Tunisia; [2], Department of Anaesthesia, Sousse, Tunisia; [3], Department of Endocrinology, Sousse, Tunisia

Introduction
Thyroidectomy in the pediatric population is a seldom-performed surgical procedure, primarily associated with thyroid neoplasms. However, certain benign thyroid gland conditions, such as Graves' disease, toxic adenomas, congenital hyperthyroidism, and goiter, also necessitate surgical intervention in children. Performing such surgeries in pediatric patients poses significant challenges for surgeons. This study aims to investigate the epidemiological and clinical characteristics, as well as therapeutic outcomes, of children undergoing thyroid surgery in our institution.
Materials and Methods
A retrospective study was conducted on 25 children who underwent thyroid surgery in our department between 2010 and 2023, including systematic histopathological analysis.
Results
The average age of the patients was 14.6 years, with a notable female predominance (90.5%). Relevant medical histories included Graves' disease in 5 cases (22.7%) and one case of congenital hypothyroidism. The most common presentation was basi-cervical swelling. The surgical indication was established based on compressive thyroid nodules in 17 patients (68%) and in 7 cases (28%) within the context of known Graves' disease. Additionally, one case involved suspicious thyroid nodules with cervical polyadenopathies and chronic cough. Total thyroidectomy was performed in 14 patients (56%), lobo-isthmectomy in 10 patients (40%), and isthmectomy in 1 patient (4%). Bilateral mediastino-recurrent functional lymph node dissection was carried out in one case. The average postoperative hospitalization duration was 3 days (range: 2 to 6 days). Histopathological examination revealed 9 cases of multinodular goiter, 5 cases of Graves' disease, 4 cases of lymphocytic thyroiditis, 5 cases of vesicular adenoma, 1 case of oncocytic adenoma, and 1 case of papillary thyroid carcinoma with lymph node and pulmonary metastases, necessitating IRA therapy. Postoperative complications were reported in 32% of cases, with hypocalcemia being the most common (60%). No recurrent laryngeal nerve paralysis was identified. Favorable outcomes were observed in all patients.
Conclusion
Pediatric thyroid disorders requiring surgical intervention are considerably rarer than in adults. Benign thyroid nodules and Graves' disease are the most common surgical indications. Surgical management in children can be intricate, necessitating careful consideration and expertise.

Exploring thyroid effects and gender-specific responses to pseudomonas aeruginosa mannose-sensitive-hemagglutinin (PA-MSHA): a rat model study

Katarina Baralić[1], Dragica Bozic[1], Đurica Marić[1], Jovana Živanović[1], Katarina Živančević[1], Evica Antonijević Miljaković[1], Aleksandra Buha[1], Marijana Ćurčić[1], Zorica Bulat[1], Biljana Antonijević[1] & Danijela Đukić-Ćosić[1]
[1]Department of Toxicology 'Akademik Danilo Soldatović', University of Belgrade — Faculty of Pharmacy, Belgrade, Serbia

Pseudomonas aeruginosa mannose-sensitive-hemagglutinin (PA-MSHA) is a bacteria-mediated cancer therapy showing promise in inhibiting cancer growth by impeding tumor cells and inducing natural cell death. Clinical studies indicate its ability to enhance chemotherapy efficacy and stimulate the immune system against cancer, presenting manageable side effects such as fever and skin irritation. Nevertheless, the safety profile of PA-MSHA requires further exploration, emphasizing the necessity for additional investigation. Hence, the aim of the current study was to investigate the thyroid effects of PA-MSHA in a rat model and elucidate gender-specific differences. Animals were subjected to a 28-day exposure to three increasing doses of PA-MSHA (PA-MSHA 1, PA-MSHA 2, and PA-MSHA 3: 0.09; 0, 18 and 0, 36×10^9, respectively), administered intraperitoneally once a week on the 1st, 7th, 14th, and 21st days. Following the conclusion of the study period, blood samples were obtained through cardiac puncture, and serum was isolated for subsequent hormone analysis. The levels of triiodothyronine (T3), thyroxine (T4), free triiodothyronine (fT3), and free thyroxine (fT4) were quantified, and the T3/T4 ratio was calculated. The results revealed gender-specific hormonal responses to varying doses of PA-MSHA. In females, both PA-MSHA 1 and PA-MSHA 3 significantly elevated T3 levels, with PA-MSHA 3 exhibiting a more pronounced effect, suggesting a potential dose-dependent response. Additionally, both doses induced comparable increases in fT3, indicating a potential threshold effect or saturation point in hormonal response. In males, PA-MSHA 2 led to a decrease in fT3 levels, suggesting a specific response to the intermediate dose, while PA-MSHA 3 showed a dose-dependent increase in fT4 levels, akin to the observed effect on T3 levels in females. However, both in males and in females, the absence of a statistically significant difference in the T3/T4 ratio suggests that the relative balance between T3 and T4 remained relatively constant across the experimental groups and the control, indicating that the overall thyroid hormonal equilibrium may have been maintained. However, these findings collectively suggest differential hormonal responses to varying doses of PA-MSHA in female and male animals, emphasizing the importance of gender-specific considerations in the development and interpretation of therapeutic interventions involving PA-MSHA.

Retrospective analysis for the utility of beta-adrenergic blockers in thyroid storm: the double-edged sword

Eman Elmenyar[1]
[1]Bahçeşehir Üniversite Hastanesi Medical Park Göztepe, Turkey

Background
Thyroid storm (TS) is a rare, acute, severe, and potentially fatal complication of untreated or poorly managed hyperthyroidism. In such cases, there is multisystem involvement and an 8-25% risk of mortality; hence, early identification and prompt initiation of vigorous treatment is crucial to reduce mortality. Beta adrenergic receptors blockers (BBs) are commonly used early in the treatment of TS, however the risk of inducing circulatory failure (BBIS) remains a major concern. We aim to explore the BBIS in a large scale-data from different populations worldwide.
Methods
Data were collected between January 2003 and December 2023 from published cases on PUBMED/MEDLINE. We included all age groups, genders who had

been diagnosed with TS based on clinical, laboratory and Burch-Wartofsky Point Scale (BWPS) and received BBs early in the treatment of TS. Patients were subdivided into non-BBIS and BBIS, and data were analyzed and compared using Chi-Square and student t test. Multivariable logistic regression analysis was performed to identify the predictors of mortality.
Results
We analyzed 367 TS cases who fulfilled the eligible criteria (65% female and 35% male) with a mean age of 40 ± 17 and BWPS 62 ± 18. The overall mortality was 11.4% and BBIS occurred in 70 patients (19%). Age, gender, BWPS, BNP and troponin were comparable between the study groups. Patients who developed BBIS had significantly higher rate of atrial fibrillation, heart failure, lower left ventricular ejection fraction, multiorgan failure, cardiac arrest and mortality compared with those without BBIS. The BBIS group received more CCB, amiodarone, TPE, CRRT, and ECMO. Multivariable analysis showed that only BBIS (Odds ratio 3.0) and CRRT (Odds ratio 8.0) were the predictors of mortality after adjusting for age, gender, low ejection fraction, and renal failure and liver failure and the use of CCB, ECMO, and TPE. The mortality is 5 times higher in the BBIS group compared to non-BBIS.
Conclusion
BBIS in the treatment of TS occurs almost in one out of five TS patients treated with BBs. In addition to CRRT, BBIS independently predicts the mortality in TS patients.

Ultrasound and cytological characteristics of NIFTP tumors compared to papillary carcinomas

Sofia Ouhessaine[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy, University Hassan II, Casablanca, Morocco

Introduction
Non-invasive follicular neoplasm with nuclear features of papillary carcinoma 'NIFTP', formerly encapsulated non-invasive follicular variant of papillary carcinoma, has been removed from the carcinoma category due to its indolent nature and good prognosis. This change impacts clinical and therapeutic care.
Objective of the work
To identify preoperative ultrasound and cytological differences between NIFTP and papillary carcinoma (PTC).
Material and methods
retrospective study includes 153 patients who underwent total thyroidectomy or lobectomy with a histological diagnosis of papillary carcinoma, NIFTP or invasive follicular variant of papillary carcinoma, between 2019 and 2023. Data from ultrasound and cytology were analyzed and compared between NIFTP and non-NIFTP (papillary carcinoma and invasive follicular variant of papillary carcinoma).
Results
Our study included 45 NIFTP, 108 papillary carcinomas including 47 follicular variants. Compared to papillary carcinomas, the nodules corresponding to NIFTP are more isoechoic (69.2% vs 17.4%, $P = .0007$) and have regular contours (92.3% vs 31.1%, $P = .0001$) and have an EU-TIRADS score 3 or 4. Cytologically, NIFTPs are classified categories III, IV and V of the Bethesda classification, while CPTs are mainly classified in categories V and VI of the Bethesda classification. Bethesda. Only the presence of nuclear pseudo-inclusions isemerged as significantly associated with the non-NIFTP group ($P = 0.0031$).
Conclusion
NIFTPs appear mostly non-suspicious on pre-operative ultrasound with absence of nuclear inclusions on cytopuncture. These differences compared to papillary carcinomas can make it possible to suspect the diagnosis preoperatively and to best adapt surgical management towards more conservative management.

Papillary thyroid carcinoma arising from thyroglossal duct cyst: Report of three cases and review of the literature

Rachida Bouattay[1], Nawres Bouaziz[1], Hanen Grisia[1], Mahdi Ferjaoui[1], Amel El Korbi[1], Nawrez Kolsi[1], Khaled Harrathi[1] & Jamel Koubaa[1]
[1]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Introduction
The malignant degeneration of thyroglossal duct cyst (TDC) is a very rare phenomenon. It occurs 1% of operated cysts. The incidence appears to be greatest in patients in the fifth decade with a slight preponderance in women. Papillary carcinoma represents the most common histologic type. In this study, we report 3 cases of a papillary carcinoma of thyroid occurring in a TDC in adult population in order to present diagnosis and therapeutic aspects of degenerated thyroglossal duct cyst.
Patients and methods
This is a retrospective study of adult patients who underwent surgery for thyroglossal duct cyst at Fattouma Bourguiba University Hospital between 2006 and 2019, and for whom the pathological study revealed a TDC carcinoma.
Results
Of 61 cases of TDC, 3 (4.9%) were found to have TDC carcinoma. Our study investigated two women and one men. The mean age was 42.3 years. All three patients presented with a painless, slowly growing anterior neck mass of several months duration. They had no past history of irradiation. Physical examination was remarkable for a midline neck mass located above the thyroid gland. The mean diameter of the mass was 4 cm. It was non-mobile with swallowing in 2 cases. In all patients, the thyroid gland examination was normal, as were thyroid function tests. Cervical ultrasound and computed tomography scan were performed. Therefore, a diagnosis of TDC was made, and the patients underwent a Sistrunk operation; the cyst was found to be separate from the thyroid gland, which was itself normal. The frozen section from the mass was done in two cases and confirms the diagnosis of papillary carcinoma. A total thyroidectomy with central neck dissection were performed. The final histologic exam confirmed a thyroglossal duct papillary carcinoma in all patients. Wider resection is so indicated in the third case. A complementary treatment by radioactive iodine 131 and thyroxine suppressive treatment were undertaken. The follow-up was marked by the absence of recurrence in a patient and the death in another patient. The third case was not followed up.
Conclusions
Thyroglossal duct carcinoma, most commonly papillary carcinoma, is a rare condition that should be considered in patients presenting with cystic midline neck masses. Surgery and complete excision is the main treatment and the optimal patient management includes multidisciplinary consultation in order to improve survival. The diagnosis of malignancy is made postoperatively, as in the present cases.

Epidemiological, clinicopathological, and evolutionary profile of familial non-medullary thyroid carcinoma (FNMTC) in 3 families

Doaa El Bazi[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital - Casablanca, Morocco Clinical Neuroscience and Mental Health Laboratory Faculty of Medicine and Pharmacy - Hassan II University, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Familial Non-Medullary Thyroid Carcinoma (FNMTC) is defined as the occurrence of thyroid cancer in two or more first-degree relatives, in the absence of predisposing environmental factors.
Objective of The Study
Describe the epidemiological, clinical features and its evolutionary profile.
Materials and Methods
A retrospective study including 3 families (10 patients) with FNMTC, collected at the endocrinology and diabetology department of Ibn Rochd University Hospital in Casablanca.
Results
Two families had parent-child relationship, and one family consisted of 2 sisters and a nephew. The average age was 38 years, with a clear male predominance and a male-female ratio of 2.3. The circumstances of discovery were mainly multiheteronodular goiter. For one family, three members discovered it during screening at an average young age of 21 years. All patients presented with clinical and biological euthyroidism. All patients underwent total thyroidectomy, with histopathological examination revealing papillary carcinoma in 3 patients, papillary with vesicular or trabeculovesicular differentiation in 5 patients, microcarcinoma in 1 patient, and papillary carcinoma with high columnar cells in 1 patient. The latter had retrospinal lymph node metastases. Multifocality was observed in 20% of patients, and bifocality in 60%. All patients received additional iratherapy. No recurrence was noted in our series.
Conclusions
Although FNMTC have a higher recurrence rate, with an earlier age of onset, no patient in our series had a recurrence. Early diagnosis and screening can improve prognosis and treatment.

Papillary carcinoma reveled by cystic metastases

Amel Elkorbi[1, 2], Nawres Bouaziz[2], Mahdi Ferjaoui[2], Rachida Bouatay[2], Naourez Kolsi[2], harrathi khaled[2] & Jamel Koubaa[2]
[1,2]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Introduction
Cystic cervical metastases of papillary thyroid carcinoma are rare. They precise incidence remains unknown. They can be indicative of a particularly papillary thyroid cancer. However, there is no negative prognostic character compared to non-cystic lymphadenopathy of thyroid carcinoma of the same histopathological type. We aim through this series of cases to discuss diagnostic and therapeutic features of cystic metastases of papillary thyroid carcinoma.
Materials and methods
This is a retrospective study of eight patients who managed for cervical cystic metastasis related to thyroid cancinoma in our ENT department over a period of 11 years (2010-2023). The following data were studied: age, sex, patients 'plaints, data from the clinical examination and explorations as well as the therapeutic approach.
Results
The patients'mean age was of 45.8 years [26-84 years]. The sex ratio is 0.57 with female predominance. The circumstance of diagnosis was a laterocervical swelling in seven patients and an incidental mass on a cervical ultrasound in one case. The supraclavicular localization was found in three cases and in the jugulo-carotid chain in four cases. All of our patients underwent a cervical ultrasound which showed the presence of a cervical cystic mass in all cases. Cervical CT scan was performed in four cases. Malignancy was suggested in three cases based on the presence of intra-cystic microcalcifications. Suspicious thyroid nodules were found in four patients. A fine needle aspiration were performed in all patients. It concluded to cystic metastasis of papillary thyroid carcinoma in five cases. Total thyroidectomy with bilateral recurrent and functional lymphadenectomy was performed in all patients. The histological examination confirmed the diagnosis of papillary thyroid carcinoma in the thyroid gland with cystic metastases. Iratherapy was performed in all patients. Recurrence occurred in only one patient after an average of eight years of fellow-up.
Discussion/Conclusion
Cystic metastases of papillary thyroid carcinoma is a classical but not common. Even though, there are no differences in therapeutic procedure or prognostic compared to classical metastases, we should think about cystic metastases in cases of cervical cystic mass in adult particularly in women. High resolution cervical ultrasound and fine needle aspiration are good tools to accurate the diagnosis.

Locally extended thyroid carcinoma: report of a case series

Amel elkorbi[1], Nawres Bouaziz[1], Mahdi Ferjaoui[1], Rachida Bouatay[1], Naourez Kolsi[1]. harrathi khaled[1] & Jamel Koubaa[1]
[1]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Introduction
Locally extended thyroid cancer is a rare situation that lead to management discussion. Therapeutic strategy depend on the histological type of the cancer and the extension limits. We through this study to discuss therapeutic strategy and relate the evolution features of such cancers.
Materiel and Methods
We performed a retrospective descriptive study collecting all locally extended thyroid cancer managed in our department over a period of ten years [2009-2023].
Results
They were four women and two men. The mean age was 64 years [49-80 years]. The main complaint was an anterior basicervical mass in all cases. It was associated with laterocervical mass in three cases. Dyspnea was reported in two cases and dysphonia in one case related to a recurrent paralysis. Ultrasound was suggestive of malignancy in all cases. A cervical CT scan, was performed in four cases, showed an invasive heterogeneous goiter extended to the trachea in three cases and the trachea and larynx in the fourth one which required emergency tracheostomy due to severe inspiratory dyspnea. Total thyroidectomy was performed in all cases, it was enlarged to the larynx in one case of medullary carcinoma. A recurrential lymphadenctomy was performed in all cases. Lateral lymphadenctomy was performed in four cases: it was unilateral radical in two cases, unilateral functional in one case and bilateral functional in one case. The definitive histological examination concluded to an invasive papillary carcinoma in three cases, a poorly-diffrentiated carcinoma two cases and medullary carcinoma associated with papillary carcinoma in one case. Distant metastases were noted in the two cases poorly-diffrentiated carcinoma: it was a bone in one case and pulmonary in the other case. Ablative iodine-131 radiotherapy was performed in all cases. It was associated to an external radiotherapy in two cases and radio-chemotherapy for the poorly differentiated carcinoma with lung metastases. The course was marked by loco-regional recurrence in one case, and the appearance of distant metastases in one case. The average follow-up was four years.
Discussion/Conclusion
Locally advanced thyroid cancer is a challenging situation. Surgery is the standard and the efficient treatment, even though it can be mutilating in some cases. External radiotherapy remains a complementary treatment and can be an alternative in non-operable tumors.

Coexistence of thyroid cancer and sarcoidosis Series of cases.

Olga Wajtryt[1], Elwira Bakuła-Zalewska[1], Aleksandra Budrewicz[1], Joanna Długosińska[1], Andrzej Kowalczyk[1] & Marek Dedecjus[1]
[1]Maria Sklodowska-Curie National Research Institute of Oncology, Warsaw, Poland.

Sarcoidosis is a systemic inflammatory disease of unknown etiology characterized by the formation of granulomas. It most often involves the lungs, although there are evidences that it can be presented in any organ. Involvement of the thyroid gland is a very rare manifestation, defined as below 1% of cases. Thyroid cancer, on the other hand, is a cancer occurring with a frequency of approximately 1-1, 3% of all cancers, but with an increased incidence associated with growing diagnosis in the era of precision imaging. There is limited information suggesting a potential relationship between thyroid cancer and sarcoidosis. Currently, we have limited data based on the coexistence of diseases. Unfortunately, knowledge is based mainly on case reports and small groups of patients. However, there are several hypotheses linking the pathophysiology of both diseases. The impact of the etiology of autoimmune sarcoidosis and the frequent occurrence of autoimmune thyroid diseases remain unclear. Most often, the diagnosis was based on lymph node monitoring. Sarcoid nodes have been found in patients with thyroid cancer. However, in patients with sarcoidosis, changes in the thyroid gland were observed during imaging diagnostics, suggesting diagnosis of thyroid cancer. In both cases, indication to biopsy and cytology are often a difficult challenge. Moreover, in radioiodine scintigraphic examinations, the presence of pleural effusion or the presence of sarcoid lymph nodes may cause false uptake of radioiodine. Based on case reports of 3 patients from our Department, possible manifestations of sarcoidosis, as well as diagnostic paths to diagnosis, imaging and histopathological documentation, and diagnostic difficulties, were presented, as well as possible manifestations of sarocidosis observed in literature descriptions.

[3]Hospital García Orcoyen, Endocrinology, Estella, Spain

Introduction
MUTYH (MutY homolog Escherichia coli, homolog of MYH, hMYH) is a repair enzyme with a crucial role in the correction of DNA errors, being considered a protective factor of the cell. MUTYH mutations have been linked to MUTYH-associated polyposis syndrome (MAP), an autosomal recessive disorder characterized by multiple colorectal adenomas. Patients with MAP show a much higher lifetime risk of gastrointestinal cancers as an additional role of MUTYH, it appears to contribute in the involvement of pathologies based on oxidative stress damage, as well as in the prevention of inflammatory and degenerative based disorders. Although the development of extraintestinal pathology is not fully defined, it seems to increase the risk of tumors and endocrinological pathology.
Materials and methods
Prospective study, selecting 27 living patients diagnosed and registered with MUTYH syndrome under follow-up from the Digestive Department of the

Hospital Universitario de Navarra (HUN) with current or past follow-up in the Endocrinology Department. Radiological tests, clinical, and analytical variables were analyzed.
Results
The study population included 14 men (51.8%) and 13 women (48.2%), with a mean age of 56 years. The median age at diagnosis of FAP was 48 years, with a mean follow-up time of 8 years. All patients underwent thyroid ultrasound examination and blood tests with the determination of thyroid autoimmunity. The prevalence of nodular pathology was 63% (17/27), of which 9 had single nodules and 8 had multinodular goiters. Patients with nodular pathology, 5 had nodules >1 cm (18.5% of the total sample). Of these, 4 had indications for cytologic study. The result of the cytologic study was Bethesda II in two cases. Bethesda III in two, in one of them ultrasound follow-up was decided and in the other surgical was performed revealing nodular hyperplasia. There was another patient who had undergone total thyroidectomy before the study, with a result of incidental papillary carcinoma of 1 mm.
Conclusions
The prevalence of thyroid nodularity in the sample of patients with MAP is above that described in the general population. Studies with a larger sample size are probably necessary to obtain results with greater statistical significance.

Thyroid hormone profiles during pregnancy in women with gestational diabetes mellitus

Sawsen Nouira[1], Taieb ACH[1], Asma Ben Abdelkrim[1], Amel Maaroufi[1], Yosra Hasni[1] & Molka Chaieb[1]
[1]University Hospital Farhat Hached, Endocrinology, Sousse, Tunisia

Introduction
Pregnancy induces significant hormonal alterations, potentially affecting thyroid hormones. Our study aimed to assess the prevalence of thyroid dysfunction in pregnant women diagnosed with gestational diabetes Mellitus (GDM).
Methods
A descriptive study was conducted, including 197 pregnant women diagnosed with GDM, under the care and monitoring at the Diabetology, Endocrinology department in Farhat Hached university Hospital, Sousse Tunisia. Our population underwent an evaluation to assess their thyroid function. Exclusion criteria included individuals with pre-existing thyroid dysfunction before the onset of pregnancy.
Results
The average age was 34 ± 5 years. Pre-gestational body mass index (BMI) averaged at 27 ± 6.02 kg/m^2. No cases of hyperthyroidism were identified. Hypothyroidism was observed in 4% of patients. Among patients diagnosed with hypothyroidism, the average TSH (Thyroid Stimulating Hormone) level measured at 6.1 mU/l. The anti-thyroid peroxidase antibodies (anti TPO Ab) tested positive, in one patient with hypothyroidism. Age exhibited a significant positive correlation with hypothyroidism ($P=0.039$). While there was no statistically significant difference in the average HbA1C ($P=0.488$). Patients with higher pre-gestational BMI displayed an elevated risk of developing hypothyroidism ($P=0.026$).
Conclusion
The prevalence of hypothyroidism among pregnant women diagnosed with GDM underscores the imperative for proactive and comprehensive screening strategies. Early detection and management of hypothyroidism during gestation are paramount in mitigating potential obstetric and fetal complications, prioritizing the optimal health outcomes for both the mother and fetus.

A pediatric case of abscessed thyroiditis: unveiling an unexpected etiological discovery

Heyfa Belhadj-Miled[1], Houas Jihene[1], Monia Ghammam[1], Oussama Khalfi[2], Malika El Omri[1], Abir Meherzi[1], Mouna Bellakhdhar[1], El Ghali Wassim[3], Yosra Hasni El Abed[4], Wassim Kermani[1] & Mohamed Abdelkafi[1]
[1]Farhat Hached Hospital, ENT dapartment, Sousse, Tunisia; [2], department of radiology, Sousse, Tunisia; [3], Department of Anaesthesia, Sousse, Tunisia; [4], Department of Endocrinology, Sousse, Tunisia

Introduction
Thyroid abscess in the pediatric population is an uncommon presentation and the rarest form of thyroiditis. Anomalies of the third and fourth branches account for 2-8% of cases. Through the observation of febrile torticollis secondary to an acute suppurative thyroiditis, we describe our diagnostic and etiological approach and specify its therapeutic management.
Materials and Methods
We present a rare case of an abscessed thyroiditis complicated by febrile torticollis, reported in our ENT Department.
Results
The patient is a 6-year-old with no significant medical history, presenting with febrile torticollis and a left basicervical swelling evolving for ten days. Examination revealed a febrile swelling in the left lateral thyroid compartment, measuring 5 cm in the major axis, firm, painful, with inflammatory signs. The rest of the ENT and general examination showed no anomalies except for a fever of 39°C. Ultrasound demonstrated an irregular oval mass with lobulated contours, measuring 54×1 mm, multilocular, located in the left basicervical region, pushing back the ipsilateral carotid axis and the left lobe of the thyroid. Cervical CT revealed a lobulated and multilocular mass in the left lateral and basicervical region, measuring $54 \times 42 \times 57$ mm. Posteriorly, it extended into the retro-pharyngeal space, causing bulging of the left lateral wall of the hypopharynx and reducing the lumen of the ipsilateral piriform sinus. Esophageal transit revealed the presence of an opacified fistulous tract originating from the left piriform sinus. Hypopharyngoscopy showed a small fistulous opening at the bottom of the left piriform sinus, leading to the diagnosis of a fourth branchial cleft cyst. The initial treatment involved incision and drainage combined with intravenous antibiotic therapy. Subsequently, after resolution of the infectious episode, cyst excision was performed along with left lobo-isthmectomy and cauterization of the fistulous opening with silver nitrate. The patient's evolution was favorable with a one-year follow-up.
Conclusion
Febrile torticollis in children is an infrequent reason for consultation. It can be the revealing pattern of extremely rare ENT pathologies, including congenital cervical anomalies in children.

Assessment of quality of life in elderly patients with primary hypothyroidism

Meriem Antit[1], Ibtissem Oueslati[1], Amani Terzi[1], Dorra Khomsi[1], Arige Abid[1], Meriem Mabrouk[1] & Melika Chihaoui[1]
[1]La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Hypothyroidism is a prevalent endocrine disease among the elderly. The thyroid hormones have a wide range of effects on the body, and hypothyroidism can significantly impact both physical and mental functions. The objectives of this study were to evaluate the quality of life in patients over 65 years old with substituted hypothyroidism and to assess their relationship with Thyroid Stimulating Hormone (TSH) level.
Methods
The study was a cross-sectional assessment of 80 patients over 65 years old who had primary hypothyroidism. They were treated with levothyroxine for at least one year. Clinical data and TSH level were collected from medical files. The SF-36 questionnaire was used to evaluate the quality of life (QoL). QoL was good if the overall SF36 score was above 60, poor if it was below 30 an average if it was between 60 and30.
Results
The mean age of the participants was 69.9 ± 4.6 years (Extremes: 65-82 years). The majority of patients (63%) were adequately controlled. The mean SF36 global score was 52.4 ± 22.5. QoL was good in 38% of cases, average in 41%, and poor in 21%. There was neither relationship between QoL and TSH nor QoL and levothyroxine dose. The percentage of patients who were adequately controlled was 70% in patients with good QoL compared to 58% in patients with average or poor QoL ($P=0.002$).
Conclusions
Decreased QoL was prevalent among elderly patients with hypothyroidism. Good control of the disease was significantly associated with better QoL.

Pazopanib-induced hypothyroidism in a patient with metastatic renal carcinoma

Zineb Ait Si Ali[1], Hind Ouakrim[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction
Pazopanib is a tyrosine kinase inhibitor (TKI), approved for the treatment of metastatic renal cell carcinoma and could improve progression-free survival and overall survival. The frequency of Pazopanib-induced hypothyroidism was reported to be 10–29%. We aim through this case to highlight the importance of thyroid function monitoring during treatment with TKI.
Case report
Female patiente of 41 years old, followed in oncology departement for clear cell renal carcinoma with hepatic metastasis, treated with pazopanib 1 mg per day for 8 months. During the follow-up the patient was refereed to our department for an elevated TSHus 1 ui/l. She presented an intermittent constipation and frilosity. Clinical examination noted no goiter. Neck-ultrasoud showed a normal thyroid gland volume with heterogenous stucture of thyroiditis aspect. Anti-TPO and anti-TG antibodies were negative. The patient started L-thyroxine 75 mg per day with good evolution and normalisation of TSHus levels. After 5 months the patient stopped Pazopanib for 2 months (availability issu), and presented signs of thyrotoxicosis with suppressed TSHus level 0.1 UI/l, L-thyroxine therapy was discontinued 6 weeks later TSHus remained normal 2.1 UI/l. One month later Pazopanib has been restarted, then the patient, represented once again an elevated TSHus: 8.1 UI/l requiring resumption of L-thyroxine therapy. The clinical evolution was favorable, appropriate follow up is planned.
Conclusions
In patients treated with TKI, the thyroid toxicity is common and pauci-symptomatic at the beginning of their evolution but can lead to prolonged hypothyroidism. Pathophysiological mechanisms linked to hypothyroidism in patients receiving TKI are unclear. Some researchers have hypothesized that the hypothyroidism may be due to the direct toxicity of TKI on the thyroid. Other hypotheses have been suggested; VEGF/R-TKI block thyroid hormone biosynthesis through thyroid peroxidase inhibition, increasing type 3 deiodination... The classic presentation of dysthyroidism associated with TKI is silent thyroiditis, beginning with a phase of thyrotoxicosis secondary to thyroid vesicles destruction releasing the stock of thyroid hormones, it can be treated with non-cardioselective β-blockers or even with cholestyramine. Then the patient may develop hypothyroidism, which is reversible in half of the cases. Thyroid function monitoring is important, it's recommended by the French Society of Endocrinology, to measure the TSH/free T4 levels before starting treatment, and every 3 to 4 weeks during the first 6 months as changes in free T4 levels precede the changes in TSH by 3 to 6 weeks. After this period, TSH measurement alone may be conducted every 2-3 months.

Persistent post-procedure hyperthyrotropinemia with an RTH? phenotype: a case report

Radvile Matukaitiene[1,2], Martyna Juskiene[2] & Birute Zilaitiene[1,2]
[1]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania, [1]Clinic of Endocrinology; Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Kaunas, Lithuania

Resistance to thyroid hormone beta (RTH?) is a rare disorder which poses challenges in both diagnostics and management. The prevalence varies from 1/19,000 to 1/40,000. In 14% of individuals manifesting with RTH? phenotype no THRB mutations were identified.
The management of these patients, especially after total thyroidectomy, in the absence of generalized consensus is complicated. 36-year-old woman was referred to endocrinologist with symptoms of thyrotoxicosis and dissonant thyroid hormone levels (TSH 1.3-2.5 mU/l n0.4-3.6, FT4 22-30 pmol/l n7.87-20.3; FT3 5.5-8 pmol/l n3.34-5.14). Medical history revealed the exclusion of thyrotropinoma, toxic adenoma, autoimmune thyroid diseases. In 2009, she underwent hemithyroidectomy for thyroid nodules, at that time she was experiencing milder thyrotoxicosis symptoms. Post-surgery, she felt well for several years. Center endocrinologists suspected resistance to thyroid hormone, particularly RTH?, beta-blockers were prescribed and patient was referred for genetic testing. Despite that she was doing relatively well on propranolol, genetic results were pending, she declined to wait and insisted on a thyroidectomy (based on her well condition after hemithyroidectomy in 2009 and the presence of several 1-1,5cm diameter nodules near the isthmus). Thyroidectomy took place on 13-04-2023. After surgery, she was prescribed 100 mg of Levothyroxine per day. Approximately 1.5 months post-surgery, hypothyroidism was observed (TSH19.4; FT4 11.34; FT3 3.06), leading to an adjustment in Levothyroxine dosage to 100/125mcg. Genetic testing, at least for now, exluded thyroid pathology. Following the dose increase, she experienced a burning sensation in the chest area, spreading to the shoulders, back, and abdomen. Additionally, there was an increase in resting pulse rate to 120 beats/minute, heart palpitations, and a slight tremor in the legs. Beta-blockers were prescribed for tachycardia. The symptoms resolved after several days of discontinuing thyroxine. Due to possible intolerance, Euthyrox was prescribed, the symptoms worsened (severe headache, dizziness), prompting the patient to revert to L-thyroxine with a lower dose. No adverse symptoms were reported on levothyroxine 50mcg, but laboratory tests indicated hypothyroidism (TSH23.8; FT4 9.24; FT3 2.35). Novothyral was added, resulting in a with tachycardia and profuse sweating (beta-blockers were ineffective), leading to the discontinuation of Novothyral. The levothyroxine dose is currently being increased slowly (25mcg over 1-2 months), now on 100mcg p/d. Hypothyroidism is regressing, albeit slowly. Optimal management of RTH? cases is still not known, it seems that thyroidectomy brings a new challenges in postoperative hypothyroidism treatment. Because this pathology is rare, the best solutions can only come from sharing experiences, creating hope for a consensus soon.

Thyroid parameters in healthy pregnant women without autoimmune thyroid disease

Violeta Mladenovic[1, 2], Sanja Medenica[3, 4], Zoran Gluvic[5, 6] & Milena Mitrovic[7, 8]
[1]University Clinical Center Kragujevac, Clinic for Endocrinology, Kragujevac, Serbia; [2]Faculty of Medical Sciences University of Kragujevac, Internal Medicine, Kragujevac, Serbia; [3]Clinical Center of Montenegro, Department of Endocrinology, Internal Medicine Clinic, Clinical Center of Montenegro, Podgorica, Montenegro; [4]University of Montenegro, School of Medicine, Podgorica, Montenegro; [5]Zemun Clinical Hospital Center, Division of Internal Medicine, Deptartment of Endocrinology, Beograd, Serbia; [6]University of Belgrade - Faculty of Medicine, Beograd, Serbia; [7]Clinical Center of Vojvodina, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Novi Sad, Serbia; [8]Medical Faculty in Novi Sad, Novi Sad, Serbia

Introduction
Pregnancy has a significant effect on the thyroid gland and thyroid function. Thyroid hormone regulates metabolism, growth, and development in most tissues of the body, including various physiological processes. Normal thyroid function is important in order to ensure the best outcome.
Aim
The aim of this study is to analyse values of thyroid parameters during pregnancy in healthy population of pregnant woman.
Matherial and methods
The study included 77 pregnant women in the first trimester registered in Clinic for endocrinology UCC Kragujevac that were tested using OGTT, according to ADA criteria: pregestational and gestational diabetic women were excluded, and also determinaning thyroid parameters (fT4, TSH, TPOAb). The sample size included women in each trimester. We analyzed the values of thyroid parameters in 46 healthy pregnant women (without gestational diabetes mellitus and thyroid disorders including autoimmune thyroiditis). The characteristics of the participants were expressed as mean ± standard deviation.
Results
The mean age of 46 healthy pregnant women was 29.4±4.5 years. The results has been shown in the tables.

Table 1. The mean values of thyroid status parameters during pregnancy

X±SD (95%CI)	1. trimester	2. trimester	3. trimester	After delivery
fT3 (pg/ml)	2.67±0.49 (2.53-2.82)	2.13±0.49 (1.99-2.28)	2.15±0.45 (2.02-2.29)	2.44±0.5 (2.29-2.59)
fT4 (pg/ml)	10.68±2.16 (10.04-11.32)	7.58±2.11 (6.96-8.21)	7.18±1.48 (6.75-7.63)	10.48±2.27 (9.81-11.16)
TSH(mIU/l)	2.09±1.11 (1.76-2.42)	2.59±1.47 (2.16-3.03)	2.48±1.18 (2.13-2.83)	1.97±0.89 (1.7-2.24)

Table 2 Range of values in the examined population for the movement of thyroid function parameters during pregnancy

parameter (min-max)	1. trimester	2. trimester	3. trimester	After delivery
fT3 (pg/ml)	1.98-3.16	1.64-2.62	1.7-2.6	1.94-2.94
fT4 (pg/ml)	8.52-12.84	5.47-9.69	5.7-8.66	8.21-13.11
TSH (mIU/l)	0.98-3.2	1.12-4.06	1.3-3.66	1.08-2.86

Conclusion
This study demonstrates that as the pregnancy progresses, the average values of fT3 and fT4 decrease, and TSH increases, only to return to values similar to before pregnancy after delivery.

Euthyroid sick syndrome in severe sars-cov-2 disease
Ifigenia Kostoglou-Athanassiou[1], Lambros Athanassiou[2], Eleni Ziambara[3], Alexandra Konstantinou[3], Sofia Nikolakopoulou[3], Charilaos Samaras[3] & Panagiotis Athanassiou[4]
[1]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece; [2]Asclepeion Hospital, Voula, Department of Rheumatology, Athens, Greece; [3]Asclepeion Hospital, Voula, 1st Department of Medicine, Athens, Greece; [4]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece

Euthyroid sick syndrome also known as nonthyroidal illness syndrome is the reaction of the thyroid gland to severe disease. The SARS-CoV-2 virus affects the thyroid gland and may cause subacute thyroiditis, autoimmune Hashimoto's thyroiditis, Graves' disease, exacerbation of Graves' disease and a form of silent thyroiditis. The aim was to study thyroid hormone levels and identify the presence of euthyroid sick syndrome in the context of severe SARS-CoV-2 disease. A group of 108 patients (68 male and 40 female) who were hospitalized for severe SARS-CoV-2 disease were studied. In these patients the levels of TSH, FT_4 and FT_3 were measured. TSH levels were measured in serum by the ARCHITECT TSH immunoassay (Abbott Park IL, USA). FT4 levels were analyzed in the serum of the patients via the ARCHITECT FT4 microparticle chemiluminescent immunoassay (Abbott Park IL, USA). FT3 was measured in serum using the ARCHITECT FT3 microparticle chemiluminescent immunoassay (Abbott Park IL, USA). TSH levels were 1.25 ± 01.19 μIU/ml (mean $\pm$ SEM), FT_4 levels 9.31 ± 0.5 ng/dl and FT_3 levels 3.5 ± 0.09 pg/ml . In 42 patients the presence of euthyroid sick syndrome was identified. The presence of euthyroid sick syndrome was related to the outcome of SARS-CoV-2 disease. The SARS-CoV-2 virus affects the thyroid gland and may cause autoimmune and autoinflammatory disease such as subacute thyroiditis, autoimmune Hashimoto's thyroiditis, a form of silent thyroiditis and exacerbation of Graves' disease. In patients with severe COVID-19 disease the presence of euthyroid sick syndrome was identified. In other reports the presence and severity of euthyroid sick syndrome was related to disease severity and disease outcome in COVID-19 patients.

Therapeutic plasmapheresis for the treatment of thyrotoxicosis: a case series
Zineb Ait Si Ali[1], Ilham Midhat[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Centre Hospitalo-Universitaire Mohammed VI Marrakech, Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakech, Morocco

Introduction
Hyperthyroidism is the excessive secretion of hormones by the thyroid gland. Synthetic antithyroid agents, surgery and radioactive iodine are the main available treatments. Plasmapheresis is a rapid and effective treatment option in cases where euthyroidism must be achieved rapidly because of the complications of thyrotoxicosis and the major adverse effects of antithyroid drugs.
Patients and methods
We report a series of 6 patients who underwent plasmapheresis for the treatment of hyperthyroidism. Our aim is to highlight the crucial role played by plasmapheresis in the treatment of hyperthyroidism, especially when other therapeutic options are contraindicated.
Résultats
The average age of our patients was 40, ranging from 22 to 60 years. The etiologies of hyperthyroidism varied between toxic multinodular goitre (2 cases), grave's disease (3 cases) and Hashitoxicosis (1 case): The indications for plasmapheresis were: Preparation for surgery in 5 cases, with contraindications to antithyroid agents in 4 cases (1 case of pregnancy, 3 cases of hepatic cytolysis) and one case of resistance to antithyroid agents, and severe hashitoxicosis in a 12-day-old pregnancy In our 6 cases, we noted normalization of FT4 levels, and a favorable outcome in 5 patients, with one case of death (hepatic failure).
Discussion and conclusion
In the treatment of hyperthyroidism, synthetic antithyroid drugs, radioactive iodine 1131 and surgery may be options, depending on the etiology. In cases where synthetic antithyroid drugs are insufficient or cannot be prescribed due to major adverse effects, free thyroid hormone levels can be reduced by plasmapheresis prior to radical treatment. Plasmapheresis has been reported in the literature in patients with thyrotoxicosis, and is a reliable and effective therapeutic option. However, it cannot be used on a large scale, as it is costly and invasive. In our study, plasmapheresis proved effective in reducing thyroid hormone levels and preparing patients for appropriate radical treatment.

Next generation sequencing study in follicular differentiated thyroid cancer: a prospective indian study
Ramesh Bangaraihgari[1], Ramakanth Bhargav Panchangam[2], Sabaretnam Mayilvaganan[3], Rajesh Bangaraiahgari[1] & Udaya Kumar N[4]
[1]TRR Institute of Medical Sciences, Hyderabad, India; [2]BGH, Endocrine and Metabolic Surgery, Vijayawada, India; [3]Sgpgims, Endocrine Surgery; [4]AIMS, Biochemistry

Background
Follicular differentiated thyroid cancer (FDTC) is the most common endocrine cancer, globally. Next-generation sequencing (NGS) in thyroid cancer allows for high-throughput genetic sequencing with quick turnover. NGS Studies on papillary thyroid cancer are scanty from South East Asia. In this context, we conducted this study of a genetic panel wide somatic mutations in thyroid cancer.
Methods
We selected 21 FDTC cases. All of them underwent total thyroidectomy with neck dissection as needed. Tumour tissue samples extracted and paraffin embedded, were taken from ex-vivo specimens. Sample processing, DNA extraction, cDNA preparation and PCR amplification was performed. Mutation analysis with a thyroid cellular pathway specific 56-gene mutation panel using real-time PCR and ThyroSeq v2 on the Ion Torrent PGM sequencer was employed. Common single nucleotide polymorphisms (SNPs) with a minor allele frequency of >0.05 were excluded. Mutations were also manually checked using the Integrated Genomics Viewer v2.4.10 to filter out false positives.
Results
The analysis found mutations commonly in BRAF (17), CDKN2A (9), NRAS (6), PI3KCA (8), RET (4), RAS (12) and TP53 (3) genes. The common mutations found in the samples was RET (M918T), NRAS (Q61R), BRAF (V600E) and missense mutation in TP53 (c.217 – c.1178). A mutation has also been identified in KMT2D gene in two of the patient samples. BRAF, CDKN2A, PI3KCA were more common in papillary cancer. RAS, NRAS, RET mutations were common in follicular cancer. TP53 and KMT2D were seen only in poorly differentiated cancer.
Conclusions
NGS appears to be helpful in patient management and providing risk. More prospective studies are needed for its routine use at clinical level.

Skin metastasis of papillary thyroid carcinoma as a late complication of subcutaneous hematoma associated with fine needle aspiration
Yotsapon Thewjitcharoen[1, 1], Ekgaluck Wanothayaroj[1], Soontaree Nakasatien[1], Veekij Veerasomboonsin[1] & Thep Himathongkam[1]
[1]Theptarin Hospital, Diabetes and Thyroid center, Bangkok, Thailand

Background
While needle tract seeding has long been recognized as an uncommon complication of the fine needle aspiration (FNA) of the thyroid nodules, seeding

tumor metastasis resulted from subcutaneous hematoma following FNA is extremely rare. Herein, we present a challenging case of skin metastasis of papillary thyroid carcinoma as a late complication of subcutaneous hematoma associated with fine needle aspiration.
Clinical case
A 57-year-old male presented with anterior neck mass for 6 months. Neck ultrasound revealed a huge cystic mass with a hypervascularity exophytic solid nodule, 2.7 cm in diameter at the left thyroid lobe. Approximately 55 ml of hemorrhagic fluid was aspirated and followed by FNA of the solid component with a 23-gauge needle. Two days later, he returned with swollen and ecchymosis of the surrounding neck. The cervical hematoma resolved conservatively and total thyroidectomy was done one month later. Classic variant of papillary thyroid carcinoma (PTC) in the left thyroid gland with lymphatic invasion was found. No metastatic lymph node was detected. Postoperative high-dose radioiodine (RAI) ablation and thyroxine suppressive therapy were given. He was doing well with persistent biochemical incomplete response at one year after treatments and subsequently lost to follow-up. He came back two years later with palpable multiple subcutaneous nodules along the right side of the neck for 3 months. Ultrasound revealed small well-defined nodules (0.3 to 0.7 cm in diameter) located superficially over the right sternomastoid muscle. Further investigations revealed no distant metastases. Neck reoperation confirmed skin metastasis of PTC. The patient was in stable condition with persistent biochemical incomplete response at the last follow-up.
Conclusions
FNA of the thyroid is regarded as a safe procedure. However, physicians should be watchful of hemorrhagic complications in high-risk patients and aware that late complications such as seeding tumors could develop many years after bleeding complications.

EP180

Autoimmune thyroid disease as a risk factor of atherosclerosis

Tamuna Gvianishvili[1, 2] & Maia Kapanadze[2, 3]
[1]Ivane Javakhishvili Tbilisi State University, Alexandre Natishvili Institute of Morphology, Tbilisi, Georgia; [2]Tbilisi State Medical University, Tbilisi, Georgia; [3]Academician O. Gudushauri National Medical Center, Tbilisi, Georgia

The relationship between subclinical hypothyroidism (SH) and Atherosclerotic (At) cardiovascular diseases (CVD) has been one of the most popular and discussing topics, because the existence of a causal relationship between Hashimoto's thyroiditis (HT), the lipid profile, and the molecular biology of the follicular epithelium has not been conclusively established. We investigated 59 patients (female), which had undergone total thyroidectomy, lobectomy. Patients were divided into 3 groups: group I – HT ($n=22$), group II – HT with At ($n=12$), group III – At ($n=25$). Thyroid function and lipid profile were determined by international guidelines of laboratory tests, coronary and femoral arteries intima-media thickness (IMT) - high-resolution ultrasonography, histological (H&E) and immunohistochemical markers were used: transcriptional protein p63 and neuroectodermal marker protein S100. The obtained results showed that: dyslipidemia and the diastolic hypertension accelerate the hypothyroidism in II group (HT with At) by predisposing carotid and femoral arteries IMT. FT4 is related to clinical features of atherosclerosis, THS and anti-TPO antibody levels are directly linked to the cardiovascular disease complications (myocardial infarction and hypertension). Biomarkers S100 and p63 data revealed a direct negative correlation between hypercholesterolemia and high morphological risks of Hashimoto's parenchyma changes. Namely, the trend of follicular epithelial dysplasia changes in the form of remodeling of parenchyma stem cells was revealed.

Predictive biomarkers of thyroid dysfunctions associated with the treatment of tumors with immune checkpoint inhibitors

Ketevan Lomidze[1, 2], Marine Gordeladze[3] & Nino Kikodze[2]
[1]Israeli-Georgian Medical Research Clinic Healthycore, Clinical Trials Department, Tbilisi, Georgia; [2]Tbilisi State Medical University, Immunology, T'bilisi, Georgia; [3]Tbilisi State Medical University, Endocrinology, T'bilisi, Georgia

Background
Treatment with immune checkpoint inhibitors (ICIs) for advanced malignancies has been associated with developing immune-related adverse events (irAEs) severe enough to require the cessation of life-saving tumor immunotherapy.
Objectives
The present study aimed to identify predictive inflammatory markers of the development of immune-related thyroid dysfunctions in patients with cervical cancer (CC) and non–small cell lung cancer (NSCLC) treated by ICIs.
Methods
A retrospective study was conducted on twenty-seven patients with CC and NSCLC treated by ICIs. The data were collected before and 12 weeks after treatment. Complete blood count-derived inflammatory markers: dNLR (derived neutrophil to lymphocyte ratio), NLR (neutrophil to lymphocyte ratio), SSI (systemic inflammation index), PLR (platelet to lymphocyte ratio), WHR (white blood cells to hemoglobin ratio) were calculated. In addition, thyroid functional tests were collected. Data statistical analysis was performed by STATISTICA (Stat soft, Inc, USA).
Results
Five patients out of twenty-seven with CC treated by PD-1 and CTLA-4 inhibitors who developed hypothyroidism showed significantly high baseline PLR and low WHR compared to patients without clinical symptoms of hypothyroidism and reference levels of TSH and FT4. Association between NLR, dNLR, SSI, and thyroid dysfunction was not observed.
Conclusions
Our findings strongly correlate with hypothyroidism and WHR and PLR biomarkers. As a result, using these biomarkers for early identification of hypothyroidism helps treat thyroid dysfunction and improves cancer immunotherapy outcomes.

Antithyroid medication (carbimazole and propylthiouracil) induced haemolytic anaemia- a case report

Ishara Ranathunga[1], Chandima Idampitiya[1] & Fathima Pambinezhut[1]
[1]Cumberland Infirmary, United Kingdom

Background
Haematological side effects of Carbimazole such as aplastic anaemia, thrombocytopenia and agranulocytosis are widely reported. However, Carbimazole induced haemolytic anaemia is rare. Proplythiouracil is known to cause leucopenia, agranulocytosis, bone marrow hypoplasia and pancytopenia. Nevertheless, Propylthiouracil associated haemolytic anemia is rarely reported. In such situations, the options for managing Hyperthyroidism are limited, especially in frail elderly individuals. We report a case of Carbimazole and Propylthiouracil induced haemolytic anaemia which resolved following discontinuation of the medication and starting on steroids.
Case presentation
An 83-year-old female presented with tiredness, low mood, indigestion, palpitations and anxiety. She was mildy thyrotoxic with no clinically evident goitre. TSH was suppressed at <0.02 mU/l with a fT4 of 32.1 pmol/l. Her thyroid receptor antibody (TRAb) was negative. Thyroid uptake scan revealed a total uptake of 0.7% with 0.5% left lobe and 0.3% right lobe. Both thyroid lobes appeared large with heterogeneous uptake, but there were no discrete avid nodules. The diagnosis of hyperthyroidism due to thyroid autonomy was made and she was started on Carbimazole 10 mg once daily. After 3 weeks, she presented with jaundice and worsening tiredness. On clinical evaluation she was anaemic with a haemogloblin of 1 g/l. The reticulocyte count of 412×109/l, with polychromasia, spherocytes and positive auto anti-e, pan reactive IAT antibody confirmed the diagnosis of Carbimazole induced haemolytic anaemia. Carbimazole was discontinued and high dose corticosteroid was started which was gradually tapered according to the clinical response. Six months following discontinuing Carbimazole, she presented with a relapse of hyperthyroidism. Her TSH was suppressed (<0.1 mU/l) with raised Free T4 32.1 pmol/l and Free T3 7.1 pmol/l. Due to the frailty, the alternative treatment options were limited. Therefore, she was started on a trial of propylthiouracil 1 mg twice daily with close monitoring. Subsequently, she developed a recurrence of haemolytic anaemia with a haemoglobin of 80 g/l just 1 week following Propylthiouracil initiation. Propylthiouracil was discontinued and she was treated with corticosteroids. Cholestyramine 1 g once daily was started as an adjunctive treatment for hyperthyroidism. She responded well to the medications with improvement in the haemoglobin and remains euthyroid to date.
Conclusions
Antithyroid induced haemolytica anemia is an extremely rare adverse effect of the medication. A patient developing haemolytic anaemia to both Carbimazole and Propylthiouracil has not been documented in the literature. The awareness of rare adverse effects related to antithyroid medication and timely management can improve the patient outcomes.

Hydatid cyst disease of the thyroid gland: about five cases

El Omri Malika[1], Jemli S[1], Bellakhdher Mouna[1], Meherzi Abir[1], Houas Jihene[1], Ghammem Monia[1], Ach Taieb[2], Kermani Wassim[1] & Abdelkefi Mohamed[1]
[1]ENT department Farhat Hached Hospital, Sousse, Tunisia; [2]Endocrinology Department Farhat Hached Hospital, Sousse, Tunisia

Introduction
The hydatid cyst location in the thyroid gland is very rarely mentioned with an incidence varying between 0% and 3.4%due to the absence of specific clinical elements and the exceptional nature of this location. The aim of our work to study the epidemiological, clinical and therapeutic aspects of hydatid cyst of the thyroid gland. We report five cases of hydatid cyst of thyroid gland carried out in our ENT department.
Results
The average age of the patients was 40 years old with a range of 26 to 51 years. All patients were living in a rural area. Only one patient had undergone previous surgery for hydatid cyst disease. The patients consulted with firm basicervical swelling in 4 cases and renitent in one case. No sign of compression was associated (no dyspnea or dysphonia if dysphagia). Cervical ultrasound showed a multinodular goiter with multiple cystic nodules in 3 cases and a solitary solidocystic nodule in 2 cases. The treatment was loboisthmectomy in 2 cases and total thyroidectomy in 3 cases. The diagnosis was confirmed post operatively by pathology. There was no recurrence after an average follow-up of 3 years
Conclusion
The location of the hydatid cyst in the thyroid gland is rare, even in countries with high endemicity. The clinical symptoms depend on the location and size of the cyst. Positive diagnosis can be difficult preoperatively. The treatment is exclusively surgical, removing the cyst without breaking it.

Gynecomastia as the first manifestation of thyrotoxicosis: an unusual case report

Catarina Cidade-Rodrigues[1], Vania Benido Silva[1], Bruna Silva[1] & Margarida Almeida[1]
[1]Centro Hospitalar do Tamega e Sousa, Endocrinology, Penafiel, Portugal

Introduction
Gynecomastia is a benign excessive proliferation of glandular tissue in the male breast and results from an increased breast estrogen/androgen activity ratio. It may be physiological (infancy, puberty or aging) or pathological. The most common cause is drug-induced. Although hyperthyroidism is a rare cause(1.5%), gynecomastia occurs in up to 25-40% of males with Graves' disease and is often undiagnosed. Its development as the first manifestation of this thyroid disease is quite unusual. We present a case of a young man with gynecomastia as a presenting sign of Graves' disease.
Case report
34-years-old male with chronic kidney disease (reflux nephropathy) since childhood, arterial hypertension and hyperuricemia, treated with lercanidipine, alopurinol and sodium bicarbonate, was referred to Endocrinology appointment due to a nonpainful increase in breast volume, right breast tension for 1 year, mild hyperprolactinemia and a newly diagnosed thyrotoxicosis. Clinically, he referred a recent slight hands' tremor at rest and notion of bilateral periorbital edema for 2 weeks. He denied galactorrhoea, headaches, visual disturbances, symptoms of hypogonadism, drug or steroid consumption as well as other thyroid function disruptors, previous testicular surgery, radiation or trauma. Physical examination: bilateral nonpainful gynecomastia, inversion of left nipple, bilateral exophthalmos, resting tremor, BP 153/1 mmHg, HR 107-117 bpm. Blood workup: TSH < 0.01 uUI/ml (0.38-5.33), FT3 5.91 pg/ml (2.5-4.4), FT4 2.1 ng/dl (0.54-1.24), TRAbs 8.1 UI/l (<2.9), prolactin 36.8 ng/ml (2.6-13.1), LH 9.8 mUI/ml (1.2-8.6), FSH 8mUI/ml (1.3-19.3), total testosterone 5.1 ng/ml (1.98-6.79), estradiol 32 pg/ml (<30), SHBG 73.5 nmol/l (13-71), beta-hCG 0.5 mUI/ml (<2.7), alpha-fetoprotein 1.1 ng/ml (<9). Thyroid ultrasound:normal volume, hypoechogenic heterogenous structure, no nodules. Breast ultrasound:asymmetric gynecomastia (more pronounced on the right) and 1 mm left retroareolar cyst. Scrotal ultrasound:mild asymmetry in testicular dimension, homogenous structure, regular margins, no nodules. Diagnosis:hyperthyroidism due to Graves' disease and hyperprolactinemia likely due to chronic kidney disease. Treatment:methimazole (MMI)1 mg/day. At 2 months follow-up, thyroid function tests were TSH <0.01uUI/ml, FT4 1.1 ng/dl (normal), FT3 3.74 pg/ml (normal), allowing for slow reduction in MMI.
Discussion and Conclusions
In this patient, possible causes of gynecomastia were chronic kidney disease, hyperprolactinemia and hyperthyroidism. However, due to long-standing kidney disease with no documented recent worsening of their baseline function, a very slight elevation of prolactin and recent development of gynecomastia and symptoms of hyperthyroidism, the most likely cause is the latter. Hyperthyroidism induces gynecomastia through a combination of decreased free androgen levels and overproduction of estrogens. It is important that clinicians perform thyroid function tests when evaluating a patient with gynecomastia, even when other possible causes coexist, so that the diagnosis and treatment of hyperthyroidism are not missed.

Refractory hypothyroidism: 5-days levothyroxine absorption test to diagnose pseudomalabsorption

Doaa El Bazi[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital - Casablanca, Morocco Clinical Neuroscience and Mental Health Laboratory Faculty of Medicine and Pharmacy - Hassan II University, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Refractory hypothyroidism is defined by clinical or biochemical signs of hypothyroidism (serum TSH level >4.5 mU/l after an interval of six weeks after the last dose increase), despite increasing levothyroxine (LVT) doses beyond 2.5 µg/kg per day.
Observation
A 67-year-old female patient, followed for a 1 mm NIFT-P classified as pT1a, low risk, initially put on LVT 150 mg/day, presented with hypothyroidism, clinically with asthenia, constipation, and biologically with a TSHus of 145 mUI/l, despite titration of LVT up to 1 mg/day (i.e, 4.1 mg/kg/day), liothyronine sodium 0.1 mg/day and dexamethasone 1 mg/day. The patient reports good therapeutic compliance, with good levothyroxine conservation. She does not report signs of malabsorption.
Methods
The patient was hospitalized in the endocrinology and metabolic diseases department for a 5-days levothyroxine absorption test. The principle consists of supervised administration of LVT on an empty stomach with monitoring the patient 1h after the ingestion. TSHus and FT4 blood samples were taken before LVT administration in 1st day of the test and 2h after administration in 5th day of the test.
Results
On the first day, TSHus before LVT administration was 91 mIU/l (0.25-5), with FT4 at 0.3 ng/dl (0.7-1.5). Then, on the 5th day, TSHus 2 hours after administration was 40.27 mIU/l (0.25-5), and FT4 was normal at 20.5 pmol/l (10-28.2). The patient was subsequently, switched to LVT tablets (due to the high cost of liquid LVT). A thyroid function test was repeated after 5 days, showing normalization of TSHus at 1.39 mIU/l (0.25-5), and FT4 at 20.4 pmol/l (10-28.2). In addition, a malabsorption check-up was revealed intestinal amebiasis of the Entamoeba histolytica histolytica, treated with a negative control work-up. Associated with a Helicobacter pylori chronic gastritis under treatment.
Conclusions
The 5-days LVT absorption test allowed the diagnosis of pseudomalabsorption in this patient, given the normalization of the thyroid function test, despite the presence of Helicobacter pylori gastritis.

Taking nothing for granted- Levothyroxine formulation

Irene Samperi[1], Chiara Bima[1], Piero Radaelli[1], Mara Steffanini[1] & Maria Chantal Ponziani[1]
[1]SSD of Diabetology and Metabolic Diseases - Azienda Sanitaria Locale Novara, Novara, Italy

Background
levothyroxine is the most common medication for the treatment of hypothyroidism. Usually, it is capable of restoring euthyroidism in most conditions. Absorption can be challenging, therefore different formulations are available (tablet, soft gel, liquid). Rarely it is necessary to use liothyronine to achieve normal TSH values.

Clinical case
a 23 y/o woman was admitted to our outpatient clinic for severe hypothyroidism. She was diagnosed with autoimmune thyroiditis at the age of 10. She also has celiac disease and schizoaffective disorder. She lived in a community and was followed by medical personnel. She was on a gluten-free diet and antipsychotic drugs: Lithium, Duloxetine, Lorazepam, Clozapine and quetiapine. On medical examination, she has obesity with no cushingoid aspect, normal heartbeat and blood pressure. She felt tired and had regular menses. She denied any other specific symptoms. She was on treatment with Levothyroxine tabs 200 mg/day (1.78 mg/kg/day), and her TSH was 386 mU/l with no measurable Ft3 and FT4. We excluded Helicobacter pylori infection and emphasized the need for a gluten-free diet and the correct way of taking medication. We advised a shift to soft gel formulation increasing the dose up to 250 mg/day After two months her TSH was 18.1 mU/l. Four months later her TSH was 1 mU/l, we therefore gradually increased levothyroxine to 1 mg shifting to liquid formulation with no benefit. We then changed the levothyroxine brand. We gradually added liothyronine up to 15 mg 3 times per day. After 2 months she was on levothyroxine 1 mg (3 mg/kg/day) and liothyronine 1 mg per day and her TSH was 1 mU/l. We investigated with caregivers who assured us she took medication correctly and properly followed the diet. She could have severe malabsorption so we undertook the levothyroxine absorption test. While she was having the test we realized that she couldn't empty the bottle. We then explained to her and her caregiver how to take the medication and she restored euthyroidism with levothyroxine 164 mg/day (1.6 mg/kg/day) without the need for liothyronine. Regardless of thyroid hormone values she never complained of any other symptoms, or benefit from the restored euthyroidism.
Conclusion
psychiatric patients can be challenging and symptoms can be underestimated. The new formulation of levothyroxine allows us to tailor approaches. Using the right medication and the right formulation for the right patient is crucial. Levothyroxine absorption test can still be used in specific settings.

Thyrotoxicosis in a molar pregnancy

Leah Antonette Tabuyo[1] &Hannah Corpuz[1]
[1]Lorma Medical Center, Internal Medicine, San Fernando City, Philippines

Hydatidiform moles are categorized as either complete or partial and can only be confirmed by karyotyping. Complete moles are more frequently associated with medical complications such as hyperthyroidism. A 46-year-old Filipino female presented with tachycardia, hypertension, b-hCG > 10,000 mIU/ml, suppressed TSH 0.006 mIU/l, high FT3 19.04 pg/ml (NV: 2.02 - 4.43) and FT4 7.77 ng/dL (NV: 0.93 - 1.71). Uterus was enlarged with contractions. Antihypertensives and Propylthiouracil (PTU) were given to facilitate urgent hysterectomy due to profuse bleeding. Post-operatively, FT4 decreased (3.94 ng/dl). Antihypertensives were continued, PTU discontinued and she was discharged stable. On follow-up, hCG decreased to 1021 mIU/ml, and she was euthyroid (FT4 9.27 pmol/L). Mechanisms of molar pregnancy-induced hyperthyroidism:
- structural similarity of hCG and TSH molecules and their receptors provides the basis for the thyrotropic action of hCG
- "spillover effect" which refers to a phenomenon where hormones that are not intended to act on a particular receptor can still bind to it and produce an effect
- the hCG found in hydatidiform moles lack the C- terminus and contain lower sialic acid which cause greater stimulation of the TSH receptor Reports have shown that hyperthyroid symptoms become apparent once ?-hCG levels reach 200,000 m[IU]/ml. It has been estimated that for every 10,000 m[IU]/ml increase in serum hCG, TSH decreases by 0.1 mIU/ml and free T4 increases by 0.1 ng/d
This case highlights an important yet uncommon etiology of thyrotoxicosis. Clinical presentation varies from asymptomatic to life-threatening thyroid storm, hence, early recognition and prompt intervention are essential to prevent disease progression. Molar evacuation is the definitive treatment. B-hCG titers and thyroid hormones are expected to normalize after. Up to date, there are no existing guidelines with regard to the use of anti-thyroid medications prior to or after surgery. Further studies are needed to deepen our understanding of this condition to improve early detection, optimize management, and reduce associated complications.

Analysis of clinical and ultrasound results after treatment with percutaneous ethanol injection in benign cystic thyroid nodules

Víctor José Simón Frapolli[1,2,3], Diego Fernández García[1], Ana María Gómez Pérez[1], Isabel Mancha Doblas[1] & Francisco Tinahones Madueño[1,2,3]
[1]Hospital Universitario Virgen de la Victoria, Málaga, Spain; [2]School of Medicine, Málaga, Spain; [3]BIONAND, Málaga, Spain

Introduction
Percutaneous ethanol injection (PEI) or thyroid enolisation is a minimally invasive technique applicable to benign cystic thyroid nodules, not adhered to neighbouring structures, due to local compressive symptoms or aesthetic discomfort. Classically, the treatment of choice for these nodules has been simple aspiration, followed by surgery in refractory cases. Currently, PEI has emerged as an alternative to surgery due to its high efficacy, speed, safety, low rate of serious side effects, outpatient nature and low cost. Although it is a procedure with limited experience, it is safe when performed by experienced professionals.
Method
Prospective observational study including 14 patients undergoing PEI in our Endocrinology Clinical Management Unit between January 2020 and December 2022. Demographic, clinical and ultrasound data were collected prior to the procedure. All patients underwent prior ultrasound-guided fine needle aspiration puncture (FNA) with a cytological diagnosis of benignity, and all had a history of simple evacuation with subsequent recurrence of the nodule. Technique: a single ultrasound-guided puncture was performed, without anaesthesia, following a transisthmic approach; using a double guidewire, the cystic content was emptied almost entirely, immediately followed by the administration of 10cc of 99% ethanol; a 30-minute observation was then maintained for the possible appearance of symptoms and/or immediate complications. Evacuated content was quantified and an ultrasonographically follow-up at 3 and 6 months was performed.
Results
The highest percentage of reduction was observed in men vs women (68.0 ± 23.71 vs 23.10 ± 31.6); in patients over 70 y.o. vs under 50 y.o. and between 50-70 y.o. (35.30 ± 27.54 vs 20.0 ± 39.77 and 29.90 ± 25. 22, respectively); in single nodule vs multinodular goitre (34.4 ± 21.57 vs 20.0 ± 25.60); in TIRADS-2 vs TIRADS-1 and TIRADS-3 (32.6 ± 38.37 vs 25.7 ± 24.84 and 21.4 ± 15.91, respectively) and in older nodules vs those with a shorter time of evolution (37.3 ± 28.05 vs 23.4 ± 33.23).
Conclusions
PEI is an effective treatment for symptomatic cystic thyroid nodules, with a mean reduction in nodule size of 29.7% at 6 months. After a second PEI, performed in 3 patients, the performance of the technique improved with a mean reduction of 35.7% at 12 months follow-up. No serious side effects were reported (transient pain in 53.8% of cases). The highest percentage of reduction is observed in men, older than 70 y.o., with single nodule, TIRADS-2 and > 5 years of evolution. These results are not statistically significant, probably due to the small sample size.

Dilated cardiomyopathy as a rare complication of inadequately treated hyperthyroidism – a case report

Ana Majic Tengg[1], Vlatka Pandzic Jaksic[1], Jasmina Catic[2] & tomislav novosel[3]
[1]Clinical Hospital Dubrava, Department of Endocrinology, Diabetes, Metabolic Diseases and Clinical Pharmacology, Zagreb, Croatia; [2]Clinical Hospital Dubrava, Department of Cardiovascular Diseases, Zagreb, Croatia; [3]Clinical Hospital Dubrava, Department of Otorhinolaryngology and Head and Neck Surgery, Zagreb, Croatia

Introduction
Thyrotoxic cardiomyopathy is a rare but potentially fatal form of dilated cardiomyopathy caused by hyperthyroidism not timely diagnosed or inadequately treated. The first-line treatment is a treatment of the underlying thyroid disease as the structural and functional cardiac alterations are potentially reversible after achieving a euthyroid state.
Case presentation
A 41-year-old man was admitted to hospital due to the symptoms of heart failure and tachycardic atrial fibrillation. He complained of dyspnea, peripheral edema, and palpitations. Before admission, he had been treated for thyrotoxicosis caused by Graves' disease in another country for seven months. Initially, he was given tiamazole, but it was replaced by propylthiouracil due to an allergic reaction (skin rash). Additionally, he had undergone electrocardioversion three times in the past six months, including the period of current hospitalization, to treat his tachycardic atrial fibrillation. His blood test results were as follows: TSH < 0.01 mIU/l, FT4 3.71 pmol/l, FT3 – 7.8 pmol/l. His TRAb level was 13.03 IU/l and his NT-proBNP level was 2444 pg/ml . Echocardiography revealed a dilation of the left heart chambers. The global contractile ability of the left ventricle was moderately reduced, with an ejection fraction (Simpson method) of 35%. Additionally, global hypokinesia of all segments, moderately severe mitral regurgitation, and a diastolic dysfunction were observed. As other causes of cardiac dysfunction had been ruled out, his heart condition was concluded to be a consequence of

unsatisfactory treatment of his thyroid disease. Therefore, his thyrostatic therapy was adjusted and the standard-of-care treatment for heart failure was initiated. He was also referred to the Multidisciplinary team for thyroid diseases, and it was decided that he would undergo a total thyroidectomy once his cardiac and thyroid status had stabilized. Four months later, a follow-up echocardiography showed that the global contractile ability of the left ventricle had improved significantly, with an ejection fraction (Simpson method) of 64%. There were no more signs of global hypokinesia. Due to the patient's suppressed TSH levels with normal FT3 and FT4 levels, it was decided to administer Lugol's Iodine solution prior to the total thyroidectomy, to achieve a preoperative euthyroid state. The total thyroidectomy procedure was successfully performed, and the patient was discharged as fully recovered. The patient's follow-up visits with a cardiologist and an endocrinologist are scheduled.

Conclusions

Hyperthyroidism should be considered as an etiological factor for dilated cardiomyopathy in the absence of other causes of structural and functional cardiac alterations.

DOI: 10.1530/endoabs.99.EP222

EP225

Post-partum thyroiditis with concurrent enlargement of thyroglossal duct cyst due to presumed thyroiditis within the cyst wall- a pathophysiological link or a coincidence?

Fatima Azad[1], Nadia Zarif[1] & Jana Bujanova[1]
[1]Southampton University Hospital NHS Foundation Trust, Department of Diabetes and Endocrinology, Southampton, United Kingdom

Introduction

The thyroglossal duct is an embryonic structure, lined predominantly by respiratory and squamous epithelium and typically involutes by the 10th week of gestation. If the thyroglossal duct does not involute, it can form cysts due to recurrent inflammation or infection, as it is lined by epithelium that is secretory in nature, with or without the presence of ectopic thyroid tissue. Thyroid tissue is present in the wall of the cyst/duct in 30-60% of cases.

Case report

38-year-old female presented five months postpartum with symptoms of heat intolerance, palpitations and weight loss. Her bloods confirmed hyperthyroidism with a FT4 of 31.8 pmol/l (7.7-15), TSH of 0.01 mU/l (0.34-5.6), WBC-4.7x10^9/l (4-11) and CRP- 1 mg/l (0-7.5). This was consistent with transient postpartum thyroiditis, followed by spontaneous recovery without the need for anti-thyroid medications. She had a family history of Grave's disease, but her thyroid stimulating immunoglobulins and anti-TPO antibodies were normal. She also had a background history of a stable small 1 mm thyroglossal duct cyst (TGDC) noted on ultrasound in 2010. On examination she was noted to have nontender, firm upper midline neck swelling at site of the known TGDC, however she reported TGDC size increase corresponding with the onset of hyperthyroid symptoms. Neck ultrasound confirmed a thin wall cyst with viscous fluid content and increase in size from 17x12x1 mm in 2010 to 30x15x1 mm). Her thyroid was of normal size with features of thyroiditis. There was no solid component within the cyst and the enlargement of TGDC was presumed to be related to thyroiditis within the cyst wall. The cyst was managed conservatively as ultrasound did not show any suspicious solid components and there was no evidence of infection.

Discussion

Autoimmune thyroiditis and thyroid cancer (predominantly papillary) have been reported within the ectopic thyroid tissue in the TGDC wall. The prevalence of cancer within the excised TGDS is reported at 0.7-4%, but there is no data on prevalence of thyroiditis in excised TGDCs. Our case illustrates that TGDCs might enlarge significantly as part of the post-partum thyroiditis process. In our case, the main contributor to the enlargement, in the absence of solid component on ultrasound, was accumulation of fluid from the epithelium in response to the presumed inflammation of the thyroid tissue within cyst wall. This might explain, why the TGDC size did not regress to baseline with resolution of thyroiditis (last follow up 9 months post onset).

Efficacy of Photobiomodulation as an additional Therapy in Hashimoto Thyroiditis

Venera Berisha-Muharremi[1, 2], Bernard Tahirbegolli[3, 4], Ruth Phypers[5] & Reem Hanna[6, 7, 8]
[1]Faculty of Medicine, University of Prishtina., Prishtina, Kosovo; [2]Poliklinika Endomedica., Prishtina, Kosovo; [3]Heimerer College, Prishtina, Kosovo; [4]National Sports Medicine Centre, Prishtina, Kosovo; [5]Laser Medicine Centre, London, United Kingdom; [6]King's College Hospital NHS Foundation Trust, London, United Kingdom; [7]University of Genoa, Genoa, Italy; [8]UCL-Eastman Dental Institute, Faculty of Medical Sciences, Rockefeller, University College London, London, United Kingdom

Hashimoto thyroiditis (HT) is a thyroid-specific autoimmune disorder, and the most common cause of hypothyroidism in a population with an adequate dietary intake. Despite the current conventional treatment focused on the permanent replacement of levothyroxine (LT4) deficiency, it appears that thyroid autoimmunity remains the cause of persistent symptoms in patients with HT, even when they achieve to be in biochemically euthyroid state. Photobiomodulation (PBM) showed to be an effective additional therapy in treatment of autoimmune diseases, but with limited evidence. Hence, our study was conducted to appraise the efficacy of PBM therapy with supplements in restoring thyroid gland homeostasis in patients with HT compared with supplements alone. Seventy-four female subjects aged between 20 and 50 years old were recruited and divided equally into two groups: PBM+conventional treatment group (group 1); and conventional tretament alone group (group 2). The PBM dosimetry and treatment protocols were as follows: wavelength, 820 nm; power output, 200 mW; continuous emission mode; irradiating time, 20 s per point; fluence, 32 J/cm2 per point; treatment frequency, twice a week (excluding weekends); and treatment duration, three consecutive weeks. Whereas, both groups had the conventional treatment protocol, as follows: An appropriate dose of LT4 determined before their enrolment, subjects with a serum level of vitamin D3 <40 ng/dl, received replacement according to their serum levels, and all the subjects had a daily intake of 100 µg of oral selenium. The biochemical (FT3, FT4, antiTPO and antiTG) and anthropometric measurements were evaluated before, after three-months and after six-months follow-up. Our findings showed significant improvement in group 1 parameters (PBM+ convenentional) compared with group 2 (conventional only) in terms of reduction in the following parameters: TSH, antiTPO, antiTG, treatment dose of LT4, BMI, hip and waist circumference, waist/hip ratio ($p<0.05$). Our results, for the first time, demonstrated an efficacy of PBM delivered at a lower fluence with supplements in restoring thyroid function, anthropometric parameters and lifestyle factors in patients with HT. Hence, extensive studies with a longer follow-up period are warranted.

Keywords: Hashimoto thyroiditis; photobiomodulation; autoimmune thyroiditis; Data from the study are published in August 2023 in Journal of Personalized Medicine: https://www.mdpi.com/2075-4426/13/8/1274

Thyroid storm: One major endocrine emergency revealing another !!

Ahmed Boukhalfa[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Mohamed VI University Hospital Center, Marrakech, Morocco, Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakesh, Morocco

Introduction

Thyroid storm (TS) is a severe manifestation of thyrotoxicosis, (1). It is most commonly seen in Graves' disease and can occur due to a non-compliance to anti-thyroid medications Management includes both addressing end organ damage and attaining a euthyroid state. We report the case of a patient who presented a thyroid storm complicating a grave's disease and unmasking, during its management, a corticotropic insufficiency.

Clinical Case

Fifty one year-old patient, diagnosed since 10 months with grave's disease under anti-thyroid-drugs (ATD) with non compliance, Admitted to the emergency department for vomiting, abdominal pain and fever. Clinically, we noted blood pressure at 16/10 cmhg, heart rate 146, temperature 38.7°C, widespread abdominal tenderness. Biological tests: TSH us <0.001, fT4 >100 pmol/l, fT3: 38, 25 pmol/l, with hepatic cytolysis, CRP: 127 mg/l, WBC: 14610. Thyroid storm was retained and patient undergone plasmapheresis. After an intensive care stay and challenging surgery preparation following deterioration in clinical condition and of biological parameters, a total thyroidectomy was performed without malignant signs in histological study. In the post-operative period, the patient began to experience arterial hypotension reaching 80/40 mmgh, and started vomiting again. Adrenal crisis suspected and 8 h cortisol was: 9 mg/dl. Treatment of an acute adrenal crisis was started with rehydration and bolus of intravenous HSHC with oral hydrocortisone relay, clinical and biological improvement. During follow-up, the patient revealed that she had been self-medicating with corticosteroid (dexamethasone) to gain weight for several years with a sudden stop.

Discussion
Symptoms that highly correlate with thyroid storm include fever ≥38°C, tachycardia ≥130 beats per minute, central nervous system manifestations, congestive heart failure, and gastrointestinal/ hepatic manifestations. First line therapy is represented by: antithyroid drugs, beta-adrenergic blockers, potassium iodid, glucocorticoids, antipyretics. If severe symptoms persist or no improvement, contrindications or toxicity, plasmapheresis is indicated before radical treatment (2). Our patient has non compliance of ATD and his body probably remained in a state of thyrotoxicosis which, in the presence of unrecognized adrenal insufficiency, led to a thyroid storm. Thyroid storm, initially masked adrenal insufficiency, but after surgery the clinical picture was transformed and corticotropic insufficiency due to prolonged corticosteroides self medication has been unmasked.
Conclusion
Our clinical case illustrates the difficulty of diagnosis in the case of association between thyroid storm and adrenal crisis and emphasizes the importance of questioning and physical examination in therapeutic management.
Keywords: thyroid storm, anti-thyroid drugs, thyroidectomy, adrenal crisis.

Importance of timely diagnosis and treatment of graves' orbitopathy in euthyroid patient

Ann Kobaidze[1], Nino Tedoradze[1], Ilona Tserediani[2] & Meri Davitadze[3, 4, 5]
[1]Caucasus Medical Center, Endocrinology, Tbilisi, Georgia; [2]Medical center VIvamedi, Ophtalmology, Tbilisi, Georgia; [3]Clinic NeoLab, Endocrinology, Tbilisi, Georgia; [4]; [5]University of Birmingham, Institute of Applied Health Research, Birmingham, United Kingdom

Background
Graves' orbitopathy (GO) is one of the extrathyroidal manifestations of Graves' disease (GD), an autoimmune condition characterised by increased antibodies against TSH receptors (TRAb). The prevalence of GO among patients with GD is up to 40%. Moderate-to-severe, sight-threatening and sometimes even mild GO have significant negative impact on patient's quality of life (QoL). Various clinical presentations of GD itself, evaluation and timely management of GO can oftentimes become challenging resulting in delayed treatment and worsening of patient's QoL. Here, we describe a case of moderate-to-severe form of GO with delayed treatment.
Case
A 57-year-old woman first noticed right eye bulging about 2.5 years ago which she relates to an emotional stress. She was referred to an endocrinologist. Laboratory investigations revealed: TSH = 0.06 μIU/ml, FT4 = 1.1 ng/dl, FT3 = 3.4 pg/ml, Anti-TPO = 1300 IU/ml, TRAb = 3.47 IU/l. Despite GD, antithyroid drugs were not started. Although no treatment was provided, after 9 months, patient's symptoms resolved spontaneously and the laboratory tests revealed euthyroidism. Another year later, patient again suffered an emotional stress following which she developed unilateral right-sided exophthalmos. Laboratory tests revealed elevated TRAb of 1.78IU/l with euthyroidism (TSH = 1.64 μIU/ml). On thyroid ultrasound total volume of the gland was 5.1 cm^3 with heterogeneous structure and moderately increased vascularity, no nodularity. Orbital MRI showed infiltration of the right eye inferior and medial recti muscles. Activity and severity of GO was assessed with CAS = 5 and NOSPECS. The diagnoses of euthyroid GD and unilateral active moderate-to severe GO were established. However, relevant treatment was not initiated even at this point. 6 months later, she presented at our hospital with right-sided exophthalmos, diplopia, and eye movement restriction with upward and lateral gaze. Currently, thyroid function tests again showed euthyroidism with elevated TRAB (TSH = 1.61 μIU/ml, FT4 = 12.1 ng/dl, FT3 = 5.48 pg/ml, TRAb = 1.43 IU/l). Repeated assessment of GO now revealed inactive moderate-to severe form. At the same time, patient's daily activities are affected and QoL severely reduced. Patient was referred to an ophthalmic surgeon and strabismus surgery is now being considered in order to restore binocular single vision.
Conclusions
As our case demonstrates, it is crucial to recognise and treat active forms of GO independent of the thyroid function. Delayed treatment can result in irreversible changes in the orbits that can only be managed by surgery, simultaneously severely worsening patients' quality of life.

Impact of smoking on thyroid gland functioning: a literature review

Houas Jihene[1], Heyfa Belhadj-Miled[1], Monia Ghammam[1], Malika El Omri[1, 2], Abir Meherzi[1], Mouna Bellakhdhar[1], Yosra Hasni El Abed[2], Wassim Kermani[1] & Mohamed Abdelkafi[1]
[1]Farhat Hached Hospital, ENT department, Sousse, Tunisia; [2], Department of endocrinology, Sousse, Tunisia

Introduction
Smoking is a major public health problem with a role as an endocrine disruptor, particularly on the thyroid. The aim of our study is to assess the effects of tobacco on the thyroid.
Methods
We conducted a systematic literature review from 1984 to 2022. The keywords used for the search included "Tobacco, " "Thyroid, " "Goiter, " "Thyroid nodule, " "Hypothyroidism, " "Hyperthyroidism, " "Thyroid cancer, " and "TSH." Evaluation in different studies focused on thyroid function, TSH levels, FT4 levels, thyroglobulins, anti-TPO and anti-TG antibodies, goitrogenic effect, impact on Graves' disease, Graves' ophthalmopathy, and the effect on thyroid cancer.
Results
Eleven articles were included in this literature review, involving a total of 19, 621 subjects, including 17, 000 smokers. The average age of the patients was 47 years. 43.66% of the subjects were male, and 56.33% were female, with a sex ratio of 0.77. According to the studies reviewed, smoking leads to a decrease in TSH levels, potentially resulting in hyperthyroidism. It has a goitrogenic effect, which can be explained by elevated plasma concentrations of thiocyanates in smokers, with the implicated mechanism being a decrease in iodide uptake. Smoking may also worsen Graves' ophthalmopathy and appears to reduce the effectiveness of treatments. Tobacco has not been implicated in the genesis of thyroid cancers.
Conclusion
Tobacco has a direct and often detrimental effect on neuroendocrine and thyroid function. It promotes hyperthyroidism, has a goitrogenic effect, and exacerbates Graves' ophthalmopathy.

An uncommon and distinctive type of goiter to recognize: about 5 cases

Houas Jihene[1], Heyfa Belhadj-Miled[1], Monia Ghammam[1], Oussama Khalfi[2], Malika El Omri[1], Abir Meherzi[1], Mouna Bellakhdhar[1], El Ghali Wassim[3], Yosra Hasni El Abed[4], Wassim Kermani[1] & Mohamed Abdelkafi[1]
[1]Farhat Hached Hospital, ENT Department, Sousse, Tunisia; [2], Department of radiology, Sousse, Tunisia; [3]Department of Anaesthesia, Sousse, Tunisia; [4]Endocrinology Department, Sousse, Tunisia

Introduction
Dyshormonogenetic goiter is a rare entity that affects 1 in 30, 000 to 50, 000 live births, and it is the second most common cause (10% to 15%) of permanent congenital hypothyroidism. It is morphologically characterized by architectural and cellular pleomorphism that may mimic thyroid malignancy and cause difficulties in differential diagnosis.
Material and Methods
We present five cases of dyshormonogenetic goiter gathered at our service.
Results
The cohort comprised three patients, 2 females, and 3 males, with an average age of 18.6 years (range: 7 to 32 years). All five were offspring of consanguineous marriages and were under observation for congenital hypothyroidism. The chief complaint in all patients was a basal cervical swelling. Clinical examination revealed multinodular goiter in 4 patients and a right lobar nodule in one patient. Delayed growth and psychomotor development were noted in two patients. Cervical ultrasound and thyroid scintigraphy were performed in all cases. Ultrasound demonstrated multinodular goiter in all patients. Scintigraphy revealed overall thyroid hyperfixation in all cases, with a hypofixation zone on the right side in one patient. Thyroid function tests indicated hypothyroidism in all five patients. All patients underwent surgical treatment: total thyroidectomy in four cases and right lobectomy in one case. Histopathological examination confirmed dyshormonogenetic goiter in all five cases. Favorable outcomes were observed in all cases, with no recurrence.
Conclusion
Dyshormonogenetic goiter represents a rare benign condition characterized by architectural and cytological characteristics that, if not well understood, may contribute to the overdiagnosis of malignancy. Recognition of this entity becomes crucial in cases lacking strict histological criteria for malignancy, particularly in individuals with a history of hypothyroidism since infancy. An exact molecular diagnosis allows genetic counseling and the identification of asymptomatic mutation carriers

EP276

Thyrotropin-receptor antibodies - diagnostic and prognostic significance in graves' disease - a clinical case

Radina Dimitrova[1, 2], Kiril Hristozov[1, 2], Savi Shishkov[1, 2] & Yana Bocheva[3, 4]
[1]Medical University "Prof. Dr. Paraskev Stoyanov ", Second department of internal medicine, Varna, Bulgaria; [2]St. Marina's Hospital, Clinic of Endocrinology and Metabolic Diseases, Varna, Bulgaria; [3]Medical University "Prof. Dr. Paraskev Stoyanov ", Department of General Medicine and Clinical Laboratory, Varna, Bulgaria; [4]St. Marina's Hospital, Clinical Laboratory, Varna, Bulgaria

Introduction
Graves' disease (GD) is unique among autoimmune endocrinopathies because the underlying immune disorder results in thyroid stimulation rather than functional or structural inhibition of the gland. However, thyrotropin-receptor antibodies (TRAbs), a specific and sensitive immunological marker for GD, are heterogeneous both in terms of their molecular structure and their biological activity. Stimulating TRAbs (TSIs) activate the thyrotropin (TSH) receptor. Blocking TRAbs reduce the action of TSH but can also be weak agonists. Neutral TRAbs have no effect on TSH binding. They are probably involved in the generation of oxidative radicals and the induction of apoptosis. Some TRAbs also inhibit agonist-independent ("constitutive") signaling and are called "inverse agonists". In fact, the clinical picture of GD is determined by the balance between the opposing activities of these antibodies, but this balance could change in the course of the disease.
Clinical case
A 67-year-old woman was admitted emergently to a cardiology unit due to acute heart failure based on high-frequency atrial fibrillation. The heart rate reached 167 beats per minute. During digitalization, normofrequency atrial fibrillation was achieved. Due to accompanying complaints of weight reduction, increased sweating and anxiety, thyroid function was also investigated, and thyrotoxicosis was established (TSH <0.004 mIU/ml, FT4 1 pmol/l, FT3 13.1 pmol/l). Based on the ultrasound of the thyroid gland (diffuse inhomogeneity with pseudonodulation and increased blood flow) and the examined immunological markers (thyroperoxidase antibodies (TPO Ab) <10 U/ml; TSI 5.7 IU/l), GD was diagnosed. Treatment with 1 mg propranolol and 1 mg thiamazole daily was initiated. Two months later, according to hormonal parameters (TSH 3.8 mIU/ml, FT4 8.1 pmol/l, FT3 4.1 pmol/l), the dose of thyrostatic was reduced to 1 mg daily. Restoration of sinus rhythm was also recorded. Control hormonal tests on the 4th month after diagnosis revealed severe hypothyroidism (TSH 101.25 mIU/ml, FT4 2.1 pmol/l, FT3 2.1 pmol/l) regardless of the reduced dose of thiamazole (1 mg daily). Analysis of immunological markers revealed high TRAbs titers (>40 IU/l) and reduced levels of stimulating immunoglobulins (TSI 2.11 IU/l). The therapeutic regimen was continued with 10 mg thiamazole in combination with 25 μg levothyroxine daily, but without β-blocker.
Conclusion
Both TRAK and TSI are useful for the diagnosis of GD, but their comparison is more important for treatment monitoring. The marked predominance of TRAbs over TSIs in the presented clinical case may be related to the presence of blocking/neutral TRAbs. This conclusion is supported by the observed clinical course of the disease.

EP280

Role of ultrasound elastography in improving the correlation between thyroid nodule TIRADS scoring and FNA bethesda categories in solitary thyroid nodules

Nishanth David Thomas[1]
[1]Amrita Institute of Medical Sciences, Endocrinology, Kochi, India

Background
TIRADS scoring is used to assess the thyroid nodules using USG, commonest used is ACR-TIRADS; another is K-TIRADS scoring. Nodule stiffness is assessed by elastography strain Rago scoring & FNA nodule gives lower (benign) or higher Bethesda (possible malignant) category report. The combined use of TIRADS & Rago scorings with Bethesda as final output can assess whether addition of elastography improves the correlation between thyroid nodule TIRADS scoring and FNA Bethesda categories.
Methods
This was a Cross sectional study in Endocrinology Deptarment, AIMS. Patients with STNs were assessed because it would not affect elastography findings. ACR-TIRADS, K-TIRADS & Rago scores were done and based on standard criteria, FNA was done with Bethesda categorisation. Those who have Bethesda category II grouped as one & categories III to VI (possible malignant) grouped as other group (higher Bethesda categories). Pearson's Chi square test used for associations; in both groups, the data of ACR-TIRADS, K-TIRADS & Rago scores each alone; and combination of ACR-TIRADS with Rago & of K-TIRADS with Rago analysed with relation to prediction of higher Bethesda categories in them. ROC curves were plotted based on predicted probability scores and its AUC, sensitivity and specificity estimated.
Results
The AUCs for ACR-TIRADS, K-TIRADS & Rago scoring each alone in predicting higher Bethesda categories were not significant (sensitivity & specificity best for Rago alone); same for combined ACR-TIRADS & Rago scoring, and combined K-TIRADS & Rago scoring were statistically significant. Even though TIRADS scores were higher, the lower the elastography Rago score in nodules, the lower were the prediction probability of higher Bethesda categories in nodules.
Conclusions
This study showed that combination of USG elastography and TIRADS scoring data in cases of STNs, predicted higher Bethesda categories on FNA in them. Also showed that the lower the elastography Rago score in STNs, lower was the prediction probability of higher Bethesda categories, however higher the TIRADS scores were.

The relevance of a gluten-free diet in the treatment of patients with hashimoto's thyroiditis without celiac disease

Aline Alcantara[1]
[1]UNINOVE - Campus Vergueiro, Department of Medicine, São Paulo

Hashimoto's thyroiditis is an autoimmune condition characterized by the infiltration of lymphocytes into the thyroid gland, resulting in the subsequent production of antibodies directed against thyroglobulin and thyroid peroxidase. This pathology is the primary etiology of hypothyroidism in developing countries. Recently, researchers have focused on studying the inflammatory potential of gluten, not only in the intestinal context, where it can act as a trigger for dysbiosis but also systemically, with the ability to influence the production of pro-inflammatory cytokines by T cells. However, there is controversy regarding individuals without gluten intolerance or celiac disease concerning the inflammatory potential of gluten and whether there is any benefit in its exclusion from the diet. This article aims to conduct a comprehensive literature review covering the last six years, based on records available on the PubMed platform, to clarify the relevance of implementing a gluten-free diet in patients diagnosed with Hashimoto's thyroiditis who do not have concomitant celiac disease. The keywords "Hashimoto thyroiditis gluten" were used, covering the publication period between 2018 and 2023, identifying 34 scientific articles. Excluded were those not directly related to the research topic or duplicated, resulting in the inclusion of 14 works, comprising literature reviews, meta-analyses, case reports, and original articles. As a conclusion, there was no evidence of symptom improvement or antibody reduction with the introduction of a gluten-free diet in patients without celiac disease or gluten intolerance. However, it is important to note that patients with autoimmune diseases, such as Hashimoto's thyroiditis, are statistically more susceptible to developing food intolerances. Thus, a significant number of patients with Hashimoto's thyroiditis may have undiagnosed celiac disease or gluten intolerance and would benefit from gluten removal from their diet. Nevertheless, gluten withdrawal for the rest of the population without indications tends to result in increased caloric intake, higher consumption of processed foods, reduced fiber intake, and approximately a 30% increase in food expenses. Therefore, it is concluded that the addition of a gluten-free diet is not beneficial for patients without a diagnosis of celiac disease or gluten intolerance. However, in patients with autoimmune diseases, such as Hashimoto's thyroiditis, investigating even asymptomatic food intolerances is essential due to their higher prevalence in this population.

Diagnostic difficulties in a patient with thyroid lymphoma

Agnieszka Maksymiuk-Klos[1], Joanna Sobolewska[1], Jerzy Zabłocki[2], Agnieszka Wojciechowska-Luzniak[1] & Przemysław Witek[1]
[1]Medical University of Warsaw, Department of Internal Medicine, Endocrinology and Diabetology; [2]Medical University of Warsaw, Department of General and Vascular Surgery

Primary thyroid lymphoma (PTL) is a rare disorder, representing merely 1-5% of all thyroid malignancies, 1-2% of extranodal lymphomas and 3% of non-Hodgkin's lymphomas. It affects mainly women. PTL incidence is low in individuals younger than 40 years old. The most common clinical presentation of PTL is a palpable mass in the neck. It may be accompanied by other symptoms: dysphagia, dyspnea, and hoarseness. Diffuse B-cell lymphoma (DLBCL), is the most common pathological subtype of PTL. Hashimoto thyroiditis (HT) is essential risk factor of PTL. In clinical practice, a rapidly enlarging neck mass, accompanied by compressive symptoms, in women with HT should prompt the exclusion of PTL. Core-needle biopsy is superior to fine-needle biopsy in this cases. A 40-year-old female patient with AIT, on substitution therapy with L-thyroxine, was admitted to the hospital due to increased dyspnea accompanied by stridor. She presented a history of upper respiratory tract infection symptoms for two weeks, a feeling of mild dyspnea and an enlargement of the neck circumference. On admission to the Emergency Department (ED), the patient was cardiovascularly and respiratorily stable, with neck oedema, palpable thyroid enlargement and an exacerbated alveolar murmur on physical examination. Laboratory tests on admission were as follows: WBC 5.97 10^3 [4.00—10.00], CRP 24.00 mg/l [< 5.00], PCT 0.11 ng/ml [< 0.5], TSH 4.898 uIU/ml [0.350-4.940]. Chest X-ray demonstrated tracheal stenosis. In ED, a patient was treated with improvement with hydrocortisone intravenously. Ultrasound evaluation revealed a markedly enlarged thyroid gland (V = 86, 1 cm^3), with heterogeneous reduced echogenicity with focal/infiltrative changes and markedly enlarged pre-tracheal lymph nodes below the isthmus. In an examination performed five months earlier, the dimension of the thyroid gland was significantly smaller (V = 22, 1 cm^3). The BACC performed at that time resulted in a category II in the Bethesda classification. In the following days, due to a massive goitre with associated increasing compression symptoms, she was qualified for a total thyroidectomy. The conditions of the procedure were challenging - numerous adhesions and problematic infiltration of the thyroid parenchyma with surrounding tissues. Postoperative wound healing was as expected, and ENT evaluation revealed no vocal fold mobility disorders. In the following days, due to a tetanic seizure, patient was treated with calcium chloride intravenously, with clinical improvement. Histopathological evaluation revealed a pattern suggestive of large B-cell lymphoma infiltration. Oncological treatment has been initiated. This case emphasizes the difficulties in the early diagnosis of thyroid lymphoma.

Ideas commonly held about the treatment of hypothyroidism during pregnancy

Belhadi Leila[1], Bensbaa Salma[1], Haraj Nassim Essabah[1], El Aziz Siham[1] & Chadli Asma[1]
[1]University Hospital Center Ibn Rochd, Department of Endocrinology and Metabolic Diseases, Casablanca, Morocco

Introduction
The occurrence of pregnancy in patients with hypothyroidism is a common event. Thyroxine requirements increase in nearly 80% of pregnant women. Educating young patients with hypothyroidism about the adaptation of treatment and the need for close biological monitoring helps prevent complications of maternal hypothyroidism in the fetus.
Objective
The objective of our study was to assess the knowledge of patients about the management of levothyroxine during pregnancy and the need for TSH monitoring during pregnancy.
Patients and Methods
A descriptive study included 33 patients followed for hypothyroidism in the pregnancy consultation at the Endocrinology and Metabolic Disease Department at CHU Ibn Rochd. We developed a questionnaire of misconceptions reported by our pregnant women in our context. The analysis was performed using the SPSS software.
Results
The average age of our patients was 32 years (21-49). A low socioeconomic level was observed in 89% of patients. The referring physician was a gynecologist in 76% of cases, a general practitioner in 19% of cases, and an endocrinologist in 5% of cases. Pregnancy was not desired in 17% of cases, and 83.3% of patients had planned their pregnancy. The gestational age at the first consultation with us was on average 20 weeks. The average dose of levothyroxine before pregnancy was 100 µg/day. None of the patients had a pre-conception consultation for TSH measurement and adaptation of levothyroxine dose. None of the patients knew their TSH target. Discontinuation of levothyroxine upon pregnancy diagnosis was adopted by 46.1% of patients, and 53.9% of patients kept the same dose while waiting to see their doctor; however, none of the patients titrated the levothyroxine dose. Regarding complications of hypothyroidism on fetal development, 98.8% had no idea about these consequences. For breastfeeding, 74.3% of pregnant women thought that levothyroxine passes into breast milk but did not know if they should stop it.
Conclusion
Women with hypothyroidism of childbearing age should receive education on the vital necessity of substitute treatment and its adaptation before conception and during pregnancy, as well as the need for biological monitoring, to prevent the consequences of maternal hypothyroidism on fetal brain development.

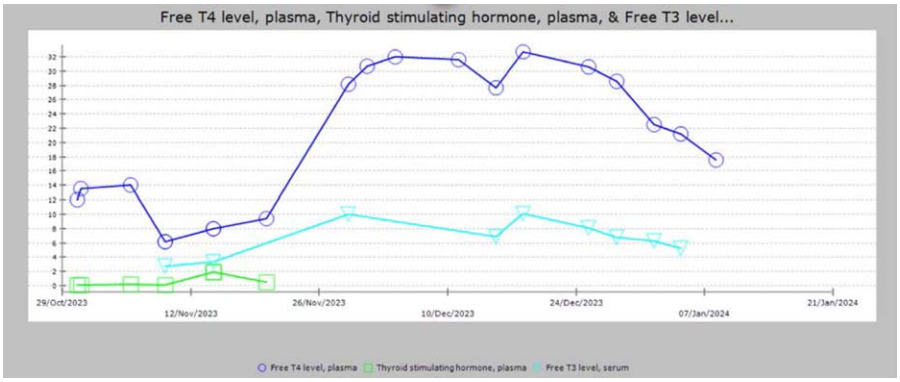
Propylthiouracil-induced severe hepatotoxicity in grave's disease: a unique case illustrating complex challenges and therapeutic strategies

Sulmaaz Qamar[1], Beenish Masood[1], Raghavendra Palani[1], Nazanin Karimaghaei[1], Ahmed Yousseif[1, 2], Dipesh Patel[1, 2], Bernard Khoo[1, 2], Efthimia Karra[1] & Eleni Armeni[1]
[1]Royal Free Hospital, Endocrinology and Diabetes, London, United Kingdom; [2]University College London, London, United Kingdom

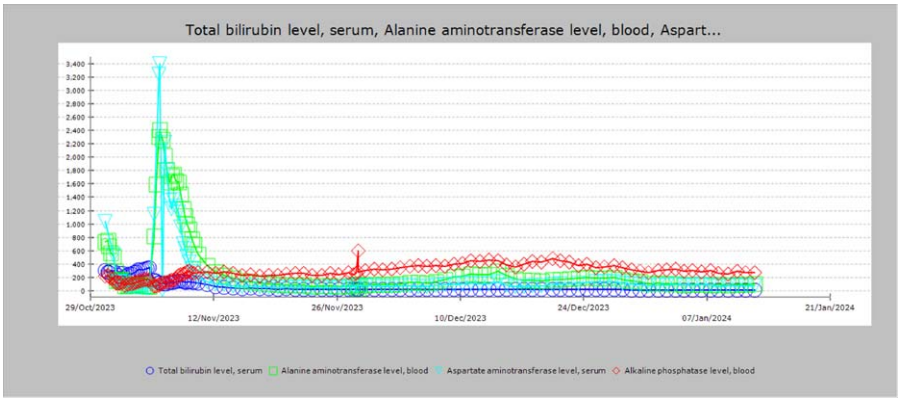
Background
Hyperthyroidism often presents with aberrant liver function. The differential diagnosis of this presentation includes thyrotoxicosis-associated liver dysfunction or antithyroid drug-induced liver dysfunction. We present a case where Propylthiouracil treatment resulted in acute liver failure.
Case Presentation
A female patient diagnosed with Grave's disease in August 2023 initially received carbimazole but discontinued this due to vomiting. Subsequent initiation of PTU in September 2023 resulted in admission with decreased conscious level, jaundice



(Abstract EP310)

TSH remained < 0.01 mIU/l after the 20th November

(Abstract EP310)



and severe acute liver failure after six weeks of starting. Laboratory findings on admission included a bilirubin level of 384, INR of 10.9, ALT of 1200. Propylthiouracil was discontinued.

Intervention and Post-Transplant Course

Urgent liver transplantation was performed in early November 2023, with post-surgical Klebsiella hospital-acquired pneumonia, a prolonged stay in intensive care and a slow wean requiring a tracheostomy. Despite transplantation, she had persistent abnormal liver function. Liver USS and Doppler studies confirmed mild hepatic steatosis with patent vessels. Liver biopsies done at four weeks post-transplant and six weeks revealed severe steatosis and minimal portal inflammation, excluding rejection as a cause. The patient continued azathioprine, tacrolimus, and prednisolone (1 mg daily) for liver function and hyperthyroidism management.

Challenges in Thyroid Management

Efforts to manage hyperthyroidism post-transplant with carbimazole were met with vomiting, which was managed with a dose reduction. She is planned for elective thyroidectomy as of writing.

Importance and Rarity

This case underscores the challenges in navigating severe hepatotoxicity induced by PTU in Grave's disease. Clinicians should be vigilant for this rare but severe complication of PTU treatment.

Conclusion

This distinctive case provides valuable insights into the intricacies of thyroid medication-associated liver failure. It highlights the importance of cautious PTU use, contributing to the growing body of evidence guiding clinicians in managing similar challenging clinical scenarios.

Keywords: Grave's disease, propylthiouracil, hepatotoxicity, liver transplantation, caution. TSH remained <0.01mIU/l after the 20th November

Increased psychological distress among patients with two or more endocrinopathies during Covid-19 pandemic: the EPITOME Study

Vasiliki Daraki[1], Theano Roumeliotaki[2], Panagiotis-Nikolaos Tsakalomatis[1], Grigoria Betsi[1], Maria Sfakiotaki[1], Maria Chrysoulaki[1], Eleni-Konstantina Syntzanaki[1], Vasiliki Venetsanaki[1], Rodanthi Vamvoukaki[1], Kalliopi Kontolaimaki[1], Eirini Makraki[1], Ioannis Kopidakis[1], Christos Dimas[1], Stella Lioudaki[3], Christos Ioannou[3], Konstantinos Krasagakis[4], Panagiota Goulia[5] & Paraskevi Xekouki[1]

[1]University General Hospital of Heraklion, Endocrinology and Diabetes Clinic, Crete, Greece; [2]University of Crete, Department of Social Medicine, Heraklion, Crete, Greece; [3]University General Hospital of Heraklion, Department of Vascular Surgery, Crete, Greece; [4]University General Hospital of Heraklion, Department of Dermatology, Crete, Greece; [5]Cambridgeshire & Peterborough NHS Foundation Trust, Cambridge, United Kingdom

Background

Psychological distress is elevated during pandemics such as the COVID-19 outbreak. Patients with diabetes mellitus (DM), are a particularly vulnerable risk group. However, data of the impact of other endocrinopathies on psychological status of patients during pandemics are lacking so far.

Aim

To compare psychological distress about COVID-19 pandemic, between endocrine patients with a variety of endocrinopathies and patients with non-endocrine diseases (controls) seen in the outpatient clinics of the University Hospital, Heraklion, Crete, Greece.

Methods

One hundred and seventy four endocrine patients seen at the outpatient Endocrine clinic and two hundred and four controls without endocrinopathies seen at the Dermatology and Vascular Surgery outpatient clinics completed questionnaires about demographics, need for information, sources of information worries about the COVID-19 pandemic and the Greek version of the DASS-21 for psychological distress questionnaire. The levels and prevalence of stress, anxiety, and depression about the COVID-19 pandemic between the two groups were compared after controlling for age, gender, education, residence, employment status and ever diagnosed with psychiatric disease in multiple logistic regression models. Ethical approval was obtained by Institutional Review Board.

Results

Mean age of endocrine patients was 50.8 years and controls 45.7 years ($P<0.001$); with predominance of women in both groups ($P=0.017$). Among endocrine patients 62.1% suffered from thyroid diseases, 29.9% from DM, 18.9% from gonadal dysfunction and 12.1% from pituitary disorders. Adrenal and calcium disorders were mentioned in less than 10% of patients. The majority of endocrine patients (83.1%) were well-controlled, whereas 28.7% had two or more endocrinopathies. Hypertension and coronary vascular disease were more common in endocrine patients compared to controls (28.7% vs 16.2% and 8.7% vs 3.4% respectively), Mild and moderate stress symptoms were observed in both groups. Patients with two or more endocrinopathies reported significantly increased prevalence of stress symptoms compared to controls (odds ratio (OR): 2, 1; $P=0$, 045). We found no differences in anxiety and depression symptoms between the two groups, which showed low rates of both.

Conclusions

The current study highlights the increased risk of stress symptoms in endocrine patients with two or more endocrinopathies during Covid-19 pandemic. These results are relevant when designing policies on information on pandemics and supportive measures for endocrine patients in General Hospitals.

Intrathyroidal dexamethasone therapy in subacute thyroiditis: preliminary findings from the DLISAT Study

Magdalena Stasiak[1, 2], Magdalena Rosińska[2], Zuzanna Berkan[2], Arkadiusz Zygmunt[2, 3] & Andrzej Lewinski[2, 3]

[1,2]Polish Mother's Memorial Hospital - Research Institute, Department of Endocrinology and Metabolic Diseases, Lodz, Poland; [3]Medical University of Lodz, Department of Endocrinology and Metabolic Diseases, Lodz, Poland

Background

Clinically severe or recurrent subacute thyroiditis (SAT) frequently requires treatment with high cumulative doses of systemic steroids. Such therapy is associated with high risk of steroid-related complications. The DLISAT study

aims to evaluate the efficacy and safety of intrathyroidal dexamethasone and lidocaine injections (DLI) in specific patient cohorts compared to standard oral steroid therapy. This report presents preliminary results after the initial six months of the study.
Methods
The study group (SG) comprised five patients, including two patients with treatment-naive SAT and contraindications or lack of consent for systemic therapy, two patients experiencing SAT recurrence soon after completion of oral therapy and one patient with steroid-dependent SAT. The control group (CG) consisted of five consecutive patients treated with oral prednisone. In SG patients, 4 mg of dexamethasone (1 ml of solution), with or without 1 ml of 2% lidocaine, was injected into each thyroid lobe. The injections were ultrasound (US)-guided. On the basis of the obtained results doses were repeated every 2-5 days, as required. Parameters measured before and after injections included pain severity, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), thyroid-stimulating hormone (TSH), free thyroxine (FT4), free triiodothyronine (FT3), and thyroglobulin (Tg). Ultrasound and shear wave elastography (SWE) results were analyzed before and after each injection.
Results
All SG patients exhibited an excellent rapid and long-term response with no side effects, except for injection-related discomfort. The first injection in SG patients led to significant pain reduction, improved ESR, CRP, thyroid parameters, US and SWE findings. The number of doses required for total recovery were 2-6 and a mean dexamethasone dose for the entire therapy was 32 mg. The longest therapy period was 20 days and no recurrence was observed. Persistent hypothyroidism occurred in one CG patient. In comparison, the mean therapy period in CG was 93 days and a mean dose of oral prednisone was 1580 mg.
Conclusion
The efficacy and safety of DLI in SAT were excellent and the method seemed more beneficial than standard oral steroid therapy, especially in patients with high risk of steroid-related complications.

Surgical management of graves' disease: personal experience and literature review

Rachida Bouattay[1], nawres bouaziz[1], Amaidi Rami[1], Mehdi Ferjaoui[1], Elkorbi Amel[1], Naourez Kolsi[1], Harrathi Khaled[1] & Jamel Koubaa[1]
[1]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Background
Graves' disease (GD) is a predominantly female autoimmune disorder of the thyroid gland. It is characterized by a diffuse goiter and biological hyperthyroidism. The optimal treatment of GD is still controversial. Surgery is one treatment option along with radioactive iodine (RAI) and antithyroid medication (ATM). The aim of the study is to review our experience in the surgical management in Graves' disease.
Patients and Methods
This is a retrospective study involving patients who underwent surgery for Graves' disease over a twelve-year period from January 2010 to December 2021.
Results
Our series included 51 patients, 38 women (75%) and 13 men (25%) with an average age of 39.41 years and extremes of 14 to 69 years. The mean time between diagnosis and surgical treatment was 18.4 months. At the time of diagnosis, cervical examination revealed a diffuse and homogeneous goiter in 22 cases (43%), nodular goiter in 6 cases (12%) and multi-nodular goiter in 23 patients (45%). Hyperthyroidism was observed in 23 patients (45.1%), and euthyroidism was noted in 28 patients (54.9%). In our series, surgery was indicated in cases of: resistance to medical treatment with an average duration of treatment with ATM of 12 months (84%), poor compliance (8%), associated thyroid carcinoma (6%) and treatment intolerance (2%). All our patients underwent total thyroidectomy with extemporaneous exam in 32 patients (62.7). Intraoperative examination suggested malignancy in 9 cases (17.6%). So, a bilateral central neck dissection was performed in these cases. Postoperative complications included transient hypocalcemia in 21 patients (41.17%), transient dysphonia in 3 patients (5.88%), hematoma in 2 patients (3.92%) and keloid scarring in 1 patient (2%). Histologic exam confirmed the diagnosis of thyroid cancer associated with Graves' disease in 9 patients (17.6%): 8 papillary microcarcinomas and one papillary carcinoma. A radioiodine therapy was indicated in these cases.
Conclusions
If surgery is considered for definitive management, evidence-based criteria support total thyroidectomy as the surgical technique of choice for GD. Available evidence also supports surgery in the presence of severe endocrine Graves' ophthalmopathy. Children with GD should be treated with an ablative strategy. Whether this is achieved by total thyroidectomy or RAI may still be debatable. Data on long-term cancer risk are missing; and until RAI has proven harmless in children, authors continue to recommend surgery in this setting. Postoperative complications are frequent and not negligible, hence the need for preoperative medical preparation.

The mutual relationship between trace elements (Ca, Cu, Zn, Fe, Se, I) and thyroid parameters in mothers and neonates

Dorota Filipowicz[1], Ewelina Szczepanek-Parulska[1], Sabrina Asaad[2], Thilo Samson Chillon[2], Aniceta Ada Mikulska[3], Marta Karaźniewicz-Łada[3], Franciszek Główka[3], Lutz Schomburg[2] & Marek Ruchala[1]
[1]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences; [2]Institute of Experimental Endocrinology, Charité University Medicine; [3]Department of Physical Pharmacy and Pharmacokinetics, Poznan University of Medical Sciences

Introduction
Pregnancy is a challenging time to maintain proper thyroid function in mothers and to provide sufficient thyroid hormones to the developing fetus. Micronutrient deficiencies are very frequent during gestation. So far only a few microelements are recommended as a routine supplementation and there is a gap in understanding the mutual relationship between multiple trace elements. The study aimed to verify the micronutrient status concerning thyroid parameters in the cohort of mothers and newborns.
Materials and methods
Women in the 3rd trimester of pregnancy (114), healthy and with autoimmune thyroiditis (AIT), together with their newborns (93) were recruited in the obstetric department before delivery in the tertiary reference Polish centre. Blood serum and spot urine samples from mothers and additionally neonatal cord blood were analysed. Microelement status was assessed in serum by Total Reflection X-ray Fluorescence analysis (on TXRF spectrometer S4 T-STAR). Additionally, thyroid parameters with antithyroid antibodies were measured in mother-newborn pairs and TSH concentrations from neonatal screening were analysed. The research was funded by the National Science Centre in Poland (2019/33/N/NZ5/02303) as PRELUDIUM-17 grant.
Results
More than half of mothers were poorly supplied in Ca, around 1/4 had Se and Zn shortages and 1/10 were deficient in Cu, where only 2.5% had insufficient Fe concentration. Median ioduria was 101 μg/l, which is below the WHO recommended value. Multinutrient formulas dedicated to pregnancy were taken by 68% of women. Maternal and neonatal micronutrients (Ca, Cu, Zn, Se) were adequately correlated with the strongest relation for Ca ($r=0.5$, $P<0.001$). Multiple correlations were also noticed among various trace elements in mothers and newborns, with the most prominent between Zn and Ca in mothers ($r=0.78$, $P<0.001$) and neonates ($r=0.68$, $P<0.001$). Maternal Ca, Fe and Se were related to ioduria. Additionally, Ca, Cu, Zn in mothers and Fe, Cu, Se in neonates correlated inversely with TSH screening values. Micronutrient supply was not different in AIT vs non-AIT women, although maternal Cu, Ca, Zn and neonatal Se, Fe, Zn correlated negatively with TRAb level.
Conclusions
Many pregnant women are at risk of health-relevant trace element deficiency, despite common supplementation of multinutrient preparations. Maternal supply may affect the newborn microelements status. Trace element screening and supplementation verification in pregnancy would be beneficial to mothers and newborns. Proper nutritional intake may improve thyroid parameters and decrease the concentration of thyroid antibodies. More studies on the mutual interplay between various microelements in pregnancy are warranted.

Thyroid and lipid profile values in patients with vs without Graves' ophthalmopathy

Ana-Maria Stancu[1,2], Anastasia Patricia Stanescu-Smocot[3], Daniela Alexandrescu[3], Cristina Stancu[3] & Corin Badiu[2,3]
[1]Mioveni City Hospital, Endocrinology, Mioveni, Romania; [2]University of Medicine and Pharmacy "Carol Davila", Faculty of Medicine, Bucharest, Romania; [3]National Institute of Endocrinology "C.I. Parhon", Endocrinology IV, Bucharest, Romania

Context
Graves' ophthalmopathy (GO) is a debilitating condition that affects 30% patients with Graves' disease (GD). It is the most common extra-thyroidal manifestation of GD, but only 3-5% of GO cases are sight – threatening.
Objective
To compare the thyroid and lipid profile of GD patients who developed GO vs those without GO. The second objective is to analyze the prevalence of smoking status and insufficient 25 (OH) vitamin D levels.
Design
This is an observational, cross-sectional study in a tertiary endocrinology center.
Subjects and Methods
The study includes 151 GD adult patients treated with methimazole (MMI) alone ($n=95$) or MMI with levothyroxine (LT4) ($n=56$), with no history of radioactive iodine therapy or thyroidectomy. Pregnant women were excluded. Patients were divided into two subgroups according to the absence (GO-) or presence (GO+) of GO.
Results
The GO- subgroup included 92 (60.93%) patients aged 46.6±14.5 years and the GO+ subgroup included 59 (39.07%) patients aged 49.7±12.3 years. The proportion of smokers in GO+ subgroup was higher than in the GO- subgroup (*P*-value 0.004). The number of hypothyroid patients (fT4 <8 pmol/l) was higher in the GO+ subgroup than in the GO- subgroup, 4/92 (4.32%) patients vs 8/59 (13.55%) patients (*P*-value 0.04). The mean dose of LT4 was higher in patients on block and replace therapy in the GO+ subgroup than in those in the GO- subgroup, 55.4±21.3 mg/day vs 42±17.9 mg/day (*P*-value 0.01). No differences in mean doses of MMI, treatment regimens and lipid profile were observed between the two subgroups. In patients with mild GO, triglyceride levels were lower than those with moderate-severe and severe GO (90.9±32.6 mg/dl vs 137.3±97 mg/dl, *P*-value 0.012). 25 (OH) vitamin D was measured in 60 patients in subgroup GO- and 42 patients in subgroup GO+. The mean level of 25 (OH) vitamin D was similar between the two subgroups: 26.17±9.74 ng/ml in subgroup GO- vs 23.3±11.8 ng/ml in subgroup GO+, *P*-value 0.2. When 25 (OH) vitamin D <20 ng/ml was selected, 16 (26.67%) of 60 patients in subgroup GO- and 21 (50%) of 42 patients in subgroup GO+ had insufficient vitamin D levels, *P*-value 0.01.
Limitation
The study did not include data on other risk factors for metabolic syndrome.
Conclusion
Identifying and manage GO' risk factors such as smoking, hypothyroidism and high lipid profile may influence the course of GO. Vitamin D cut off below 20 ng/ml could be a risk factor for development of GO.

Liothyronine (LT3) prescribing in england – are cost constraints inhibiting guideline implementation?

Adrian Heald[1], Lakdasa Premawardhana[2], John Warner-Levy[1], Peter Taylor[2], Nadia Chaudhury[3], Onyebuchi Okosieme[2], Mike Stedman[4] & Colin Dayan[2]
[1]Salford Royal Hospital, Salford, Department of Endocrinology and Diabetes, Salford, United Kingdom; [2]Thyroid Research Group, Systems Immunity Research Institute, Cardiff University School of Medicine, Cardiff, Wales, Cardiff, United Kingdom; [3]University Hospitals Coventry and Warwickshire, Department of Endocrinology and Diabetes, Coventry, United Kingdom; [4]Res Consortium, Andover, England, Andover, United Kingdom

Introduction
Primary hypothyroidism affects about 3% of the general population in Europe. In most cases, people are treated with Levothyroxine. In relation to the recent British Thyroid Association guidance and the 2020 Competitions and Marketing Authority (CMA) ruling, we examined prescribing data for levothyroxine, NDT and liothyronine by dose, regarding changes from 2016 to 2022.
Design
Monthly primary care prescribing data for each British National Formulary (BNF) code (England Monthly GP Practice thyroid replacement prescribing data. Accessed 17 July 2023). was analysed for Levothyroxine, Liothyronine and NDT
Patient and Measurements
The rolling 12-month total/average was used to identify the moment of change. Results included the number of prescriptions, the actual costs, and the cost/prescription/ mg.
Results
Liothyronine: In 2016 94% of the total 74, 500 prescriptions were in 1 mg dose. In 2020 the % in 1 mg and 1 mg doses started to increase so that in 2022 each reached 27% of total liothyronine. The average Cost/prescription in 2016 of 1 mg was £404/prescription and fell by 80% to £101 in 2022; while the 1 mg cost £348/prescription fell much less by 35% to £255 and 1 mg £355/prescription fell much less by 38% to £242/prescription. Total prescriptions 74, 605 issued in 2016 fell by 30% until 2019 and then started to grow again at 60, 990 15% lower, so total costs have fallen by 70% to £9m/year.

Table 1: Change in the cost between 2016 to 2022 - for LT4, by tablet dose for LT3 and NDT

Drug	Cost per prescription (% change vs 2016)		Total prescriptions (% change vs 2016)		Total cost/year (% change vs 2016)	
	2016	2022	2016	2022	2016	2022
LT4	£2.74	£1.47 (- 48%)	30.8 million	33.4 million (8%)	£90,504, 057	£52,439, 700 (-42%)
Total LT3**	£404 £348	£101 (- 75%)	74, 500	60,999 (- 18%)	£30,034, 992	£ 9,029, 544 (- 70%)
20 mg	£355	£255 (- 27%)				
10 mg 5 mg		£242 (- 32%)				
NDT	£207	£440 (+113%)	4257	2384 (- 44%)	£885s,887	£1,049, 192 (18%)

Conclusions
Liothyronine costs fell after the CMA ruling but remain orders of magnitude higher than levothyroxine so the remaining 0.2% of patients are still absorbing 16% of medication costs. Lower liothyronine doses as recommended by BTA are 240% of the costs of the 1 mg dose, so following the latest BTA guidance incurs substantial additional costs. High drug price continues to impact clinical decisions limiting therapy availability to a considerable number of patients.

A case of levothyroxine malabsorption corrected with vitamin c

Yaşar Aydoğmuş[1], Beril Turan Erdoğan[1], Sevgül Fakı[1], Berna Öğmen[1], Cevdet Aydın[1], Oya Topaloğlu[1], Reyhan Ersoy[1] & Bekir Çakır[1]
[1]Ankara Bilkent Şehir Hastanesi, Endokrinoloji, ankara, Turkey

Introduction
Malabsorption of levothyroxine is an important clinical problem. Changes in gastric pH due to various medical conditions might cause challenges in maintaning normal TSH values.
Case
A forty-nine years old female who has been followed up with a diagnosis of primary hypothyroidism for 12 years admitted to our outpatient clinic with a complaint of unachievement of euthyroidism despite increasing the levothyroxine dose up to 200 mg. He did not have any other chronic disease and was not using any other medication. In laboratory examination, free T3 was 1.14 ng/l (2.3 - 4.2), free T4 was 0.32 ng/dl (0.89 – 1.76) and TSH was 129 mU/l (0.55 – 4.78). Thyroid autoantibodies were markedly high (antithyroglobulin >1000 IU/ml and antithyroid peroxidase antibody >13000 U/ml) and thyroglobulin was <0.20 µg/l Tthyroid ultrasonography showed heterogeneous parenchyma with widespread patchy hypoechoic areas and thin-thick fibrous bands. Free T4 was was measured just before and after the administration of oral levothyroxine 200 mg. Basal, first hour and second hour free T4 were 0.23 ng/dl, 0.29 ng/dl and 0.29 ng/dl, respectively. A malabsorption test was performed with 500 mg levothyroxine. Accordingly, free T4 was 0.40 ng/dl at basal state, 0.41 ng/dl in the first hour, 0.50 ng/dl in the second hour and 0.47 ng/dl in the fourth hour. Thus, free T4 level increased by a maximum of 25%. The patient's celiac and anti-pariatel cell antibodies were negative. Helicobacter Pylori antigen tested in the stool was detected positive. The patient's upper gastrointestinal endoscopy revealed antral gastritis and colonoscopy revealed Grade 1 internal hemorrhoids, He was given 1000 mg/day vitamin C. At the third day of vitamin C, serial free T4 levels were measured after ingestion of 250 mg levothyroxine. While basal TSH

was 112 mU/l and free T4 was 0.5 ng/dl, free T4 increased to 0.71 ng/dl at the first, 0.80 ng/dl at the second and 0.80 ng/dl at the fourth hour. A maximum increase of 60% in free T4 value was detected.
Conclusion
There are publications in the literature showing that vitamin C corrects abnormalities in serum free T4, T3 and TSH in patients with hypothyroidism and gastrointestinal pathology. Although the mechanism was not explained clearly, it was suggested that decreasing pH via vitamin C might increase the absorption of the drug. Co-administration of vitamin C with L-T4 may be useful in the treatment of patients with high TSH values despite high doses of L-T4.

Management of methimazole allergy with methimazole: about two cases

Oumeyma Trimeche[1], Bilel Ben Amor[1], Ekram Hajji[1], Ines Bayar[1], Sana Abid[1], Héla Marmouch[1], Hanene Sayadi[1] & Inès Khochteli[1]
[1]Fattouma Bourguiba University hospital, Monastir, Tunisia

Introduction
Graves' disease is a frequent endocrine disorder, often treated as first-line therapy with antithyroid drugs. Herin, we report two female patients with Methimazole allergy while detailing its management.
Case Reports
TWO female patients aged respectively 27 and 28 years old were diagnosed with Graves' disease (GD), diagnosed given the association of peripheral hyperthyroidism and elevated anti TSH receptor antibodies. The first developed a generalized dermographism urticaria one week after being put on 10 mg per day of methimazole (MTZ). After being ceased, she was put on 16 mg of Methyprednisone, 25 mg of Hydroxyzine and 10 mg of Cetirizine and careful restart of low dose MTZ. The lesions disappeared after two days and MTZ dose was progressively increased, to an optimal dose of 1 mg per day. Control thyroxine level was normal. The second developed urticaria shortly after MTZ introduction. Thus, she was put on Benzythiouracile (BZT), which was complicated with severe neutropenia. BZT was stopped. A first trial of low dose methimazole, Cetirizine and cholestyramine was carried out but failed since she redeveloped diffuse urticaria. MTZ was ceased and then carefully reintroduced at a dose of 2.5 mg per day associated with Cetirizine, Hydroxyzine and 0.5 mg per kg of prednisone. A significant improvement of her clinical symptomatology was noted few days later. Prednisone was tapered down and parallelly MTZ dose was increased to 40 mg per day. The two patients are actually euthyroid with MTZ and after three months of therapy corticoids were stopped. The first had thyroidectomy and is actually on optimal dose of Levothyroxine and the second had radioactive iodine therapy and was lost to follow up thereafter.
Conclusion
These cases highlight the possible treatment of methimazole allergy with corticoids and anti-histamine drugs and their reintroduction thereafter, while detailing the used protocol.

EP365

Tocilizumab for the treatment of active steroid-resistant graves' orbitopathy - 2 case reports from a romanian endocrinology department

Aurelian E Ranetti[1], Florentina Smeureanu[1] & Creanga Andreea[1]
[1]Spitalul Universitar de Urgenţă Militar Central 'Dr. Carol Davila', Endocrinology, Bucureşti, Romania

Purpose
To describe pre- to post-treatment changes in clinical activity score (CAS) in patients with Graves orbitopathy treated with tocilizumab (TCZ).
Introduction
Graves' ophthalmopathy (GO) is an autoimmune disorder that affects 30-50% of patients with Graves' disease. The first-line treatment of moderate to severe GO according to EUGOGO is intravenous glucocorticoids, but 20-30% of the cases appear to be corticosteroid refractory. Steroid-resistant GO constitutes a major clinical and therapeutic challenge but promising results have been described with TCZ as a second-line moderate to severe GO treatment. We report a case series of severe GO treated with tocilizumab.
Case report 1
41-year-old man, former smoker who was diagnosed two years ago with hyperthyroidism and GO, presented in our hospital for reevaluation. The patient was in a thyrotoxic state and he was treated with methimazole and with intravenous methylprednisolone (cumulative dose 4.1 gr) with only partial response. He presented with unilateral eyelid swelling, orbital pain, redness and tearing. His CAS was 5 out of 7. A MRI orbits scan showed enlargement of the extraocular muscles, more prominent in the right orbit. The patient rejected radiotherapy. We initiated therapy with TCZ, a monoclonal antibody that inhibits the IL-6 receptor. 'Off-label' authorization for the use of tocilizumab was asked to Pharmacy Committee of our center. After its approbation, he received 4 intravenous doses (8 mg/kg) every 28 days, according to Perez-Moreiras RCT. On follow up, symptoms were improved impressively, and CAS score regressed to 1/7.
Case report 2
52-year-old men diagnosed with Graves' hyperthyroidism and GO one year ago, presented in our hospital for corticosteroid resistant GO. The patient had no general symptoms of thyroid disease. He previously received bolus of methylprednisolone with a weak response. He presented with bilateral eyelid swelling, orbital pain, redness and visual loss on the left side. His CAS was 4 out of 7. Due to the severity and the progression of the disease despite the corticosteroid treatment, we decided to initiate the treatment with TCZ. He received 4 intravenous doses (8 mg/kg) every 28 days. On follow up, symptoms were significantly improved including improved vision in his left eye, and CAS score regressed to 1/7.
Conclusions
We present this cases to raise awareness for the relative efficacy and tolerability profile of intravenous tocilizumab in the management of moderate to severe, corticosteroid resistant or refractory GO, of recent-onset, with lower cost compared to other novel therapies such as teprotumumab.

EP366

Evaluation of quality of life in pregnant women with dysthyroidism

Meryem Chakir[1], Bensbaa Salma[1], Haraj Nassim Essabah[1], El Aziz Siham[1] & Chadli Asma[1]
[1]Ibn Rochd University Hospital of Casablanca, Morocco Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy-University Hassan II- Casablanca-Morocco, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casablanca, Morocco

Introduction
Physiological changes during pregnancy expose pregnant women to an increased risk of thyroid disorders or decompensation of underlying thyroid conditions, which can impact the quality of life of patients.
Objective
To assess the quality of life of Moroccan pregnant women with thyroid disorders.
Materials and Methods
A case-control study conducted at the Endocrinology-Diabetology Department of Ibn Rochd University Hospital in Casablanca, involving pregnant patients with thyroid disorders. Two groups were included: the first diagnosed during the current pregnancy, and the second followed for thyroid disorders before pregnancy. Patients with other pathologies and thyroid cancers were exclu + ded. Participants completed the ThyPRO questionnaire.
Results
We included 53 patients divided into two groups; 20 were diagnosed with thyroid disorders during the current pregnancy, and 33 had thyroid disorders before pregnancy. The average age was 29.6, with 17.3% having hypothyroidism and 82.7% having hyperthyroidism. 20% reported an unwanted pregnancy. The mean score of thyroid symptoms was higher in the first group, 52 vs 19.3. Patients diagnosed with thyroid disorders during their pregnancy also exhibited more pronounced cognitive problems (33.8 vs 7.6), depression with an average score of 43.03 vs 24.9, and higher anxiety (45 vs 23.3). Additionally, they had a higher average fatigue score, 42.14 vs 32.2. These differences were statistically significant ($P < 0.01$). Maternal-fetal complications affected 74.2% of patients in the first group vs 42% ($P < 0.02$).
Conclusion
Targeted interventions, such as patient education, as well as improvement in the monitoring and management of thyroid disorders during pregnancy, could contribute to improving the quality of life in this population.

EP367

A case of myasthenia gravis associated with hashimoto's thyroiditis

Raida Ben Salah[1], Siddiqa Soomauroo[2], Faten Hadjkacem[2], Abdelmuhaymen Missaoui[2], Ahmad Ridwaan Auckburally[3], Wiem Feki[3], Mouna Mnif[2], Sameh Marzouk[1], Mohamed Abid[2], Nabila Rekik[2] & Zouheir Bahloul[1]
[1]Hedi Chaker University Hospital, Department of Internal Medicine, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [3]Hedi Chaker University Hospital, Department of Radiology, Sfax, Tunisia

Introduction
Myasthenia gravis (MG) is a chronic neuromuscular condition characterized by weakness in voluntary muscles. It is an autoimmune disorder. The emergence of the condition can be abrupt. As with any autoimmune disease (AID), it may be associated with other AIDs. We report a case of MG associated with Hashimoto's thyroiditis (HT).
Observation
The diagnosis of MG was established in a 58-year-old patient, based on the progressive onset of fatigue, excessive salivation, difficulty in chewing, and ptosis. Electromyography revealed signs indicative of neuromuscular junction involvement. Anti-acetylcholine receptor antibodies were positive. The patient was prescribed Pyridostigmine (Mestinon®) and showed a good response to treatment. The diagnosis of MG was made 3 months before identifying profound hypothyroidism, which was incidentally discovered during the investigation of other autoimmune diseases. The hypothyroidism was attributed to HT, confirmed by positive anti-thyroid peroxidase antibodies and anti-thyroglobulin antibodies. The patient received treatment with L-thyroxine for the thyroid disorder. The clinical and biological outcomes were favorable, achieving euthyroidism.
Discussion/Conclusion
The diagnosis of MG is based on the clinical presentation - often starting with ocular symptoms such as ptosis or diplopia, extending to other muscles in 80% of cases, worsening with exertion, and characterized by episodic progression -, the response to anticholinesterase medications, the detection of anti-acetylcholine receptor antibodies, and the presence of a decrement in electromyography. MG can be associated with numerous autoimmune thyroid diseases (AITDs), especially autoimmune thyroiditis. The underlying pathophysiological basis connecting these conditions is not clearly established, but an immunological cross-reaction between the neuromuscular junction and thyroid components has been identified in both MG and AITD, such as autoimmune thyroiditis. The prevalence of AITD among individuals with MG is generally higher than that in the general population. In fact, 9% of men and 18% of women with MG exhibit autoimmune thyroid diseases. These diseases are predominantly characterized by hyperthyroidism (17.5%), simple goiter (1.7%), or more rarely, hypothyroidism (0.4-0.7%).

EP368

Adrenal decompensation precipitated by severe graves' thyrotoxicosis

Nauman Jadoon[1]
[1]NHS Greater Glasgow & Clyde, Endocrinology, Glasgow, United Kingdom

Background and Aims
Thyroid hormone can accelerate glucocorticoid turnover and there have been cases of adrenocortical insufficiency reported after radioactive iodine treatment. However, the patient presented here did not have any such precipitant nor any underlying adrenal disease, and her adrenal insufficiency resolved after treatment of thyrotoxicosis.
Methods
A case of a 45-year-old lady with Graves' disease is presented, who developed hypoadrenalism at the time of her diagnosis which settled with the treatment of underlying thyrotoxicosis.
Results
A 45-year-old lady presented with nausea, light-headedness, and sweats which started 3 weeks after her COVID vaccine booster. Her symptoms included syncopal symptoms, muscle weakness, nausea, vague abdominal pain, constipation, dry mouth, intermittent headache, legs feeling shaky, weight loss, and appetite loss. Her blood pressure at the time of presentation was 107/70 with no significant postural drop. She was normoglycemic with no neck lumps and an otherwise normal physical examination. Her initial blood tests showed a free T4 level of 82.9 pmol/l with a TSH of <0.01 mU/l. Her morning cortisol level was 218nmol/l, and short synacthen test showed a rise from 178nmol/l to 371 nmol/l. She was commenced on carbimazole 1 mg daily and hydrocortisone 1 mg BD. Her symptoms improved with treatment and her dose of Carbimazole has gradually been reduced to 1 mg daily over a year. Three months after the initial presentation when her free T4 level dropped to 18.1 pmol/l, she had a repeat short synacthen test which showed a rise of cortisol from 342nmol/l to 546nmol/l. The patient was advised to discontinue hydrocortisone, however, due to her concerns about symptoms it was continued for another 3 months after which a repeat SST was carried out which again showed a satisfactory response, and hydrocortisone was withdrawn. Her adrenal antibodies were checked which were negative while the thyroid receptor antibody was positive at 27U/l.. She remains well on 1 mg of carbimazole a year after her initial presentation and has been off steroids for 6 months.
Conclusions
It is important to be aware of the possibility of adrenal insufficiency in patients with autoimmune hyperthyroidism, which can be a concomitant presentation of autoimmune adrenal insufficiency but in rare cases can be due to increased clearance of cortisol due to an excess of thyroid hormone.

Does a dedicated endocrine surgery unit impact treatment decision in patients with thyroid disorders? experiences from an endocrine-surgeon naïve area in southern india

Shreyamsa Manjunath[1] & Praveen Kumar Devarbhavi[2]
[1]Maax Superspecialty Hospitals, Endocrine & Breast Surgery, Shivamogga, India; [2]Maax Superspecialty Hospitals, Endocrinology & Metabolism, Shivamogga, India

Background
Appropriate management of thyroid diseases is crucial, as outcomes directly affect quality-of-life. High-volume thyroid surgeons provide best results, least complications. We aim to assess if a dedicated endocrine-surgery unit influences treatment-decisions(TD) of patients in an endocrine-surgeon naïve area.
Method
Study of 153-patients at Maax Superspecialty Hospitals(Shivamogga, India), from November/2021-October/2023. Previously diagnosed & under treatment elsewhere, referred for or sought expert opinion. These patients had deferred definitive-treatment(fear of complications arising from pre-surgical discussion with physician) or desired radical surgery for low risk lesions where observation was an option("may turn into cancer" as a result of discussion with physician or information obtained from other sources). Multiple consults and difference of opinions also added to this issue. Six questions were asked as a part of self-assessment- Did we add additional information/value with respect to: Q1-Diagnosis? Q2-Overall condition/course-of-disease? Q3-Treatment options? Q4-(a)Why surgery, Q4-(b)why observation? Q5-Advanced procedures? Q6-Complications, how we tackle it? Responses were recorded with a 3-point Likert scale: 1-No useful/convincing additional information 2-New information provided, but not enough to influence TD 3-Meaningful additional information, positive influence on TD.
Results
F:M = 147:6. Sixty-nine had multinodular goitre (14:compressive-symptoms, 9:retro-sternal, 3:toxic-MNG, 4:thyroiditis, 33:high-risk, 9:low-risk), 18-Graves' disease, 12-Diffuse goitre, 51-solitary nodules (25:high-risk, 26:low-risk). On multiple regression analysis, Q1-3 did not significantly influence TD, while Q4, Q5 & Q6 resulted in significant change in TD(p-value: <0.001). Q4, Q5 & Q6

The response and analysis of scores are as follows:

Criteria	Score-1	Score-2	Score-3	No-change in TD	Change in TD	p-value	Multiple-regression analysis
Q1	2	85	66	87	66	0.07	0.512
Q2	6	53	94	59	94	0.02	0.570
Q3	6	69	78	75	78	0.09	0.588
Q4(a) ($n=103$)	2	18	83	20	83	0.001	0.001
Q4(b) ($n=50$)	2	9	39	11	39	0.03	0.001
Q5	1	35	117	36	117	0.001	<0.001
Q6	2	31	120	33	120	0.001	<0.001

strongly correlated with change in TD($\rho = 0.79$, 0.84, 1 respectively).
Conclusions
Dedicated endocrine-surgery unit leads to better acceptance of treatment-plan, reduces fear/anxiety, and unnecessary surgeries. Objective discussion, availability of advanced procedures & reduced fear of complications positively influence TD.

Thyroid function in patients with MUTYH syndrome

Joaquin de Carlos[1], Lucia Zabalza[1], Ana Irigaray[1], Maria Rosario Aznarez[2], Susana Oquiñena[2], Javier Pineda Arribas[1] & Emma Anda Apiñariz[1]
[1]Hospital Universitario de Navarra, Endocrinology, Pamplona, Spain; [2]Hospital Universitario de Navarra, Gastroenterology, Pamplona, Spain

Introduction
MUTYH (MutY homolog Escherichia coli, homolog of MYH, hMYH) is a repair enzyme with a crucial role in the correction of DNA errors, being considered a protective factor of the cell. MUTYH mutations have been linked to MUTYH-associated polyposis syndrome (MAP), an autosomal recessive disorder characterized by multiple colorectal adenomas. Patients with MAP show a much higher lifetime risk of gastrointestinal cancers as an additional role of MUTYH, it appears to contribute in the involvement of pathologies based on oxidative stress damage, as well as in the prevention of inflammatory and degenerative based disorders. Although the development of extraintestinal pathology is not fully defined, it seems to increase the risk of tumors and endocrinological pathology.
Materials and methods
Prospective study, selecting 27 living patients diagnosed and registered with MUTYH syndrome under follow-up from the Digestive Department of the Hospital Universitario de Navarra (HUN) with current or past follow-up in the Endocrinology Department. Radiological tests, clinical, and analytical variables were analyzed.
Results
The study population included 14 men (51.8%) and 13 women (48.2%), with a mean age of 56 years. The median age at diagnosis of FAP was 48 years, with a mean follow-up time of 8 years. All patients underwent thyroid ultrasound examination and blood tests with the determination of thyroid autoimmunity. None of them had received radiation therapy treatment in childhood or had been exposed to radioactive sources. 48% (13/27) were diagnosed with this disease in the context of endoscopy by digestive clinic, 37% (10/27) by family screening and 4/27 (15%) in the colorectal cancer screening test. The overall prevalence of autoimmunity is 22.2% (4/18). Measured thyroid autoimmunity was peroxidase antibodies. All of them had normal thyroid function, except for two patients who had undergone total thyroidectomy and were on replacement therapy. These two patients had TSH in the normal range before surgery.
Conclusions
The prevalence of thyroid autoimmunity in the sample of patients with MAP is above that described in the general population. Studies with a larger sample size are probably necessary to obtain results with greater statistical significance.

Management of hot thyroid nodules: experience of our department

El Omri Malika[1], Jemli S[1], Lazid Sarra[1], Meherzi Abir[1], Houas Jihene[1], Ghammem Monia[1], Ach Taieb[2], Kermani Wassim[1] & Abdelkefi Mohamed[1]
[1]ENT department Farhat Hached hospital, Sousse, Tunisia; [2]Endocrinology department Farhat Hached hospital, Sousse, Tunisia

Introduction
Hot nodules represent 10% of thyroid nodules. They are defined by scintigraphic examination, which shows areas fixing the radiotracer more intensely than the rest of the gland. The aim of our work is to study the clinical, paraclinical aspects and therapeutic modalities of hot thyroid nodules.
Materials and methods
We report a retrospective study about 45 observations of hot thyroid nodules collected at our department
Results
The average age of our population was 42 years with a sex ratio of 5.4. The nodule was isolated in 28 cases, associated with signs of hyperthyroidism in 17 cases and signs of compression in five cases. The Physical examination revealed a thyroid nodule or isthmolobar located at right in 33 cases and left in 12 cases. The average size of nodule was 3.61 cm. The ultrasound revealed an heterogeneous appearance in 39 cases, homogeneous in six cases, punctiform calcifications in two cases and macrocalcifications in two cases. Thyroid scintigraph showed a completely extinct nodule in 19 cases (42.2%), partially extinguished in six cases (13.3%), not extinguished in 12 cases (26.7%) and necrotic in eight cases (17.8%). Treatment was surgical for 44 patients and radioactive iodine for one patient. Histopathological examination was in favor of benignity in all operated cases.
Conclusions
Hot nodules represent only a small part of hyperthyroidism (2 to 17%). Toxic nodules must be treated because of their cardiac consequences. Surgery is the most cautious in this case, especially in young subjects. The treatment by radioactive iodine is indicated in elderly people or people with a surgical contraindication.

Assessment of iodine deficiency among pregnant women in tirana, albania

Ira Xhemollari[1], Dorina Ylli[2] & Agron Ylli[2]
[1]Municipial Hospital, Endocrinology, Kavajë, Albania; [2]Mother Teresa University Hospital Center, Endocrine and Metabolic Diseases Unit, Tirane, Albania

Background
Iodine Deficiency (ID) represent a significant public health problem globally, particularly among pregnant women.
Aim
To estimate the prevalence and predictors of ID among pregnant women residing in Durres Albania
Methods
A survey cross-sectional study conducted on 162 pregnant women, from May to June 2021. Demographic information, iodized salt usage, and other clinical information were collected using a questionnaire cum interview face to face. The presence of iodine deficiency disorders was observed through urinary iodine concentration (UIC). Statistical analysis was done using the methods included in the statistical package of social science SPSS16. A P value <0.05 was considered statistically significant.
Results
Of 162 pregnant women, the higher percentage (48.7%) were in the first trimester. 52.7% of them had 2-3 births, 72% had no history of abortion, 95.6% with no history of premature birth, 95% of them lived in non-coastal areas. The mean age was 28.96 $\pm$ 5.197. UIC median (m UIC) among pregnant women was 114.6 µg/l (7.8-433). mUIC was reduced with increasing gestational age and the lowest value appeared in the third trimester (UIC $<$99.7 µg/l (21.7 -298.5 µg/l) P 0.03). 71.6% of pregnant women had UIC $<$150 µg/l regardless of age, number of births, abortions, premature births and living, reflecting iodine deficiency. Among them, the highest percentage (52.4%) appeared with mild ID, 13% with moderated ID and 6.1% with severe ID. Statistically significant differences were found between trimesters of pregnancy and age groups among women who received supplements of iodine vs those who did not (P 0.01) but there was no statistical difference in m UIC between these two groups. Women who were aware of iodine salt had higher level of m UIC (P 0.01). According to the results models of multi nominal regression the factors of UIC who identified as independent were no history of abort (OR^ 0.45, P 0.048), living in coast areas (OR ^ 0.34, P 0.041), trimesters of pregnancy (OR ^ 0.23 P 0.042) and consumption of fish, meat and fruit.
Konkluzion
Prevalence of ID was high in pregnant women reflecting low iodine intake. UIC reduced with incresing gestational age. Predictors of UIC were no history of abort, living in coast areas, the trimesters of pregnancy and consumption of fish, meat and fruit.

Keywords: UIC, iodine deficiency, pregnant women, supplement of iodine

Congenital hypothyroidism presenting as myxedema coma in adulthood treated using oral levothyroxine in a limited setting: a case report

Genwil Agabon[1]
[1]Zamboanga City Medical Center, Internal Medicine, Zamboanga, Philippines

Background
Congenital hypothyroidism is rare and is screened for in the Philippines during the newborn period in order to prevent a treatable cognitive delay. Myxedema coma is a complication due to severe hypothyroidism resulting from failure of homeostatic processes, causing altered mental status, edema, and vital sign abnormalities. It is a rare, life-threatening complication of hypothyroidism, an estimated 0.22 per million new cases of myxedema coma are diagnosed each year.
Case Presentation
A 29-year-old female with a history of untreated hypothyroidism presented to the emergency department after being found on the floor unconscious. In the emergency department, the patient's vital signs were remarkable for a body temperature of 35 C. The patient was also bradycardic to 51 beats per minute with stable blood pressure. On examination, the patient was stuporous, respond to painful stimuli with a GCS of 7 (E1V1M5). Physical examination was remarkable abnormal facies, short stature, and edema of extremities. Based on the history and all findings of clinical signs of hypothyroidism with alteration of consciousness, bradycardia and hypothermia, myxoedema coma was diagnosed and L-thyroxine therapy was promptly initiated. Thyroid function test results showed a free thyroxine (FT4) level of 0.1 ng/dl (0.70-1.48), free triiodothyronine (FT3) level of 1.53 pg/ml (1.71–3.71) and TSH level of >100 uIU/ml (0.35–4.94), and thyroperoxidase antibodies were negative. Thyroid ultrasonography demonstrated Thyroid Hypoplasia which raised suspicion for congenital hypothyroidism. Due to the altered level of consciousness, a nasogastric tube was inserted to allow the administration of oral medications. She was given oral levothyroxine 200 µg every 8 hours, together with intravenous hydrocortisone 100 mg every 8 hours. The patient was admitted to the ICU for close monitoring. Supportive measures were applied, including oxygen support, temperature control, empirical ceftriaxone therapy, and hydration. After 3 days in ICU, the patient was awake and alert. Blood and urine cultures showed no growth. The patient remained comfortable, alert, and oriented with no complaints. She was later discharged with oral 1 mg of levothyroxine daily and outpatient follow up.
Conclusion
Myxedema coma may be rare due to the currently available diagnostic tools and therapies, but it remains a life-threatening condition. In resource-limited settings, oral levothyroxine may be a suitable alternative to the intravenous formulation in the initial treatment of myxedema coma. Early diagnosis, administration of thyroid hormones, and supportive management are vital for a good prognostic outcome.

EP447

Hypothyroidism and bilateral foot droop

kalyani Nagarajah[1] & Sam Rice[1]
[1]Swansea, Department of Endocrinology and diabetes, Swansea, United Kingdom

Introduction
Hypothyroidism and hyperthyroidism are commonly encountered medical disorders that can be associated with neurologic and neuromuscular dysfunction. Muscle involvement is a common manifestation of both clinical and subclinical hypothyroidism, although this may not always be clinically appreciated. Hypothyroid associated myopathy can cause weakness, cramps, aching and painful muscles, sluggish movements and Severe myopathy secondary to hypothyroidism leading to Rhabdomyolysis and renal failure has also previously been reported.
Case
Here we present a case of a 49 year old male patient with known Type 1 Diabetes and hypothyroidism diagnosed in 2012 with associated raised anti TPO antibody levels of 279 IU/ml (reference range: <34 IU/ml). There was a previous described history of poor compliance with his Levothyroxine. His regular medications were Levothyroxine 150 mg OD, Novorapid and Lantus. He was admitted with 3 days history of bilateral feet swelling and bilateral foot droop. His admission blood tests demonstrated a combination of an acute kidney injury, rhabdomyolysis and severe hypothyroidism. These were his initial admission investigations: TSH >100 mU/l (0.27-4.20 mU/l), Free T4: 0.7 pmol/l (11-25 pmol/l), 9 am Cortisol 490 nmol/l (>420 nmol/l) and Creatine Kinase: 56600 U/l (40-320 U/l). Subsequent test was negative for hepatitis. His MRI spine reported degenerative changes of the L4/l5 intervertebral disc with impingement of L4 nerve root bilaterally. However, there was no evidence of significant cord compression. Vasculitis screening (ANA, ANCA, DsDNA, Anti-GBM) were also negative. Nerve conduction studies indicated peroneal nerve paresis, secondary to anterior compartment syndrome felt to be a results of acute swelling of his lower legs due to severe hypothyroidism which in turn led the development of rhabdomyolysis and renal failure. With Levothyroxine dosed at 200 mg once daily and improved compliance his thyroid function improved rapidly. His TSH was normal within three months, with some improvement of his foot drop. However, his peroneal nerve palsies has not fully resolved.
Conclusion
Anterior compartment syndrome associated with rhabdomyolysis and foot drop is a rare complication of severe hypothyroidism. Anterior compartment syndrome is most commonly unilateral. However, bilateral presentations should trigger the search for metabolic explanations.

Thyroxine intolerance: a rare but significant clinical entity

Asif Nawaz[1], David Williams[1], Peter Taylor[2], Thinzar Min[1, 3] & Win Yin[1]
[1]Swansea Bay University Health Board, Endocrinology and Diabetes, Swansea, United Kingdom; [2]Cardiff and Vale University Health Board, Endocrinology, Cardiff, United Kingdom; [3]Diabetes Research Group, Swansea University Medical School, Endocrinology and Diabetes, Swansea, United Kingdom

Introduction
Levothyroxine, the standard therapy for hypothyroidism, is usually well tolerated and very few cases of true allergy to levothyroxine have been reported to date. Here we report two cases of rare occurrence of levothyroxine allergy.
Case 1
A 56-year-old woman with no previous history of allergies started levothyroxine post-thyroidectomy for Graves' disease. She developed facial flushing and urticarial rash within 15 minutes of the first-dose of levothyroxine 1 mg. She was treated with steroids and antihistamine. She developed similar symptoms on the next dose, and tryptase levels confirmed allergy. She was trialed on levothyroxine elixir to exclude excipient-related allergy, but symptoms recurred despite concurrent antihistamine and steroid. Later, she tolerated liothyronine, with no adverse symptoms. Desensitization to levothyroxine was undertaken. A rash appeared at higher doses but settled within 24hours. She currently tolerates 1 mg daily. Given her lack of other allergies and as excipient-related allergy is common in other drugs, we are now investigating an allergy to dextrothyroxine.
Case 2
We report a 56-year-old man with autoimmune hypothyroidism. TSH was 7.1 mU/l when he presented with tiredness, which improved with levothyroxine. Over the last 18 months, his levothyroxine requirement increased to 1 mg daily, with TSH frequently >1 mU/l. Compliance issue and malabsorption disorders were excluded. He gained weight, and developed type 2 diabetes. He developed bilateral foot swelling, and cracking of his feet with facial rash and swelling. He trialed several oral forms (liquid and tablets) of levothyroxine. He was then trialed on Armour Thyroid 1 mg three times daily without adverse effect. His thyroid function improved and he lost weight leading to diabetes remission. Later, due to supply issues he was changed to liothyronine 1 mg twice daily and levothyroxine 1 mg daily with stable thyroid function.
Conclusions
Hypersensitivity to levothyroxine is rare and most patient with reaction to levothyroxine tolerated to alternative thyroxine preparation. It is hypothesized that levothyroxine allergy is likely due to the excipients or fillers rather than the thyroid hormone itself.

A rare case of immune thrombocytopenia in a patient with hashimoto's thyroiditis: a case report

Quennie Bien Bien Yu[1], Kurt Bryan Tolentino[1], Sahra Paragas[1], Jasmine Grace Asinas[1] & Fidela Salvador-Badilles[1]
[1]St. Luke's Medical Center, Internal Medicine, Taguig City, Philippines

Background
Immune thrombocytopenia (ITP) is an autoimmune condition where the immune system targets and destroys platelets, resulting in reduced platelet levels. The manifestations of ITP range from cases with no apparent symptoms to severe, spontaneous bleeding that can be life-threatening. ITP is differentiated into primary or secondary categories depending on its correlation with other diseases

or exposure to drugs. Hashimoto's thyroiditis is an autoimmune condition where the immune system attacks and destroys thyroid cells through both cell-mediated and antibody-mediated immune mechanisms. The coexistence of Hashimoto's thyroiditis with immune thrombocytopenia is uncommon. In these instances, ITP may exhibit resistance to conventional first-line and second-line treatments due to a more substantial impairment in immune tolerance. We present a case of a 25-year-old male who was admitted with ITP and was found to have Hashimoto's thyroiditis.

Case Presentation

A 25-year-old Filipino woman with no known comorbidities sought consultation at the ER due to a progressive petechial rash on bilateral lower extremities lasting for 3 days. This was associated with hematoma on the right thigh, dizziness, epistaxis, and spontaneous gum bleeding. The patient denies having colds, cough, fever, or any recent contact with sick individuals. She also denies the intake of any new medications. A complete blood count revealed a platelet count of 8, 000/ul, with a normal white blood cell count (8.6x103/ul) and hemoglobin (11.1 g/dl). Peripheral blood smear (PBS) showed thrombocytopenia with no poikilocytosis, and schistocytes were noted. Common causes of thrombocytopenia were ruled out before diagnosing ITP. The patient received an initial transfusion of 12 units of platelet concentrate, resulting in an initial increase in platelet count to 28, 500/ul. However, the following day, the platelet count decreased again to 18, 000/ul. The patient was then managed as a case of ITP and started on Dexamethasone for 4 days. A workup to rule out secondary causes of ITP was performed, including a hepatitis panel, Dengue virus test, and autoimmune disorder tests, all of which showed unremarkable results. TSH, however, was elevated at 9.844uIU/ml, with a normal fT4 at 1.1 ng/dl. Anti-TPO antibodies were also ordered and showed elevated results at 319.3 IU/ml. The patient was started on Levothyroxine and noted to have improving platelet trends. After 6 days, the patient was discharged with a platelet count of 81, 000 and a home medication of levothyroxine 1 mg. On a follow-up checkup after 1 month, TSH was now normal, and the platelet count was 395, 000.

Clinical genetic aspects of CYP17A1 gene polymorphism (RS743572) in the uzbek population

Aziza Nasirova[1] & Dilorom Najmutdinova[1]
[1]Tashkent Medical Academy, Endocrinology, Tashkent

This article discusses the role of gene polymorphisms in the development and clinical progression of autoimmune thyroiditis (AIT) based on our research. By considering the genotypic polymorphism of the studied genes, we aim to develop new effective methods for prognosis, treatment, and prevention in AIT.

Introduction

Autoimmune thyroiditis (AIT) is a significant endocrine problem characterized by autoaggressive lymphoid and plasmacytic infiltration leading to the destruction of the thyroid gland. AIT affects 3-4% of the global population and is more prevalent in women aged 40-50 years. Subclinical hypothyroidism (SH) is a common condition associated with AIT, with a prevalence of 6-17% in the population. The understanding of pathogenetic mechanisms, diagnostic methods, and therapeutic measures for AIT remains insufficient.

Methods

Our study aimed to investigate the role of CyP17a1 gene rs743572 polymorphism in the formation and clinical course of AIT. DNA samples from 113 AIT patients and 94 healthy donors were genotyped using Sintol nPF npF reagent kits. Hormonal and ultrasound studies were conducted to categorize patients into hypothyroidism, euthyroidism, and hyperthyroidism groups.

Results

The study revealed significant differences in the frequency of genotypes and alleles of the CYP17A1 rs743572 SNP among various thyroid status groups. The G197A polymorphism was more prevalent in AIT patients, particularly in the hypothyroidism group, compared to the control group. The IL17A G197A genotypes also exhibited significant differences between AIT patients and the control group, indicating potential associations with thyroid dysfunction.

Conclusion

Our findings suggest a potential association between the G197A polymorphism in the CyP17a1 gene and thyroid dysfunction, especially in patients with hypothyroidism. The study emphasizes the relevance of genetic factors in thyroid diseases and provides insights for further investigations into the molecular mechanisms underlying hypothyroidism. Future research should consider expanding the patient sample and analyzing additional genetic factors for more personalized approaches to diagnosis and treatment. The study establishes a pronounced association of the CyP17a1 gene rs743572 polymorphism with the risk of AIT development in the Uzbek population.

Benign thyroid nodules evaluation in lithuania 2018 – 2022. single-centre study

Kamilė Antanavičiūtė[1, 2], Raimonda Klimaite[1, 2], Gabrielė Riškutė[1], Laura Arbatauskaitė[1] & Viktorija Pareikaitė[1]
[1]Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Endocrinology department, Kaunas, Lithuania

Introduction

As our population ages, more people are diagnosed with thyroid nodules (TN). The prevalence of TN varies by country. In this study, we would like to present the evaluation of benign thyroid nodules in Lithuania in 2018 – 2022.

Material and methods

The medical history of 719 patients treated for thyroid nodules (TN) in the Hospital of Lithuanian University of Health Sciences Kaunas Clinics Endocrinology and Surgery departments from 2018 to 2022 were analyzed. The patient's medical history, fine needle aspiration (FNA) of TN cytology results, and histological findings of operative material were interpreted. Calculations were performed using the IBM SPSS Statistics 28.0 package.

Results

The study population comprised 82, 9% women and 17, 1% men with a median age of 54 [10-90] years. We found a slight decrease in cases compared to 2018 (177) and 2022 (123). More than half (53%) of patients' TN were evaluated EU-TIRADS score 3, 18% EU-TIRADS score 4 and 5. Almost half of the patients (52%) had nodules larger than 3 cm. 54% of patients had nodules only in one thyroid gland lobe. There was no statistically significant age difference between genders at the time of the first TN finding ($P = 0, 058$). Women were observed for a statistically longer time before surgery ($P < 0.001$) with a median of 30 [1 - 636)] months. 26% of patients were discussed by a multidisciplinary council before surgery. The most common reason for thyroid surgeries (48%) was shortness of breath or difficulties swallowing. Other reasons: thyrotoxicosis (31%), malignant nodule was suspected (14%), TN were found after parathyroidectomy (4%), cosmetic defect (3%). Due to malignancy being suspected by ultrasound, 33% of patients had a fine needle aspiration biopsy (FNA) before thyroid surgery. Unfortunately, the results of cytology and surgery material's histology differed in 27, 27% of cases, when FNA showed malignancy, but histology showed benign lesions.

Conclusion

The main clinical concern is to exclude malignant nodules and avoid overdiagnosis, because misdiagnosis can decrease the patient's quality of life. Although TN has a low risk of malignancy and patients should continue ongoing surveillance through physical examination and periodic ultrasound evaluations.

Immune response mediated by immunoglobulin e in patients with autoimmune thyroiditis: an intricate connection

Sladjana Pejaković[1, 2], Ivana Bajkin[1, 2], Dragana Tomić-Naglić[1, 2], Mia Manojlović[1, 2], Andrijana Milankov[1, 2], Nikolina Vuković[2] & Stefan Janičić[2]
[1]Medical Faculty Novi Sad, University of Novi Sad, Novi Sad, Serbia; [2]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Novi Sad, Serbia

Introduction

Autoimmune diseases have a high prevalence in the general population, and AITD is one of the most common representatives. Although IgE is the main regulator of allergic reactions, there is evidence to suggest a link between AITD and allergic diseases, demonstrated by the example of chronic spontaneous urticaria (CSU).

Aims

For this research, we have set the following goals: to determine whether there is an association between the serum level of total IgE and the presence of primary hypothyroidism of autoimmune genesis; to determine whether there is a difference in the presence of extrathyroid manifestations of autoimmune thyroid disease in patients with high IgE levels; to determine whether there is a correlation between the severity of the clinical picture of primary hypothyroidism in relation to the height of the IgE and anti-TPO antibody titers.

Materials and Methods
The research was conducted as a prospective study at the Clinic for Endocrinology, Diabetes and Metabolic Diseases as well as at the Clinic for Dermatovenerology, on a sample of 62 patients. All subjects underwent to laboratory tests of interest for the research from a sample of peripheral venous blood, as well as ultrasonography of the thyroid gland. All subjects were divided into two groups based on total serum IgE level (group with elevated total IgE level and group with normal level).
Results
All patients included were diagnosed with AITD, with or without thyroid function disorder. The population in our sample was dominated by females. 19.4% had urticaria. 24.1% of subjects had elevated levels of total serum IgE, and subjects with combined AITD and urticaria had significantly higher values of total serum IgE. Average TSH values were statistically significantly lower in patients with elevated total serum IgE values. The most common ultrasonographic finding was the heterogeneity of the thyroid gland parenchyma. A low moderate, negative correlation was detected regarding the value of total serum IgE and the level of anti-TPO and anti-Tg antibodies.
Conclusion
The results of the conducted research indicate the existence of a statistically significantly higher titer level of the total serum IgE antibodies in the group of subjects with CSU, with statistically significantly lower values of TSH, which implies the possible epipathogenetic effect of an elevated serum level of IgE on the occurrence of the thyroid dysfunction, as well as that a high level of IgE antibodies shows a tendency towards the presence of extrathyroidal manifestations of autoimmunity.

Navigating complexities: a case study of mixed hypothyroidism induced by durvalumab in cancer immunotherapy

Carla Ciobanu[1, 2], Carmen Sorina Martin[1, 2], Ahmed Al Jumaili[1] & Simona Fica[1, 2]
[1]Spitalul Universitar de Urgenţă Elias, Endocrinology, Bucureşti, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucureşti, Romania

Introduction
Immune checkpoint inhibitors targeting cytotoxic T-lymphocyte-associated protein 4 (CTLA-4), programmed cell death ligand 1, and its ligand (PD-1/PD-L1) have become the current standard of care for many cancers. The mechanism of action of these drugs results in some new types of adverse events related to the immune system, most frequently involving the pituitary and thyroid glands.
Case report
We present a case of mixed hypothyroidism (primary and secondary) induced by Durvalumab (PD-L1 inhibitor) that is associated with immune-mediated endocrinopathies. A 64-years female, ex-chronic smoker with a medical history since March 2022 of small cell lung carcinoma of the left superior lobe with secondary cerebral, peritoneal, and lymphatic involvement, has been transferred in October 2023 from the oncology department to the endocrinology ward for facial and bilateral leg edema, fatigue, and shortness of breath. The patient was started on Durvalumab in 04/2022 after chemotherapy and radiation treatment. Physical examination showed facial, bilateral leg edema, hoarse voice, slurred speech, and bradypsyhia. She was afebrile, normotensive, and bradycardic. Laboratory analysis detected mildly elevated TSH = 9.21 uUI/ml with undetectable free T4 levels (0.1 ng/ml-n = 0.8-1.7). Further investigation revealed normal prolactin levels (17.1 ng/ml-n = 4.79-23.3) and normal corticotrope (cortisol = 10.1 ugdl-n = 4.82-19.5; ACTH = 14.16 pg/ml -N:7.2-63.3) and somatotropic axes. The pituitary gonadotropin levels indicated menopause, consistent with age. Ultrasonography showed a hypoechoic shrunken thyroid gland consistent with chronic autoimmune thyroiditis. Thus far, thyroid antibody tests were negative. Based on laboratory tests, thyroid ultrasound findings, and clinical symptoms, the patient was diagnosed with severe hypothyroidism of mixed etiology (primary and secondary) associated with Durvalumab, and treatment with levothyroxine (1 mg) has been initiated. Symptoms worsened after initiating treatment with levothyroxine, leading to suspicion of secondary adrenal insufficiency. We didn't perform stimulated tests for adrenal insufficiency in the acute phase and we preferred to initiate GC therapy replacement, following to be retested after treating thyroid insufficiency. Hydrocortisone hemisuccinate IV was initiated for 2 days with the improvement of symptoms. After two days, HC was switched to prednisone (1 mg/day), and the levothyroxine treatment was gradually increased to 1 mg/day. Follow-up after 2 months was recommended.
Conclusion
The case described the potential complications associated with the PD-L1 inhibitor Durvalumab, in the context of mixed hypothyroidism. Thyroid dysfunction occurs primarily with PD-1/PD-L1 blockade, and the pattern of inflammatory, destructive thyroiditis is observed, which evolves into hypothyroidism. In a minority of cases, central hypothyroidism can develop (TSH deficiency), mostly along with ACTH deficiency which should not be missed. Prompt management is crucial for mitigating adverse events.

Cardiovascular manifestations in a complex case of thyroid storm secondary to graves: challenges and therapeutic considerations

Margarida Oliveira[1], Catarina Gama[1], Bruna Pimentel[1], Paula Calvo[1], Carolina Antunes[1], Leonor Lopes[1], Rute Ferreira[1] & João Sequeira Duarte[1]
[1]Centro Hospitalar de Lisboa Ocidental, Endocrinology, Diabetes, and Metabolism Departmen

Introduction
Thyroid storm, a life-threatening manifestation of hyperthyroidism, presents a complex clinical challenge that demands swift and precise intervention. The heart is one of the most important target organs affected by the thyrotoxic state. Thyrotoxicosis may lead to sinus tachycardia, hypertension, tachycardiomyopathy, atrial fibrillation and heart failure.
Case Presentation
A 46-year-old female presented to the emergency department with symptoms of sweating, insomnia, diarrhea and fatigue for three months, and with increasing shortness of breath and palpitations, over the last week. She had a previous history of psoriasis and family history of her father with thyroid malignancy, who underwent thyroidectomy, at the age of 50. At observation, the cardiovascular exam revealed an irregular rhythm, with a heart rate ranging between 105 and 150 beats/min and bilateral edema of the lower limbs. She was afebrile. Thyroid function tests revealed thyroid-stimulating hormone (TSH) 0.008 uIU/ml (0.27- 4.20 uIU/ml), FT3 43.1 pmol/l (3.10-6.80 pmol/l) and FT4 > 100 pmol/l (12.0-22-0 pmol/l) and TRABs 27.3 U/l (< 1.58). The electrocardiogram showed atrial fibrillation. She was diagnosed with a thyroid storm, scoring 55 on the Burch-Wartofsky Point Scale. She started methimazole, hydrocortisone, beta-blocker, anticoagulant and was admitted for further stabilization and treatment. A transthoracic echocardiogram reported a reduced ejection fraction of 34%, moderate biauricular dilation, severe mitral regurgitation, and moderate tricuspid regurgitation. Over a 13-day in-hospital stay, the patient had received increasing doses of methimazole, propranolol, prednisolone, digoxin, and furosemide. However, she remained symptomatic, with frequencies between 100-120 bpm, and high levels of FT3 and FT4. On the 20th day of treatment, she developed a cholestatic pattern secondary to methimazole. The decision to perform a total thyroidectomy, with plasmapheresis before the surgery, was made. After two plasmapheresis sessions, levels of thyroid hormones decreased, and a total thyroidectomy was successfully performed. Maintaining atrial fibrillation, she underwent electric cardioversion and was discharged on the 30th day. One month later, thyroid function normalized with levothyroxine replacement. A holter revealed paroxysmal atrial fibrillation and she remained with anticoagulant and beta-blocker therapy.
Conclusion
Thyroid storm secondary to Graves disease, represents a therapeutic challenge to the clinician, especially when the hyperthyroid state leads to cardiovascular complications. Achieving a euthyroid state may resolve cardiovascular effects, but in this case, prolonged exposure to high levels of circulating thyroid hormone resulted in thyrotoxic cardiomyopathy and atrial fibrillation as sequelae.

Thyroid function assessment in individuals previously infected with SARS-CoV-2

Nassim Ben Hadj Slama[1], Taieb ACH[1], Ghada Saad[1], Asma Ben Abdelkrim[1], Molka Chadli[1] & Koussay ACH[1]
[1]Farhat Hached University Hospital, Endocrinology, Soussa, Tunisia

Introduction
COVID-19 is a viral infection that can affect various endocrine tissues, including the thyroid. In some patients, symptoms may persist after the infection, defined as Long COVID. Given the similarity of some of these symptoms to those encountered in thyroid disorders, we have decided to assess thyroid function in patients previously infected with SARS-CoV-2.
Patients & Methods
This was a prospective study conducted from January to December 2022 in the Endocrinology Department of Farhat Hached University Hospital in Sousse,

including patients previously infected with SARS-CoV-2, completely recovered (G1), and patients experiencing Long COVID (G2). A thyroid function assessment was performed by measuring TSH and FT4 levels.
Results
A cohort of 64 patients underwent hormonal evaluation, and the median duration for hormonal exploration was comparable between G1 (fully recovered) and G2 (Long COVID), with respective values of 11.5 months [Q1–Q3]=[9-14] and 11 months [Q1–Q3]=[6-14] ($P=0.498$). Predominant manifestations in the Long COVID group included asthenia and cognitive disturbances, observed in 84.4% and 93.8% of cases, respectively. Mean TSH levels were 5.19 $\pm$ 16.12 mIU/l for G1 and 4.33 $\pm$ 14.38 mIU/l for G2 ($P=0.702$), while mean FT4 concentrations were 9.60 $\pm$ 2.25 pg/ml for G1 and 10.06 $\pm$ 1.93 pg/ml for G2 ($P=0.388$). Within G1, two instances of overt peripheral hypothyroidism were identified, constituting 6.3% of the patients, compared to one case in G2, representing 3.1% of patients. Notably, these cases exhibited positive antithyroid antibodies. No occurrences of central hypothyroidism were observed in the study cohort.
Conclusion
Despite potential symptom overlap between dysthyroid conditions, notably hypothyroidism, and Long COVID, our findings suggest that thyroid dysfunction does not contribute significantly to the pathogenesis of the post-COVID-19 syndrome. Our study aligns with the prevailing evidence from most investigations evaluating thyroid function in the phase following SARS-CoV-2 infection.

Unusual distant metastasis of thyroid cancer: about 4 cases

El Omri Malika[1], Jemli S[1], Bellakhdher Mouna[1], Meherzi Abir[1], Houas Jihene[1], Ghammem Monia[1], Ach Taieb[2], Kermani Wassim[1] & Abdelkefi Mohamed[1]
[1]ENT department Farhat Hached Hospital, Sousse, Tunisia; [2]Endocrinology Department Farhat Hached Hospital, Sousse, Tunisia

Introduction
Distant metastases of thyroid tumors are rare. They are mainly localized in the lungs (10-15%), bones (9%) and brain (1%). Metastases to the facial area are exceptional. These metastases are more common with carcinoma of the vesicular (20%) than papillary (3.5%) carcinoma. The aim of our work is to support clinical and radiological aspects as well as therapeutic modalities of these entities.
Observations
Cases 1 and 2: Woman aged 38 and a boy aged 13, admitted for a chronic dry cough. Physical examination found thyroid nodules with lymphadenopathies. Chest x-ray showed a micronodular military. They had a total thyroidectomy with bilateral functional dissection confirming multifocal papillary carcinoma. A supplement with radioactive ablation therapy was associated. Case 3: A 55 years old woman admitted for lumbosciatalgia with a motor deficit. Osteomedullar biopsy revealed a metastasis of a vesicular carcinoma of the thyroid. Additional imaging revealed 2 left thyroid nodules. The patient had a decompressive radiation followed by thyroidectomy associated with bilateral central dissection. Case 4 A 43 year old woman admitted for chronic nasal obstruction. Examination found thyroid nodules. CT showed a mass extended to the right nasal fossa, maxillary sinus, sphenoid sinus, sella turcica and associated with a right lobar thyroid mass. Biopsy was in favor of nasal infiltration by a poorly differentiated carcinoma of the thyroid. The patient had chemotherapy.
Conclusion
Distant metastases of thyroid cancers have no clinical or radiological specificity. These metastases are more frequent with the vesicular histological type and have a more guarded prognosis.

Primary thyroid lymphoma: experience of our department

El Omri Malika[1], Jemli S[1], Lazid Sarra[1], Bellakhdher Mouna[1], Meherzi Abir[1], Houas Jihene[1], Ghammem Monia[1], Ach Taieb[2], Kermani Wassim[1] & Abdelkefi Mohamed[1]
[1]ENT department Farhat Hached hospital, Sousse, Tunisia; [2]Endocrinology department Farhat Hached hospital, Sousse, Tunisia

Introduction
Primary thyroid non-Hodgkin's lymphoma, which is defined as a lymphoma occurring in the thyroid gland, is a quite rare pathologic entity, accounting for 1, 3-1, 5 % of thyroid neoplasm, and 0, 5% of lymphoma. The aim of our work is to evaluate the clinicopathological features and treatment outcomes of patients with primary thyroid lymphoma.
Material and methods
We report 8cases of primary thyroid lymphoma collected at our department between 2000 and 2023.
Results
There were 6 women and two men with an average age of 63 years. One patient had a history of neoplasia of the right breast and adenocarcinoma of the colon. The reason for consultation was an anterior basicervical swelling in all patients associated with dysphonia in one patient, dysphagia in one patient, and dyspnea in three patients. The clinical examination revealed a huge painless goiter compressive in one patient, associated with bilateral lymph nodes in two patients, and ipsilateral in a patient. One patient had an emergency tracheotomy. Four patients had biopsy and the other four patients had thyroidectomy. Histological examination concluded to a mantle lymphoma in two cases, a diffuse large B-cell lymphoma in four patients, and a MALT lymphoma in two cases. Only one patient presented an invasion of the medullary bone confirmed by biopsy. All patients underwent chemotherapy. Three patients died and 4 patients presented no recurrence.
Conclusion
Primary thyroid lymphoma is an uncommon pathologic entity. The prognosis is primarily dependent on age, staging, and disease spread, then the histologic subtype.

Keywords: autoimmune thyroiditis, hypothyroidism, euthyroidism, genetic polymorphism.

Aggressive papillary microcarcinoma: clinical manifestations and prognostic factors

El Omri Malika[1], Jemli S[1], Kechiche Jaweher[1], Bellakhdher Mouna[1], Meherzi Abir[1], Houas Jihene[1], Ghammem Monia[1], Ach Taieb[2], Kermani Wassim[1] & Abdelkefi Mohamed[1]
[1]ENT Department Farhat Hached Hospital, Sousse, Tunisia; [2]Endocrinology Department Farhat Hached Hospital, Sousse, Tunisia

Introduction
Metastasis in adenopathy accompanying thyroid microcarcinoma (TMC) is a rare clinical situation. We propose to study the risk factors for their occurrence, their clinical characteristics and their therapeutic methods.
Material and methods
A retrospective study of 14 cases of TMC associated with metastatic cervical adenopathy collected in our ENT department, between 1990 and 2023.
Results
The cases studied represented 25% of all TMCs operated on during the same period. The mean age was 47.2 years, with a female predominance. The mean size of the adenopathy was 3 cm. The thyroid gland was clinically anodular in 10 cases. 13 patients had a cervical ultrasound scan showing calcifications within the adenopathy in 4 cases, considered to be a branchial cyst in one case. The thyroid was anodular in 7 cases. A cervical Computed tomography scan was performed in the case of an 8 cm lesion that had fistulated to the skin. It showed the appearance of an 84 mm multiloculated left latero-cervical mass with hypodense necrotic content and heterogeneous calcified peripheral enhancement infiltrating the lateral border of the sternocleidomastoid muscle, and an 8 mm left lobar thyroid nodule. Total thyroidectomy was performed in all our patients, together with a bilateral mediastino-recurrent dissection with unilateral lateral lymph node dissection in 12 cases and bilateral dissection in one case. Adjuvant treatment was performed in 13 patients with Iodine-131.
Conclusion
The presence of adenopathy during TMC is rare. This diagnosis should be considered in young patients. It reflects aggressivity of the tumor.

Strange association of graves, hashimoto and papillary thyroid carcinoma

Elena Roxana Novac[1], Velicescu Cristian[2] & Cotirlet Valentin Adrian[3]
[1]Emergency Hospital Moinesti, Bacau, Romania; [2]Universitatea de Medicină şi Farmacie 'Grigore T. Popa' din Iaşi, Med, Iaşi, Romania; [3]Vasile Alecsandri University of Bacău - Mărăşeşti Campus, Bacău, Romania

We present the case of a 32 yeas old male, diagnosed 7 years ago with Basedow disease, with numerous recidives which needed anti-thyroid medication, with poor response (hypo to hyper-thyroid status, with high variations of TSH and FT4) whom after a period of remission (8 months, no treatment) came in for a polymorphic symptomatology sugestive for hyperthyroidism. The hyperthyroid state was confirmed he had high TrAb ()31 UI/ml vs < 1.75 UI/ml)- and we need to mention that on his last check in the detection rate of TrAb was under 0.3. The thyroid ultrasound revels on the left lobe a small mass of 0.8/0.8 cm, with EU-TIRADS score of 4, that was newly diagnosed. At that moment we initiated thyamazole 30 mg/day and non-selective beta-bloker for the four weeks until surgery. Postoperative histopathology revealed papillary microcarcinoma developed on hashitoxicosis-pT1aN0, of 1 mm in the middle of left thyroidian lobe. The particularity of this case consists in a long evolution of Basedow-Graves disease with numerous recalls, the appearance of a thyroid nodule after 7 years in which they identified a papillary microcacinoma associated with Hashimoto thyroiditis and also the postoperative recovery that was slowed by the parathyreoprive tetany.

Diagnostic-therapeutic management in patients with non-invasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP)

Raúl Rodríguez Juárez[1], Antonia Garcia Martin[1], Mercedes Caba Molina[2] & Pablo J López-Ibarra Lozano[1]
[1]Granada, UCG Endocrinología y Nutrición, Granada, Spain; [2]Granada, Unidad Provincial Intercentros de Anatomía Patológica de Granada, Granada, Spain

Objective
Non-invasive follicular thyroid neoplasm with papillary-like nuclear features (NIFTP) it's a histological entity that describes a low-aggressive neoplasm previously classified as encapsulated follicular variant of papillary thyroid carcinoma and well differentiated tumour of uncertain malignant potential. The preoperative diagnosis it's difficult, and if we suspect it hemithyroidectomy or lobectomy it's the therapeutic management of choice. Therefore, we will evaluate the features and diagnostic-therapeutic management of patients with NIFTP.
Materials and Methods
Retrospective observational study with 23 patients with NIFTP diagnosis in Granada's hospitals between the years 2016 and 2022. Demographic (sex, age), radiological (pre and postoperative ultrasonography), anatomopathological (pre and postoperative sample type, tumoral size) and therapeutic (indication and operation type, postoperative thyroglobulin and treatment and follow-up) variables were collected.
Results
23 patients with NIFTP (73.9% females, 50 ± 13 years). In the preoperative ultrasonography the nodules were classified in TI-RADs 4 and 5 in 47.8% and 8.7% respectively. Fine-needle aspiration (FNA) results were 4.3% for Bethesda I, 34.8% for Bethesda II, 21.7% Bethesda III, 17.4% Bethesda IV, 17.4% Bethesda V and 4.3% Bethesda VI. The surgical indication was PAAF's result in 60.9% of the patients, being total thyroidectomy the technique of choice in 65.2% of patients. The average size of the tumours was 31.8 ± 14.7 mm. After surgery, 65.2% had performed ultrasonography and thyroglobulin levels, and three cases were treated with radioiodine. 87% were followed-up after treatment.
Conclusions
Our study confirms the difficulty in suspecting NIFPT presurgically, that's why total thyroidectomy was performed in more than a half of patients, and follow-up is subsequently performed in the majority of cases.

The correlation between the presence of histopathologically different subtypes and aggressive behavior and recurrence in patients with papillary thyroid carcinoma

Müge Keskin[1], Bugra Durmus[1], Gökhan Rıza Baykal[1], Ali Abbas Tam[2], Buket Özdemir[3], Ayca Dilsad Caglayan[4], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakır[2]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yildirim Beyazit University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara Bilkent City Hospital, Department of General Surgery, Ankara, Turkey; [4]Ankara Etlik City Hospital, Department of Pathology, Ankara, Turkey

Aim
Papillary thyroid cancer (PTC) accounts for 85% of thyroid cancers. Classical PTC has a 10 year survival rate of over 95%. Although the histopathological diagnosis of thyroid tumors, which started in the 1950s, has improved significantly in the last few decades, the effect of aggressive subtypes on survival has not been fully clarified. In our study, we investigated the effect of aggressive cytologic subtypes on behavior and prognosis in patients followed up with a diagnosis of PTC.
Method
Our retrospective study included 484 patients who underwent bilateral total thyroidectomy and were diagnosed with PTC. There were 11 patients with aggressive subtype (columnar cell, tall cell, diffuse sclerosing, solid, hobnail PTC), 382 patients with nonaggressive subtype (papillary, follicular PTC), and 91 patients with mixed subtype. 36 month follow-up results were analyzed. Demographicall findings, imaging and laboratory results, histopathological features (tumor diameter, capsule invasion, vascular invasion, extrathyroidal invasion, lymphatic invasion, distant metastasis), radioactive iodine (RAI) treatment were noted from the records. Dynamic risk scoring (excellent response, biochemical incomplete response, structural incomplete response, indeterminate response) was performed.
Results
The mean age at diagnosis was lower in the aggressive subtypes (44.36 ± 10.63) than in the nonaggressive and mixed subtypes (46.14 ± 12.82 and 47.71 ± 13.24, respectively) ($P = 0.501$). Tumor size was significantly larger in the aggressive subtypes (1.83 ± 2.27 cm) than in the nonaggressive and mixed subtypes (1.21 ± 1.1 cm and 1.60 ± 1.1 cm, respectively) ($P = 0.019$). According to the American Thyroid Association (ATA) risk classification, the proportions of those identified as intermediate and high risk were higher in the aggressive and mixed subtypes (72.7% and 68.1%, respectively) than in the nonaggressive subtypes (23.9%) and the difference was statistically significant ($P < 0.001$). Remission, persistence, recurrence and metastasis rates during follow-up did not differ significantly between groups ($P = 0.926$, $P = 0.903$, $P = 0.776$ and $P = 0.920$, respectively). There was no significant difference in treatment responses according to dynamic risk scoring after initial treatment 6-12 months, 12-18 months, 18-24 months, 24-36 months ($P = 0.931$, $P = 0.961$, $P = 0.892$, $P = 0.698$, respectively).
Conclusion
In our study, we found that tumor size was larger in the aggressive subtype, and those with intermediate and high risk, according to the ATA risk classification, were more common in the aggressive and mixed subtypes. In patients with PTC, aggressive and mixed subtypes in the initial treatment phase may create differences in approach, and further studies are needed.

DOI: 10.1530/endoabs.99.EP507

Evaluation of dry eye parameters and vitamin E levels in patients with papillary thyroid carcinoma

Müge Keskin[1, 1], Belma Özlem Tural Balsak[1], Neslihan Bayraktar[2], Keskin Caglar[3], Fatma Dilek Dellal Kahramanca[3], Oya Topaloglu[4], Reyhan Ersoy[5] & Bekir Cakır[4]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Bilkent City Hospital, Department of Ophthalmology, Ankara, Turkey; [3]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [4]Ankara Yildirim Beyazit University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey; [5]Ankara Yildirim Beyazit University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey

Aim
Dry eye syndrome(DES) is a common finding in patients with thyroid orbitopathy. There are few studies on DES in patients with papillary thyroid cancer (PTC). Retinal pathology may develop in case of vitamin E deficiency, which has antioxidant, anti-inflammatory and anti-apoptotic properties.
Materials and Methods
In our study, 29 patients who received radioactive iodine (RAI) treatment (Group 1) and 22 patients who did not receive RAI treatment (Group 2) with a diagnosis of PTC were included. 26 healthy individuals without PTC were determined as the control group (Group 3). Exclusion criteria were diabetes mellitus, rheumatologic diseases, keratoconus, glaucoma, history of contact lens use, previous eye surgery. Ocular surface disease index, meibomian gland secretion quality, lid margin score, noninvasive tear breakup time were evauated with sirius device and meibomagraphy in all patients. Thyrotropin (TSH), free thyroxine, free triiodothyronine, and vitamin E levels were measured.
Results
TSH levels were significantly lower in Group 1 and 2 compared to Group 3 ($P < 0.001$, $P < 0.001$, respectively). There was no significant difference between

the groups in terms of vitamin E levels ($P=0.599$). The proportion of those with normal noninvasive tear breakup time (>17) was similar in Group 1, Group 2 and Group 3 (30.8%, 27.3%, and 44.6%, respectively, $P=0.145$). The proportion of those with an upper lid margin score of ≥1 was significantly higher in Group 1 and Group 2 than in the control group (64.9%, 56.8% and 17.9%; respectively, $P=0.025$). Lower meibomian gland expressivity was >1 in 34.5% of the patients in Group 1, 22.7% in Group 2, and 7.1% in Group 3 ($P=0.002$). The proportion of patients with lower meibomiagraphy values of ≥1 was significantly higher in Group 1 and Group 2 compared to the control group (61.1%, 52.5%, and 29.5%, respectively, $P=0.007$). There was no significant difference between the groups in terms of lower lid margin score, Oxford values, upper meibomian gland expressibility, and upper meibomiagraphy grades ($P=0.485$, $P=0.064$, $P=0.256$ and $P=0.069$, respectively). OSDI (survey questioning eye-related irritation symptoms) values were 6.25 in Group 1 and 8.12 in Group 2 and were significantly higher than the control group (2.27) ($P=0.034$).

Conclusion

Meibomian gland dysfunction is observed in patients with PTC who received and did not receive RAI. This may be related to TSH suppression. It is important to question these patients for a dry eye because it might affect their daily living activities.

Challenges and pitfalls in the management of medullary thyroid cancer – Real-life data from a tertiary center in Romania

Stanescu Laura-Semonia[1, 2], Andrei Muresan[3], Dumitru Ioachim[4], Sofia-Maria Lider-Burciulescu[2, 5], Mara Băetu[2] & Corin Badiu[2, 3]
[1]"C.I. Parhon" National Institute of Endocrinology, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Bucure?ti, Romania; [3]"C.I. Parhon" National Institute of Endocrinology, Genetics, Bucharest, Romania; [4]"C.I. Parhon" National Institute of Endocrinology, Pathology, Bucharest, Romania; [5]"Ana Aslan" National Institute of Grontology and Geriatrics, Endocrinology, Bucharest

Introduction

Medullary thyroid cancer (MTC) is a thyroid neuroendocrine tumor with a genetic basis and average biological aggressiveness, with a 5-year survival rate of around 90%. However, the presence of calcitonin (CT) biomarker along with genetic beckground could further improve these data, by earlier diagnosis and proper surgical management of genetically predisposed patients.

Patients and Methods

To set specific thresholds for basal CT and calcium-stimulated CT for predicting thyroid malignancy, we included two groups: 74 women with elevated basal CT (>9.82 pg/ml) and 31 women with normal basal CT. After the calcium test, the histopathology of those submitted to surgery was correlated with basal and stimulated calcitonin. The best cut-offs for distinguishing female patients with medullary thyroid carcinoma or C-Cell-hyperplasia from other thyroid disorders are: 12.9 pg/ml, respectively 285.25 pg/ml . For the genetic approach, RET testing for germline mutations was performed in 74 subjects, (58 complete gene analyses and 16 targeted analyses), 72 of whom were diagnosed with MTC. Among all subjects submitted to germline RET analysis, 16/74 (21.6%) were clinically affected by a hereditary disease at diagnosis and 58/74 (78.3%) were presumed to have sporadic MTC. We identified a germline RET variant in a total of 24/74 (32.4%) cases; from these, 16/16 (100%) had a positive family history, while only 8/58(13.8%) were initially considered sporadic cases. We identified five different RET pathogenic variants. When classified in ATA risk categories, two mutations were of high-risk level (12/24, 50% cases) and three mutations of moderate risk level (12/24, 50% cases). The most common RET proto-oncogene alteration was Cys634 in 11/24 (45.8%) cases. All known pathology results of patients with a positive germline mutation and 5/37 with known wild-type RET patients had multifocal disease. Out of 50 cases tested negative for germline RET mutation, eight cases with advanced, metastatic MTC underwent RET somatic testing. From 6/8(75%) cases, a somatic RET mutation was found, 5/6 (83.3%) having Met918Thr mutation, and one case with Cys634Arg mutation. Among patients with known cancer staging, 7/24(29.1%) of those with a germline RET mutation and 20/50 (40%) of wild-type RET patients had locally advanced disease (T>1). We observed a more aggressive disease in patients with a somatic RET mutation, with metastatic disease, requiring systemic treatment with tyrosine kinase inhibitors, vandetanib, or cabozantinib.

Conclusions

Mutational screening is mandatory in all patients with MTC and crucial in selecting targeted treatment with TKI inhibitors and predicting responsiveness to therapy.

The epidemiological, clinical, and pathological characteristics of differentiated thyroid cancer in children and adolescents

Hana Charfi[1], Issam Jardak[2], Fatma Hamza[2], Mohamed Maaloul[2], Wissam Amouri[2], S Charfeddine[2], Fadhel Guermazi[2], Khalil Chtourou[2], Mohamed Abid[1] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker Hospital, Endocrinology-Diabetology Departement, Sfax, Tunisia; [2]مستشفى الحبيب بورقيبة بصفاقس,Nuclear Medecine Departement, Sfax, Tunisia

Introduction

Differentiated thyroid cancer (DTC) in children is rare, accounting for 1.5 to 3% of all pediatric cancers. Its clinical presentation differs from that in adults. The aim of our study is to investigate the epidemiological, clinical, and anatomopathological characteristics of DTC in children and adolescents.

Patients and Methods

A descriptive retrospective study was conducted at the Nuclear Medicine Department of Habib Bourguiba University Hospital in Sfax over a 21-year period (January 1996-December 2017), including 20 patients, children, and adolescents, followed for DTC.

Results

The average age of our patients was 14.9 years, with a female-to-male ratio of 1.5. Seventy percent of our patients presented with a thyroid nodule, associated with cervical lymphadenopathy in 10% of cases. One patient had a history of radiation exposure, and another had thyroid dysfunction. Family history of thyroid cancer was present in 3 patients, and thyroid dysfunction in 3 others. All patients underwent total thyroidectomy, with 90% undergoing lymph node dissection. The diagnosis of DTC was based on the histopathological examination of the surgical specimen, revealing papillary carcinoma in 80% of cases and follicular carcinoma in 20%. Pulmonary metastasis was observed in 15% of cases. All patients received thyroid hormone therapy. Complete remission was achieved in 65% of cases.

Conclusion

DTC in children and adolescents is a rare but aggressive entity. Its treatment is based on surgery and radioiodine therapy, resulting in an excellent prognosis.

The profile of the patients associating differentiated thyroid cancer and autoimmune thyroiditis – a single center experience

Lazarescu Monica Valentina[1], Andrei Goldstein[2] & Mirela Gherghe[3]
[1]Oncologic Center Sanador, Romania; [2]Oncologic Center Sanador, Bucureşti, Romania; [3]Nuclear Medicine Department, University of Medicine and Pharmacy 'Carol Davila', Bucharest

Background

Differentiated thyroid cancer is the most prevalent thyroid cancer subtype, accounting for more than 95% of cases. Autoimmune thyroiditis, a frequent autoimmune disease, is reported in 25-30% patients with nodular goiter, according to the literatures. Differentiated thyroid cancer is associated with less aggressive disease and better outcome in patients with coexisting thyroid autoimmunity, but the studies already published revelead discordant data.

Aim

To observe the characteristics of patients diagnosed with differentiated thyroid carcinoma associated with autoimmune thyroiditis admitted to the Nuclear Medicine Department.

Methods

We present a retrospective analysis of our patients with differentiated thyroid cancer with coexisting thyroid autoimmunity who were evaluated from January1 to December 31, 2023 in a tertiary Nuclear Medicine Department - Oncologic Center Sanador, Bucharest. The pre- and post-operative thyroid function tests, ultrasound, histological exams as well as clinical history and examination were evaluated.

Results

30 out of 103 patients hospitalized in our department with indication for radioactive iodine therapy had an association of autoimmune thyroiditis with differentiated thyroid cancer. Only two patients (ages 37 and 68) were males, whereas the remaining 28 were women (26 to 71 years). Preoperative the majority of patients (26 out of 30) were euthyroid, 3 had hypothyroidism, and one had autoimmune thyroiditis with the onset of hyperthyroidism. We registered one case of follicular carcinoma and 29 cases of papillary thyroid carcinoma, associated with autoimmune thyroiditis. Multifocality was observed in 40% of cases. 11 patients had lymph node metastases, with N stage: pN1a -5 patients and pN1b – 6 patients. According to ATA guidelines, our patients were divided as follows: 11 low-risk, 12 intermediate-risk, and 7 high-risk. At the moment of the admission in

our Departement the Anti-thyroglobuline antibodies (Tg- Ab) remained elevated in 19 individuals (63.3%), with average values of 677 Ui/ml (35.7 to 3014 UI/ml). Despite being in the high-risk category with nodal involvement, the patients with very high values of Anti-thyroglobulin antibodies (>1000 UI/ml) had a stimulated thyroglobulin level below 1 ng/ml.
Conclusion
The association of autoimmune thyroiditis and differentiated thyroid cancer had lead to better prognostic. Most of our patients were low- and intermediate-risk, necessitating low doses of iodine therapy. More extensive studies are needed to establish a guideline for this subgroup of patients.

Differentiated thyroid carcinoma in graves disease

Ruxandra Paula Ristea[1], Teodora Puşcaş[1], Claudiu Zaharia[1], Serghei Tutovan[1] & Mihaela Stanciu[1, 2]
[1]County Clinical Emergency Hospital of Sibiu, Endocrinology, Sibiu, Romania; [2]'Lucian Blaga' University of Sibiu, Faculty of Medicine, Endocrinology, Sibiu, Romania

Introduction
Recent studies have revealed that thyroid autoimmunity and thyroid cancer may coexist, although a pathogenic relationship has not been clearly established. Graves' disease (GD) is an autoimmune thyroid disease and is considered the most common cause of hyperthyroidism. Thyroid cancer is the most common malignancy of the endocrine system and represents the eighth most diagnosed cancer worldwide. Although in patients with GD, the presence of thyroid nodules is not uncommon, thyroid cancer is a very rare occurrence.
Case report
We report the case of a 46-year-old male patient, diagnosed with Graves disease, Graves orbitopathy, and a micronodular goiter in 2018, with two hypoechoic nodules in the right lobe, with a maximum of 0.92/0.67/0.90 cm, and another in the left lobe, measuring 0.45/0.50/56 cm. Thyroid function was effectively controlled with thiamazole, and the morphology was evaluated through periodical cervical ultrasound (US). At the last follow-up in November 2023, the US showed the rapid enlargement of the nodules, with more than 1 cm since the last follow-up in 2022, with hypoechogenicity, microcalcifications, poorly defined margins, and irregular appearance, associated with bilateral lymphadenopathy. Elastography displayed an Asteria score of 3 in strain elastography, indicating a high level of suspicion. A decision was made for the patient to undergo a total thyroidectomy with lymph node dissection. The pathological evaluation following the procedure described multifocal classical papillary carcinoma in both thyroid lobes with lymph node metastasis (pT1b(m)N1aL/V0Pn0Ro). Following surgery, the patient is due to receive radioactive iodine therapy and thyroid-stimulating hormone suppression therapy with levothyroxine.
Conclusion
The case reported highlights the fact that, although rare, the risk of thyroid cancer in patients with both GD and thyroid nodules exists. Further studies are needed to assess if there could be a causal relationship between these entities and the prevalence of thyroid cancer among patients with GD. Clinicians should consider careful evaluation, including ultrasound, nuclear imaging, and fine needle aspiration, when appropriate, in patients with GD and thyroid nodules, as there is no consensus or recommended protocol for the detection of thyroid cancer in these patients.

Occult thyroid papillary carcinoma lymph node metastasis discovered on lymphadenectomy specimen of laryngeal cancer

Amel Elkorbi[1], Nawres Bouaziz[1], Mahdi Ferjaoui[1], Rachida Bouatay[1], Nawrez Kolsi[1], Harrathi Khaled[1] & Jamel Koubaa[1]
[1]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Introduction
Occult or subclinical thyroid carcinomas are not uncommon. Metastases of thyroid cancers may be discovered incidentally during cervical dissection for squamous cell carcinoma of the upper aero digestive tract. The prevalence of these thyroid metastases is estimated to be between 0.3 and 1.6%. The therapeutic impact is poorly codified, partly related to the frequently severe prognosis of those cancer. We aim through this case to discuss the therapeutic consequences of such metastases.
Case report
This is a 46-year-old smoker patient, presented with chronic dysphonia progressing evolving over eight months with intermittent inspiratory dyspnea. Panendoscopy under general anesthesia showed a voluminous left hemilaryngeal tumor extended to the Morgani's ventricle and the subglottic region. Biopsy confirmed the diagnosis of well-differentiated keratinizing squamous cell carcinoma. The tumor was classified T4AN0M0 according to the UICC/AJCC of 2017. The patient underwent a total laryngectomy with recurrential and functional bilateral lymphadenectomy and total thyroidectomy. The final histopathological examination concluded to a laryngeal squamous cell carcinoma with the presence of lymph node metastasis from papillary thyroid carcinoma. The thyroid gland showed no histological lesions. Iratherapy with cervicofacial external radiotherapy were performed. The patient is currently without evidence of recurrence after 24 months of follow-up.
Discussion/Conclusion
In our case, there was no discussion after the definitive histological findings, as we already performed a total thyroidectomy justified by the subglottic tumor extension. Otherwise, in other cases, incidental histological thyroid metastases should be discussed based on the results of thyroid ultrasound during follow-up and the discovery of a thyroid nodule justifies thyroidectomy for diagnosis confirmation.

Insular carcinomas of the thyroid: diagnostic and prognostic evaluation: a study of 13 cases

Neni Dezoumbe[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital, Endocrinology, Diabetology, Metabolic Diseases, and Nutrition, Casablanca

Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department Ibn Rochd University Hospital of Casablanca, Morocco
Neurosciences and Mental Health Laboratory Faculty of Medicine and Pharmacy-University Hassan II- Casablanca-Morocco

Introduction
Insular carcinoma of the thyroid is an extremely rare tumor, accounting for 4% of cases, with a poor prognosis and malignancy intermediate between differentiated and anaplastic cancers. The objective of this study is to specify the characteristics of this cancer by examining its diagnostic and prognostic aspects.
Patients and Methods
A retrospective study was conducted in the endocrinology and diabetology department, including 13 patients followed for insular thyroid cancer between 1986-2023, among all thyroid carcinomas (1005 patients).
Results
The prevalence was 1.3%. The average age was 56 years. Eight patients presented with multi-heteronodular goiter, and four with an isolated nodule, including one toxic nodule. All patients underwent total thyroidectomy with lymph node dissection. Radioiodine therapy (100 mCi) was administered to all patients. Insular carcinoma represented the entire tumor in 4 cases or was associated with awell-differentiated follicular (2 cases) or papillary (6 cases) component. The average tumor size was 4 cm (2–8 cm). Histological stages (pTNM): T2 (6 cases); T3 (4 cases); T4 (3 cases); N0 (10 cases); N1 (3 cases). Recurrence was observed in 3 patients (locoregional recurrence and bone metastasis) after an average period of 28 months. Predictors of poor prognosis included age, large size, multifocality, and capsule invasion.
Conclusion
Our results emphasize the rarity of insular carcinoma with potential severity (pTNM stage, recurrence frequency).

Hyperthyroidism induced by metastatic distant thyroid carcinoma

Dorina Ylli[1, 2], Violeta Hoxha[2], Klodiana Poshi[1, 2], Marjeta Kermaj[2] & Agron Ylli[1, 2]
[1]University of Medicine Tirana, Tirana, Albania; [2]Mother Teresa University Hospital Center, Tirana, Albania

Background
We present a rare case of a 64-year-old patient diagnosed with longstanding untreated Graves' disease and co-occurrence of metastatic thyroid cancer. Very

few cases are reported in literature where the thyrotoxicosis in due to the distant metastasis and optimal treatment remains challenging.
Case Presentation
The patient came to the endocrine unit for thyrotoxicosis treatment. He was diagnosed with Graves' disease and following treatment initiation and hormone normalization, he underwent total thyroidectomy. The histological evaluation revealed a follicular variant of papillary thyroid cancer with capsular invasion (T3aNxMx). Post-surgery, aberrations in thyroid function parameters persisted, marked by suppressed thyroid-stimulating hormone (TSH), elevated free thyroxine (FT4), positive anti-thyroglobulin antibodies, and remarkably elevated thyroglobulin levels (50, 000 ng/ml). Levothyroxine was initially tapered down and later suspended due to persistent hyperthyroidism. However, two months after suspention TSH remained suppressed (0.01 mUI/ml) and FT4 elevated (22 pg/ml). Iodine-131 therapy (100 mCi) was scheduled it was discussed whether the therapy should be postponed since the TSH target was not met. However, Given the high levels of anti-TSH receptor antibodies (40 UI/ml), the decision to proceed with I131 treatment was made, revealing multiple lung and bone metastases on post-I131 imaging. Two months post-I131, symptomatic hyperthyroidism prompted the initiation of a low dose of methimazole, effectively normalizing thyroid function. At 6 months post-I131, thyroglobulin levels decreased to 19, 753 ng/ml with a TSH of 0.5 mUI/ml showing good biochemical response to therapy. However dispite improving Tg remains very high and close follow-up is fondamental and posing a challenge in determining the optimal approach for pre-I131 treatment, especially in countries were where recombinant TSH is not availability
Discussion
This case underscores the intricate balance required in addressing both cancer and hyperthyroidism. Despite the convention of advocating a lower TSH in metastatic thyroid cancer, the persistence of elevated TSH receptor antibodies suggests continued stimulation of residual thyroid cancer cells.
Conclusion
Given the scarcity of such cases, further exploration through additional cases and an extensive literature review is crucial for refining optimal management strategies.

Clinical case of a combination of giant prolactinoma and medullary thyroid cancer

Margarita Perepelova[1], Elena Przhiyalkovskaya[1], Ekaterina Pigarova[1], Petr Nikiforovich[1], Lilia Selivanova[1], Anna Roslyakova[1], Aleksandra Shutova[1] & Larisa Dzeranova[1]
[1]Endocrinology Research Centre

Background
The combination of various endocrine tumours is presented both as hereditary syndromes and sporadic forms. Medullary thyroid cancer and prolactinoma are neuroendocrine tumours, the presence of these two pathologies simultaneously has not been previously described in the literature.
Objective
To present a clinical case of a patient with giant prolactinoma and medullary thyroid cancer.
Materials and Methods
To describe the clinical case of a 67-year old patient with giant prolactinoma and medullary thyroid cancer.
Case presentation
The results of magnetic resonance imaging of the cervical spine dated in 2022 revealed an endo-infra-ante-latero(D)sellar pituitary adenoma with the size of $43\times22\times31$ mm. Laboratory tests were as follows: prolactin 94340 mEd/l (60-355), bioactive prolactin 90360 mEd/l (50-300), calcitonin 1340 pg/ml (0-11.8). The patient was initiated on cabergoline therapy. Calcium, parathormone and parathyroid glands - without pathology. US examination of the thyroid gland showed nodules: in the right lobe a moderately reduced echogenicity mass with single fluid inclusions, with clear contours, $p.2.1\times1.9\times1.1$ cm (EU-TIRADS 4), and isoechogenic mass with fluid zones d 0.1 cm (EU-TIRADS 2). Cytogram corresponded a C-cell carcinoma, based on the criteria of the classification system of Bethesda V. A flush from the puncture needle for calcitonin showed concentration of 2000 pg/ml on the right and 705 pg/ml on the left, and a calcium gluconate test was performed. At the 3rd and 5th minute, the calcitonin level was >2000 pg/ml, which indicates a high risk of medullary cancer. The results of computed tomography of the chest revealed a peripheral mass in S8 of the right lung and single small foci in the lungs that require dynamic monitoring. Computed tomography of abdominal organs did not reveal any masses. A right-sided hemithyroidectomy was performed, and the results of the morphological examination showed medullary cancer in the right lobe of the thyroid gland, classified as pT1bN1aMx R0 Pn0 LV0. Family history was negative for diseases of the pituitary gland, thyroid gland, oncopathology and other endocrine diseases.
Conclusions
The occurrence of pituitary tumor in combination with thyroid cancer is rare. According to a literature search, this is the first described clinical case of a prolactinoma and a medullary thyroid cancer. It is necessary to expand the spectrum of possible combinations of different neuroendocrine tumours and to perform additional screening.

Effectiveness of radioactive iodine (RAI) therapy and its associations with different factors in people presenting with hyperthyroidism; an analysis from Karachi-Pakistan

Sarwat Anjum[1]
[1]Asian Institute of Medical sciences, Medicine, Hyderabad Sindh Pakistan, Pakistan

Back ground
Hyperthyroidism is a common disorder with multiple etiologies and radioactive iodine (RAI) is the important modality to treat it. Successful treatment is determined by development of euthyroidism and / or Hypothyroidism within 6 months of radioactive iodine treatment. The aim of this study was to find out the outcome of RAI treatment and its association with factors like age, gender various etiologies of hyperthyroidism and baseline TSH, FT4 in our population.
Methods
This retrospective case series study was conducted at Karachi institute of Radiotherapy and Nuclear Medicine' (KIRAN) from January 2018 to June 2020. A total of 199 participants with complete data were recruited in study after IRB approval. Demographic details, age, gender, underlying cause of hyperthyroidism (graves disease, toxic multinodular goitre, solitary toxic nodule etc,) were obtained from medical records along with baseline FT4 & TSH. A fixed dose of 15mci of radioactive iodine was given to all patients and TSH and FT4 were measured at 6 weeks 3, 6, and 12 months to evaluate the outcome of RAI treatment. Data was analyzed by SPSS version 20 to compute mean standard deviation and percentages.
Results
In our study 77.9% were females, 22.1% males, mean age was 41.32 ± 0.99 years. 74.4% participants had Graves' disease, 15% had solitary toxic nodule or toxic multinodular goiter. Post RAI TSH target was achieved earlier compared to FT4. Outcome of RAI treatment in patients with Graves' disease and toxic nodule revealed statistically significant and early result. Females revealed significant improvement in both biochemical markers i-e TSH and FT4 compared to males. Successful treatment was noticed in 35%, 56%, 75.6%, at 6 weeks, 3, 6, 12 months respectively.

Asymptomatic subacute thyroiditis presenting as bilateral thyroid nodules and pyrexia of unknown origin

Eirini Kaliakatsou[1], Athanasios Fountas[1], Labrini Papanastasiou[1], Vasiliki Pikou[2], Dimitra Koutete[2], Christos Mpaltas[3] & Athina Markou[1]
[1]'G. Gennimatas' General Hospital of Athens, Athens, Greece, Unit of Endocrinology and Diabetes Center, Athens, Greece; [2]'G. Gennimatas' General Hospital of Athens, Athens, Greece, 3rd Department of Internal Medicine, Athens, Greece; [3]'G. Gennimatas' General Hospital of Athens, Athens, Greece, Radiology Imaging Department, Athens, Greece

Introduction
Subacute thyroiditis (SAT) is an acute inflammatory disorder which can rarely present as pyrexia of unknown origin without other symptoms. Diffuse thyroid heterogeneity, focal hypoechoic areas and decreased/normal gland vascularity are the most common ultrasound findings of SAT. We report a case of asymptomatic SAT presenting as bilateral thyroid nodules and pyrexia of unknown origin.
Case Presentation
A 72-year-old male with a history of tachycardia/bradycardia syndrome (with pacemaker implantation) and thyroid nodule of the left lobe (Bethesda II) was referred to emergency department due to a 2-week history of fever. He complained of a 5 kg weight loss in last 3 months, with no other symptoms. Clinical examination was unremarkable, apart from patient being febrile. Blood tests revealed anemia, leukocytosis, increased inflammation markers and

thyrotoxicosis (TSH 0.01 µIU/l, fT4 31.13 pmol/l, NR: 9-19) with negative anti-TPO, anti-TG and TRAb antibodies. Further investigations were negative for infections and autoimmune diseases, while bone marrow aspiration biopsy was normal. Whole body CT scan showed hypoechogenic lesions in both thyroid lobes but no other findings. Due to exposure to intravenous iodine contrast, thyroid scintigraphy was not performed. Thyroid ultrasound revealed a 4.4×2.3 cm well marginated isoechoic nodule in the right lobe with regular shape, cystic degeneration and hypoechoic halo sign with peripheral/central vascularity (EU-TIRADS 3) and two other nodules in the left lobe, 3.6×2.5 cm and 1.2×2.2 cm, (EU-TIRADS 3) with similar features to the right lobe nodule. Cytology of the two larger nodules revealed atypia of undetermined significance (Bethesda III). Treatment with naproxen 500 mg twice daily for the pyrexia and thiamazole 10 mg daily for the thyrotoxicosis was initiated. One-week later, patient was afebrile, improved thyroid function and decreased inflammation markers were noted; naproxen was continued, while thiamazole was stopped due to borderline fT4 levels. After one month of treatment, naproxen was finally discontinued due to normal inflammation markers and thyroid function. The patient was reviewed three months later and remained asymptomatic and euthyroid without treatment. Repeat thyroid ultrasound revealed complete remission of the 4.4 cm and 3.6 cm nodules and presence of the, already known, 1.5 cm nodule in the left lobe.

Conclusion

This very rare case demonstrates the importance of SAT to be included in the differential diagnosis of fever of unknown origin, even in asymptomatic patients. Furthermore, clinicians should be aware that, in some cases, SAT-associated thyroid lesions may mimic thyroid nodules.

Harmony and complexity: unveiling the multifaceted nature of multiple autoimmune syndrome

Raida Ben Salah[1], Siddiqa Soomauroo[2], Faten Hadjkacem[2], Abdelmuhaymen Missaoui[2], Ahmad Ridwaan Auckburally[3], Wiem Feki[3], Mouna Mnif[2], Sameh Marzouk[1], Mohamed Abid[2], Nabila Rekik[2] & Zouheir Bahloul[1]

[1]Hedi Chaker University Hospital, Department of Internal Medicine, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [3]Hedi Chaker University Hospital, Department of Radiology, Sfax, Tunisia

Introduction

Despite being organ-specific autoimmune diseases (AID), autoimmune thyroid diseases (AITD) may be associated with other AIDs either specific to other organs or systemic. These associations are not uncommon. They may be grouped in the form of an autoimmune polyendocrinopathy or multiple autoimmune syndrome (MAS). MAS is defined by the presence in the same person of at least three AIDs.

Patients and Methods

It is a retrospective study over a period of 18 years of patients with AITD associated with another type of AID. The aim of this study was to describe the characteristics of MAS in this population.

Results

one hundred and thirteen cases were collected. A female predominance was observed with a sex ratio (F/M) of 3.52. The average age at the diagnosis of thyroid dysfunction was 38.22 years. The etiology of the AITD was predominantly Hashimoto's thyroiditis (69 patients), followed by Graves' disease (19 patients). In each patient with thyroid disorder, one or more AID were found: 17 types of AIDs distributed into 10 organ-specific AID and 7 systemic AID. The AITD was the primary presenting condition in 35 cases (26.51%), diagnosed concomitantly with another AID in 40 cases (30.3%), and preceded by an AID in 54 cases (40.92%). In our study, we collected 11 patients who presented with a MAS. They were all female. Two of them presented with a MAS type 2 and the 9 others were of type 3. A Hashimotos' thyroiditis was diagnosed in all the cases.

Conclusion

This syndrome was described by Humbert and Dupond[1] in 1988 as the association of at least three AIDs in the same patient. There are 3 types depending on associated pathologies. Family history, genetic, infectious, immunological and psychological factors have been implicated in the development of MAS. Generally, one of the autoimmune disease associated in the MAS, is a skin disease, such as psoriasis or vitiligo. According to the literature, vitiligo is the first AID to be diagnosed during the course of MAS associated with an autoimmune thyroid disease in the majority of cases.

Hypothyroidism: what do our patients know?(about 140 cases)

El Jadi Hamza[1] & Moustaghit Imane[2]

[1]Oued Eddahab Military Hospital, Endocrinology, Agadir, Morocco; [2]Oued Eddahab Military Hospital, Endocrinology, Agadir, Morocco

Summary

Hypothyroidism is a frequent and generally chronic pathology. Hypothyroid patients, particularly women of childbearing age, the elderly and/or cardiac patients, need to have a minimum level of knowledge of their pathology. The aim of our study was to assess the level of knowledge of a group of hypothyroid patients. The study involved 140 hypothyroid patients over a period of 06 months. The evaluation was carried out using a questionnaire, and the responses were recorded and analyzed using Excel software. 88.7% of patients knew that they had a hypo functioning thyroid gland, with 84% identifying the cause of hypothyroidism. 85% knew how to take L-Thyroxine, 22% had an idea of the notion of drug interactions, 2% knew the signs of overdosage and only 3% knew the signs of underdosage. In the case of 52 patients of childbearing age, 92% are unaware that pre-conceptional balancing is compulsory, compared with 8% who are already aware of it. Hypothyroidism is a frequent pathology, predominantly female. It corresponds to a thyroid hormone deficiency, either due to primary thyroid gland or hypothalamo-hypophyseal axis disease. It's often requiring lifelong treatment. If left untreated or inadequately treated, hypothyroidism can have harmful consequences. It can lead to myxedematous coma, cardiovascular complications such as coronary insufficiency, heart failure and conduction disorders, and sleep apnea syndrome. On the other hand, if over-treated, it can lead to osteoporosis and/or atrial fibrillation, as well as impaired quality of life secondary to signs of thyrotoxicosis. Hypothyroid patients must have a minimum of knowledge about how to take L-Thyorxine, the duration of treatment, the risk of drug interactions and the signs and complications of over- and under-dosing. Women of childbearing age must be informed about the obligation of preconception balance. They also need to know how to increase their doses if a pregnancy occurs without being scheduled, while waiting to see their treating physicians. This underlines the major importance of therapeutic education in avoiding the complications mentioned below. Our present survey reveals a significant lack of knowledge among hypothyroid patients, and has enabled us to re-educate this group of patients. Medical prescription must be backed up by proper therapeutic education, which remains a cornerstone of chronic disease management.

EP577

Prevalence of side effects of synthetic antithyroid drugs

Deus Niyongabo[1], Nassim Essabah Haraj[1], Siham El aziz[1] & Asma Chadli[1]

[1]Ibn Rochd University Hospital of Casablanca, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casablanca, Morocco

Introduction

Hyperthyroidism is characterized by an overproduction of thyroid hormones. Synthetic antithyroid drugs are essential to reduce these hormones before definitive treatment, but they can lead to side effects. This study aims to assess the frequency of these effects and their management.

Patients and Methods

A retrospective descriptive study over 5 years (2018-2023) involving 79 patients treated for hyperthyroidism who experienced side effects of synthetic antithyroid drugs.

Results

The mean age of the patients was 38 years, with a female predominance. The most common etiologies were Graves' disease (54.4%), toxic nodular goiter (32.9%), and toxic nodule (7.5%). Approximately 96.2% received initial treatment with synthetic antithyroid drugs (47.3% Neomercazole, 36.8% Thiamazole, 15.7% PTU). 23.6% of patients experienced side effects: agranulocytosis (2.6%), neutropenia (3.9%), hepatic cytolysis (6.5%), and skin rash (10.5%). No cases of acute pancreatitis or vasculitis were recorded. These effects primarily occurred within the first three months of treatment. Management varied from prescribing antihistamines for skin rashes to temporary discontinuation followed by reintroduction of antithyroid drugs after the disappearance of adverse effects, or definitive discontinuation of treatment with rapid medical preparation for definitive therapy. The outcome was favorable in 98.7% of cases, except for one patient who died due to agranulocytosis.

Conclusion

Synthetic antithyroid drugs are associated with potentially serious side effects that need to be clearly explained to patients. Clinical and laboratory monitoring is crucial, especially during the first three months of treatment.

An uncommun cause for thyroid cysts: about 5 cases and review of litterature

Houas Jihene[1], Heyfa Belhadj-Miled[1], Monia Ghammam[1], El Ghali Wassim[2], Malika El Omri[1], Abir Meherzi[1], Mouna Bellakhdhar[1], Yosra Hasni El Abed[3], Wassim Kermani[1] & Mohamed Abdelkafi[1]
[1]Farhat Hached Hospital, ENT Department, Sousse, Tunisia; [2], Department of Anaesthesia, Sousse, Tunisia; [3], Department Of Endocrinology, Sousse, Tunisia

Introduction
While hydatid cysts can manifest in various organs, reports on their occurrence in the thyroid gland are limited in the literature. This report aims to present five cases of thyroid hydatid disease along with a comprehensive literature review.
Materials and Methods
A retrospective analysis was conducted on 5 patients who underwent surgical intervention for thyroid hydatid cysts between 1982 and 2023.
Results
The average age of the patients was 55.8 years, ranging from 31 to 79 years, and none had a significant pathological history. Consultation was sought due to anterior basicervical swelling, raising suspicion of a thyroid nodule. Thyroid ultrasound revealed a multivesicular fluid formation with a regular, thin wall in 4 cases and calcification in one case. Thyroid scintigraphy, performed in 4 patients, indicated a cold nodule. All patients exhibited normal thyroid function. Three patients also presented with hydatid cysts in other organs. Surgical treatment was individualized for each cyst, guided by intraoperative macroscopic observations and histopathological findings.
Conclusion
Although rare, hydatid disease affecting the thyroid gland should be considered in the differential diagnosis of cystic lesions in patients with hydatid cysts in other organs or those hailing from endemic regions. Treatment exclusively involves surgical intervention to excise the cyst without rupture. The prognosis is excellent in cases where total cyst removal is achieved without rupture.

On the issue of functional changes in the thyroid gland in patients with breast cancer

Makhbuba Azimova[1, 1] & Khurshidakhon Nasirova[1]
[1]Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

The endocrine and reproductive systems of women work in close relationship and moderates the functional state of visceral systems. In patients with concomitant diseases and breast cancer (BC), some hypofunction of the thyroid gland (TG) was revealed and there is a direct dependence of the decrease in functional activity on the progression and luminal forms of pathological changes in the mammary gland. However, the effect of antitumor methods of treatment in BC on the clinical and morphological structure and function of the TG has not been practically studied.
Purpose
to determine the methods of correcting functional changes in the TG in BC patients by retrospective analysis.
Material and methods
The following gradations of the functional state of the TG in BC were the subject of the study: volume and size, parenchyma structure, hormonal status indicators, local cytomorphological structure of the parenchyma. The object of the study were 38 patients with verified BC: II - and III - stages. The age of patients ranged from 34 to 68 years. Patients received antitumor therapy in accordance with the standards: polychemotherapy - 31, hormone therapy-5 and immuno-chemotherapy-2. Ultrasound, MSCT, the study of biochemical parameters and thyroid hormones, cytomorphology of fine-needle biopsy of the thyroid parenchyma were used to study the studied gradations.
Results
There was a change in the average volume and flatness of the contours depending on the stage of breast cancer, histological type and differentiation of the tumor process. At the same time, a statistically significant decrease in the functional (based on the study of hormones) thyroid activity from 23 to 35% was established against the background of the appearance of new heterogeneous areas in the thyroid parenchyma. Most often, these changes were characteristic of patients aged >50 years and receiving polychemotherapy ($+$immunotherapy). In contrast, in patients with a hormone-dependent form of BC, functional changes in the TG turned out to be insignificant on the background of specific therapy and did not require special correction. The cytomorphological picture of local changes in the study of fine-needle biopsy specimens in 17 patients showed the absence of polymorphism and atypical changes. In 8 patients with breast cancer, there was a parallel development of nodular goiter during polychemotherapy. Thus, the analysis of the obtained results showed the presence and correlation dependence of local changes in the thyroid gland on the stage of BC and the type of therapy.

Late relapse of severe graves' ophthalmopathy: a case report

Hamdi Frikha[1], Mona Rekik[2], Sonda Kammoun[2], Yoldez Ben Jemaa[2], Khouloud Boujelben[1], Dhoha Ben Salah[1], Fatma Mnif[1], Mouna Mnif[1], Mohamed Abid[1], Amira Trigui[2] & Nabila Rekik Majdoub[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Tunisia; [2]Habib Bourguiba University Hospital, Department of Ophtalmology, Tunisia

Introduction
Graves' disease (GD) is an autoimmune disorder characterized by hyperthyroidism, and it often involves the development of Graves' ophthalmopathy (GO). The latter occurs in a significant percentage (25-50%) of Graves' disease cases. Active and severe ophthalmopathy can lead to a worsened prognosis and, in extreme cases, result in blindness. Reports about late ocular manifestation of GD have become scarce due to improved management.
Case Report
A 68-year-old woman with a 25-year history of Graves' disease presented a unique case of late relapse of GO. Remission had initially been achieved using thyroid synthesis blockers. However, sudden hypothyroid state due to overdose of treatment led to the development of severe active ophthalmopathy, with an activity score of 6 and significant sight impairment. Concomitant Thyrotropin Receptor Antibody (TRAK) levels were remarkably high at 43 UI. The patient underwent methylprednisolone boluses followed by a course of mycophenolate mofetil, resulting in a partial remission of inflammatory phenomena. Decompressive surgery was subsequently performed, leading to partial improvement in sight.
Discussion
This case highlights the challenges associated with late relapses of Graves' ophthalmopathy, even after an extended period of disease management. The importance of caution in thyroid-blocking treatments is underscored, as treatment overdose in this case contributed to the severe manifestation of ophthalmopathy. TRAK play a significant role in the assessment and management of the patient as they correlate with the severity of ophthalmopathy and could therefore guide the use of immunosuppressive therapies like methylprednisolone and mycophenolate mofetil. The successful outcome following decompressive surgery suggests its potential role in ameliorating sight impairment in severe cases of Graves' ophthalmopathy. In conclusion, this case emphasizes the importance of vigilant management in Graves' disease, considering the potential for late relapses of ophthalmopathy. Clinicians should exercise caution in thyroid-blocking therapies to prevent exacerbation of ophthalmic complications. Regular monitoring, prompt intervention, and a multidisciplinary approach are essential in optimizing outcomes for patients with Graves' ophthalmopathy.

Hypothyroidism and high CK an association or a coincidence?

Lubna Etbinah[1, 2], Rabia Mahmoud[1], Mustafa alsinan[1], Agne Jovaisate[1], Godwin Simon[1], Lina El-tayeb[1], Bashir Mahmoud[1], Ayan Mohammed[1], Edel Casey[1], Audrey Limbe[1], Belayet Hossain[1], Ali Akram[1], Mariana Dram[1], Furhana Hussain[1], Cathriene Cheung[1] & Gideon Mlawa[1]
[1]Queen's Hospital, Acute Medicine, Romford, United Kingdom; [2]Queen's Hospital, Acute Medicine, Romford, United Kingdom

Introduction
Hypothyroidism presentation can be variable. Some patients are asymptomatic whilst other present with general lethargy and cold intolerance. Depending on the degree of hormone deficiency, patient can also present with by skeletal muscle involvement characterized by muscle aches and weakness (proximal myopathy). In some cases, patients with hypothyroidism will have elevated CK but this usually less that 5000
Cases
1. 46 years old was referred under the medical team directly from GP with a history of 6-8 months history of muscle aches. He also reported feeling cold and lethargic with weight gain. He was found to be severely hypothyroid with high CK. He was cycling to work daily and that might have contributed to high CK. Elevated TSH 57.4, FT4 0.5, FT3 0.6, Cortisol 332, with High CPK levels. CK 8723, Creatinine, He was started on levothyroxine and discharged home. He

improved clinically and after 4 weeks blood test showed CK 1043, FT10.4, TSH 22, FT3 3.8 2. 33 year old male presented with few months' history of tiredness, muscle weakness, weight gain, and being sleepy most of the time. His blood test showed evidence of severe hypothyroidism and high CK4157, cortisol 135, FT4 0.5, TSH > 100, and creatine 130. He was treated with IV fluids and started on Levothyroxine 1 mg once daily. The short synacthen test was normal.

Discussion

Hypothyroidism is a common endocrine disorder which is encountered in non-acute settings. It can be associated with tiredness, weight gain, and cold intolerance as well as proximal muscle weakness (myopathy). Elevated CK (rhabdomyolysis) may be associated with severe hypothyroidism. Heavy exercise, statins, or excessive alcohol intake are some of the factors which may contribute to elevated CK in patients with hypothyroidism. The cause of CK elevation in hyporthyroid patients remains unknown, but is thought to be due to interference or defective mitochondrial oxidative metabolism, insulin resistance. Thyroxine plays a key role in the energy metabolism. Thyroid hormone deficiency leads to impaired metabolism of glycogen (glycogenolysis), triglyceride turnover, and mitochondrial oxidative metabolism which in turn impair muscle function.

Conclusion

Severe hypothyroidism can be associated with high CK (rhabdomyolysis), proximal myopathy and muscle aches. Blood tests including CK and cortisol should be checked in patients with new diagnosis of hypothyroidism. Patients with elevated CK and hypothyroidism should be advised to avoid any precipitating factors rhabdomyolysis such heavy exercise, statins and alcohol.

Are thyroid function test ordering practices appropriated?

Dhouha Zouari[1], Rim Marrakchi[1], Mohamed Chaher Rabah[1], Mariem Boudaya[1], Kamel Jamoussi[1], Mohamed Abid[2] & Mouna Turki[1]
[1]Laboratory of Biochemistry, Hédi-Chaker Hospital, Sfax, Tunisia; [2]Endocrinology departement, Hedi Chaker Hospital, Sfax, Tunisie

Introduction

Inappropriate laboratory test utilization can result in unnecessary patient testing and increased healthcare costs. Thyroid-stimulating hormone (TSH) is recommended as the first-line test for investigating and monitoring thyroid dysfunction. We evaluate Thyroid function tests (TFTs) ordering in our hospital practice.

Methods

A retrospective descriptive study included 400 TFTs requests. TFTs of interest were: TSH and FT4. These tests request were classified according to the reasons and origins of ordering. Frequencies of each testing pattern were calculated. Demographic data (sexe, age) are determinate. Thyroid stimulating hormone (TSH), free thyroxine (FT4) were performed based on electrochemiluminescence immunoassay (eCLIA) by Dxi600® Beckman Coulter.

Results

The mean age of patients was 46.7 years, with extremes ranging from 1 month to 86 years with a male/female sex ratio of 0.49. The majority of TFTs requests were from the endocrinology department (43.3%), followed by the cardiology department (12.8%) and the paediatrics department (11.9%). Reasons for prescription were dysthyroid follow-up in 37.3% of cases, suspicion of dysthyroidism in 37% of cases, dysthyroid screening in 23.7% and the presence of thyroid nodules in 2%. TFTs's ordering were for TSH alone in 78.5% of cases, and a TSH + FT4 in 21, 5% of cases. Among subjects suspected of having dysthyroidism and subjects having thyroid nodule only 40% had dysthyroidism (35% had hypothyroid and 5% had hyperthyroid) and only % had dysthyroidism (% had hypothyroid and % had hyperthyroid) respectively. Among subjects who underwent a thyroid check for dysthyroidism, 65% returned normal, 17% with hypothyroidism and 2% with hyperthyroidism. Among subjects with a thyroid nodule or goitre, only 28.6% had hypothyroidism, the rest returned normal.

Conclusion

There was an over-ordering for thyroid tests in our hospital practice. This suggests that this request should be more rational in order to limit costs and invasiveness.

An unusual hyperthyroidism presentation

Megi Lekbello[1], Eni Celo[2] & Dorina Ylli[1]
[1]Mother Teresa Hospital, Endocrinology, Tiranë, Albania; [2]Trauma University Hospital, Intern Medicine, Tiranë, Albania

We would like to report the case of a 45-year-old woman who came to our emergency department two months ago complaining of exhaustion, vomiting, and stomach pain. In the last three weeks, she had three admissions to the ER due to vomiting. She did not have any chronic illnesses, and her only medication for the vomiting was oral electrolytes. In the last two months, she claims to have lost four to five kilograms. The physical examination showed tachycardia (135 beats per minute), hypotension (90/60 mmHg), and subfebrile temperature (37.5 °C). The results of the laboratory test revealed mildly increased bilirubin and transaminases along with pancytopenia. For further testing, she was admitted to the gastrohepatology department. Her minor gastritis following fibrogastroscopy does not account for her vomiting. The following were the outcomes of the laboratory findings in the gastrohepatology report: WBC 2.33×10^3/mm^3 (4.0-10), RBC 3.4×10^6/mm^3 (3.8-5.20), HGB 9.75 g/dl (12.0-15.0), HCT 28.1% (35-45), MCV 82.56 μm^3 (80-87), MCH 28.65 pg (27-32), PLT 95×10^3/mm^3 (150-440), AST 53 U/l (8-45), ALT 59 U/l (7-55), Total protein 5.1 g/dl (6.6-8.3), Na 136 mmol/l (138-146), K 2.98 mmol/l (3.5-5.5), TSH < 0.005 mIU/ml (0.27-4.2), FT4 > 100 pg/ml (12-22), FT3 30.44 pmol/l (3.1-30.44), Anti-R-TSH 17 IU/l (< 1.5). Ultrasounds of the abdomen and heart were normal. The first courses of treatment included methimazole 5 mg (4 pills daily) and propranolol 40 mg (1 tablet, twice daily). Within a week of the treatment beginning, the symptoms improved. Leucopenia and thrombocytopenia were completely resolved following discharge: RBC 3.5×10^6/mm^3, MCV 88 μm^3, MCH 28.8 pg, PLT 177×10^3/mm^3, WBC 4.7×10^3/mm^3, HGB 9.9 g/dl, HCT 29.9%. The atypical clinical presentation with vomiting in thyrotoxicosis delayed the diagnosis, resulting in overt hyperthyroidism. Anemia is the most typical symptom of thyroid hormone's effects on the hematopoietic system, but it can also impact other cell lineages. Pancytopenia, in rare cases, is associated with thyrotoxicosis, and the relationship between thyrotoxicosis and pancytopenia is rarely discussed in the literature; typically, hematologic values are corrected once the treatment is initiated, and the thyrotoxicosis is addressed.

Lipid profile in patients with peripheral hypothyroidism

Latifa Boutaybi[1], Fatima Zahra Najioui[1], Hajar Charif[1], Zerrouki Fatim Zahra[1], Siham Rouf[2] & Hanane Latrech[2]
[1]Department of Endocrinology-Diabetology and Nutrition CHU Mohammed-VI Oujda, Faculty of Medicine and Pharmacy, Mohammed Premier University Oujda, Morocco, oujda, Morocco; [2]Department of Endocrinology-Diabetology and Nutrition CHU Mohammed-VI Oujda, Faculty of Medicine and Pharmacy, Mohammed Premier University Oujda, Morocco, [2] Laboratory of Epidemiology, Clinical Research and Public Health, Oujda Faculty of Medicine and Pharmacy, Mohammed Premier University Oujda, Morocco, Oujda, Morocco

Introduction

Hypothyroidism is a state of hypometabolism at the origin of numerous metabolic disturbances, including dyslipidemia, which may increase cardiovascular risk in these patients. The aim of our study is to assess the lipid profile in patients with peripheral hypothyroidism.

Materials and methods

Retrospective descriptive study including 130 patients, followed at the Endocrinology-Diabetology and Nutrition Department of the University Hospital of Oujda for peripheral hypothyroidism. Statistical analysis was performed using SPSS version 21 software.

Results

The mean age was 46.15 ± 18.6 years, with an F/M sex ratio of 2.9, the mean TSH value at discovery was 21.84 mu/ml, Hashimoto's thyroiditis was the most frequent cause 63.2%.33% of patients had hypothyroidism of frust origin Dyslipidemia was noted in 44.6% of our patients, represented essentially by hypertriglyceridemia in 55.6%, hypercholesterolemia in 39.2%, hypoHDLemia in 31.8%, hyperLDLemia the least frequent abnormality (24%). Dyslipidemia was noted in 54.6% of patients with Hashimoto's thyroiditis and in 34% of patients with hypothyroidism of frust origin.

Discussion-Conclusion

Hypothyroidism is often associated with dyslipidemia, this atherogenic lipid profile must be systematically detected when this pathology is diagnosed, and reassessed after treatment to prevent cardiovascular complications.

Thyroid ectopia: a report on 3 cases

Neni Dezoumbe[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital, Endocrinology, Diabetology, Metabolic Diseases, and Nutrition, Casablanca

Introduction
Thyroid ectopia is a rare condition resulting from an anomaly in the development or migration of the gland. We present two cases of thyroid ectopia.
Case Reports
Case 1: A 44-year-old woman underwent orbital CT scan due to chronic right eye tearing, revealing a lesion at the base of the tongue. Thyroid palpation was negative, and oropharynx examination was unremarkable. Tongue MRI showed a 43 × 37 mm lesion at the base with heterogeneous enhancement after gadolinium injection and global thyroid atrophy. Scintigraphy revealed sublingual ectopic thyroid. Hormonal exploration was normal, and due to its asymptomatic and uncomplicated nature, surveillance was recommended. Case 2: A 40-year-old patient presented with dysphonia and a non-palpable thyroid. Nasofibroscopy revealed a tongue base mass compressing the vocal cords, leading to acute respiratory distress during the procedure, requiring emergency tracheotomy. Surgical excision of the mass was performed, and histopathological examination revealed thyroid parenchyma within fibromuscular tissue, including a focus of thyroid vesicular carcinoma. Case 3: A 61-year-old patient complained of neck discomfort with a grade 1 goiter on clinical examination. Cervicothoracic CT scan showed a heterogeneous goiter extending to the anterior mediastinum, along with an anterior mediastinal mass suggestive of thyroid heterotopia. The patient underwent total thyroidectomy and resection of the mediastinal mass. Histopathological examination revealed a dystrophic thyroid nodule within the anterior mediastinal mass.
Discussion
Thyroid ectopia may be asymptomatic or present with hypothyroidism or compression symptoms. Malignancy risk is rare. In asymptomatic cases, biological and morphological surveillance is recommended, while surgery is indicated for compression or suspected malignancy.

Marine-lenhart syndrome: a rare cause of hyperthyroidism

Mohamed Khairi Arous[1], Houcem Elomma Mrabet[1], Fadia Boubaker[1], Mariem Souissi[1], Baha Zantour[1], Wafa Alaya[1] & Mohamed Habib Sfar[1]
[1]University Hospital Taher Sfar, Endocrinology and Internal medicine Department, Mahdia, Tunisia

Background
Marine-Lenhart syndrome (MLS) is defined by the coexistence of Graves' disease and a hyperactive nodule or multinodular goiter. Although rare, its diagnosis by functional imaging coupled with ultrasound is necessary in order to propose a radical treatment. We report the case of a patient followed for hyperthyroidism related to a SML.
Case presentation
A 52-year-old patient consulted for a picture of thyrotoxicosis associating tremor, weight loss, polyphagia, irritability and thermophobia. Physical examination revealed a small goiter with a right lobar nodule and bilateral exophtalmia. Hormonal assessment showed a TSH at 0.002 mIU/l and FT4 at 47.1 pmol/l confirming peripheral hyperthyroidism. Anti-TSH receptor antibodies were positive at 40. The Graves' disease was diagnosed confronted to the proptosis and the positivity of the antibodies. Neck ultrasound showed a hypervascularized goiter and two right lobar nodules classified EU-TIRADS III measuring 7.1 mm and 2.3 mm respectively. Scintigraphy showed an increased diffuse iodine uptake of the thyroid gland along with a partially extinctive thyroid nodule. The patient was put on 20 mg/d of thiamazol in preparation for a radical treatment by total thyroidectomy
Conclusions
The diagnosis of MLS is present in 2-4% of patients with MB; hence the inecessity of a neck ultrasound even in the presence of clinically or biologically obvious Graves' disease, especially in the presence of a thyroid nodule. Scintigraphy is also required to characterize the nodule. The treatment of MLS is surgical, since resistance to synthetic antithyroid drugs is noted in these cases.

Symptomatic multinodular goitre with compressive symptoms complicated by obstructive sleep apnoea and hypoxaemia

Rachel Cronin[1], Ali Al-Ashbal[1], Julen Borlle[1], Justin Hintze[2], Paul Lennon[2] & Ma Pyeh Kyithar[1]
[1]Midland Regional Hospital Portlaoise, Portlaoise, Ireland; [2]St James's Hospital, Ireland

Introduction
Most goitres are asymptomatic and do not require surgical intervention. Surgical management is recommended for goitres with compressive symptoms, suspected malignancy, drug-resistant hyperthyroidism, or retrosternal extension.
Case
63-year-old female with a background history of hypertension, type 2 diabetes, obesity (BMI 43 kg/m^2) and possible obstructive sleep apnoea (OSA), presented to Emergency Department following a one-minute episode of apnoea during sleep resulting in peripheral cyanosis, episodes of dyspnoea and stridor. She also had history of partial thyroidectomy in 1993, however no history of thyroid cancer or radiation exposure. CT scan two years prior to admission, showed a multinodular goitre and she was treated with carbimazole for subclinical hyperthyroidism for two years. Clinical examination demonstrated a very large multinodular goitre that was firm in consistency, moving with deglutition. Arterial blood gas on admission showed PO_2 10 kPa, PCO_2 5.61 kPa, bicarbonate 30.1 mmol/l, pH 7.48. During the first night of admission, the patient's SpO_2 level decreased to 60% on room air whilst sleeping. The patient desaturated further to 60% on 4L O_2 on lying down and oxygen saturation improved to 95% on sitting up, and she was subsequently transferred to the intensive care unit for airway monitoring. CT neck and thorax demonstrated a large bilateral multinodular goitre (11x6x1 cm) extending from the neck to thoracic level with predominantly left sided compression of trachea, and the upper neck vascular structures appeared displaced because of the large goitre. Thyroid profile showed free T4 12.1 pmol/l, free T3 5.1 pmol/l TSH 1.37 mIU/l, thereby euthyroid state. The patient was transferred for an urgent Ear/Nose/Throat team review given the significant risk of airway compromise. She subsequently underwent total thyroidectomy without complications. She desaturated on post-op day 1, possibly due to mucous plugging, an element of tracheomalacia, or pre-existing OSA, and was re-intubated for one day. She was then extubated to non-invasive ventilation and the overnight oximetry demonstrated 240 events of desaturation, likely in keeping with OSA. She was discharged on post-op day 9. Her histopathology of thyroidectomy revealed an incidental multifocal papillary thyroid cancer on a background of significant follicular nodular disease and will require ongoing clinical follow-up.
Conclusion
Significant thyroid enlargement, including multinodular goitre, may occasionally cause the upper airway compression, leading to respiratory compromise. Surgical treatment is the management of choice in patients that are surgically fit. Careful post-operative management is important in cases such as this, where a co-existing pathology such as OSA may complicate the clinical picture.

A case report of anaplastic thyroid carcinoma

Raimonda Klimaite[1, 2, 3], Ugne Janonyte[3] & Gintaras Kuprionis[4]
[1]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Department of Endocrinology, Kaunas, Lithuania; [3]Lithuanian University of Health Sciences, Kaunas, Lithuania; [4]Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Kaunas, Lithuania

Introduction
Anaplastic thyroid cancer (ATC) is a highly aggressive endocrine tumor formed of undifferentiated follicular thyroid cells. ATC accounts for only 1-4% of all thyroid cancers. The therapeutic approach is typically multimodal, combining surgery, radiation and chemotherapy. However, ATC is often resistant to treatment. Hence, the reported median overall survival of ATC patients is ~3 months, with nearly 100% disease-specific mortality.
Case
A 65-year-old man presented to our outpatient endocrinology department with complaints of generalized weakness, sore throat, neck pain and fever. These symptoms lasted about four weeks. Upon examination, a solid ~3 cm nodule at the front of the neck was palpated. A full diagnostic work-up was performed.
Diagnostic tests: Laboratory tests: TSH 2.30 (0.4-3.6) mU/l, FT4 21.63 (7.87-20.3) pmol/l, FT3 4.29 (3.34-5.1) pmol/l, ATPO 3.00 (0-3.2) kIU/l, Anti-Tg 466.5 (0-13.6) kU/l, calcitonin 12.8 (normal range 0.56-2.81) pmol/l.

Thyroid ultrasound
A ~4.4x6.3 cm heterogeneous mass with calcifications in the right lobe of the thyroid gland and enlarged lymph nodes on the right side of the neck were detected.
Microscopic examination
A core needle biopsy (CNB) of the left thyroid lobe identified a stromal tumor, formed by atypical cells with large, polymorphic nuclei and background necrosis. An elevated mitotic rate and multinucleated giant cells resembling osteoclasts were also detected. Immunohistochemically, tumor cells were positive with PAX-8, vimentin, CK7 and focally positive with TTF-1 staining. Immunohistochemical staining with calcitonin and thyroglobulin - negative. CNB of an enlarged lymph node on the right side of the neck was not informative, with no apparent neoplastic changes.
Chest and neck CT
Imaging revealed a $\sim 4.7 \times 4.3 \times 7.5$ cm non-homogeneous nodular right thyroid lobe with calcifications. The mass descends retrosternally to the middle mediastinum, displacing the trachea and esophagus, infiltrating surrounding tissues. Paratracheal lymphadenopathy and an enlarged lymph node near the root of the right lung were visualized.
Treatment
A chemotherapy course with paclitaxel (135–175 mg/m^2) and carboplatin (AUC 5–6) once every three weeks was initiated. The patient has undergone the third cycle of chemotherapy, reporting an overall sense of well-being and a notable reduction in discomfort in the cervical region. As for now, the regiment is continued. If chemotherapy proves effective, surgery will be scheduled.
Conclusion
ATC is a rare and highly aggressive type of thyroid cancer, characterized by uncontrolled and rapid growth. Thus, a prompt and comprehensive differential diagnosis and treatment plan are needed.

DOI: 10.1530/endoabs.99.EP605

EP606

A transiently toxic solitary thyroid nodule in the context of amiodarone therapy

Denise Sant[1], Simon Mifsud[1], Sarah Craus[1], Arlène Gatt[1], Ebony Sciberras Giusti[1] & Sandro Vella[1]
[1]Mater Dei Hospital, L-Imsida, Malta

Background
Thyrotoxicosis is a well-known complication of amiodarone therapy. Three types of amiodarone-induced thyrotoxicosis (AIT) are recognized; type 1 AIT, type 2 AIT, and mixed/indefinite forms of AIT. Type 1 AIT is an iodine-induced hyperthyroidism that usually occurs in patients with pre-existing nodular goitre or latent Graves' disease[1]. We present a case of type 1 AIT associated with a transiently toxic solitary thyroid nodule, with hyperthyroidism resolving once amiodarone therapy was stopped.
Case Presentation
A 74-year-old lady with paroxysmal atrial fibrillation receiving long-term amiodarone therapy was referred because of biochemical thyrotoxicosis (free thyroxine: 30.1 pmol/l [reference range: 11.9-1 pmol/l], free triiodothyronine: 6.1 pmol/l [reference range: 3.5-6.1 pmol/l], and thyroid-stimulating hormone: 0.018 micIU/ml [reference range: 0.3-3.0 micIU/ml]). She complained of occasional episodes of palpitations and heat intolerance but was otherwise asymptomatic. Physical examination revealed a heart rate of 92 beats per minute with a blood pressure of 130/1 mmHg. There were no signs of thyroid eye disease, and no palpable thyroid nodules or goitre were appreciated. Investigations revealed a negative TSH-receptor antibody status, whilst a neck ultrasound showed a 1.1×0.1 cm hypoechoic nodule on the left thyroid lobe. Thyroid scintigraphy revealed a single focus of increased tracer uptake in the left thyroid lobe with no uptake in the rest of the thyroid gland suggesting a solitary toxic nodule. After consulting with the patient's cardiologist, amiodarone was stopped, and carvedilol was prescribed instead. She was also commenced on carbimazole for type 1 AIT secondary to a solitary toxic thyroid nodule. The patient was reviewed at outpatients regularly and her carbimazole dose was titrated against her thyroid function. Follow-up neck ultrasound studies revealed stable findings. After twenty months, treatment with carbimazole was stopped. Six months following the cessation of carbimazole, she remained clinically and biochemically euthyroid.
Conclusions
This case is noteworthy for two main reasons; (i) the association between AIT and a solitary toxic thyroid nodule is rare[1], and (ii) following the cessation of amiodarone, the patient was eventually able to come off thionamide therapy as her hyperthyroidism resolved, highlighting the transient nature of this toxic thyroid nodule in the context of amiodarone use. Whilst mild AIT may subside in 20% of cases[1], usually patients with type 1 AIT end up requiring definitive treatment because of the underlying thyroid disorder.

Central hypothyroidism induced by bexarotene preceding graves' disease after interferon therapy for cutaneous t-cell lymphoma

Mafalda Martins Ferreira[1], Sofia Lopes[1], Tânia Carvalho[1], Patrícia Oliveira[1] & Isabel Paiva[1]
[1]Centro Hospitalar e Universitário de Coimbra, Portugal, Endocrinology, Diabetes and Metabolism, Coimbra, Portugal

Introduction
The simultaneous occurrence of two drug-induced thyroid dysfunctions is rare. We present a case of central hypothyroidism due to bexarotene (BXC), followed by Interferon-α (IFNα)-induced Graves' disease (GD) thyrotoxicosis after 2 years.
Case Report
A 56-year-old man with no prior thyroid disease was diagnosed with cutaneous T-cell lymphoma and commenced treatment with BXC 600 mg/day and IFNα 90 mg/week concurrently. After two weeks, TSH was <0.004 uUI/ml (0.4-4.0) and FT4 was <0.49 ng/dl (0.7-1.5). MRI revealed no selar or parasellar lesions. Central hypothyroidism due to BXC was diagnosed and levothyroxine (L-T4) was initiated at 50 mg/day, gradually reaching 88 mg/day (1.4 mg/kg/day). BXC dose was reduced to 300 mg/day due to severe hypertriglyceridemia and the therapy with IFNα was maintained. After 25 months, TSH remained <0.004 uUI/ml and FT4 was 2.04 ng/dl under L-T4 88 mg/day, which was reduced to 75 mg/day. Four months later, the patient exhibited weight loss, tremors, palpitations, and abnormal thyroid levels (TSH <0.004 uUI/ml, FT4 4.60 ng/dl, FT3 >20 pg/ml (1.8-4.2); anti-TPO antibodies 342 UI/ml (<5.6), TRAbs 30 U/l (<2). IFNα-induced GD was diagnosed. L-T4 was ceased and methimazole (MMI) 15 mg/day initiated. One week later his thyroid function was: TSH <0.004 uUI/ml, FT4 0.79 ng/dl (0.7-1.5), FT3 3.1 pg/ml (1.8-4.2). Recently the patient was under IFNα 90 mg/week and BXC 150 mg/day, maintaining unmeasurable TSH, a FT4 of 1.5 ng/dl and FT3 of 5.3 pg/ml on MMI 12.5 mg/day (increased to 15 mg/day). Unfortunately, the patient deceased at 58 years old due to the progression of the cutaneous T-cell lymphoma with neurolymphomatous involvement.
Conclusions
BXC leads to central hypothyroidism in 30% cases by decreasing TSH secretion and increasing peripheral thyroid hormone metabolism. L-T4 can be initiated with or after confirming reduced FT4 levels, with doses up to 3 mg/kg/day. IFNα can induce autoimmune (Hashimoto's thyroiditis (HT) and GD) and non-autoimmune (non-autoimmune hypothyroidism and destructive thyroiditis) thyroid diseases via immune dysregulation, T cell activation, and direct follicular cell toxicity. IFNα-induced GD is less common than HT and destructive thyroiditis, often irreversible with dose reduction or cessation. In this case, diagnosing GD was delayed as TSH suppression was inherent to central hypothyroidism from BXC and since the initial FT4 elevation was interpreted as excessive L-T4 dosage. The gradual BXC dose reduction led to increased MMI dosage due to predominant IFNα-induced hyperthyroidism. Vigilant thyroid function monitoring during concurrent medication therapies causing thyroid dysfunction is crucial.

Distant metastasis at the time of diagnosis in a young male patient with classical subtype of papillary thyroid carcinoma and graves' disease

Sofia Chatzi[1], Gerasimos Tsourouflis[2], Eleni Koukoulioti[1] & Georgios Boutzios[1]
[1]National and Kapodistrian University of Athens, Department of Pathophysiology, Medical School, Athens, Greece; [2]National and Kapodistrian University of Athens, Second Department of Propaedeutic Surgery, Medical School, Athens, Greece

Introduction
Patients with Graves' disease (GD) and thyroid nodules have an elevated risk of developing papillary thyroid carcinoma (PTC). Distant metastasis observed in 1-9% of patients with PTC. The classical subtype usually demonstrates favorable prognosis compared to other more aggressive PTC subtypes, for which an increased risk of extranodal metastases is observed.

Aim of the Study
We present an unusual case of a young male diagnosed with classical subtype PTC and Graves' disease, metastasized to the lungs, at the time of diagnosis.
Case Presentation
A 36-year-old male patient presented with suppressed TSH levels (TSH = 0, 01 mIU/l) and multinodular goiter in thyroid ultrasound. Laboratory tests showed elevated T3 = 2, 19 nmol/l, FT4 = 20, 1 pmol/l and TSI = 114 IU/l (nv: < 1, 0 IU/l). Thus, diagnosis of GD was established. Thyroid ultrasound revealed two large hypoechoic nodules, 1 mm and 1 mm respectively, with micro-calcifications (TIRADS 5), and suspicious deep cervical lymph nodes at compartment II. Fine needle aspiration biopsy for both nodules and lymph nodes with cytological findings were consistent with malignancy. Patient underwent total thyroidectomy with central and left lateral compartment lymph node dissection. The histological examination revealed multifocal PTC of classical subtype without thyroid capsule invasion and metastatic infiltration of lymph nodes (7/33), (pT2N1bMxR0). Subsequently, he received 120 mCi RAI. In the whole-body scan multiple foci of abnormal uptake concentration in lung parenchyma were observed. We performed a chest computed tomography confirming multiple nodular lesions, highly suggestive for metastatic infiltration. Noteworthy, as an incidental finding a solid renal mass 5, 4 cm in the upper pole of the right kidney, suspicious for malignancy, was noticed. Subsequently, patient underwent partial right nephrectomy and histological examination revealed a clear cell renal carcinoma Grade 2 (ISUP/ WHO 2022). Six months later, an additional RAI ablation treatment with 160 mCi, for the PTC derived lung metastases, was performed. Due to the unusual presentation of distant metastases from a classical subtype PTC and the presence of a second primary malignancy, genetic testing was performed for VHL and BRAF V600E/K gene mutation with no pathologic findings.
Conclusions
These findings suggest that prompt and meticulous evaluation of nodules in any patient with GD associated with nodular alterations must be considered. Autoimmunity seems to play a crucial role in tumor behavior since distant metastases from a PTC of classical subtype is an unusual finding.

Combination of primary and secondary myopathy in a patient with severe hypothyroidism

Margarita Perepelova[1], Valeria Slokva[1], Ekaterina Pigarova[1], Aleksandra Shutova[1], Anna Kolodkina[1] & Larisa Dzeranova[1]
[1]Endocrinology Research Centre

Background
One of the complications of hypothyroidism is the disorder of the neuromuscular system. Myopathic changes often accompany hypothyroidism and are observed in 30-80% of patients. A distinctive feature of hypothyroid myopathies is the reversibility of clinical manifestations and significant improvement of well-being after levothyroxine compensation of the disease. However, the absence of a vivid clinical picture of hypothyroidism, combined with its rare occurrence, complicates early diagnosis and often requires differential diagnosis with other types of myopathies.
Case presentation
Patient T. was complained on progressive pain and muscle weaknessin the lower limbs, impaired coordination. At the time of admission he moved only with support of relatives. From the anamnesis vitae it is known that the patient is the first of 4 children from a close cousin-sister marriage. Primary hypothyroidism was detected at the age of 17, but he did not receive therapy. Physical examination showed pseudohypertrophy of the upper and lower limb girdle muscles, muscle strength was diffusely reduced to 4 points, tone was symmetrically increased, tendon-periosteal reflexes were high, with expansion of reflexogenic zones. Movements in large joints are limited due to muscle contractures. Hormonal blood analysis revealed a significant increase in the level of TSH - more than 500 mIU/l (0.25-3.5), at dilution - 836 mIU/l, of which bioactive TSH - 174 mIU/l; free T4 - 5.15 pmol/l (9-19), free T3 - 2.3 pmol/l (2.6-5.7). Genetic study revealed homozygous mutations in *MICU1* gene previously described in myopathy with extrapyramidal symptoms (OMIM: 615673) with autosomal recessive type of inheritance and in *IGSF1* gene (NM 001555.5) in exon 8 a variant in hemizygous state leading to amino acid substitution of p.(Lys420Thr), not previously described in the literature. After 2 months from the beginning of therapy with levothyroxine - medically compensated primary hypothyroidism: TSH 1.134 mIU/l (0.4-4.0), T4 free 12.95 pmol/l (7.0-17.6). The patient noted improvement of general well-being, regression of hypothyroidism symptoms, but still had complaints of pain and weakness of lower limb muscles, difficulties with independent movement.
Conclusions
Hypothyroid myopathy usually manifest by nonspecific symptoms in the form of myalgia, muscle cramps, especially increasing with exercise. The severity of myopathy correlates with the duration and degree of thyroid hormone deficiency, which should be taken into account to determine the management of patients with this pathology. An atypical severe course or lack of correction during treatment with levothyroxine should initiate an additional diagnostic search to exclude other forms of myopathy.

A perplexing clinical challenge in the follow-up of papillary thyroid cancer: sarcoidosis

Hayri Bostan[1], Gokhan Colpan[2], Ceren Tufan[3] & Ersen Karakilic[3]
[1]Canakkale Mehmet Akif Ersoy State Hospital, Endocrinology and Metabolism, Turkey; [2]Ezine State Hospital, Internal Medicine, Turkey; [3]Canakkale Onsekiz Mart University, Faculty of Medicine, Endocrinology and Metabolism, Turkey

Background
Neck ultrasonography (USG) is an important imaging tool in the postoperative follow-up of papillary thyroid carcinoma (PTC). Sarcoidosis is an inflammatory disease characterized by non-caseating granulomas with involvement in various organs and lymph nodes. Herein, a case with atypical lymph nodes detected on neck USG during routine follow-up for PTC and diagnosed with sarcoidosis will be presented.
Case presentation
A 52-year-old female patient, diagnosed with PTC 7 years ago, applied to our clinic for follow-up. The pathology after total thyroidectomy was compatible with classical-type PTC which was multicentric, bilateral, and had the largest diameter of 22 mm. No residual focus or metastatic lymphadenopathy (LAP) was detected in the patient's 1-year follow-up whole-body iodine scan, who received postoperative 100 millicuries of radioactive iodine therapy. The patient, who has not had regular follow-up for the last 2 years, had TSH: 0.21 uIU/ml (reference range (RR):0.35-4.94), thyroglobulin (Tg): < 0.01 ng/ml (RR:3.68-64.15) and anti-thyroglobulin (a-Tg): 1.14 IU/ml (RR < 4.11) under 125 mg levothyroxine replacement. On neck USG, conglomerate, hypoechoic lymphadenopathies with no echogenic hilum were observed at bilateral cervical levels 3 and 4, the largest of which had a longitudinal dimension of 23 mm. Leukopenia (WBC: 2.92 10^3/ul (RR:4.0-10.5), neutrophil: 1.65 10^3/ul (RR:1.5-6.6), lymphocyte: 0.92 10^3/ul (RR:1.5-3.5)) and hypercalcemia (Ca: 10.8 mg/dl (RR:8.5-10.4)) were also detected in her laboratory tests. Considering hematological malignancies, thoracoabdominal computed tomography (CT) examination was performed. Multiple conglomerated LAPs, the largest of which was paratracheal, measuring 27x25 mm, were observed in the mediastinum, and multiple paraaortic and intraaortocaval LAPs were observed in the retroperitoneal area in thoracoabdominal CT. Her right supraclavicular lymph node was excised and histopathological examination revealed non-caseating granulomas that tended to coalesce. The patient was diagnosed with sarcoidosis, as her serum angiotensin-converting enzyme (ACE) level was found to be high along with the present histopathological findings. The patient, who was in remission in terms of PTC, was planned to continue follow-up by reducing the levothyroxine dose replacement to 100 mg.
Conclusions
The coexistence of PTC and sarcoidosis has been reported as rare case reports. Sarcoid lesions can easily be confused with PTC metastases due to their involvement in both neck lymph nodes and lungs. The current case highlights that granulomatous diseases such as sarcoidosis should also be included in the differential diagnosis if pathological LAP with an advanced hypoechoic, conglomerate appearance is detected in a PTC follow-up patient with no increase in Tg levels.

Severe hypothyroidism due to thyroxine malabsorption in a patient with non-celiac gluten sensitivity after thyroidectomy; a rare case report

Vasiliki Daraki[1], Panagiotis-Nikolaos Tsakalomatis[1], Eleni-Konstantina Syntzanaki[1], Rodoula Vamvoukaki[1], Vasiliki Venetsanaki[1], Katerina Augoustaki[2], Maria Sfakiotaki[1], Grigoria Betsi[1] & Paraskevi Xekouki[1]

[1]University General Hospital of Heraklion, Department of Endocrinology Diabetes and Metabolic Diseases, Crete, Greece; [2]University General Hospital of Heraklion, Department of Gastroenterology, Crete, Greece

Introduction
Non-celiac gluten sensitivity (NCGS) belongs to gluten-related disorders. Patients with NCGS develop a variety of intestinal and/or extraintestinal symptoms such as abdominal pain, bloating, bowel habit abnormalities, nausea, gastroesophageal reflux disease and aphthous stomatitis, that improve when gluten is removed from the diet. The diagnosis is made after exclusion of coeliac disease and wheat allergy. Although thyroxine malabsorption has been described in patients with coeliac disease, data on thyroxine absorption in patients with NCGS is lacking so far.
Case-report
A 41-year-old female, with a history of thyroidectomy 2 years ago, presented at the outpatient clinic with chronic hypothyroidism despite progressively increasing doses of levothyroxine (400 μg oral L-thyroxine tablets, plus 100 μg triiodothyronine tablets daily). She stated that she had been experiencing persistent tiredness, general weakness, menorrhagia and severe anemia due to iron deficiency. She had also been suffering from abdominal pain and bloating, and was diagnosed with reflux esophagitis a year ago. Clinical evaluation confirmed severe hypothyroidism with periorbital edema, swelling of the face and lips, dry skin, muscle weakness and bradycardia. Laboratory tests revealed elevated TSH levels (72, 2 mIU/l) with remarkably low FT3 ($<$0, 1 ng/dl) and FT4 ($<$0.42 ng/dl). The patient did not tolerate iv thyroxine; thus she switched on 150 μg/d oral L-thyroxine in liquid form, which was increased progressively to 200 μg/d. Laboratory workup for a possible malabsorptive etiology was negative for coeliac disease or intrinsic anemia as tissue transglutaminase antibodies type IgG and IgA, anti-gliadin IgG antibodies, anti-endomysial antibodies and antiparietal cell antibodies were undetectable. Additionally, endoscopic control revealed the histological picture of mild esophagitis and chronic duodenitis with lymph follicle hyperplasia. However no mucosal changes typical for coeliac disease were identified. The patient was started on pantoprazole 40 mg once daily but 2 months later gastroenteric symptoms persisted and TSH level was still elevated to 25 mIU/l. NCGS was suspected and the patient was advised to follow a gluten-free diet. Subsequently she had normal thyroid function values, with remarkable improvement of her clinical symptoms. Currently, she is on treatment with 200 μg/d oral L-thyroxine in liquid form and remains euthyroid with normal hematological and biochemical laboratory tests.
Conclusion
Data on thyroxine malabsorption associated with NCGS are scarce. Our case highlights that unknown mechanisms associated with gluten sensitivity may be involved in the malabsorption of oral L-thyroxine in solid tablets format. An empirical switch to liquid formulation concomitantly with a free-gluten diet may resolve this therapy refractory issue.

Lichenoid dermatitis secondary to a thiamazole-induced toxidermia: a case report

Fatma Ben Zaied[1], Elyes Kamoun[1], Nadia Khessairi[1], Ibtissem Oueslati[1], Fatma Chaker[1], Meriem Yazidi[1] & Melika Chihaoui[1]
[1]Hospital La Rabta Tunisia, endocrinology, Tunis, Tunisia

Introduction
Antithyroid drugs are the firstline medical treatment for hyperthyroidism in addition to symptomatic treatment (rest, beta-blockers). The most widely used in Tunisia is Thiamazole. They are generally well tolerated, but side effects have been reported. The most serious ones are agranulocytosis and liver damage. Allergic skin reactions (pruritus, urticaria) are the most common. We herein report a case of a lichenoid dermatitis bullous toxidermia induced by Thiamazole.
Case report
A 35-year-old female patient was referred to the endocrinology department of Rabta Hospital for the management of a hyperthyroidism. She presented with tachycardia, hand tremor and a weight loss, with TSH = 0.05 mUI/l and FT4 at 3 times the normal range, confirming the diagnosis of hyperthyroidism. Graves disease diagnosis was established based on the positivity of TSH receptor antibodies. Management of our patient relied on beta-blockers and Thiamazole 1 mg/day for 3 months, followed by a dose reduction to 1 mg/day with FT4 level of 21.1 pmol/l (n= 8.9 - 21.6) and TSH level of 0.11 mUI/l. After 5 months of treatment, the patient developed diffuse pruritic erythematous-papular lesions. Other drug intake was ruled out during the interview. A skin biopsy was inconclusive, showing histological features consistent with either bullous toxiderma or bullous pemphigoid. Direct immunofluorescence was performed, revealing a lichenoid dermatosis with IgM vasculitis, and a dermo-epidermal detachment supporting the diagnosis of bullous toxiderma. The decision was made to discontinue Thiamazole and initiate radioactive iodine therapy. The patient's condition improved with a reduction in lesions and disappearance of pruritus, confirming the association with Thiamazole.
Conclusion
This case illustrates the importance of meticulous clinico-biological monitoring after administration of Thiamazole, even several months after the start of treatment, as toxidermia is a potentially serious adverse drug reaction especially when associated with fever, polyadenopathy and multivisceral involvement (DRESS Syndrome), which can be life-threatening. In such rare cases, it is necessary to discontinue the ATS and switch to radical treatment.

A case of graves with recurrence after mepolizumab treatment

Ekin Yiğit Köroğlu[1], Güler İnönü[1], Nagihan Beştepe[1], Hüsniye Başer[2], Ahmet Dirikoç[2], Oya Topaloğlu[2], Reyhan Ersoy[2] & Bekir Çakır[2]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara; [2]Ankara Yıldırım Beyazıt University Faculty Of Medicine, Endocrinology and Metabolism, Ankara

Introduction
Targeted therapies and monoclonal antibodies are known to trigger thyroid autoimmunity. No case of autoimmune thyroid disease with mepolizumab, an anti-IL-5 monoclonal antibody, is reported in the literature. In this case report, we present a case of Graves' disease that recurred after Mepolizumab treatment.
Case
A 74-year-old male patient was referred to the endocrinology outpatient clinic upon detection of hyperthyroidism on 11/2021. The patient, who had known aortic valve replacement, allergic asthma, and benign prostatic hyperplasia, was using warfarin 1×5 mg, atorvastatin 1×20 mg, inhaler salmeterol, 1×5 mg levocetirizine and 1×8 mg silodesin. In the patient's examinations, TSH $<$0.008 mU/l, free T4:3.94 ng/dl, free T3:11.99 ng/l, anti-tg:2.4 IU/ml, and TSH receptor antibody (TRAB):6.77 IU/l ($<$1.5 IU). /l) was seen. On electrocardiography, his pulse was 98 beats/minute, and his rhythm was normal sinus rhythm. While no nodule was detected in the patient's thyroid ultrasonography, bilateral parenchymal heterogeneous and sparse patchy hypoechoic areas were observed. Color flow doppler pattern was observed as 2 in thyroid doppler. The patient, who had no history of recent contrast exposure or amiodarone use, was evaluated as having Graves' disease, and methimazole 3x5 mg and propranolol 2x20 mg were started. No signs of ophthalmopathy were detected in the eye examination performed at the time of diagnosis. After one month, propranolol was discontinued, and methimazole dosage was adjusted, and periodic checks were scheduled. On 05/2023, in the 19th month of treatment, while receiving methimazole 1×2.5 mg treatment, TSH was measured:2.4 mU/l, free T4:1.04 ng/dl, free T3:3.62 ng/l, thyroid stimulating immunoglobulin was 0.52 IU/l (0.1-0.55 IU/l). The treatment was discontinued at this point. In the follow-ups performed one month and two months later, it was observed that the patient was euthyroid. On 07/2023, as the patient's complaints about allergic asthma increased, the pulmonologist started Mepolizumab to be administered 100 mg subcutaneously once a month. On 09/2023, after the patient received two doses of mepolizumab, TSH:0.02 mU/l, free T4:1.86, and free T3:4.68 ng/l were observed in the controls performed in our outpatient clinic, and the patient was started on methimazole 1×5 mg again. The patient, who was evaluated as having a relapse of Graves disease, was assessed in a multidisciplinary council, and radioactive iodine treatment was planned.
Conclusion
Thyroid autoimmunity may be triggered after Mepolizumab, an anti-IL-5 monoclonal antibody. Patients receiving this treatment should also be followed in this respect.

Amiodarone-induced hypothyroidism: from myxedema coma to euthyroidism

Daniela Soares[1] & Lia Ferreira[1]
[1]Unidade Local de Saúde de Santo António, Endocrinology, Porto, Portugal

Introduction
Myxedema coma is the most serious manifestation of hypothyroidism and, although rare, it is associated with high mortality. Amiodarone therapy can lead to

thyroid dysfunction, either hyperthyroidism or hypothyroidism; however, in this context, myxedema coma is rare. Amiodarone discontinuance is not recommended in hypothyroidism's treatment, but may lead to its resolution if there is no pre-existing thyroid pathology. We present a clinical case of amiodarone-induced hypothyroidism meeting myxedema coma criteria, reverted to euthyroidism after drug suspension.
Clinical Case
Female, 76 years-old, history of valvular heart disease and atrial fibrillation (AF) treated with amiodarone since 2012. Admitted to the emergency department on 02/2021 presenting with lethargy, dyspnea, orthopnea and peripheral edema. Physical examination revealed hypothermia (34°C), bradycardia (45 bpm), hypotension (88/58 mmHg) and anasarca. Additionally, the presence of type 2 respiratory failure, acute kidney injury (creatinine 3.17 mg/dl), hyponatremia (127 mmol/l), hyperkalaemia (5.74 mmol/l) and AF with slow ventricular response was documented. Under the suspicion of myxedema coma (Popoveniuc score 90 points) thyroid function was assessed, which confirmed the presence of hypothyroidism: TSH 71 uUI/ml (0.30-3.94), T4L 0.42 ng/dl (0.95-1.57) and T3L 1.10 ng/ml (0.78-1.90), with negative thyroid autoimmunity. The patient was diagnosed with severe hypothyroidism meeting myxedema coma criteria, associated with neurological, cardiovascular, respiratory and renal dysfunctions. Levothyroxine therapy was iniciated (200 µg loading dose, followed by IV 100 µg/daily), associated with IV hydrocortisone 100 mg (until adrenal insufficiency was excluded), furosemide and non-invasive ventilation. The patient presented favorable evolution with resolution of all dysfunctions, being discharged under 150 µg levothyroxine and bisoprolol 1.25 mg instead of amiodarone, according to Cardiology recommendations. In outpatient consultations, thyroid ultrasound was performed revealing no changes, supporting amiodarone-induced hypothyroidism. Subsequent assessments documented progressively lower levothyroxine needs leading to its discontinuance on 04/2022, with the patient presenting clinically and analytically euthyroid since then.
Discussion
Amiodarone-induced hypothyroidism can occur in up to 30% of patients undergoing this therapy, which can lead to the development of myxedema coma in extreme situations, especially when its diagnosis is not carried out in a timely manner. Discontinuation of amiodarone in cases of hypothyroidism is not indicated; however, if performed, it may induce hypothyroidism's resolution.

Graves' disease resistant to carbimazole, rai and lugol's solution

Hadjer Zeguir[1], Amel Mokrane[1], Safia Achir[1] & Leila Oucherif[1]
[1]CHU Isaad Hassani de Beni Messous hôpital, endocrinology, Alger, Algeria

Introduction
Graves' disease (GD) is the most common cause of primary hyperthyroidism. The standard approach to managing GD involves the use of antithyroid drugs (ATD), radioactive iodine (RAI), and surgery. Additional supportive treatments include beta-blockers (Bb), corticosteroids (CTC), Lugol's solution. In exceptional cases, some patients may exhibit resistance to these conventional methods, necessitating additional forms of management. We report a case of Graves' Disease where ATD, Lugol's solution and RAI failed to produce the expected response.
Case presentation
A 38 years old female, with personal history of gestational diabetes and familial autoimmunity field, referred with symptoms of clinical and biochemical thyrotoxicosis, which were not improving on Carbimazole 80 mg daily and propranolol 1 mg daily, despite of good compliance for 10 months. TRAb was strongly positive confirming diagnosis of Graves' Disease. There was no evidence of malabsorption and a negative serology for Coeliac disease. She was then given methylprednisolone with Lugol's Iodine for 13 days to make her euthyroid before thyroidectomy. However, she remained symptomatic with no improvement in her thyroid functions' tests. Two doses of RAI were then administered 6 months apart. Unfortunately, she did not achieve remission after the 2nd RAI therapy, neither ATD dose reduction.
Conclusion
This case underscores the various management options available for patients with resistant GD. In challenging cases, radioactive iodine and surgery emerge as definitive modes of treatment, with steroids and/or Lugol's solution playing a crucial role in preparing patients for those definitive interventions. The presented case involves a rare scenario where GD exhibited resistance to high-dose of ATD, Lugol's solution and RAI.

Twenty years of experience in the use of medial thyroidectomy

Pamputis Sergey[1], Yuriy Aleksandrov[1] & Artem Dyakiv[1]
[1]Yaroslavl State Medicfl University, surgery, Yaroslavl, Russian Federation

Twenty years of experience (4, 573 operations) of performing medial access and thyroid mobilization according to the Nikolaev's method is presented. The operation is preceded by an ultrasound performed by a surgeon. Changes have been made to the primary technique: subcutaneous veins and short neck muscles do not intersect. The secretion of the thyroid gland begins from the trachea with traction of the thyroid gland to the lateral side. Ligation of large vessels begins at the lower pole, while the parathyroid glands are visualized and separated. With subsequent cranial traction of the thyroid gland, it is possible to move away from the esophagus (left) and recurrent nerves with a visual assessment. Vascular ligation at the upper pole is performed last after visualization of the upper parathyroid glands. Twenty years of experience in using this technique (medial thyroidectomy) suggests that it is effective and radical (for thyroid tumors). At the same time, it is possible to preserve thyroid tissue in the upper pole during a benign process. Complications (1.2%) arising during surgery are associated with an incorrect choice of access (including size), excessive traction of the thyroid lobe during its mobilization, and irrational use of electrocoagulation. The technique of the operation allows the use of neuromonitoring, however, the visualization of the nerve by the surgeon is performed at the second stage (cranial traction), in which the nerve should be maximally removed from the manipulation zone, which is achieved due to surgical technique. The technique of medial access has proven itself positively in giant goiter (up to 2000 grams) and large toxic goiter (more than 200 grams). The frequency of complications after surgery: dysphonia–2.1%, bleeding in the early postoperative period–0.3%, hypocalcemia–2.2%. In 93% of patients, dysphonia and hypocalcemia were transient (stopped within 6-12 months)

Comparative assessment of hematological, autoimmune and hormonal status of patients with autoimmune thyroiditis

Farida Saidova[1], Jale Aslanova[1], Oruc Shahsuvarov[1] & Nizami Muradov[2]
[1]Scientific Center of Surgery after M.A. Topchubashov, endocrine surgery, Baku; [2]Scientific Center of Surgery after M.A. Topchubashov, anaesthetiology and reanimatology, Baku

The purpose of the study is a comparative assessment of the hematological, autoimmune and hormonal status of patients with autoimmune thyroiditis (AİT).
Material and methods
45 patients with AIT aged from 25 to 76 years were examined (average age 44.3±1.5). 39 of them women (86.7%), 6 men (13.3%). Two groups were determined: 1st group - patients with AIT with anemia - 36 people (average age 44.1±1.7); 2nd group - patients with AIT without anemia - 9 people (average age 45.4±3.8). Mild anemia was observed in 34 (94.4%), moderate anemia - in 2 (5.6%) patients. HGB, HCT, RBC, MCV, MCH, MCHC, serum Fe and ferritin were determined. Immune status was assessed by the level of CD3+, CD4+, CD8+, CD19+, CD4+/CD8+, CİC, Ef, ATPO, hormonal status – according to the level of TSH, T4 free.
Results
İn 1st group by the erythrocyte volume 23 patients (63.9%) were identified with microcytic anemia, 13 patients (36.1%) had normocytic anemia. According to the morphological indicator of anemia MCH-25 (63.9%) patients had a hypochromic type of anemia, 11 (30.5%) patients - normochromic. İn 1st group 23 (63.9%) patients had microcytic-hypochromic anemia, which characteristic for iron deficiency anemia, and 11 (30.5%) patients - normocytic-normochromic anemia, characteristic for anemia of chronic diseases. A comparative assessment of the level of HGB and indicators of iron metabolism in patients with AIT with anemia revealed a decrease in HGB by 21.4%, serum Fe by 33.7%, ferritin by 39.5% in comparison with the corresponding control indicators. To a greater extent, the depletion of iron stores (ferritin) is due to the fact that the development of anemia is preceded by 'latent iron deficiency, ' an indicator of which is ferritin.
Conclusion
AIT is characterized by a high incidence of anemia, often mild (94.4%), microcytic-hypochromic (63.9%), which characteristic for iron deficiency anemia. Severe hematological disorders identified in patients with AIT with anemia are accompanied by profound autoimmune changes and, in 25% of cases with subclinical hypothyroidism.

The onset of thyroid eye disease in hyperthyroidism after covid-19 infection: a case report

Hager Khiari[1], Sabrine Mekni[1, 2], Sawsen Essayeh[1], Imen Rojbi[1], Bennacef Ibtissem[1], Youssef Lakhoua[1], Nadia Mchirgui[1] & Karima Khiari[1]
[1]Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia; [2]Charles Nicolle Hospital, Endocrinology

Introduction
Thyroid eye disease (TED) is an autoimmune inflammatory disorder affecting the orbital tissues. It occurs with thyroid dysfunction notably Graves' disease. TED exhibits different severity patterns and has a lot of risk factors. We, herein, report a rare case of a severe TED developing after COVID-19 infection in a patient initially treated for hyperthyroidism without ocular manifestations.
Observation
A 48-year-old female with a history of hyperthyroidism and toxic nodule treated by radioiodine therapy in 2017 was addressed to the endocrinology department for TED symptoms with inflammatory features. In 2017, at the initial diagnosis of thyrotoxicosis, the patient had a toxic thyroid nodule diagnosed by thyroid ultrasound and scintigraphy. Thyroid peroxidase antibodies (TPOAb) and thyroid stimulating hormone (TSH) receptor antibodies (TRAb) were both negatives. She was treated with Benzyl thiouracil then radioactive iodine (RAI) therapy. After developing hypothyroidism post-RAI, she was on 100 mg of levothyroxine daily. In 2021, she was diagnosed with COVID-19 infection and ten days later, she developed eye redness, eye fullness and diplopia. On physical examination, she had active TED with clinical activity score (CAS) of 4/7 points, asymmetric exophthalmia and a restrictive ocular dysmotility. Ocular computed tomography (CT) confirmed the diagnosis of a severe Graves' orbitopathy (GO). Laboratory tests showed elevated TRAb 2.5 mIU/l (<2) and TSH 8.17 mIU/l (0.4-4). The patient was treated with 1 mg of levothyroxine daily and received intravenous methylprednisolone (1 g/day for 3 days) then oral prednisone during three months. Though inflammatory symptoms improved, diplopia worsened and heavily impacted the patient's quality of life. A decompressive eye surgery then a strabismus surgery were ultimately performed. No complications occurred after surgery and the symptoms improved significantly.
Conclusion
In conclusion, we reported a very uncommon case of a TED presenting after COVID-19 infection. It was also a severe case of a restrictive dysmotility caused by Graves's orbitopathy that was treated by surgery. It reinforces the eventual link between COVID-19 and autoimmunity.

Propylthiouracil-induced ANCA associated vasculitis: a diagnostic and therapeutic challenge

May Myat Mon[1], Win Lei Yin[1] & Thinzar Min[1, 2]
[1]Swansea Bay University Health Board, Diabetes and Endocrinology, Skewen, United Kingdom; [2]Swansea University, Sketty, United Kingdom

Introduction
Graves' disease, a common cause of hyperthyroidism, occasionally poses therapeutic challenges. This case report highlights complexities of Graves' disease management, particularly an unusual complication: Propylthiouracil (PTU) - induced ANCA vasculitis.
Case report
A 51-year-old lady with Graves' disease diagnosed in 2008, achieved remission with 18 month course of Carbimazole. She experienced a relapse in February 2021 and Carbimazole proved to be ineffective leading to a switch to PTU in May 2022. Twelve months after PTU, she developed recurrent joint pain and intermittent non-blanching vasculitic rash on knees and ankles associated with a rapid decline in renal function and positive ANCA (P+C ANCA), anti-MPO and anti-PR3 antibodies. She had no other features of autoimmune connective tissue disease. Renal biopsy confirmed absence of classical renal vasculitis. Due to her spectrum of presentations, various speciality were involved. A diagnosis of PTU-induced vasculitis was made. Following the replacement of PTU with Carbimazole and immunosuppressant therapy (prednisolone and methotrexate), joint pain and rashes resolved, renal function improved dramatically, and thyroid function improved. Since the complete withdrawal of immunosuppression in October 2023, symptoms of thyrotoxicosis returned with TSH <0.01 mU/l and FT4 >100 pmol/l. Carbimazole dose was up-titrated along with glucocorticoid therapy. She is due to have follow-up in 4 weeks. Total thyroidectomy is considered as a definite therapy once her thyroid function improves.
Discussion
PTU-induced vasculitis is rare and requires a high index of clinical suspicion. Prompt discontinuation of PTU would be sufficient for most case but severe cases might require immunosuppressant therapy.

Early approach in a patient with an incipient thyrotoxic crisis

Ignacio Jiménez Hernando[1], Mónica Gómez-Gordo Hernanz[1] & Laura González Fernández[1]
[1]Gregorio Marañón General University Hospital, Endocrinology and Nutrition, Madrid, Spain

Introduction
Thyroid storm or thyrotoxic crisis is a severe manifestation of thyrotoxicosis. Mortality rate is 20-30%. The most common trigger is hyperthyroidism due to Graves-Basedow Disease. There are two validated scales for diagnosis: the Burch Wartofsky scale (BWPS) and the Japanese Thyroid Association scale (JTA). These scales are based on cardiovascular, neurological, digestive, and thermoregulatory clinical manifestations. If clinical suspicion is high, treatment should not be delayed in order to identify and treat precipitating factors, achieve euthyroid state, and address multiorgan damage.
Presentation of the case
A 37-year-old woman with Graves-Basedow Disease without treatment presented to the Emergency Department with symptoms of dyspnea, edema, fever, cough, vomiting, diarrhea, nervousness, and palpitations. On arrival, she had a fever of 38.5ºC, diffuse grade III goiter with a murmur and thrill, and fine distal tremor. Laboratory tests showed hepatic profile alteration and elevated levels of Nt-proBNP and acute phase reactants. Electrocardiogram revealed sinus tachycardia at 137 bpm; bilateral pleural effusion and left bronchopneumonia were observed on chest X-ray. Due to an elevated D-dimer, thrombosis was ruled out with Doppler ultrasound and CT angiography. Echocardiogram showed no structural heart disease. Microbiological isolates were negative. Thyroid profile tests showed suppressed TSH, free T4 at 3.2 ng/dl, and free T3 at 4.78 pg/ml. Suspecting an incipient thyrotoxic crisis, high-dose antithyroid drugs, beta-blockers, steroids, diuretics, and antibiotics were initiated. The ICU was consulted and decided not to admit the patient due to stability and prompt initiation of treatment. The patient was diagnosed with left basal pneumonia that triggered a thyrotoxic crisis with multiorgan dysfunction (BWPS 75). At the first follow-up visit two weeks after discharge, she showed favorable progress, leading to consensus on I131 treatment.
Conclusions
Thyrotoxic crisis is a potentially life-threatening condition that can cause multiorgan dysfunction. Therefore, clinical suspicion and early initiation of treatment are important.

Clinical aspects of the schmidt's syndrome: a retrospective monocentric study

Oumayma Zarrouk[1], Taieb Ach[1], Rihab Khochtali[1], Ghada Saad[1], Asma Ben Abddelkrim[1], Molka Chadli Chaieb[1] & Koussay Ach[1]
[1]University Hospital of Farhat Hached, Endocrinology Departement, Sousse, Tunisia

Introduction
Schmidt's syndrome also known as autoimmune polyglandular syndrome type 2 (APS type 2) is a rare endocrine disorder defined by the combined occurrence of Addison disease with autoimmune thyroid disease. The rarity of the condition and the atypical presentation of adrenal insufficiency and hypothyroidism often lead to misdiagnosis with life-threatening consequences for the patient. In this study we report an exhaustive monocentric analysis of 22 patients diagnosed with a Schmidt's Syndrome.
Patients and Methods
We carried out a retrospective study of all the patients diagnosed of a Schmidt syndrome or APS type 2 in the Department of Endocrinology and Diabetology of University Hospital Farhat Hached of Sousse, over a period from 1999 to 2013. Adrenal insufficiency was diagnosed with a basal cortisol level <40 ng/ml or peak <180 ng/ml after Synacthen. Autoimmune Hypothyroidism was diagnosed with a T4<7 pg/ml and TSH>10 mUI/l associated with the positivity of anti-Peroxydase antibodies. We analyzed clinical and biological aspects of these patients with SPSS ver. 23.0 software.

Results
We reported 22 cases, with a mean age of 31.77 ± 11.26 yo, with 36.3% between 20 and 39 yo ($P = 0.02$) and a predominance for female sex with a sex ratio = 0.22 ($P < 10^{-3}$). The mean age of discovery of Addison's disease was 32.5 ± 9.2 with extremes ranging from 12 to 58 years. According to the age of discovery compared to hypothyroidism, Addison disease was diagnosed significantly before the diagnosis of Hashimoto's disease in 59% ($P = 0.03$), concomitant in 27.2% and posterior in 13.6%. Clinical symptoms made of melanodermia and hypoglycaemia suggested the diagnosis in 47% of all patients. An acute adrenal insufficiency was triggered by the hormonal thyroxin substitution in one case. Other autoimmune diseases were found in 27.2%, as a celiac disease (8%), type 1 diabetes (8%), Biermer anemia (7%) and autoimmune ovaritis in 4.2%.
Conclusion
Schmidt's Syndrome is more likely to be associated with the female sex and young age. In our study, Hashimoto's hypothyroidism was the first autoimmune disease discovered. The presence of at least one component of the APS type 2 must lead to the autoimmune screening of the other diseases. This screening could avoid the triggering of an adrenal insufficiency in thyroid hormonal substitution.

Lack of thyroid-stimulating hormone receptor expression on natural killer t cells: implications for the immune-endocrine interaction
Magdalena Stasiak[1], Emilia Adamska[1], Przemysław Śliwka[1], Arkadiusz Zygmunt[1, 2] & Andrzej Lewinski[1, 2]
[1]Polish Mother's Memorial Hospital - Research Institute, Department of Endocrinology and Metabolic Diseases, Lodz, Poland; [2]Medical University of Lodz, Department of Endocrinology and Metabolic Diseases, Lodz, Poland

Introduction
The functional interaction between the immune and endocrine systems remains intricate, and the relationships among various cell types and humoral mediators are not fully elucidated. Natural killer T (NKT) cells, being a heterogeneous T cell subpopulation, express markers specific for both natural killer (NK) cells (NK1.1, CD56) and T cells (TCR - T cell receptor). Thyroid-stimulating hormone (TSH) influences the immune system, and TSH receptors (TSHR) have been identified in various immune cell types. Although the impact of TSH levels on the quantity of NKT cells in peripheral blood has been postulated, no reported studies have explored the expression of TSHR on NKT cells. This study aimed to assess the expression of TSHR on NKT cells, with analyses conducted on NKT cells isolated from the peripheral blood of individuals with and without autoimmune thyroid disease (AITD).
Methods
NKT cells were isolated from peripheral blood mononuclear cells (PBMC) using a magnetic beads cell separator. Fluorescence-activated cell sorting (FACS) was employed to analyze TSHR expression on the surface of NKT cells. TSHR gene expression was assessed using the RT-PCR method on total RNA isolated from both PBMC and NKT cells. Blood samples were collected from 81 individuals, including 16 AITD patients and 65 persons without AITD.
Results
Neither FACS analysis nor RT-PCR gene assays revealed the expression of TSHR on the surface of NKT cells. These findings were consistent in both AITD and non-AITD patient groups.
Conclusion
Our results suggest the absence of direct TSH-mediated effects on NKT cells via TSHR. Further investigations are warranted to elucidate potential indirect mechanisms underlying the influence of TSH on NKT cells.

Thyrogastric syndrome: a case report
Jaddi Oussama[1], Manar Bari[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Mohammed VI university hospital of Marrakesh, Department of Endocrinology, Diabetes, Metabolic diseases and Nutrition, Marrakesh, Morocco

Introduction
Thyroid-gastric autoimmune syndrome (TGS), described in the 1960s, is the autoimmune association of thyroid disease (Hashimoto's or Graves' disease) and gastric mucosal disease (Biermer's disease) in the same patient. Although this association is part of the autoimmune polyendocrinopathies, its prevalence is largely underestimated in the literature. We report the case of a 56-year-old female patient with TGS.
Observation
Patient aged 56; followed for mitral stenosis on VKA, followed for Biermer's disease discovered during an etiological workup of macrocytic anemia with positive anti-parietal cell and anti-FI Ac levels, the patient was put on Hydroxocobalamin. The patient consulted for asthenia and recent weight gain considered moderate, a TSH us requested returned at 22.4 mUI/l, thyroid ultrasound objective an aspect of thyroiditis, anti TPO Ac returned positive confirming the diagnosis of Hashimoto's thyroiditis. The patient was put on a progressive dose of Levothyroxine in view of the atrial fibrillation she presented on ECG.
Discussion
Biermer disease (BD) is an autoimmune atrophic gastritis causing vitamin B12 deficiency, frequently associated with other autoimmune diseases, notably endocrinopathies. Autoimmune thyroid disease generally has a favorable course, but when associated with autoimmune gastritis, there is a risk of developing gastric tumors. Digestive malabsorption also affects medications (levothyroxine), making it difficult to substitute for hypothyroidism. The prevalence of BD is around 10-15% in prospective series of autoimmune thyroiditis. The search for this association is important because of its frequency and its therapeutic and prognostic implications.
Conclusion
Systematic thyroid assessment during BD is necessary to detect and treat these thyroid disorders, which are sometimes in the sub-clinical stage.

Treatment of pediatric grave's disease: a single-center experience
Telma Moreno[1, 2], Joana Filipe Ribeiro[3], Sofia Ferreira[2, 4], Carla Costa[2, 4], Rita Santos Silva[2, 4] & Cíntia Castro-Correia[2, 4]
[1]Centro Hospitalar Universitário de São João, Endocrinology, Porto, Portugal; [2]Universidade do Porto, Faculty of Medicine, Porto, Portugal; [3]Hospital Sousa Martins, Pediatrics, Guarda, Portugal; [4]Centro Hospitalar Universitário de São João, Pediatrics, Porto, Portugal

Introduction
Grave's disease is a rare disease in children. Treatment options are the same as in adults but remission rate with antithyroid drugs (ATD) appears to be lower in children and more prolonged courses of ATD are recommended. We aimed to evaluate the outcome of ATD treatment and to identify factors associated with remission.
Methods
Retrospective study of 36 pediatric patients diagnosed with Grave's disease at the Pediatric Department of a tertiary hospital in Portugal between 2002 and 2023. Remission was defined as euthyroidism for more than 12 months after stopping ATD treatment. Patients who achieved remission were compared to those treated for more than 2 years with ATD without remission. Statistic results are expressed as median (interquartile range) or frequency (percentage).
Results
Twenty-eight patients (77.8%) were female and median age at diagnosis was 14 (5.50) years. Twenty-four patients were sypmtomatic at diagnosis, mostly presenting with tachycardia (35.3%) and unintentional weight loss (26.5%). The median thyroid-stimulating hormone (TSH), free T4 (fT4), free T3 (fT3) and TSH-receptor antibodies (TRAbs) at diagnosis were 0.002 (0.01) µUI/ml, 2.49 (1.57) ng/dl, 8.76 (11.62) ng/dl and 14.35 (36.90) U/l, respectively. All patients started methimazole with a median initial dose of 10 (5) mg/day and a median treatment duration of 24 (28.50) months. Mild side effects were reported for only one patient. During follow-up, 9 patients achieved remission, 2 patients experienced relapse after discontinuation of ATD and 13 patients were treated for more than 2 years with ATD without remission. The ATD course duration for both patients who had a relapse was less than 2 years. In patients who achieved remission, the fT4 at diagnosis [1.80 (0.72) vs 2.91 (1.66) ng/dl, $P = 0.020$], the time for fT4 normalization [24.5 (13.5) vs 49.0 (107.5) days, $P = 0.010$], the time for TSH normalization [4.5 (6.8) vs 12.9 (11.0) months, $P = 0.010$] and TRAbs levels at diagnosis [3.30 (12.65) vs 40.00 (25.35) U/l, $P = 0.002$] were significantly lower than the non-remission group.
Conclusion
The overall remission rate after ATD treatment in our cohort was 25%, which is in accordance with previously reported rates. Lower fT4 and TRAbs levels at diagnosis and lower time for fT4 and TSH normalization were associated with higher chances of remission.

Thyroid carcinoma in a 7 year old child: a case report

Redhouane Longo[1], Mourad Benrabah[2], Abdelkader Yahi[3], Benabdelatif Katia[3] & Ould Kablia Samia[3]
[1]Endocrinology department, Regional University Military Hospital of Oran, Algeria; [2]Nuclear medicine department, Regional University Military Hospital of Oran, Algeria; [3]Endocrinology department, Central Military Hospital, Algiers, Algeria

Introduction
Thyroid nodules are much less common in children and adolescents than in adults. However, thyroid nodules in children are more likely to be malignant. Most thyroid cancers in children are differentiated thyroid cancers, which arise from the follicular cells of the thyroid gland. Although extremely rare (1.5% of all tumours before the age of 15), there are two types of differentiated thyroid cancer in children: papillary and follicular. Around 90% of paediatric thyroid cancers are papillary thyroid cancers. Despite the higher tendency to spread in children compared with adults, differentiated thyroid cancer has an excellent outcome, with a survival rate of over 95%.
Observation
Child aged 07, with no particular history, consults following the appearance of a basal cervical mass. It is a hard, painless mass, roughly oval in shape, approximately 03 cm long, mobile axis with swallowing movements, non-compressive, without inflammatory signs, and in clinical euthyroidism. Cervical ultrasound reveals a solid isthemic nodular formation, with presence of micro calcifications measuring 23x1 mm, classified EU-TIRADS V, associated with multiple bilateral cervical lymphadenopathy. TSH and thyrocalcitonin levels returned to normal. Patient underwent a total thyroidectomy with lymph node dissection and was placed on levothyroxine 100 $\mu g/m^2$/day. Anatomopathological study concluded that there was a 4 cm non-encapsulated intrathyroidal papillary carcinoma with 4 recurrent lymph node metastases, classified pT2N1bMx.
Discussion-Conclusion
Accounting for around 90% of paediatric thyroid carcinomas, papillary thyroid cancer is the most common type of thyroid cancer in children and adolescents. The second most common type of thyroid cancer is follicular thyroid cancer, and both types can usually be treated similarly.

Injury to the mandibular branch of the facial nerve after thyroid surgery. a not so uncommon case

María Isabel Gutiérrez[1], Angel Luis Sanchez Alvarez[1], Raquel Sanchez Gutierrez[2] & Jorge Loro Perez[1]
[1]Complejo Hospitalario Universitario Insular Materno Infantil, Cirugia General Y Aparato Digestivo, Las Palmas De Gran Canaria, Spain; [2]Complejo Hospitalario Universitario Insular Materno Infantil, Logopedia, Las Palmas De Gran Canaria, Spain

The most feared nerve injury when treating thyroid cancer is that of the recurrent laryngeal nerve. However, there are other nerve complications, underestimated and underpublished, such as the lesion of the mandibular branch of the facial nerve, which requires a multiprofessional approach to recover functionality and esthetics, both affected.
Clinical Case
A 44 year old woman, under study for anemia, underwent a cervical ultrasound that showed in the left thyroid lobe a nodule with lobulated edges and poorly defined, iso-hypoechoic, with micro and macrocalcifications inside and peripheral vascularization of 21 mm and an adjacent adenopathy to the ipsilateral submandibular gland (level II), with microcalcifications and minimal vascularization of 16 mm. The FNA of the thyroid nodule was category VI of the Bethesda Classification and the thyroglobulin in aspirate of the adenopathy was 34.65 ng/ml. With these findings, total thyroidectomy + bilateral central lymphadenectomy and functional left lateral cervical lymphadenectomy of compartments II, III, IV and V were performed. Intraoperative neuromonitoring of both vagus and recurrent laryngeal nerves showed a superimposable signal pre and post-surgery and intraoperative PTH determination showed a decrease of 77.87% with a final PTH of 15.2 pg/ml, so that, according to our protocol, calcium and vitamin D supplementation was not required. In the post-anesthetic recovery room, facial asymmetry was observed with deviation and descent of the left labial commissure, which persisted 24 hours later, when she was discharged. The patient was referred to the speech therapist for assessment and myofunctional rehabilitative treatment.
Discussion
Injury to the mandibular branch of the facial nerve in lateral lymphadenectomy occurs when compartment II of the neck is approached. The lesion can be produced by different mechanisms: mechanical (the most frequent), thermal or chemical. To try to avoid injuring this nerve branch, it is recommended to be careful in the traction and compression with the retractors when approaching the lympho-fatty tissue of compartment II. Although it is a less described complication than spinal nerve injury, it significantly affects esthetics and oral functionality and interferes with the patients' quality of life. For this reason, in the patient's informed consent process for a lateral lymphadenectomy, it should be mentioned as a possible complication that, although it is generally transitory, can affect the patient's social and working life.

Management of poorly differentiated follicular-derived thyroid carcinoma in an adolescent: a case report

Eva Rimkute[1], Aiste Kondratiene[1, 2] & Ruta Navardauskaite[1, 3, 4]
[1]Department of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Coordinating Center for Rare and Undiagnosed Diseases Lithuanian University of Health Sciences Hospital Kauno Klinikos, Kaunas, Lithuania; [4]Department of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction
Poorly differentiated carcinoma (PDTC) is an aggressive and rare form of thyroid carcinoma that originates from follicular cells and accounts for only 1-3 percent of all thyroid carcinomas diagnosed[1]. Most of the limited instances of PDTCs have been observed in older individuals. Instances in the pediatric population are exceedingly rare[2].
Case report
This report refers 17-year-old female, who presented moderate hirsutism (scoring 8 points on the Ferriman-Gallwey scale), normal puberty development (Tanner stage B3P4), and regular periods. Upon physical examination, the patient exhibited an enlarged thyroid (IB degree), Laboratory examination showed normal levels of sex hormones, elevated antibodies against thyroid peroxidase and thyroglobulin, and thyroid-stimulating hormone concentration. Thyroid ultrasound revealed a right thyroid hypoechoic heterogeneous structure nodule, with microcalcifications and groups of them, measuring up to $2.7\times2.8\times4.1$ cm in size. A fine-needle aspiration biopsy and cytological examination of the mass found undetermined significance atypia (Bethesda category III). Due to the abundant presence of lymphocytes, lymphocytic thyroiditis was suspected. In consideration of a potential tumor process, it was decided to carry out a complete thyroidectomy. Histopathology determined high-grade PDTC of the right thyroid lobe. The patient underwent radioactive iodine therapy following the completion of thyroidectomy. The treatment was well tolerated, with no observed side effects noted. Following the completion of the treatment, a PET/CT scan with fluorodeoxyglucose (FDG) was performed, during which no focal pathological FDG accumulation was detected. There were not detected pathological variants in PTEN, PRKAR1A, APC, TP53, RET, DICER1 genes.
Conclusions
This case emphasizes the challenges in diagnosing and treating thyroid disorders in young patients. The successful management PDTC through thyroidectomy and radioactive iodine therapy is notable. The absence of FDG accumulation post-treatment indicates a positive therapeutic response. This underscores the significance of comprehensive assessment and collaborative care for rare thyroid conditions in adolescents.
Keywords: adolescent, poorly differentiated thyroid carcinoma, thyroidectomy, radioactive Iodine therapy

Thyroid cancer incidence trends in lithuania 2018 – 2022. single-centre study

Kamilė Antanavičiūtė[1, 2], Raimonda Klimaitė[1, 2], Gabrielė Riškutė[2], Laura Arbatauskaitė[2] & Viktorija Pareikaitė[2]
[1]Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Endocrinology Department, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania

Introduction
Epidemiological studies show that thyroid nodules (TN) are found on ultrasonography in 19-67% of patients, with a predominance in women, the elderly, and populations living in areas with insufficient iodine intake. Approximately 5-15% of nodules are malignant, of which 95% are well-differentiated thyroid carcinomas.
Material and methods
The medical history of 377 patients treated for thyroid carcinomas (TC) in the Hospital of Lithuanian University of Health Sciences Kaunas Clinics Endocrinology and Surgery departments from 2018 to 2022 were analyzed. The patient's medical history, fine needle aspiration (FNA) of the TN cytology results and histological findings of operative material were interpreted. Calculations were performed using IBM SPSS Statistics 28.0 package.
Results
The study population consisted of 79% women and 21% men with an average age of 52.5±16.1 years. TN of 91% of patients were evaluated using EU-TIRADS scale. For 93% of patients FNA was performed before a thyroid surgery. EU-TIRADS median of TN, of which FNA were performed, was 5 (4-5). On average, FNA was performed 1, 16 times per patient. Median disease duration, counting from TN detection to surgery, was 8, 5 months. Cytological and histological concordance was observed in 93, 3% of cases, with a concerning 50% error rate in diagnosing anaplastic TC. The majority of patients (89, 9%) were diagnosed with papillary carcinoma, and the predominantly observed stage was pT1a (39, 4%). The total prevalence of TC is shown in Table 1. By ultrasound cancer metastases were identified in 17.1% of cases, although after surgical material examination metastases were observed in 29, 2% of cases with 90% being locoregional and 10% distant.

Table 1: The prevalence of TC.

Type of TC	Percent (%)	Predominant stage of TC	Percent (%)
Papillary carcinoma	89, 9	pT1a	39, 4
Anaplastic carcinoma	3, 7	pT3b	50
Follicular carcinoma	3, 2	pT3a	70
Medullary carcinoma	2, 9	pT1b	54, 5
Thyroid leiomyosarcoma	0, 3	pT3RxG3	100

Conclusions
According to our study, FNA shows limitations in identifying anaplastic TC. Moreover, almost 30% of patients were diagnosed with metastases. It is essential to note that patients with TN must be strictly monitored, especially those who have suspicious TN.

Medullary thyroid carcinoma – a 22-year case series from a tertiary hospital center

Tânia Carvalho[1], Mafalda Martins Ferreira[1], Joana Madeira[2], Sofia Lopes[1], Joana Saraiva[1], Patrícia Oliveira[1], Miguel Melo[1], Cristina Ribeiro[1] & Isabel Paiva[1]
[1]Centro Hospitalar e Universitário de Coimbra, Serviço de Endocrinologia, Diabetes e Metabolismo, Coimbra, Portugal; [2]Centro Hospitalar e Universitário de Coimbra, Serviço de Anatomia Patológica, Coimbra

Introduction
Medullary thyroid carcinoma (MTC) arises from thyroid parafollicular C cells and accounts for <5% of thyroid cancers. Nearly 25% occur in the context of multiple endocrine neoplasia type 2 syndrome (MEN2) or familial isolated MTC.
Objectives
Evaluation of clinical characteristics and evolution of patients with MTC.
Methods
Retrospective analysis of clinical records of patients with MTC diagnosed from 2001 to 2023.
Results
42 cases of MTC were identified. 27 (64%) were female. Mean age at diagnosis was 46.2±2.8 years (10-78). 35.7% of patients presented symptoms, mostly cervical swelling; two had diarrhea. 8 patients (19%) had a germline mutation in the RET proto-oncogene. 40 underwent total thyroidectomy, 6 of them in two surgical stages; 2 performed only lobectomy. 33.3% ($n=14$) had lymph node dissection - 5 of the central compartment, 9 central+ipsi/bi-lateral. 5 MEN2A patients performed prophylactic thyroidectomy. The median tumor size was 1 mm, 19% ($n=8$) being microcarcinomas. The most frequent location was the right lobe (42.9%); 33.3% ($n=14$) were multifocal. The remaining thyroid parenchyma exhibited nodular hyperplasia in 23.8% ($n=10$), chronic lymphocytic infiltration in 28.6% ($n=12$) and synchronous papillary microcarcinomas in 14.3% ($n=6$). Resection was R0 in most patients (90.5%). Nodal involvement was present in 28.6% (8 N1b and 4 N1a), and distant metastases in 7.1% ($n=3$). AJCC classification was I, II, III, IVA and IVC in 38.1% ($n=16$), 28.6% ($n=12$), 11.9% ($n=5$), 11.9% ($n=5$) and 7.1%($n=3$), respectively. Response to surgery was excellent in 71.4% ($n=30$), biochemical incomplete in 16.7% ($n=7$) and persistent structural disease in 11.9% ($n=5$). Stage I and II had higher probability of excellent response to surgery (93.8% and 100%, respectively) than stage III (40%) and IV (0%). All but one patient with nodal involvement ($n=12$) showed persistent disease. Among patients exhibiting excellent response, 5 (16.6%) experienced recurrence - 3 were only biochemical, and 2 MEN2A patients developed structural disease. While 59.5% ($n=25$) were cured, 35.7% ($n=15$) still have evidence of biochemical or structural disease. Seven patients (16.7%) required adjuvant therapies, 3 of whom are under tyrosine kinase inhibitors (selpercatinib or vandetanib). Deaths due to MTC occurred in 4.8% (2 patients).
Conclusions
Our center's outcomes showed a substantial rate of excellent response, especially in stages I-II, highlighting the importance of early detection and intervention. While the cure relies essentially on the surgical response, surveillance is necessary for potential recurrence, especially in MEN2 patients. Long-term clinical studies are vital to enhance our understanding of this rare malignancy.

Diagnostic workup of breast cancer metastases in the thyroid gland

Aistė Kondrotienė[1], Roberta Buginyte[2] & Lina Pužauskienė[3]
[1]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania; [3]The Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Kaunas, Lithuania

Introduction
Metastatic thyroid tumors are infrequent, accounting for just 3% of all thyroid cancers. Interestingly, 7.8% of these metastases stem from breast cancer. Previous malignancies increase metastatic suspicions when thyroid nodules, possibly accompanied by cervical lymphadenopathy, are discovered. As our case emphasizes, diagnostics can be complex, necessitating specialized treatment and monitoring plans.
Case Presentation
A 55-year-old female presented with right supraclavicular masses, neck discomfort. She was diagnosed with left breast carcinoma in 2008, with subsequent successful treatments including a right mastectomy, chemotherapy, and radiation. Clinical Examination: A 1 cm nodule was found in the right breast with skin adhesion. Clustered lymph nodes appeared in the left supraclavicular region. Diagnostic Assessments: Ultrasound: 3.8×3 cm tumor in the right breast's outer quadrant and a hypoechoic mass in the liver. The left supraclavicular area had pathological lymph nodes. Chest X-ray: Identified a 4.7×5 cm mass in the right paratracheal region. Lab. Results: CEA 19, 1->74 pg/l (0-5, 8); Ca125 8, 8 kU/l (0-35); Ca19-9 5, 5 kU/l (0-37); Ca27.29 129, 8 (0-31). TSH 1.1 mU/l (0, 4-3, 6), FT4 11, 1 pmol/l (9-21, 07), FT3 5, 1 pmol/l (3, 34-5, 14), AntiTPO 3, 0 kU/l (0-3, 2), AntiTg 6, 1 kU/l (0-13, 6), calcitonin 1, 24 (0, 12-2, 8). Histopathology: infiltrative ductal breast carcinoma, G2 (ER+), (PR+), (HER2-). Computed Tomography (CT): Highlighted tumor presence in the right breast, pathological lymph nodes, and metastases in renal, hepatic regions, and bones. PET CT: Revealed low metabolic activity neoplastic lesions in the right breast and high metabolic activity lymph nodes suggestive of lymphoma. Thyroid Ultrasound: Several nodules, largest being 0.9×0.7 cm (TI-RADS 4), and a heterogeneous 1.2×0.6 cm zone with microcalcinate-like inclusions (TI-RADS 5) are in the right lobe. The left lobe has zones up to 2.6×1.3 cm with similar inclusions (TI-RADS 5). Pathological-enlarged lymph nodes are present on both neck sides, the biggest being 2.3×1.6 cm on the left. Fine needle aspiration

biopsy revealed breast ductal carcinoma metastases in the thyroid gland. Abdominal l/m biopsy result L: infiltrative ductal carcinoma G2 spread, HER2(-), ER+, PR-. Therapeutic Recommendations: A multidisciplinary team recommended chemotherapy with ribociclib and fulvestrant. Given the reducing size of thyroid metastases and no signs of tracheal or esophageal compression, thyroidectomy was deemed unnecessary.
Conclusion
Metastases in the thyroid often indicate a poor prognosis, negating surgical intervention for some. This case underscores the importance of distinguishing primary thyroid conditions from metastatic incidences due to differing therapeutic approaches and their subsequent impact on prognosis.

EP806

Characteristics and incidence of papillary thyroid carcinoma among georgian reproductive-aged women

Nestan Bostoganashvili[1], Rusudan Kvanchakhadze[2], Shorena Tukvadze[2], Natia Chachava[3] & Badri Gvadzabia[3]
[1]University of Georgia, Tbilisi; [2]Georgian - American University; [3]National Institute of Endocrinology

Introduction
The incidence of thyroid cancer in women, especially in reproductive age seems to be significantly increasing in Georgia and generally, worldwide. Thyroid cancer is the third most common cancer after breast cancer and uterine cervical cancer, among women aged 25 to 45 years. Multiple epidemiological studies have shown, that the prevalence of thyroid cancer is higher in women in the reproductive age (18-49), which could be explained by reproductive and menstrual factors. Aim of presented study was to determine characteristics and incidence of papillary thyroid cancer (PTC) in Georgian reproductive aged females
Methods
Women aged 18–49 years ($n=3643$) diagnosed with PTC in 2015–2022 were identified from Georgian national Registry Database. For each age group (14-25, 26–35, 36-49) results were stratified by cancer stage, location, ethnicity. Age-adjusted average annual percentage changes in incidence have been estimated based on 5-year survival.
Results
In the 18-49 age group, from 2015 to 2019 incidence had been increasing, whereas 2020-2022 it had been mildly decreasing. In the particular period (2015-2022) 65.5 % of total cases was stage 1, 15.2 % - stage 2, 11.3 % stage 3, 7% stage 4. (other 2 % unidentified). 97.5 % of all cases was malignant, other 2 % was described as precancerous invasion. Incidence was lowest in 14-25, and highest in 36-49 age group. Highest incidence occurred in Tbilisi, the capital from 2015-2019 and in 2020-2022, which could be explained with high screening facilities. High incidence rates was seen in high-mountainous regions (like Svaneti), Regarding ethnicity, in 2015-2019 incidence of ethnical minorities (Russians, Azers, armenians etc) was almost 4 times higher compared to ethnically Georgians, whereas later, from 2019, incidence in ethnically Georgian women has been almost 3.5 fold higher. A-5 year survival was equally high- 95% and 94 %, respectively in stage 1 and stage 2, in both 2015-2019 and 2020-2022 years, stage 3 was insignificantly low 93% and 94.5% respectively, in 2015-2019 and 2022 years.
Discussion
Due to very high survival and other clinical characteristics, PTC seems to be not quite 'malignant' disease, however reasons of high incidence, especially in reproductive aged females needs to be investigated properly and possible preventive methods should be well determined. In this particular study, Incidence rate changes from 2015-2019 to 2020-2022 and differences in regions could also be explained with lack/ inability of screening on time because of social isolation in Covid19 pandemic period.

Infiltration of the thyroid in advanced laryngeal cancers: a retrospective analysis

Heyfa Belhadj-Miled[1], Houas Jihene[1], Monia Ghammam[1], Maroua Ben Njima[1], Malika El Omri[1], Abir Meherzi[1], Mouna Bellakhdhar[1], El Ghali Wassim[2], Yosra Hasni El Abed[3], Wassim Kermani[1] & Mohamed Abdelkafi[1]
[1]Farhat Hached Hospital, ENT Department, Sousse, Tunisia; [2]Department of Anaesthesia, Sousse, Tunisia; [3]Farhat Hached Hospital, Departement of Endocrinology, Sousse, Tunisia

Introduction
Pharyngolaryngeal cancers can invade the thyroid either by direct extension or via the lymphatic or hematogenous pathways. These three types of extension explain the indications for thyroidectomy during pharyngolaryngeal surgery, mainly documented for laryngeal cancers.
Methods
This is a retrospective descriptive cross-sectional study of 46 patients who underwent total laryngectomy (TL) associated with a thyroid procedure at the Department of Otolaryngology (ENT) and Cervicofacial Surgery, Farhat Hached Hospital, Sousse, over a period extending from January 2012 to December 2022.
Results
The mean age of our patients was 59.1 years. The sex ratio was 22. The average consultation time was 10.9 months. Dysphonia was the main symptom, found in all patients. Thyroid surgery associated with laryngectomy was performed in all our patients: loboisthmectomy in 52.2% and total thyroidectomy in 47.8%. Invasion of the thyroid gland by laryngeal carcinoma was identified in 8 patients (17.4%). Invasion was macroscopic, by direct extension of the tumour, in 6 (75%) patients and microscopic in 2 (25%). Comparison between groups of patients with and without thyroid invasion revealed that patients with evidence of glandular invasion had the following characteristics: Higher rates of invasion of the following structures by the primary tumor: Anterior commissure ($P=0.047$), subglottis ($P=0.004$), cricoid cartilage ($P=0.002$), thyroid cartilage ($P=0.089$), piriform sinus ($P=0.052$). There were no statistically significant differences between the two groups with regard to gender, age, smoking status, T, N, M staging, tumour size, surgery, histological grade and presence of vascular emboli or peri-nervous sheathing.
Conclusion
Thyroid invasion should not be underestimated in advanced pharyngolaryngeal cancers. Preoperative CT scans are essential for its evaluation. Thyroidectomy should not be performed routinely.

Lateral lymph node metastasis in papillary thyroid carcinoma: predictive factors and management

Sameh Mezri[1], chaima zitouni[1], Wadii Thabet[2] & Khemaies Akkari[1]
[1]Principal Military Hospital, ENT, Tunis, Tunisia; [2]Taher Sfar Hospital, Mahdia, Tunisia

Introduction
Papillary carcinoma is the most common histological type of thyroid carcinomas. Lymph node involvement is an important prognostic factor. But its management remains uncodified.
Objective
The aim of our study was to identify the predictive factors of lateral lymph node metastases in papillary thyroid carcinoma.
Methods
This is a retrospective study including 96 patients operated on for papillary thyroid carcinoma at our department from 2001 to 2021 with a minimum postoperative follow-up of two years with clinical, biological and ultrasound control.
Results
Our study included 23 patients with lateral lymph node metastases with a mean age of 42 years, slightly lower than that of group without lateral metastasis (48 years). The sensitivity and the specificity of neck ultrasound in identifying lateral metastatic nodes were 71% and 83% respectively. Total thyroidectomy was performed in all cases. Central neck dissection was performed in 59 cases. Metastatic nodes were found in 47% of cases. Lateral neck dissection was done either simultaneously ($n=21$) or 12 and 18 months later ($n=2$). All patients received additional radioactive iodine treatment with an average dose of 200 mci. In our study, we identified tumor capsular invasion ($P=0.04$) and recurrent lymph node invasion ($P=0.02$) as independent factors of lateral lymph node metastases.
Conclusion
Lymph node involvement is a determining prognostic factor in papillary thyroid carcinoma. Central dissection is required if the cancer is diagnosed before or during the surgery. In the presence of metastatic nodes or other risk factors, preventive or curative lateral dissection should be discussed.

Patterns of thyroid cancer incidence and mortality in lithuania over 30 years period

Lina Zabuliene[1], Viktorija Maciuliene[2], Jurgita Urboniene[3] & Giedre Smailyte[4, 5]
[1]Faculty of Medicine, Vilnius University, Institute of Clinical Medicine, Vilnius, Lithuania; [2]Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [3]Vilnius university hospital ' Santaros klinikos', Center of Infectious Diseases, Vilnius, Lithuania; [4]National Cancer Institute, Vilnius, Lithuania; [5]Faculty of Medicine, Vilnius University, Institute of Health Sciences, Vilnius, Lithuania

Background
The incidence and mortality rates of thyroid cancer (TC) vary across nations for reasons such as registry accuracy, diagnostic and management practices, care quality, and standardization methods. Risk factors for TC include genetic abnormalities, iodine intake, TSH levels, autoimmune thyroid disease, gender, lifestyle, and environmental pollutants. In 2005, a mandatory salt iodization program was implemented in Lithuania. This study aims to analyse TC incidence and mortality trends in Lithuania between 1990 and 2019.
Methods
All TC cases (ICD-10 code C73) reported to the Lithuanian Cancer Registry from 1990 to 2019 were used in this study. The Registry covers the entire population of Lithuania (2.79 million per 2019 census). Age-specific and age-standardized incidence and mortality rates were calculated using the direct method with the EU-27 + EFTA reference population[1]. A Joinpoint regression model was used to estimate the average annual percentage change (AAPC).
Results
Over a 30-year period, 7, 753 TC cases were diagnosed. The mean age of the patients was 53.57 ± 15.22 years, 84% were women. The median follow-up duration was 11.5 years. The age-standardized incidence rate of TC in males ranged between 1.42 and 4.95/100, 000. AAPC increased significantly by 6.8% (95% CI 4.4, 28.2) in 1990–2004, and the changes in AAPC was insignificant at 1.8% (95% CI -10.7, 3.6) in 2004–2019. The age-standardized incidence rate in female ranged from 3.75 to 20.51 cases per 100, 000, with a significant increase in AAPC of 9.3% (95% CI 7.9, 10.8) in 1990–2004, and significant decrease in AAPC of 2.8% (95% CI -5.3, -0.1) in 2004–2019. The male mortality rate for TC ranged from 0.53 to 3.38/100, 000, with slight change in AAPC of 4.8% (95% CI -0.1, 25) in 1990–2002, and insignificant decrease in AAPC of 5.9% (95% CI -17.7, 3.2) in 2002–2019. In females it ranged from 0.7 to 5.38 cases per 100, 000, with a significant increase in AAPC of 4.2% (95% CI 2.3, 6.6) in 1990–2006 and a significant decrease in AAPC of 12.5% (95% CI -16.1, -9.8) in 2006–2019.
Conclusions
Incidence and mortality increased until the early 2000s, whith a stable or declining trend thereafter. Since 2006, there has been a marked decrease in mortality, especially in women, associated with the salt iodization program. Further studies are needed to confirm the link between salt iodization and reduction in mortality.

Predictive factors of recurrent and refractory disease in papillary thyroid cancers

Sameh Mezri[1], Chaima Zitouni[1], Ilyes Abid[1], Wadii Thabet[2] & Khemaies Akkari[1]
[1]Principal Military Hospital, ENT, Tunis, Tunisia; [2]Taher Sfar Hospital, Mahdia, Tunisia

Introduction
Papillary cancer accounts for 90 % of all thyroid cancers. Although this cancer has a good prognosis, some patients do not respond well to the conventional treatment (surgery and iodine radiation therapy).
Objective
The aim of this study is to identify predictive factors of persistent or refractory disease in papillary thyroid cancer.
Method
This is a retrospective study including 79 patients who underwent surgery for papillary cancer from January 2010 to December 2020, with a minimum follow-up period of 24 months. We divided them into two groups: The first group included patients with persistent or radioactive iodine (RAI) refractory disease, while the second group included disease-free patients. We conducted a statistical study in order to identify predictive factors of recurrence and refractory disease.
Results
Among our patients, 61 % were disease-free, 25, 6 % had persistent response and 12, 8 % had refractory response. Predictive factors of recurrent and RAI-refractory cancer were lateral lymph node dissection ($P = 0.049$), multifocal cancer ($P = 0.003$), nodal recurrence ($P = 0.032$), thyroglobulin level ($P = 0.02$) and cumulative doses of radioiodine ($P = 0.02$). On multivariate study, nodal recurrence and thyroglobulin level were predictive factors of recurrence or refractory disease.
Conclusion
In our study, nodal recurrence and thyroglobulin level were identified as independent factors of recurrent or refractory disease. These findings can contribute to adapt treatment strategies and follow-up protocols among high-risk patients.

Preoperative biological markers in papillary thyroid carcinoma

Sameh Mezri[1], Chaima Zitouni[1], Wadii Thabet[2], Salah Menasria[1] & Khemaies Akkari[1]
[1]Principal Military Hospital, ENT, Tunis, Tunisia; [2]Taher Sfar Hospital, Mahdia, Tunisia

Introduction
Carcinogenesis results from a disturbance in the balance between apoptosis and cell proliferation. This process involves inflammatory cells, which play a pro- and anticarcinogenic role.
Objective
the aim of this study is to investigate the status of neutrophil-lymphocyte ratio (NLR) and platelet-lymphocyte ratio (PLR) as potential biomarkers in predicting the evolutionary profile of papillary thyroid cancers.
Methods
This is a retrospective study including 80 patients operated on for papillary thyroid cancer at our department between 2010 and 2019. We studied the predictive role of NLR and PLR in metastases, multifocal forms and recurrences.
Results
NLR and PLR were significantly higher in cases of extra-thyroidal invasion ($P = 0.04$), multifocal tumours ($P = 0.01$), locoregional or distant lymph node metastases ($P = 0.03$); unlike gender, age, tumor size, histological subtype or TNM stage.
Conclusion
NLR and PLR are inexpensive and easy to perform. They can also predict the evolutionary profile of papillary thyroid cancers.

Medullary thyroid carcinoma presenting with carcinoid syndrome: a case report

Beril Turan Erdogan[1], Hatice Aksu[1], Burçak Cavnar Helvacı[2], Baris Saylam[3], Aynur Albayrak[4], Cevdet Aydin[5], Oya Topaloglu[5], Reyhan Ersoy[5] & Bekir Cakir[5]
[1]Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara; [2]Ankara Etlik City Hospital, Department of Endocrinology and Metabolism; [3]Ankara City Hospital, Department of General Surgery, Ankara; [4]Ankara City Hospital, Department of Pathology, Ankara; [5]Yildirim Beyazit University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara

Introduction
Medullary thyroid cancer (MTC) is characterized by elevated calcitonin levels, stemming from genetic factors or occurring sporadically. Carcinoid syndrome involves symptoms triggered by substances released by tumors, such as hormones and amines. This case report details a patient who developed carcinoid syndrome linked to medullary thyroid cancer.
Case
A 77-year-old male presented with flushing, diarrhea, and dizziness. No other health issues or medication use were reported, except for flushing and hypotension during a hemorrhoid operation a year ago. While routine tests showed normal results, neck CT revealed calcified nodules in the thyroid and pathological lymph nodes. Calcitonin was elevated at 11312 pg/ml, CEA at 126 ng/ml. Thyroid ultrasound displayed a 19.1 × 21 × 35.9 mm calcified nodule with pathological cervical lymph nodes. Ga-68-DOTA-PET confirmed thyroid and

cervical involvement. Fine needle aspiration biopsy confirmed medullary carcinoma. Catecholamine and 5-HIAA levels were normal. Chromogranin was normal. Surgery was planned for MTC, involving bilateral total thyroidectomy and lymph node dissection. Sandostatin infusion was initiated for carsinoid symptoms 24 hours before surgery, continuing intraoperatively and 48 hours postoperatively, gradually decreasing over a week. Postoperatively, calcitonin was 639 pg/ml, CEA 110 ng/ml on day one. Three months later, similar symptoms recurred, with calcitonin at 2600 pg/ml . Re-operation confirmed MTC, with a 5 cm retrosternal mass in the right lobe. Postoperatively, calcitonin decreased to 312 pg/ml . Two months later, a patient with similar complaints had a calcitonin level of 261 pg/ml, and residual tissue? was observed in the right lobe on thyroid ultrasonography. A spherical lymph node with the largest size of 10 cm was identified in the right level IV. Biopsy results were non-diognastic, and calcitonin washouts results of 4.9 pg/ml and 15.2 pg/ml, respectively. Due to ongoing symptoms, the patient was readmitted with a preliminary diagnosis of carcinoid syndrome, and short-acting sandostatin was initiated. After the post-operative follow-up Ga-68 DOTA-PET, as regression and the absence of new metastases were observed, tyrosine kinase inhibitors were not considered. The patient was discharged with lanreotide 120 mg/month, and no attacks were observed following the treatment.

Conclusion

MTC can manifest with flushing in carcinoid syndrome. When diagnosing flushing, consider MTC, pheochromocytoma, pancreatic tumors, hyperthyroidism, and male hypogonadism. Treating carcinoid syndrome involves addressing the underlying disease, and also sandostatin relieves symptoms in these patients. Keep MTC in mind when patients present with flushing or carcinoid syndrome.

Anaplastic thyroid carcinoma: 27-year study

Heyfa Belhadj-Miled[1], Houas Jihene[1], Ghammam Monia[1], Khalfi Oussama[2], El Omri Malika[1], Merherzi Abir[1], Bellakhdher Mouna[1], El Ghali Wassim[3], Hasni El Abed Yosra[1], Kermani Wassim[1] & Abdelkefi Mohamed[1]

[1]Farhat Hached Hospital, ENT Department, Sousse, Tunisia; [2]Radiology Department, Sousse, Tunisia; [3]Department of Anaesthesia, Sousse, Tunisia

Introduction

Anaplastic thyroid carcinoma, also known as undifferentiated thyroid carcinoma, is a rare, highly aggressive malignant tumor accounting for 2 to 3 percent of all thyroid gland neoplasms. Anaplastic thyroid carcinoma continues to be one of the most deadly diseases worldwide and carries a very poor prognosis. This study aimed to investigate the epidemiological, clinical, therapeutic, and evolutionary aspects of anaplastic thyroid carcinomas.

Materials and Methods

A retrospective study was conducted on 18 cases of anaplastic thyroid carcinomas collected and treated in our department over a 27-year period (1995-2022).

Results

In this comparative study involving 11 females and 7 males, the average age of participants was 62 years, ranging from 31 to 82 years. The average consultation delay was assessed at 4 months. Local compression symptoms were predominant, accounting for 83.3% of observed cases. Physical examination revealed goiters in 88.8% of patients, with an average size of 6 cm. Recurrent laryngeal paralysis was observed in 50% of patients, including 3 cases with bilateral involvement. Lymph node involvement was present in 77.7% of patients, while distant metastases were observed in 55.5% of cases. Ultrasound results indicated the presence of multinodular goiters in all participants (100%). Cervico-thoracic CT imaging (performed on 11 cases) revealed plunging goiters in 8 cases. Regarding management, emergency tracheotomy with biopsy was performed in 61.1% of patients, while the remaining 7 patients underwent total thyroidectomy with bilateral cervical dissection. Radiotherapy was administered to 14 patients, with 9 receiving palliative treatment. Patient outcomes demonstrated a high mortality rate of 77.7%, with survival less than one year. Three patients experienced local recurrence. However, one patient remains alive with complete remission, followed up for 14 years.

Conclusion

Anaplastic thyroid carcinoma is among the most aggressive cancers. Optimal management is still debated, and a standardized treatment strategy is yet to be established.

Performance of ultrasound using Kwak-TIRADS in thyroid nodule risk stratification

Antonios Tsakountakis[1], Konstantina Vouzouneraki[2], Emmanouil Mastorakis[3] & Elena Drakonaki[4]

[1]School of Medicine, University of Crete, Heraklion, Greece; [2]Department of Public Health and Clinical Medicine, Umeå University, Sweden and Independent Endocrinology practice, Ierapetra, Greece; [3]Department of Cytopathology, General Hospital "Venizeleio and Pananio", Heraklion, Greece; [4]Department of Anatomy, School of Medicine, University of Crete & Independent Radiology Practice, Heraklion, Greece

Introduction

This study aims to assess the performance of ultrasound using Kwak-TIRADS as the primary diagnostic tool for estimating papillary thyroid carcinoma (PTC) risk in thyroid nodules within the high-prevalence region of Crete, Greece.

Methods

A retrospective analysis was conducted on 802 thyroid nodules collected between 2018 and 2021. Nodules were categorized based on Kwak-TIRADS and compared against the Bethesda System for Reporting Thyroid Cytopathology (BSRTC). TIRADS 4a/4b served as the cutoff for benign/malignant categorization. Bethesda II category was used as the benign standard reference, and Bethesda V & VI categories as the malignant. Ultrasound and cytology tests were performed by a single experienced radiologist and cytologist, respectively.

Results

Of 802 thyroid nodules, 549 (68.4%) were benign, and 185 (23%) were malignant on cytology. The majority of nodules ($n = 391$; 48.7%) were classified as TIRADS 4a. Overall accuracy stood at 76.9%. Concordance rates between TIRADS 2, 3, 4a, and Bethesda II were 81%, while for TIRADS 4b, 4c, 5, and Bethesda IV & V, it was 62.2%. Excluding TIRADS 4 subcategories improved accuracy to 93.6% and 77.3%, respectively. The probability of a malignant fine-needle aspiration cytology (FNAC) was 77.33%, 60%, 43.63%, 18.67%, 1.29%, and 0% for TIRADS 5, 4C, 4B, 4A, 3, and 2, respectively. The probability of a benign FNAC was 100%, 93.53%, 73.4%, 41.81%, 24.44%, and 9.33% for TIRADS 2, 3, 4A, 4B, 4C, and 5, respectively. Sensitivity, specificity, and positive likelihood ratio were 58.9%, 92.5%, and 7.89, respectively. Excluding TIRADS 4, sensitivity increased to 95%, and specificity to 96.9%.

Conclusion

The study affirms strong concordance between Kwak-TIRADS and BSRTC, endorsing ultrasound as an effective first-line tool for thyroid nodule risk assessment. Notably, considering more ultrasound and clinical data in TIRADS 4 subcategories may optimize diagnostic accuracy. Kwak-TIRADS, characterized by simplicity and implementability, emerges as a reliable method for thyroid malignancy risk stratification.

DOI: 10.1530/endoabs.99.EP829

EP830

Falsely elevated serum calcitonin levels

Tamara Janić[1], Mirjana Stojković[1, 2], Sanja Klet[1], Bojan Marković[1], Biljana Nedeljković Beleslin[1, 2], Jasmina Ćirić[1, 2] & Miloš Žarković[1, 2]

[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center of Serbia, Thyroidology, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Serum calcitonin (CT) screening of thyroid nodules is a highly sensitive test for early diagnosis of medullary thyroid carcinoma (MTC) and is used for initial diagnosis and post-surgical follow-up. MTC is neuroendocrine tumor derived from parafollicular C cells which produce calcitonin. It is a rare tumor, accounting for 5-10% of all thyroid carcinomas, with a favorable prognosis if diagnosed early. A 74-year-old patient was referred to our clinic due to elevated basal CT levels. Routine thyroid ultrasonography revealed hypoechoic nodule in the left lobe 14.5x9.1 mm, with multiple calcifications (TIRADS 4a), and several nodules up to 12 mm in the right lobe. The initial thyroid hormone status showed high CT (203 pg/ml ; ref. $<$9.52 pg/ml -ECLIA), confirmed by repetition in the same laboratory. During the additional diagnostic at our clinic, basal CT levels were measured by two different assays, and both showed normal findings of basal CT (CT 2.8 ng/l; ref. 1-10.1 ng/l-IRMA); CT $<$ 0.5 ng/l (0-9.1 ng/l-ECLIA). Due to suspicion of interference, we performed serial dilutions of the serum that showed linearity (dilutions: 1:1, 1:2, 1:5, 1:10; CT 2.8; 5.8; 10.4; 11.5 ng/l, respectively - IRMA). Also, calcium stimulation test was performed and calcitonin response was determined in both laboratories. Results showed normal response in both laboratories (IRMA: 2.8; 6.8; 10.8; 11.3; 5.0 ng/l; ECLIA: $<$0.5; 4.0; 5.3; 5.0; 3.2 ng/l). CEA was normal (4.4; 4.3 µg/l). Fine-needle aspiration biopsy of the suspicious nodule was performed, and cytopathology showed atypia of unknown

significance (Bethesda classification system III). Due to pathological lymphadenopathy of the left side of the neck and suspicious ultrasound characteristics of the thyroid nodule, the patient was referred to surgery. Total thyroidectomy and left neck dissection were performed. PH diagnosis: multifocal papillary thyroid carcinoma (PTC). Tumor 15x10x1 mm in the left lobe and isthmus with infiltration of the capsule and muscle, and one focus of PTC 3 mm in the same lobe, and 3/9 metastatic LN with extracapsular extension, left, in region III and IV. Control CT measured in the initial laboratory was still elevated postoperatively (151 pg/ml), while normal measured by IRMA (4.5 ng/l). Based on the results, we concluded that the falsely elevated CT observed in the first laboratory was due to immunoassay interference. Immunoassay interference in CT determination is uncommon, but it can affect the course of diagnosis and treatment, so it should be considered in cases of conflicting laboratory results. The right diagnosis may prevent patient from complex diagnostic and therapeutic procedures.

Unintentional discovery of a second cancer amidst laryngeal carcinoma surgery: case report of two patients

Heyfa Belhadj-Miled[1], Houas Jihene[1], Monia Ghammam[1], Oussama Khalfi[2], Malika El Omri[1], Abir Meherzi[1], Mouna Bellakhdhar[1], El Ghali Wassim[3], Yosra Hasni El Abed[4], Wassim Kermani[1] & Mohamed Abdelkafi[1]
[1]Farhat Hached Hospital, ENT Department, Sousse, Tunisia; [2]Department of Radiology, Sousse, Tunisia; [3]Department of Anaesthesia, Sousse, Tunisia; [4]Department of endocrinology, Sousse, Tunisia

Introduction
The occurrence of a differentiated thyroid carcinoma alongside a squamous cell carcinoma of the larynx is a seldom-encountered clinical phenomenon. Typically, it presents as a histological surprise, as clinical examinations and thyroid gland scans often show no abnormalities. Limited clinical cases have been documented in the literature, and the management of such cases remains a subject of significant controversy.
Material and Methods
We conducted a retrospective study involving two patients who underwent surgery for epidermoid carcinoma of the larynx, where the unexpected discovery of papillary thyroid carcinoma occurred.
Results
Two patients, aged 63 and 68, both chronic smokers, sought medical attention for progressive dysphonia and recent-onset inspiratory dyspnea. Fibroscopic examination revealed distinct lesions: an ulcerating-burgeoning lesion on the left vocal cord, fixed in the first patient, and a lesion encompassing the entire right hemilarynx, fixed in the second patient. Biopsy confirmed infiltrating, moderately differentiated squamous cell carcinoma in both cases. Tumor staging was T4N0M0 for the first patient and T4aN1 cm1 with bone and lytic lesions for the second patient. Surgical interventions included total pharyngo-laryngectomy with bilateral functional lymph node curage for both patients. In addition, the first patient underwent a left loboisthmectomy, revealing papillary thyroid carcinoma on extemporaneous examination, leading to totalization with bilateral mediastino-recurrent curage. The second patient underwent an immediate total thyroidectomy. The final pathology indicated the coexistence of squamous cell carcinoma of the larynx with papillary carcinoma of the left thyroid lobe (3.2 cm) in the first case and multiple papillary microcarcinomas involving both thyroid lobes (0.3 to 0.8 cm) in the second case. Both patients received external radiotherapy in conjunction with treatment for squamous cell carcinoma. Additionally, both patients were recommended further iratherapy and underwent a single 100 mCi ablative treatment with white mapping on scanning.
Conclusion
The coexistence of differentiated thyroid carcinoma with squamous cell carcinoma of the larynx is a rare clinical finding, often surprising from a histological standpoint. Despite normal clinical examinations and thyroid scans, few cases have been reported in the literature, and the optimal management strategy remains a subject of significant controversy.

Medullary thyroid cancer: case series presentation

Rachida Bouattay[1], nawres bouaziz[1], Safa Jemli[1], Mehdi Ferjaoui[1], Elkorbi Amel[1]. Naourez Kolsi[1]. Harrathi Khaled[1] & Jamel Koubaa[1]
[1]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Introduction
Medullary thyroid carcinoma (MTC) is a rare neuro-endocrine tumor arising from the parafollicular cells of the thyroid gland. MTC produces calcitonin, and elevated calcitonin level is an essential feature of this tumor. MTC constitutes approximately 4% to 10% of all thyroid cancers. The objective of our study is to discuss the clinical aspects and therapeutic modalities of MTC through our series with review of the literature.
Patients and Methods
This is a retrospective study involving 11 cases of medullary thyroid carcinoma, collected over a period of 21 years (2001-2021).
Results
The mean age was 43 years (ranging from 36 to 90 years). The sex ratio was 4.5 (9 males/2 females). The average consultation delay was 5 months. The primary reason for consultation was an anterior basicervical swelling in 81.8% of cases, dysphonia in 9.1% of cases, and bone pain in 9.1% of cases. Physical examination revealed an anterior basicervical swelling in all cases. Cervical lymphadenopathy was found in 63.6% of cases. Thyrocalcitonin levels were assessed in two patient and were found to be elevated. Neck ultrasound, performed for all patients, revealed thyroid nodules classified as EU TIRADS IV in 36.4% of cases and EU TIRADS V in 63.6% of cases. The diagnosis was made after fine needle aspiration in 45.5% of cases. All our patients underwent total thyroidectomy with central neck dissection. Eight patients had bilateral functional neck dissection in six cases. A total laryngectomy was indicated in one case, due to tumor extension to the trachea and cricoid cartilage. Adjuvent radiotherapy was performed in 9 cases. The final histologic exam showed locoregional nodal metastasis in seven patients. Distant metastases were found in 4 cases (pulmonary, hepatic, osseous, and nodal). The follow-up was marked by the absence of recurrence in 7 patients, superior mediastinal nodal recurrence in one patient, death in one case. Two patients were lost to follow-up.
Discussion/conclusion
Seventy-five percent to eighty percent of MTCs are sporadic, and the remainder is familial as part of multiple endocrine neoplasias (MEN) 2A, MEN 2B, and familial medullary thyroid cancer. Prophylactic thyroidectomy is recommended for patients with mutations that put them at high risk. Various tyrosine kinase inhibitors are approved for use in progressive, metastatic medullary thyroid cancer. Finally, prognosis depends on the age of the patient, histologic grade, and status of surgical resection. The five-year survival for stages 1 to 3 is 93% compared to 28% for stage 4.

The value of SPECT-CT in the follow-up of patients with differentiated thyroid carcinoma

Houas Jihene[1], Heyfa Belhadj-Miled[1], Monia Ghammam[1], Oussama Khalfi[2], Malika El Omri[1], Abir Meherzi[1], Mouna Bellakhdhar[1], El Ghali Wassim[3], Yosra Hasni El Abed[4], Wassim Kermani[1] & Mohamed Abdelkafi[1]
[1]Farhat Hached Hospital, ENT Department, Sousse, Tunisia; [2]Department of Radiology, Sousse, Tunisia; [3]Department of Anaesthesia, Sousse, Tunisia; [4]Departement of Endocrinology, Sousse, Tunisia

Introduction
In the follow-up of differentiated thyroid cancer (DTC), essential tools include iodine-131 scintigraphic imaging, coupled with cervical ultrasound and thyroglobulin measurement. An additional valuable tool is single-photon emission computed tomography combined with computed tomography (SPECT-CT), which precisely localizes fixation anomalies observed during whole-body scans. The aim of our study is to demonstrate, through a case study, the diagnostic contribution of SPECT-CT in identifying mediastinal lymphadenopathy during the follow-up of papillary carcinoma.
Observation
A 29-year-old woman underwent a comprehensive treatment regimen for papillary thyroid carcinoma, including total thyroidectomy, bilateral mediastino-recurrent lymph node dissection, and adjuvant radioiodine therapy. The tumor was classified as pt1b N1b M0. Following two courses of 100 mCi radioactive iodine, a post-therapeutic scan revealed a moderately intense mid-cervical focus of uptake, along with a less intense superior mediastinal focus. The thyroglobulin Tg T4 off assay showed elevated levels (>500 ng/ml). Further investigation using hybrid imaging SPECT-CT focused on the cervicothoracic region provided a more detailed response to the elevated thyroglobulin. The mediastinal focus was identified as a roughly oval-shaped tissue mass measuring 45*32*20 mm lateral to the trachea, causing a mass effect on the pulmonary apex. Surgical exploration uncovered a 5 cm right mediastinal mass adjacent to the right brachiocephalic trunk. Additional functional right lymph node dissection with excision of the mediastinal mass was performed. The final histopathological

examination confirmed the metastatic nodal nature of the mediastinal lymphadenopathy.
Conclusion
SPECT-CT plays a crucial role in studying iodine-131 fixation anomalies in the context of DTC. It enables precise anatomical localization of lesions, enhances the detection of metastases overlooked by whole-body scans, and aids in assessing questionable fixation anomalies.

Papillary carcinoma of the thyroid in patient with Graves' disease

Rachida Bouattay[1], Nawres Bouaziz[1], Amaidi Rami[1], Mehdi Ferjaoui[1], Elkorbi Amel[1], Naourez Kolsi[1], Harrathi Khaled[1] & Jamel Koubaa[1]
[1]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Introduction
The association of thyroid carcinoma with Graves' disease (GD) is considered rare. Over 85% of thyroid cancer in patients with GD was papillary thyroid carcinoma, although other histologic types including follicular, medullary, and anaplastic carcinoma could be found in some studies. We report here a series of cases of thyroid cancer discovered in patients with GD, in order to evaluate the incidence of thyroid carcinoma in patients operated on for GD and to identify criteria which may predict malignancy.
Patients and Methods
This is a retrospective study of patients who underwent surgery for Graves' disease between 2010 and 2021, and for whom the pathological study revealed a thyroid carcinoma.
Results
Among 51 patients operated on for Graves' disease, thyroid cancer was discovered in nine patients (17.6%). These were 9 women with an average age of 42 years (27 to 72 years). The indication for initial surgery was failure of medical treatment for Grave's disease in 6 cases (66.7%) and papillary carcinoma diagnosed by fine needle aspiration of a thyroid nodule classified EUTIRADS IV or V in 3 cases (33.3%). A total thyroidectomy with bilateral central neck dissection was performed in all patients; due to malignancy on frozen section examination. The final histological examination confirmed, in addition to characteristic Graves' lesions, the presence of a thyroid cancer. This one was a papillary microcarcinomas in 8 cases (88.7%) and a papillary carcinoma in one case (11.3%). Cancer was multifocal in only one patient. Furthermore, it was associated with lymph node metastasis in 8 patients. The nine patients underwent radioactive iodine therapy, with an average of 2-3 sessions per patient (100 mCi/session), until achieving a white cartography. The follow-up was marked by absence of recurrence in all patients.
Discussion/Conclusion
It was accepted that hyperthyroidism inhibited the development of neoplastic cells within the thyroid parenchyma. This concept is no longer accepted, even though the link between hyperthyroidism and cancer is controversial. The prevalence of thyroid cancer in Graves' disease varies in the series between 0.4% and 9.8%. Literature shows that the presence of thyroid nodule(s) in patients with GD (25-33% of cases) may be considered as an indication for surgery because it is a suggestive indication of cancer. The most adequate radical surgery in this situation is to perform a total thyroidectomy. It has the advantage of better adjusting postoperative substitutive opotherapy doses and allows for a therapeutic supplement based on radioactive iodine.

Undifferentiated (Anaplastic) thyroid carcinoma: a report of 8 cases

Rachida Bouattay[1], Nawres Bouaziz[1], Mehdi Ferjaoui[1], Elkorbi Amel[1], Naourez Kolsi[1], Harrathi Khaled[1] & Jamel Koubaa[1]
[1]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Objective
The epithelial cancers of the thyroid include papillary, follicular, hurtle and anaplastic. These are divided into well, poorly differentiated thyroid cancer and undifferentiated (or anaplastic) thyroid cancer (ATC). ATC is uncommon and very agressive entity. It is responsible for 7, 5% of all thyroid cancers. The aim of our study is to discuss the clinical aspects and therapeutic modalities of ATC through our series with review of the literature.
Patients and Methods
This is a retrospective study that collected patients taken care of in our department for ATC over a period of 30 years.
Results
Our series included 8 patients, comprising 7 females and one male, with a mean age of 69 years. The main reason for consultation was a rapidly-growing basicervical anterior and/or lateral cervical mass in all cases. Compressive signs were present in 3 patients. The average consultation delay was 3 months. Physical examination revealed a goiter with an average size of 5 cm, with tenderness in 3 cases. Jugulodigastric lymphadenopathy was associated in 5 cases and supraclavicular in one case. Indirect laryngoscopy performed for all patients showed laryngeal palsy in two patients. Ultrasound was performed for 6 patients and revealed a multinodular goiter classified as EUTIRADS IV in 3 cases and EUTIRADS V in 3 cases. Cervico-thoracic computed tomography was performed in 3 patients due to the presence of compressive signs. Total thyroidectomy with bilateral mediastino-recurential curage was performed in 4 cases. Lateral dissection was carried out in 3 cases and deemed impossible in two cases due to adhesion of lymph nodes to the esophagus and trachea. The tumor was considered unresectable in 3 cases. External radiotherapy was indicated in 6 cases, combined with radioactive iodine therapy in 3 cases due to the association with papillary carcinoma. The average follow-up duration was 6 months.
Discussion/conclusion
Anaplastic thyroid cancer remains one of the most deadly diseases. According to literature, patients with ATC have a median survival of 5 months and less than 20% survive 1 year. Early tumor dissemination results in 20-50% of patients having distant metastases and 90% having adjacent tissue invasion on presentation. This highlights the necessity for effective combined therapy. Resectable disease may benefit from a multimodal (surgery, IMRT for loco regional control, and systemic therapy) approach. However, a majority of patients present with unresectable locoregional disease. Early palliative care involvement is inclusive of life-prolonging therapies. ATC management demands rapid and integrated multidisciplinary decision making.

Association between hyperthyroidism and differentiated thyroid cancer: association or coincidence? about 15 cases

Doaa El Bazi[1], Haraj Nassim Essabah[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital - Casablanca, Morocco Clinical Neuroscience and Mental Health Laboratory Faculty of Medicine and Pharmacy - Hassan II University, Endocrinology, Diabetology, Nutrition and Metabolic Diseases Department, Casablanca, Morocco

Introduction
The association between hyperthyroidism and differentiated thyroid cancer has become increasingly frequent. The etiopathogenesis remains controversial. We report 15 cases of patients, in whom an incidental association with differentiated thyroid cancer was identified.
MaterialS and Methods
Retrospective study over a 37-year period (1986-2023) including 15 patients followed at the Department of Endocrinology and Diabetology for hyperthyroidism, in whom an incidental association with differentiated thyroid cancer was discovered on anatomopathological examination.
Results
The average age was 43.4 years, with a clear female predominance 11W/4M. Nine patients had a toxic nodule, four a basedow's goiters, and two had graves's disease, one of whom had a severe graves orbitopathy, who had benefited from corticosteroid boluses and decompression surgery. Total thyroidectomy was performed in all patients, with suspicion of malignancy in the preoperative evaluation in one patient. Histopathological examination revealed papillary carcinoma in four patients, microcarcinoma in nine patients, NIFT-P (Non-Invasive Follicular Thyroid neoplasm with Papillary-like nuclear features) in one patient, and papillary carcinoma with an insular component in one patient, who also had retro-orbital and spinal metastasis. Stage pT1a was the most frequent (9 patients). Iratherapy was indicated in four patients due to multifocality. The outcome was marked by remission in 93% of the patients. One death was recorded in the patient with insular carcinoma.

Conclusions
Based on our series and observations reported in the literature, hyperthyroidism does not guarantee the absence of cancer, and does not eliminate this possibility. The nature of thyroid nodules must be carefully assessed before surgery.

EP838

Intra-Thyroid metastases of clear cell renal carcinoma - analysis of two complex cases

Sara Ribeiro[1], Juliana Gonçalves[1], Joao Carlos Almeida[1], Ana Varela[1] & Joana Queirós[1]
[1]São João Universitary Hospital Center, Porto, Portugal

Introduction
Intra-thyroid metastases are infrequent, comprising only 1-3% of all thyroid malignancies. Renal cell carcinoma, particularly of the clear cell type (CCRC), stands out as the predominant kidney malignancy and the most common primary source of intra-thyroid metastases, often manifesting several years post-diagnosis. This report highlights two cases of CCRC metastasis to the thyroid, both featuring deceptive cytological findings.
Case 1
A 60-year-old woman, post-right nephrectomy for a T1bN0M0 CCRC a year prior, exhibited a 3.5×2.4×6.4 cm nodule in the right thyroid lobe on ultrasound, characterized by hypoechoicity, internal vascularization, and irregular borders (TIRADS 5). Multiple isoechoic nodules, the largest measuring 1.6×1.4×2.3 cm (TIRADS 3), were evident in the left lobe. Fine needle aspiration revealed colloid, small epithelial cell clusters with round nuclei, and rare macrophages, indicative of follicular nodular disease. Incongruence between ultrasound and cytology, coupled with the lesion's size, prompted total thyroidectomy. Macroscopical evaluation of the surgical specimen unveiled a 4×4×2 cm lesion with a "nodule in nodule" configuration and hemorrhagic areas. Histopathological analysis of the lesion showed a tumor with solid growth pattern composed of cells with clear cytoplasm, positive for CD10, racemase, and PAX8. The absence of TTF1, thyroglobulin, chromogranin, synaptophysin, and calcitonin confirmed CCRC metastasis. Left lobe lesions were due to thyroid follicular nodular disease. Case 2: A 74-year-old woman, eight years post-left nephrectomy for CCRC, was referred for an Endocrinology appointment following right adrenalectomy for a suspicious mass seven years post-diagnosis. Physical examination revealed a cervical mass. Initial ultrasound unveiled a predominantly cystic nodule (4.5×2.6 cm, ACR-TIRADS 3). A subsequent evaluation six months later showcased a transformation into a predominantly solid, isoechoic nodule, 4.6 cm in diameter, with localized vascularity. Cytology suggested benign follicular disease. Owing to the development of compressive symptoms, right lobectomy was pursued. Histological analysis of both thyroid and adrenal lesions was compatible with CCRC metastasis.
Conclusions
Identifying metastatic CCRC through fine needle aspiration proves challenging due to overlapping clear cell features with other lesions (thyroid follicular neoplasms and intrathyroidal parathyroid tumors) and to the potential for coexistence with primary thyroid neoplasms ("tumor to tumor metastasis"). A thyroid nodule in a patient with a history of RCC should evoke a high index of suspicion, demanding comprehensive judgment based on ultrasonographic and cytological findings. Surgical resection may be warranted for definitive characterization.

Chronic hashimoto's thyroiditis in patients with differentiated thyroid carcinoma- a case-control retrospective study

Adishah Çerma[1] & Agron Ylli[2]
[1]Kukës Regional Hospital, Internal Medicine, Kukës, Albania; [2]Mother Teresa University Hospital, Endocrinology, Diabetology and Metabolic Diseases, Tirana, Albania

Introduction
Co-occurrence of differentiated thyroid carcinoma (DTC) and chronic autoimmune thyroiditis (HT) is a debatable subject in many studies. It's noted that patients with HT have less aggressive tumors and a better prognosis, possibly related to the immune response against tumoral cells.
Aim
To evaluate demographic, clinical, laboratorial, histopathological parameters in patients with HT and DTC, compared to the patients without HT, focusing on differences in tumor aggressivity.
Methods
This study is a case-control retrospective study, where 106 patients were evaluated, 68 patients with HT and DTC and a control group of 38 patients without HT. The data are analyzed using IBM-SPSS v.24.
Results
Patients with HT and DTC were mostly females (95.6%) and of the age group 41-50 years old, with a mean age of 47.34 years old. In most of the patients, biopsy description was that of papillary carcinoma (52.9%), with predomination of classic variant. The majority of primary tumors in patients with HT were 0-2 cm (69.7%), unilateral (76.3%) and unifocal (68.2%). 66.1% of patients with HT had no capsular invasion, significantly less than the patients without HT (*P* 0.016). Vascular and extrathyroidal, despite being less frequent, had no statistical significance. Only 11.7% of the patients with HT have lymph node metastasis and advanced age proved to be the only relevant risk factor for that (*P* 0.002). None of the patients with HT had distant metastasis, which compared to the group without HT was statistically significant (*P* 0.05). All patient were treated with radioactive iodine and the most frequently used dose was 100 mCi (48.8%). Unlike the group without HT, all patients with HT took only one dose of radioactive iodine (*P* 0.021).
Conclusions
Patients with HT have some features which are less aggressive compared to those without HT as: less capsular invasion, lack of distant metastasis and less frequently treated with radioactive iodine. Because of their risk of malignancy, patients with HT should be monitored periodically.

Warthin-Type variant of papillary thyroid carcinoma: a case report

Rahal Amel[1]
[1]Bologhine Hospital, Endocrinology, Algiers, Algeria

Introduction
Warthin-like thyroid tumor (WLPTC) is a rare variant of papillary thyroid carcinoma characterized by a lymphoid stroma. Approximately 95 observations have been published in the literature. Like papillary carcinoma, Warthin-like thyroid tumors have a good prognosis. The key to diagnosis is anatomopathological examination. In this regard, we report a case of WLPTC because of its rarity.
Observation
Patient aged 56, known diabetic for 6 years on Glucophage. She has been followed up since 2012 (10 years ago) for hypothyroidism of autoimmune origin, and it was not until 1 year ago that an ultrasound examination revealed a thyroid of heterogeneous hypoechoic echostructure, with the presence of two supra-central nodules (right and left), classified EU TIRADS 5. Cytopuncture strongly suggestive of carcinoma on thyroiditis. The patient underwent surgery 6 months later, consisting of total thyroidectomy with bilateral central lymph node curage. Anatomopathological examination of the right and left lobes showed a malignant tumour proliferation of epithelial nature and predominantly papillary architecture. The papillae were of variable size, with a richly lymphocytic axis bordered by an epithelium of large polygonal cells with abundant granular eosinophilic cytoplasm, and enlarged nuclei with ground-glass chromatin and irregular incisure nuclear membranes. These nuclei show overlapping and moderate anisokaryosis. The stroma is squirrel-like and fibroinflammatory, with local calcospherites. This appearance corresponds to a papillary thyroid carcinoma variant warthin like class PT2m 0N+/22N, Mx. Six-month postoperative follow-up was without incidents.
Conclusion
The aim of this work is to outline the clinical, histological and immunohistochemical features, as well as the differential diagnoses and prognosis of this rare entity.

Rare find of giant lymph node metastasis due to papillary thyroid microcarcinoma

Alida Nicoleta Dumitru[1] & Alina Sucaliuc[1]
[1]National Institute of Endocrinology, IV, Bucharest, Romania

Introduction
Papillary microcarcinoma is a malignant disease of the thyroid measuring less than 1 centimeter at its highest dimension. It has a good prognosis with a small rate of metastasis and giant adenopathies with rapid growth are a rare find.
Case report
We present the case of a 75-year-old male patient, who recently underwent surgery for massive laterocervical adenopathy, measuring 50/38.5/48.5 mm in diameters, with rapid growth (in approximately three months), well defined, in close contact with right internal jugular vein. Histological exam revealed cystic metastasis of thyroid papillary carcinoma and immunohistochemical stains were positive for paired-box gene 8 (PAX8), cytokeratin 19 (CK 19), thyroid transcription factor 1 (TTF 1), Thyroglobulin (Tg), p40 with Ki67 proliferation index of 15%. Preoperative full body CT scan did not find other distant tumors, so no associated distant metastasis. He was admitted in our department in good physical condition and thyroid ultrasound disclosed three heterogenous microfoci in the right thyroid lobe, of 0.1 mm in the largest dimension. Biochemical exams showed normal thyroid function and negative calcitonin. Total thyroidectomy was performed and histological exam confirmed the presence of a 0.25/0.1 cm, non-encapsulated, lymphovascular and perivascular invasive papillary thyroid microcarcinoma. Post surgery, ultrasound found paratracheal thyroid tissue, confirmed by the 131I Thyroid scintigraphy. Therapy with 100 micrograms of Levothyroxine was initiated with good adaptation to therapy. Postoperative follow-up included non-stimulated thyroglobulin of 0.04uUi/ml, stimulated thyroglobulin of 3.14 uUi/ml, antithyroglobulin antibodies in the normal range. The next step was to administer 50mCi radioiodine. Unfortunately, the patient was lost to follow up.
Conclusions
One should consider papillary microcarcinoma when it comes to giant lymph nodes with rapid growth.

Challenging thyroid storm in pregnancy case report

Hemmat El Haddad[1], Heba Murad[1], Nehal Hamdy[1], Rokaya Abdel Aziz[1], Heba Moustafa[1], Randa Salam[1], Mohamed Magdy[1], Fady Nagy[1] & Ahmed Atef[1]
[1]Cairo University, Internal Medicine, Endocrinology, Cairo, Egypt

Introduction
Thyroid storm is a rare complication of hyperthyroidism. In pregnant patients can cause spontaneous abortions, fetal demise. Aggressive treatment is needed.
Case report
26 years female 20 weeks pregnant; Graves' disease for five years, was on carbimazole but she discontinued since she became pregnant Shortly after that, she started to complain with progressive dyspnea at less than ordinary effort, bilateral lower limb swelling, increase in abdominal girth, 10 days ago, she developed lower abdominal pain and severe vaginal bleeding, Spontaneous abortion of her twins occurred The patient was orthopnea, pulse 105 /mint, temp 38c, RR 25/mint, BP 150/90 and generalized edema, she was admitted to the Gynecological ICU for stabilization and further management Exophthalmos, staring look, Pallor, Neck veins: congested pulsating Hb 8.5 g/dl, TSH: 0.005 μIU/ml (normal range: 0.55–4.78), Free T3: 7 pg/dl, Free T4 = 3 ng/dl Ejection fraction: 48%. The patient was diagnosed as a case of thyroid storm (based on clinical manifestations and low TSH 0.005) complicated by congestive heart failure. Treatment was given (Inderal 40 mg/12 hour carbimazole 1 mg/day, hydrocortisone 1 mg/8 hours, Fursemide infusion, Spironolactone 1 mg/day, Ramipril 1 mg. The general condition of the patient partially improved and then she was discharged from ICU. Improvement of her condition on carbimazole 1 mg/day however TSH was 0.05 thyroidectomy was done on thyroxin replacement
Conclusions
Thyroid storm in pregnancy is a medical emergency needs high index of suspicion and early management by a multidisciplinary team Thyroidectomy may be the only option in selected cases like our case.

EP881

Early detection and management of hypocalcaemia after total thyroidectomy

Dewan Mahmud Hasan[1]
[1]Bangladesh Specialized Hospital, Otolaryngology & Head-Neck Surgery, Dhaka, Bangladesh

Background
After total thyroidectomy Hypocalcemia is the most frequent complication. Serum calcium levels are reliable only 48–72 hours postoperatively. Now a day's measurement of iPTH as an early predictor of postoperative hypocalcemia is practiced in many centers.
Objectives
To share our experience for the diagnosis and treatment of post-operative transient and permanent hypoparathyroidism after total thyroidectomy and to assess the ability of iPTH in predicting postoperative hypocalcemia.
Methods
Our total number of patients is 84. iPTH level was measured on 1st postoperative day. Patients were followed up for 1 to 6 months post operatively. Unfortunately, we lose a big number of our patients from follow up.
Results
iPTH on the first postoperative day equal to or less than 15 pg/ml were found to be norm calcemic. iPTH less than 10 pg/ml were disturbed parathyroid hormone metabolism. Hypocalcemia is the most common complication recognized in patients of total thyroidectomy. Around 50% of patients who suffer from transient hypoparathyroidism develop permanent hypoparathyroidism. Measurement of iPTH after surgery is the mainstay of early identification tool in our country though combining postoperative iPTH and serum calcium level can entail more accurate result.
Conclusion
Measurement of iPTH on first postoperative day allow accurate prediction of postoperative parathyroid function in 99% cases. Morbidity due to hypoparathyroidism can be reduced by appropriate dose adjustment of supplemental therapy & lifelong follow up. Till date calcium & vitamin D is the drug of choice.

Thyroiditis revealing a rare congenital anomaly: about 3 cases

El Omri Malika[1], Jemli S[1], Bellakhdher Mouna[1], Meherzi Abir[1], Houas Jihene[1], Ghammem Monia[1], Ach Taieb[2], Kermani Wassim[1] & Abdelkefi Mohamed[1]
[1]ENT Department Farhat Hached Hospital, Sousse, Tunisia; [2]Endocrinology Department Farhat Hached Hospital, Sousse, Tunisia

Introduction
Fourth branchial lesions are a rare cause of inflammatory neck masses in children. The aim is to emphasize the pathophysiology, clinical features, and therapeutic modalities of the fourth branchial cleft cyst. We report three cases of fourth branchial arch cysts complicated by superinfection, collected in our ENT and neck surgery department.
Results
There were three male children aged of 4, 6 and 18 years old respectively. They consulted our department foran acute basicervical swelling in one case and an isolated acute left cervical swelling in another case. The swelling was associated with torticollis in the third case. Physical Examination found a basicervical inflamed mass whose size varied between 4 and 8 cm. Cervical ultrasound showed a basicervical abscess pushing the homolateral thyroid lobe, hypopharyngoscopy suggested a piriform sinus fistula in two cases. Computed tomography scan revealed a left lateral thyroid cystic mass in one case. All our patients underwent intravenous antibiotics therapy. Surgical drainage of the abscess was required in two cases. In a later step, we performed chemical cauterization of the fistula within piriform sinus in two cases and hemithyroidectomy in three of them. Postoperative outcomes were favorable without any recurrence for the all the cases.
Conclusion
The fourth branchial cyst are unfrequent congenital anomalies occurring in 2% to 4%. This case highlights the significance of including congenital anomalies, especially rare etiologies, as a potential differential diagnosis when assessing pediatric neck masses.

Abnormal liver function tests in patients with graves' disease

Ibtissem Oueslati[1, 1], Cherchir Faten[2], Sabrina Ayari[1], Arige Abid[1], Meriem Yazidi[1] & Melika Chihaoui[1]
[1]La Rabta University Hospital, Endocrinology, Tunis, Tunisia; [2]La Rabta University Hospital, Endocrinology, Tunis, Tunisia

Introduction
In patients with Graves' disease, uncontrolled thyrotoxicosis causes liver dysfunction in 37 to 78% of cases. This is commonly revealed by abnormal elevation of liver enzymes including hepatic cytolysis and cholestasis. The aim of the present study was to determine the prevalence of liver dysfunction and its associated factors in patients with Graves' disease.
Methods
This was a monocentric retrospective study including 108 patients with hyperthyroidism secondary to Graves' disease. Patients with previous history of liver diseases were excluded. Baseline clinical and biological data were collected.
Results
The mean age at the diagnosis of Graves' disease was 45.9 $\pm$ 13.9 with a sex-ratio (F/M) of 1.9. Biochemical investigations revealed hepatic cytolysis and cholestasis in 20.6 and 33.3% of cases, respectively. The elevation of alkaline phosphatase was the most common abnormality (26.7 %). FT4 level ($P<0.001$), creatinine clearance ($P=0.036$) and transaminase levels ($P<0.001$) were significantly higher in patients with cholestasis compared with those without cholestasis. Moreover, male gender (O$r=1.7$, $P=0.045$), smoking (O$r=4.0$, $P=0.002$), and regular alcohol consumption (O$r=5.6$, $P=0.027$) were associated to cholestasis. Alcohol consumption ($P=0.013$) was also associated with an increased risk of cytolysis. Patients with hepatic cytolysis had higher levels of FT4 ($P=0.044$), alkaline phosphatase levels ($P=0.019$) and GGT levels ($P<0.001$) than those without cytolysis.
Conclusions
Graves' disease is associated with a considerable risk of liver dysfunction. The present study showed that gender, smoking alcohol consumption and the severity of hyperthyroidism significantly interfere with liver dysfunction.

Diagnostic challenges to differentiate central hyperthyroidism (Resistance to thyroid hormone and TSHoma): a case report

Navya Basavaraju[1], Elaf Al-Samaraaie[1], Catherine Jones[1] & Probal Moulik[1]
[1]Royal Shrewsbury Hospital, United Kingdom

Introduction
The term syndrome of 'inappropriate secretion of TSH' was originally coined to indicate two forms of central hyperthyroidism-resistance to thyroid hormone (RTH) and thyrotropin (TSH)-secreting pituitary adenomas (TSHomas). We present such a case that poses a diagnostic challenge.
Case
A 44-year-old female presented with fatigue post COVID infection four months ago. Thyroid function tests (TFT) revealed high thyroid-stimulating hormone (TSH) 6.1 mU/l (range:0.3-4.2) with raised free thyroxine (fT4) 25.1 pmol/l (range:11-22) and free triiodothyronine (fT3) 7.1 pmol/l (range:3.1-6.8). She denied palpitations, weight loss, bowel changes, or menstrual irregularities. She was not on any regular or over the counter medications. She has 2 children and no family history of thyroid disorders. On examination, BMI 1 kg/m^2, pulse 70beats/min, regular, clinically euthyroid, no palpable goitre, visual fields normal. She had normal TSH at 1.1 mU/l and 3.1 mU/l, checked 14years and 4years back. Blood investigations showed normal anterior pituitary profile including short synacthen test. Repeat TFT's revealed a similar pattern and assay interference was ruled out by DELFIA for TSH, Atellica for fT3 and radioligand binding assay for familial dysalbuminaemic hyperthyroxinemia (FDH) negative in two referral laboratories. Serum glycoprotein alpha subunit (α-GSU) was 0.37IU/l (range: <3.0). Pituitary MRI scan showed a 1 mm anterior pituitary microadenoma. Thyroid pertechnetate scan suggested increased thyroid uptake. TRH (thyrotropin-releasing hormone) stimulation test showed less than 1.5-fold rise in TSH at 20minutes from baseline. T3 suppression test showed partial suppression of TSH at day 10. She is awaiting results of genetic testing for thyroid hormone receptor β (TRβ) gene mutation and somatostatin analogue suppression test.
Discussion
Assay interference should be first excluded with high fT4, fT3 and TSH prior considering other causes. RTH and TSHoma are rare and differentiating the two could be challenging. RTH is inherited as autosomal dominant in 80% of cases, with mutation in TRβ in majority. TSHoma accounts for 1% of all pituitary tumours, with prevalence of one per million, 80% being macroadenomas. Alpha-subunit is raised in TSHoma in 70% cases. TRH stimulation test with more than fivefold increase in TSH is suggestive of RTH while in TSHoma there is an attenuated (no greater than 1.5-fold increase) response in TSH. In T3 suppression test, TSH suppression occurs in RTH while absent in TSHoma. Response to Octreotide LAR, but not short acting single octreotide injection, is seen in TSHoma, but not RTH.
Conclusion
A panel of clinical, biochemical, radiological, dynamic testing, and genetic analysis, help to differentiate between RTH and TSHoma.

Treatment-Induced myopathy in a patient with graves' thyrotoxicosis

Amina Al-Qaysi[1], Nwe Aung[2] & Chitrabhanu Ballav[2]
[1]Stoke Mandeville Hospital; [2]Stoke Mandeville Hospital, Endocrinology & Diabetes, Aylesbury, United Kingdom

Introduction
Thyrotoxicosis as well as its treatment with Carbimazole (CBZ) or Propylthiouracil (PTU) have been reported to result in myopathy. Onset of myalgia during the treatment of thyrotoxicosis may cause a diagnostic challenge in distinguishing the thyrotoxic from the drug-induced myopathy. We report such a case where myopathy was induced by treatment with both CBZ and PTU.
Case report
We report the case of a 26-year-old Chinese lady presenting with palpitations due to Graves' thyrotoxicosis (TSH <0.01 mIU/l, Free T4 52.4 pmol/l, TSH receptor antibodies 7.1 IU/ml, and Anti-Thyroid Peroxidase antibodies >1000 IU/ml). She developed myalgia, muscle cramps and weakness involving the upper and lower limbs with significantly elevated Creatine Kinase (CK) of 2651 U/l (normal range 29 – 168 U/l) when she was commenced on CBZ 40 mg daily. The MRI scan of all limbs showed normal muscle bulk with no evidence of myositis. Although her free thyroid hormones settled with CBZ, her symptoms did not respond to reducing the dose to 20 mg daily. Changing the treatment to PTU 100 mg twice daily resulted in a transient improvement of symptoms and a reduction of the CK level. Her serum potassium, calcium, and renal functions were within normal ranges. The muscle cramps and myalgia recurred while on PTU in two weeks with high CK despite normal free thyroid hormones and completely suppressed TSH. Her TSH receptor antibody level remained elevated throughout the course of treatment. Since she had myopathy with both antithyroid agents, she has been referred for total thyroidectomy.
Conclusion
We report a patient with Graves' thyrotoxicosis who developed myopathy during anti-thyroid drugs treatment. High CK and normal potassium levels are reported more frequently in drug-induced myopathy, unlike Grave's myopathy which often presents with normal CK and hypokalemia. This alongside the sequence of symptom onset may help distinguishing between the two conditions.

Transient thyrotoxicosis and hypothyroidism after combination therapy with pd-1 and ctla-4 inhibitors for cervical cancer

Ketevan Lomidze[1, 2], Nino Kikodze[1], Marine Gordeladze[3], Tinatin Chikovani[1] & Nino Charkviani[3]
[1]Tbilisi State Medical University, Immunology, T'bilisi, Georgia; [2]Israeli-Georgian Medical Research Clinic Healthycore, Clinical Trials Department, Tbilisi, Georgia; [3]Tbilisi State Medical University, Endocrinology, T'bilisi, Georgia

Introduction
Mono or combination therapy with immune checkpoint inhibitors for malignancies causes thyroid dysfunction in the form of overt or subclinical hypothyroidism, or thyrotoxicosis. Thyrotoxicosis phase is often transient and in some cases so short that it cannot be diagnosed in time and the patient is examined late when hypothyroidism is confirmed. We describe a case of Cervical Cancer woman who developed transient thyrotoxicosis and later hypothyroidism after combination treatment with CTLA-4 and PD-1 inhibitors.
Case Presentation
A 60-year-old postmenopausal female developed transient thyrotoxicosis-TSH- <0.005 (NR: 0.3-4.0 micro IU/ml) and 2 weeks later Hypothyroidism TSH-220 micro IU/ml 2 months after immunotherapy. The only complaints she

had was palpitation and increased blood pressure. Her Anti-TPO was positive, but Anti-Tg and TRab were negative. Initial therapy for thyrotoxicosis was performed with propranolol and after the development of hypothyroidism L-thyroxine replacement therapy was started.
Conclusions
Autoimmune thyroid dysfunctions can be induced by immune checkpoint inhibitors treatment: anti-PD-1, anti-CTLA-4, and anti-PD-L1. An elevated level of clinical suspicion is required for the diagnosis of endocrinopathies due to an upward trend in endocrine disorders among cancer patients receiving immunotherapy. Early management of ICI-induced endocrinopathies improves the quality of oncopatients' life and continuity of anticancer treatment.

Exploring the spectrum: complications of hyperthyroidism - insights from a series of 29 cases

Raida Ben Salah[1], Siddiqa Soomauroo[2], Faten HadjKacem[2], Ahmad Ridwaan Auckburally[3], Abdelmuhaymen Missaoui[2], Wiem Feki[3], Mouna Mnif[2], Sameh Marzouk[1], Mohamed Abid[2], Nabila Rekik[2] & Zouheir Bahloul[1]
[1]Hedi Chaker University Hospital, Department of Internal Medicine, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [3]Hedi Chaker University Hospital, Department of Radiology, Sfax, Tunisia

Introduction
Overt hyperthyroidism is the result of excessive production of thyroid hormones. The diagnosis is made on the basis of clinical characteristics and the diagnosis of certainty is made by hormone assay, combining low TSH with increased thyroid hormones. If the hyperthyroidism is left untreated, symptoms progress and can lead to complications that may jeopardize life prognosis.
Patients and Methods
A retrospective study involving 29 patients with primary hyperthyroidism was conducted. We identified various complications associated with hyperthyroidism.
Results
We enrolled 29 patients with overt hyperthyroidism, among which 18 women and 11 men. The mean age at diagnosis was 35.5 years. Weight loss, tremor and hypersudation were the most frequent clinical findings. In all patients, we found a goitre, while exophthalmos was found in only 11 patients. The mean TSH level was 0.14 µUI/l. The mean free T4 level was 54.68 pmol/l. Graves' disease was the most common diagnosis in our study. The TSH-receptor antibodies (TrAb), the thyroid peroxidase antibodies (TPOAb) and the thyroglobulin antibodies (TgAb) were positive in 19, 27 and 14 patients respectively. Nineteen patients presented with complications. The most frequent complications were metabolic such as dyslipidaemia and poorly controlled diabetes in 9 patients each, as well as haematological complications such as anaemia in 9 cases as well. Neuromuscular complications, that were observed in 5 patients included amyotrophy of the lower limbs and thyrotoxic myopathy and the cardiovascular complication was cardiothyreosis and arrhythmia by atrial fibrillation in 5 patients. Neuropsychiatric complications were found in 2 patients and liver failure in one patient.
Conclusion
Hyperthyroidism is a prevalent thyroid condition characterized by an overproduction of thyroid hormones. Graves' disease is the most common cause of hyperthyroidism. Since thyroid hormone exerts physiological effects on various organ systems, the symptoms and signs of hyperthyroidism encompass manifestations affecting multiple organs. If hyperthyroidism is not treated or managed properly, it can escalate into a severe condition known as a thyroid storm. Prolonged untreated or inadequately treated hyperthyroidism are linked to a heightened risk of acute cardiovascular events, atrial fibrillation, ischemic stroke and increased mortality.

Thyroid storm requiring plasma exchange and urgent thyroidectomy - an atypical presentation of de quervain's thyroiditis

Nikhel Sachdev[1]
[1]Singapore General Hospital

Background
De Quervain's thyroiditis is a transient inflammatory thyroid disorder, characterized by neck pain, a tender goiter and a triphasic clinical course of thyroid function evolution.
Clinical Case
A 21-year-old male presented to the emergency department with 5 days of fever, agitation, palpitations, diarrhea and cough. He had a significant past medical history of aplastic anemia, in remission after an allogeneic stem cell transplant a year ago. Thyroid function test revealed a free T4 of 67.1 pmol/l (reference range 8.8 – 14.1 pmol/l) with a thyroid stimulating hormone (TSH) of $<$ 0.1 mU/l (reference range 0.65 – 3.1 mU/l). TSH receptor antibody was negative. On physical examination, he was confused, restless and diaphoretic. He had a non-tender goitre. He was diagnosed with thyroid storm and had a Burch Wartofsky Score of 60. He was treated with oral propylthiouracil (PTU), oral Lugol's iodine, oral propranolol and intravenous hydrocortisone. Unfortunately, he developed profoundly deranged liver function which persisted even after switching PTU to carbimazole, precluding further use of anti-thyroid drugs (ATDs). ATDs were stopped and he was started on oral colestyramine and lithium. He subsequently underwent three cycles of plasma exchange (PLEX) prior to undergoing a total thyroidectomy. Intraoperative findings were that of a vascular and mildly enlarged fibrotic thyroid. Histopathology of the resected thyroid revealed a granulomatous thyroiditis. Microbiological investigations, including acid-fast bacilli smears, were negative.
Conclusion
De Quervain's thyroiditis may present atypically with the absence of neck pain or tenderness. The thyrotoxicosis is usually mild and temporary, but rarely may be associated with life-threatening manifestations including thyroid storm. PLEX is an effective bridge to safe definitive therapy for patients with thyroid storm in whom ATDs are ineffective or contraindicated.

Acute perforated viscus complicating thyroxicosis: a case series

Pei lin Chan[1], Qing Wei Lim[2], Wei Hang Lim[2], Adib Fikri Bin Azalan[2] & Jean Mun Cheah[2]
[1]Hospital Umum Sarawak, Kuching, Malaysia; [2]Bintulu Hospital, Bintulu, Malaysia

Introduction
In cases of emergent surgical conditions, pre-medication of patients with thyrotoxicosis is required to reduce the patient's risk of thyroid storm in the perioperative and postoperative state. Perforated viscus with concurrent thyrotoxicosis is rarely reported. We report 2 cases of thyrotoxicosis and acute abdomen with perforated viscus.
Case 1
A 27-year-old gentleman with underlying hyperthyroidism, presented with central epigastric pain for 3 days duration. He did not have any gastrointestinal losses. On assessment, blood pressure was stable, temperature was 38°C and patient was tachycardic at 144 beats/minute. He had fine tremors and a generalized tender abdomen with guarding. ECG showed sinus tachycardia while chest radiograph revealed air under the diaphragm. Bedside abdominal ultrasound showed free fluid in the Morrison's pouch. His Free T4 was raised at 68.1 pmol/l (12-22) with suppressed TSH $<$0.005 mIU/l (0.27-4.2). He was started on rectal propylthiouracil and intravenous hydrocortisone. To optimize his condition prior to surgery, a peritoneal drain was inserted for temporary source control while plasmapheresis was done. Post plasmapheresis FT4 dropped to 1 pmol/l and he proceeded for exploratory laparotomy. Rectal PTU was continued until patient was allowed orally. He recovered well and was discharged with oral carbimazole.
Case 2
A 46-year-old construction worker with no prior medical illness, presented with 1 day history of epigastric pain. He had a history of chronic analgesia use. An initial chest radiograph done at primary care found air under the diaphragm and he was referred to hospital. On assessment he had a mild goiter and abdomen was tense and guarded. His temperature was 38°C, BP 137/89 and heart rate was 130 beats/minute. Bedside ultrasound showed free fluid in the abdominal cavity. His FT4 was elevated at 90.1 pmol/l with TSH $<$0.005 mIU/l. He developed fast atrial fibrillation requiring intravenous infusion amiodarone. Prompt treatment with intravenous hydrocortisone and rectal propylthiouracil was initiated. He was not able to proceed with surgery as patient was deemed unstable due to the atrial fibrillation with rapid ventricular response. Plasmapheresis was done and repeated FT4 post plasma exchange was 51 pmol/l. He subsequently underwent emergency exploratory laparotomy however post-surgery he had persistent fast AF requiring multiple synchronized cardioversions. His blood investigations showed worsening septic parameters and he eventually succumbed a day after surgery.
Conclusion
The presence of a compromised gastrointestinal tract requires alternative routes of administrating vital medications in thyrotoxicosis and utilization of other modalities of treatment such as plasmapheresis.

A rare etiology miming a thyroid nodule: report of a case and literature review

Amel Elkorbi[1], Nawres Bouaziz[1], Mahdi Ferjaoui[1], Rachida Bouatay[1], Naourez Kolsi[1]. Harrathi Khaled[1] & Jamel Koubaa[1]
[1]مستشفى فطومة بورقيبة بالمنستير, Monastir, Tunisia

Introduction
Thyroid swelling is habitually a thyroid nodule, however sometimes it reveal to be another pathology that we did not expect. We aim through this case and literature revue discuss the diagnostic errance in front of thyroid mass that it correspond to a cyst of the fourth cleft.
Material and method
We report a case of cyst of the 4th cleft in adults managed in our department that presented as a thyroid nodule.
Case report
This is a 58-year-old man, with no notable pathological history, referred to our department for a right basicervical swelling evolving over two months. There was no signs of infection nor compression. Clinical examination revealed a painless 4 cm-sized mass located in the right basicervical region. It was mobile with swallowing conferred to the diagnosis of thyroid nodule. No other cervical mass was found. The rest of the ENT examination was normal. Cervical ultrasound showed a right laterocervical cystic mass closely to the right thyroid lobe sized 68×42×35 mm. Fine needle aspiration suggested the diagnosis of a branchial cyst. The patient underwent a hypopharyngoscopy that did not show any fistulous orifice of the piriform sinus. A right loboisthmectomy with the cyst excision was then performed. Histopathological examination confirmed the diagnosis of a cyst of the 4th cleft. No recurrence was observed after three years of follow-up.
Discussion/Conclusion
The fourth cleft cyst is a congenital malformation that is a challenging for the pratician. It is habitually revealed at an early age and frequently presented as a thyroid abscess. Endoscopy is necessary to research an eventual internal orifice of the fistula that explained the infection. In our case, the cyst has mimed a thyroid nodule and the absence of history of infection is explained by the absence of the internal orifice. Treatment is surgical, however cauterization of the internal orifice can be an alternative in cases of surinfected cyst when dissection closely to the recurrent nerve seems to be laborious.

Cervical pulmonary hernia: a differential diagnosis of thyroid nodule to keep in mind

El Omri Malika[1], Jemli S[1], Bellakhdher Mouna[1], Meherzi Abir[1], Houas Jihene[1], Ghammem Monia[1], Ach Taieb[2], Kermani Wassim[1] & Abdelkefi Mohamed[1]
[1]ENT department Farhat Hached hospital, Sousse, Tunisia; [2]Endocrinology department Farhat Hached hospital, Sousse, Tunisia

Introcduction
Pulmonary herniation is defined as a protrusion of the lung and its pleural layers beyond the normal limits of the rib cage. It can be cervical, intercostal or diaphragmatic. Cervical hernia develops from the apex of the lung and represents approximately one third of pulmonary hernias and 60% of congenital lesions e report a case of cervical pulmonary hernia, in order to discuss the epidemiological etiopathogenic and clinical particularities of this entity.
Observation
It was a 38 year old man smoker with chronic cough with the medical history bilateral inguinal hernia and umbilical hernia that were surgically treated He consulted our department for a right side-cervical swelling evolving for 2 years which increased in size when coughing. Physical examination revealed a right side-cervical swelling of 7 cm long axis which manifested itself during coughing. The remainder of the ENT examination was unremarkable. The cervical CT scan concluded that there was a cervical lung herniation due to the abnormal presence of lung tissue at the cervical level. The patient was referred to the vascular and thoracic surgery department for surgery.
Conclusion
Cervical pulmonary hernia is a rare clinical entity; its often difficult diagnosis is facilitated by chest CT scanning. It is almost always lateralized to the right with a possible deviation of the trachea towards the left. Their appearance results from the conjunction of a weakening of wall resistance and an increase in intrathoracic pressure. Chronic cough, emphysema, physical exertion promote the appearance of these hernias.

EP958

Macro-TSH: a case report

Najoua Lassoued[1], Souissi Mariem[1], Abdelkafi Yassmine[1], Alzeer Mahmoud[1], Alaya Wafa[1] & Sfar Mohamed Habib[1]
[1]Taher Sfar University Hospital, Endocrinology Department, Mahdia, Tunisia

Background
Macro-TSH, a rare condition, should be considered in asymptomatic patients presenting with a biological profile of subclinical hypothyroidism, thus avoiding unnecessary treatment. We report the case of a patient with macro-TSH.
Case Presentation
A 41-year-old man was transferred from the Cardiology Department for further exploration of elevated TSH. He has been hospitalized for acute decompensation of heart failure. A thyroid workup revealed a TSH of 45.5 µUI/ml, verified twice after three and six months with normal Free T4 level. There was no history of taking amiodarone or iodized products. The patient had no clinical signs of hypothyroidism on examination. Anti-thyroid peroxidase antibodies and antithyroglobulin antibodies were negative. Ultrasound showed thyroid hypotrophy, and scintigraphy revealed homogeneously increased fixation. The diagnosis of macro-TSH was most likely. Unfortunately we could not find any laboratory that could do TSH chromatography. We decided not to prescribe hormone replacement therapy. The evolution was marked by the persistence of a high TSH without any clinical or biological repercussions.
Discussion/Conclusion
Isolated elevation of TSH in the absence of thyroid symptoms can be very rarely caused by a macromolecule formed between TSH and immunoglobulins (macro-TSH), confounding the interpretation of thyroid function test results. The biochemical profile mimics subclinical hypothyroidism and may lead to inappropriate LT4 treatment. No immunoassay can reveal the presence of macro-TSH. Gel filtration chromatography is the state of-the-art method for detection of macro-TSH. Unfortunately, this test is expensive and not widely available

Atypical subacute thyroiditis associated with papillary thyroid carcinoma in a case of Graves' disease

Müge Keskin[1, 2], Kübra Solmaz[3], Cevdet Aydın[4], Ferit Taneri[5], Banu Bilezikci[6], Oya Topaloglu[4], Reyhan Ersoy[4] & Bekir Cakır[4]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [4]Ankara Yildirim Beyazit University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey; [5]Ankara Güven Hastanesi, Department of General Surgery, Ankara, Turkey; [6]Ankara Güven Hastanesi, Department of Pathology, Ankara, Turkey

Aim
In patients with papillary thyroid carcinoma (PTC), the incidence of subacute thyroiditis (SAT) is thought to be more frequent than estimated. The incidence of thyroid cancer is between 2.3% and 21.1% in Graves' Disease (GD).
Case
A 31-year-old female patient applied with complaints of amenorrhea and hair loss in the 10th postpartum month. There was no history of COVID-19 infection, but Biontech vaccine were administered two years ago. Her family history revealed GD in her sister. On physical examination, blood pressure was 120/1 mm/Hg, pulse rate was 83 beats/min. Laboratory values were TSH: <0.1 mU/l (0.55-4.78), freeT4:2.1 ng/dl (0.89-1.76), freeT3:11.1 ng/l (2.3-4.2), antithyroglobulin:2.7 IU/ml (<13), antithyroidperoxidase: 10235 U/ml (<60), thyroid stimulating immunglobulin: 6.34 IU/l (0.1-0.55), TSH receptor antibody: 3.63 IU/l (<1.5). The patient refused thyroid scintigraphy because of breastfeeding. She admitted with severe pain over the right thyroid lobe the next day. There was tenderness in the right thyroid area and the body temperature was 37.5°. Thyroid US revealed hypoechoic heterogeneous areas in the superior anterior and the inferior anterior regions of the right lobe, a 16x24x1 mm isoechoic nodule with areas of cystic degeneration in the superior region and a 22x38x1 mm conglomerated isoechoic nodule with areas of cystic degeneration in the inferior region of left lobe. In laboratory analysis, TSH: <0.1 mU/l, freeT4:2.1 ng/dl (0.89-1.76), freeT3:15.1 ng/l (2.3-4.2), sedimentation rate: 1 mm/hour(0-20), CRP:8.1 mg/l (0-5). Her pain regressed and CRP values returned to normal after one week with NSAID treatment. However, since thyrotoxicosis did not resolve (TSH: <0.1 mU/l (0.55-4.78), free T4:3.05nd/dl(0.89-1.76), free T3: 18.1 ng/l (2.3-4.2), methimazole treatment was started. On the control thyroid US, heterogeneous hypoechoic areas

have resolved. The thyroid FNAB cytology result of the dominant nodule in the left lobe was suspecious for follicular neoplasia and hurtle cell type. The patient underwent bilateral total thyroidectomy, and an infiltrative follicular subtype PTC 0.1 cm in diameter was observed in the right lobe in addition to hyperplastic colloidal nodules in non-tumor thyroid tissue.
Conclusion
SAT can be seen rarely in patients with PTC. In the literature, there are cases diagnosed with GD after SAT, cases of SAT concurrent with GD, and cases of concurrent GD and SAT after COVID-19 infection. Considering that the incidence of combinations of these three diseases is very rare, our patient is the first case in the literature with all three diagnoses.

Management of thyroid nodule in pregnancy

Furhana Hussein[1], Gideon Mlawa[1], Sivatharjini Priya Sivarajasingam[1], Lina Eltayieb[1], Elizabeth Philips[1], Josie O'Heney[1], Chineze Otigbah[1], Godwin Simon[1] & Rabia Mahmood[1]
[1]Queen's Hospital, London, United Kingdom

Introduction
Thyroid cancer is one of the common malignancies diagnosed in pregnancy and the management of thyroid nodules in pregnancy is the same as in non-pregnant patients. Ultrasound thyroid and FNA are necessary in the investigations of any thyroid nodule.
Case presentation
A 39-year-old woman of Eastern European descent presented to the joint obstetric-endocrine clinic complaining of dysphagia and swollen neck at 34 weeks gestation. Her past medical history included hypothyroidism, psoriatic arthritis and depression. Family history was noteworthy for thyroid cancer – her mother had thyroid cancer treated with total thyroidectomy and radioactive iodine therapy. In addition, the woman herself was 2 years of age and exposed to the Chernobyl nuclear disaster. An Ultrasound (USS) thyroid revealed a right-sided solid thyroid nodule (U3-U4) measuring 9x8x1 mm and fine needle aspiration (FNA) confirmed follicular lesion Thy3F. She had a successful right hemithyroidectomy 4 weeks postpartum. The histology confirmed classic features of papillary carcinoma 1 mm staged as pT1b N0 R0. She was discussed in the thyroid MDT and the outcome was for TSH suppression, surveillance and not for completion thyroidectomy.
Discussion
Pregnant women with thyroid cancer can be asymptomatic and studies have suggested pregnancy increases the risk of developing new thyroid nodules. Pregnancy can also cause an increase in the size of pre-existing thyroid nodules by up to 50%. Development of new nodules is up to 20%. A detailed history of suspected thyroid nodules should be taken including a family history of thyroid cancer. A thorough examination of the thyroid gland should be performed followed by an USS thyroid to characterize the thyroid nodule. FNA is safe in pregnancy and can be performed in any trimester. Counselling is an important part of the management of thyroid nodules in pregnancy to allay anxiety and distress. Regular (4-6 weeks) monitoring of thyroid function tests is essential and the FT4, FT3, TSH range is trimester dependent.
Conclusion
The management of thyroid nodules in pregnancy depends on whether the nodules are benign or malignant and if the pregnant mother is symptomatic. For malignant nodules, surgical intervention is ideal in the second trimester or post-partum. Hence, an MDT approach is important. The TSH range should be maintained at 0.2-2.0mIU/l.

EP966

Right jugular vein agenesis. a challenging case for experienced endocrine surgeons

Ángel Luis Sánchez Álvarez[1], Laura García García[1], M. Isabel Gutiérrez Giner[1], Ana Tejera Hernández[1], Jorge Loro Pérez[1] & Magel Fernández Alfonso[1]
[1]Complejo Hospitalario Universitario Insular Materno Infantil, General and Digestive Surgery, Las Palmas de Gran Canaria, Spain

Introduction
Jugular vein agenesis is an extremely rare condition and its prevalence is not well-established. Case reports in the medical literature are limited, emphasizing the rarity of this anatomical variation.
Case Presentation
Agenesis of the jugular vein is a rare anatomical variation characterized by the congenital absence or significant underdevelopment of the jugular vein, an essential vascular structure in the venous drainage of the head and neck. Although rare, this condition can have notable clinical implications defying expectations in medical evaluation and surgical practice. We present the amazing case of a patient with agenesis of the right jugular vein and hypertrophy of the contralateral vein. In lateral cervical dissections, the internal jugular vein is a main anatomical reference to perform the procedure. This is a 60-year-old woman with a diagnosis of medullary thyroid carcinoma and a calcitonin of 331 pg/ml . After being presented to a multidisciplinary committee it was decided to perform Total Thyroidectomy associated with bilateral central and bilateral lateral cervical dissections.. During the approach to the left lateral compartments, a highly dilated internal jugular vein with a transverse diameter of more than 3 cm was observed. When approaching the right lateral compartments, the carotid sheath was completely released from the posterior belly of the digastric muscle to the clavicle, with identification of the carotid artery and vagus nerve without being able to identify the right internal jugular vein. Intraoperatively, the images of the preoperative studies were reviewed with the Radiology Department confirmed the absence of the right internal jugular vein. Finally, the procedure was completed without incident and the patient was discharged within 24 hours.
Discussion
The case of jugular vein agenesis highlights the uniqueness and complexity of anatomical variations in the vascular system. Although this condition is exceptional, its recognition is crucial for accurate clinical evaluation and appropriate management of affected patients. The absence of the jugular vein can complicate common surgical procedures, such as vascular access, and is of vital importance in those where it constitutes an anatomical reference or in locally advanced tumors that require vascular resection where if it is not taken into account, it can have disastrous consequences for the patient. Complete understanding of the patient's specific anatomy and detailed planning are important elements in the success of the surgical intervention. Cervical endocrine surgery should be performed by experienced surgeons to identify possible anatomical variants and reduce the comorbidity of surgery.

EP967

Unveiling the multifaceted presentation of a rare case: a complex intersection of anti-TPO positive graves' disease, raised CA-125, and severe dilated cardiomyopathy with myxedema in a zimbabwean migrant woman

Sargunann Naidu Krishnasamy Naido[1] & Faizan Rao[1]
[1]Royal Bournemouth Hospital, Diabetes and Endocrinology, Bournemouth, United Kingdom

Case presentation
This detailed case report delves into the complex clinical trajectory of a 37-year-old Afro-Caribbean woman hailing from Zimbabwe, who presented with a diverse array of symptoms. Among these were diarrhea, tremor, anxiety, abdominal distension, amenorrhea and a staggering unintentional weight loss of 1 kg over the past year. Notably, her medical history features a previous open left-sided salpingectomy undertaken for a ruptured ectopic pregnancy. The persistence of diarrhea, initially attributed to a chronic intestinal infection, led to her relocation to the UK in early 2023. Following a referral to the Gynae-Oncology team due to elevated CA-125 levels, a meticulous examination ensued to probe the possibilty of gynaecological malignancy. The speculum test yielded normal findings, and bimanual palpation failed to reveal any palpable masses. Remarkably, the patient, abstinent for over a year, declined a pregnancy test. Despite negative results from contrast-enhanced computed tomography of the chest, abdomen, pelvis (CTCAP), with specific consideration given to the differential diagnosis of struma ovarii, the gynae-oncology multidisciplinary team (MDT) dismissed ovarian cancer as the likely diagnosis, prompting further exploration of alternative causes. Subsequent referral was made to the endocrine team for symptoms suggestive of hyperthyroidism and neck swelling, the patient exhibited normal anti-TSH receptor antibodies but a significant elevation in anti-TPO antibodies. Biochemical analysis confirmed hyperthyroidism, prompting the initiation of treatment with carbimazole and propranolol by the GP. Subsequent imaging, CTCAP and computed tomography pulmonary angiography (CTPA), revealed a substantial right-sided pleural effusion and ascites, generalized soft tissue edema, hyperdense gastro-intestinal tract and negative for pulmonary embolism. This necessitated therapeutic thoracocentesis, which, upon analysis of the pleural fluid, revealed a transudative lymphocytic effusion, effectively excluding malignancy as a contributing factor to the observed symptoms. Surprisingly, further cardiac investigations unraveled an additional layer of complexity: severe non-ischemic dilated cardiomyopathy with reduced ejection

fraction. This manifested as impaired left ventricular function, dilation in all cardiac chambers and valvular regurgitations possibly complicated by a late diagnosis of long-standing autoimmune hyperthyroidism. In conclusion, early detection of autoimmune hyperthyroidism is imperative, considering the characteristic symptoms. The presence of anti-TPO antibodies and myxedema, typically associated with Hashimoto's thyroiditis, adds diagnostic intricacy. Notably, this presentation can also occur in Graves' disease where severe heart failure with myxedema becomes a complication of long-standing hyperthyroidism. This highlights the crucial role of vigilant clinical suspicion, recognizing diverse manifestations, and swift diagnosis of hyperthyroidism, emphasizing the need for interdisciplinary collaboration in addressing complex clinical scenarios.

Experience of using tocilizumab for the treatment of glucocorticoid-resistant graves orbitopathy

Tatsiana Mokhort[1], Volha Shyshko[2], Kseniya Palavinkina[2], Alena Mokhort[1] & Natalya Likhorad[3]
[1]Belarusian State Medical University, Endocrinology, Minsk, Belarus; [2]Minsk City Clinical Endocrinological Center, Minsk, Belarus; [3]1th City Clinical Hospital, Endocrinology, Minsk, Belarus

Objective
to evaluate the efficacy of tocilizumab (TZM) in the treatment of glucocorticoid-resistant Grave's orbitopathy (GO).
Materials and Methods
3 patients with GO on the background of compensated Graves' disease were observed. Treatment of GO was initiated with methylprednisolone (total doses of 8, 000-13, 1 mg) without significant clinical effect with a CAS of 4 points. After that TZM was administered three times intravenously once a month at a dose of 8 mg / kg.
Results
The table shows the results of the initial CAS values (1) and the results of the examination 1 month after the end of therapy (2). We registered decrease of GO severity: reduction of proptosis, ophthalmotonus depletion and involution of thickness of oculomotor muscles. All patients noted a significant improvement in their quality of life, but 2 patients had minor leukopenia.
Conclusion
TZM has been shown to be effective in reducing CAS in patients with glucocorticoid-resistant GO, so it can be used to reduce the inflammatory process and severity in patients with GO.

A rare cause of hyperthyroidism in hashimoto disease

Samir Mkaouer[1], Elyes Kamoun[1], Nadia Khessairi[1], Meriem Yazidi[1], Oueslati Ibtissem[1], Fatma Chaker[1] & Chihaoui Melika[1]
[1]La Rabta University Hospital, Endocrinology Department, Tunis, Tunisia

Introduction
Hashimoto's thyroiditis is the most frequent cause of hypothyroidism with a relative increased risk of thyroid lymphoma compared to healthy subjects. Hyperfunctioning nodules are rarely malignant. We report the case of a rare association of thyroid carcinoma, a hyperfunctioning nodule and Hashimoto thyroiditis.
Observation
We report the case of a 40-year-old female patient treated with L-thyroxine for hypothyroidism due to Hashimoto thyroiditis for 3 years. Thyroid ultrasonography was performed due to suspicion of thyroid nodule at the clinical examination and showed a 13 mm EUTIRADS 3 thyroid nodule, which increased in size to 27 mm after 12 months. Fine needle aspiration showed a benign cytology. During monitoring, TSH levels dropped to 0.005 mIU/l after withdrawal of L-Thyroxine. Thyroid scintigraphy showed a solitary hyperfunctioning nodule. The patient had a total thyroidectomy following suspicion of carcinoma on extemporaneous examination. The definitive pathological examination of that nodule concluded to a 1 mm vesicular thyroid carcinoma within the nodule.
Conclusion
The association of a solitary hyperfunctioning nodule and Hashimoto's thyroiditis is rarely described in the literature. The majority of autonomous nodules are benign. However, in case of clinical or ultrasound criteria of malignancy, surgery is required and can reveal malignancy.

Case report: nivolumab induced dual hypophysitis and secondary hyperthyroidism

Geraint Worby[1], Brittany Cole[1], Mae Tan[1] & Umer Qazi[1]
[1]Watford General Hospital, United Kingdom

A gentleman in his 70s with a background of atrial fibrillation, hypertension, and mesothelioma undergoing immunotherapy via Nivolumab and Ipilimumab, presented with general unwellness, fevers, confusion, and headaches. He had no prior endocrine history but was found to have significantly deranged thyroid function tests. He was treated for thyrotoxicosis and an impending thyroid storm with carbimazole. He remained treatment resistant for several days, with continuous delirium, fast atrial fibrillation, refractory hypotension, and persistent pyrexia. His treatment was therefore switched to PTU with addition of Lugol's iodine, IV beta blockers, and IV hydrocortisone. The source of his thyrotoxicosis was hypothesised to be due to amiodarone, immunotherapy, or Jod Basedow effect post contrast. His TFTs started to improve after about 1 week of this treatment regimen. His medications were reduced to prevent hypothyroidism and he was discharged appropriately with a plan in place for urgent follow up. Days later, he was readmitted with hypotension; therefore, his carbimazole was reduced and prednisolone was added. The patient's TFTs normalised while in hospital and he was discharged on a low dose of carbimazole and prednisolone with repeat bloods and endocrine follow up. The discussion revolves around the potential effect of immunotherapy on hormones, and distinguishing at what level the effect is taking place. At the level of the thyroid, the increased free T4 and T3 causes negative feedback on the pituitary gland to suppress TSH in an attempt to counteract this. Similarly, if the effect is on the pituitary itself, the TSH may be dually suppressed in this manner. To distinguish whether the pituitary was also being affected, it was necessary to observe the changes in TSH as the other thyroid hormones normalised. If TSH reverted to normal levels when free T4 and T3 were within range, it is unlikely that the pituitary gland was contributing to the suppressed TSH, and much more likely that it had been low as a result of negative feedback from the elevated levels of T4 and T3 that were being produced by the thyroid gland. Additionally, we tested the other pituitary hormones to look for other derangements in values. We found that once the patient's T4 and T3 were within normal ranges, the TSH gradually also went back to normal. This suggests that the derangement occurred primarily at the level of the thyroid, as pituitary involvement would have continued to suppress TSH despite the correction on T4 and T3.

Papillary thyroid microcarcinomas and lymph node metastases: [about 20 cases]

Khouloud Boujelben[1], Fatma Hamza[2], Feriel Touzi[1], Elleuch Mouna[1], Dhoha Ben Salah[1], Yasmine Elloumi[1], Islam Jardak[2], Mohamed Maaloul[2], Mouna Mnif[1], Fatma Mnif[1], Charfi Nadia[1], Faten Hadj Kacem[1], Fadhel Guermazi[2], Khalil Chtourou[2], Abid Mohamed[1] & Rekik Nabila[1]
[1]Hedi Chaker Hospital, Endocrinology Department, Tunisia; [2]Habib Bourguiba Hospital, Nuclear Medicine Department, Sfax, Tunisia

Introduction
Papillary thyroid microcarcinomas (PTMC) usually manifest a slow progression, commonly displaying local-regional extension, contributing to a generally favorable prognosis. However, certain instances are complicated by lymph node metastasis, a pivotal factor influencing therapeutic strategies. The aim of this study was to evaluate the epidemiological, clinical, and histological characteristics of patients with PMCT and lymph node metastasis.
Patients and Methods
We performed a retrospective study and selected 20 patients who were diagnosed with Papillary Thyroid Microcarcinoma (PTMC) and had lymph node metastasis. These patients had undergone at least one total thyroidectomy and were referred to the nuclear medicine department of Habib Bourguiba Hospital for radioiodine therapy.
Results
In our study, there were 17 females and 3 males, resulting in a sex ratio of 5.66 The mean age was 43.4 years, ranging from 11 to 87 years Therapeutically, 13 patients underwent upfront total thyroidectomy, while lobectomy was performed in 7 patients. Totalization in the same procedure occurred in 6 cases, and later, after obtaining the definitive histological result, in only one patient. Histologically, the final examination revealed a diagnosis of classic papillary carcinoma in 85% of cases, with vesicular dedifferentiation noted in only 15%. The size of the tumor focus varied from 1 mm to 1 mm, averaging 4.1 mm. The tumor was multifocal in 17 cases. Capsular invasion was identified in 40% of cases, often associated with vascular emboli in 3 instances. All patients underwent a tracer dose scan with an average thyroglobulin (TG) level of 23.1 ng/ml. Hormonal replacement therapy was prescribed for all participants.
Conclusions
The detection of lymph node metastases heightens the risks of distant recurrence, justifying an exhaustive therapeutic strategy. Moreover, Surveillance should not be constrained temporally, as late recurrences remain a plausible occurrence

A case of giant toxic nodular goiter with dyspnea by pulmonary hypertension and obstructive symptom

Irida Kecaj[1], Ergita Nelaj[1], Ilir Gjermeni[1], Kei Xhixhabesi[1] & Ina Refatllari[2]
[1]University Hospital Center, Internal Medicine, Tirana, Albania; [2]University Hospital Center, Cardiology, Tirana, Albania

Introduction
Giant multinodular goiter (MNG) is a heterogeneous clinical disorder that can be asymptomatic or can cause compression of surrounding structures, and when it is accompanied by obstructive symptoms such as dyspnea, it carries an indication for surgery. Pulmonary hypertension is one of the most important complications of untreated hyperthyroidism, that can be reversible under treatment.
Case presentation
We present a case of 75 years old female with a giant MNG with a rapid increase in size within 3 years, with atrial fibrillation, palpitations, breathlessness on exertion and dyspnea. She is diagnosed with toxic nodular goiter since 60 years old, not regularly treated. Computed tomography scan of the neck shows a gross enlargement of thyroid. The trans-thoracic cardiac ultrasound shows dilatation of left atrium, right ventricular dilatation, pulmonary hypertension, with no evidence of pulmonary embolism in angio-ct. The fine needle aspiration suggested MNG with adenomatous nodules and toxic changes. She was treated with 20 mg methimazole daily; after 4 weeks the patient's palpitations improved but still complained shortness of breath. To check the heart status and pulmonary hypertension, following the treatment of thyrotoxicosis, the patient underwent echocardiography, and the pulmonary pressure was significantly reduced. A total thyroidectomy was performed and the gland was dissected successfully.
Conclusion
Pulmonary hypertension, associated hyperthyroidism, is a common complication, usually reversed after treatment of thyroid disease. Surgical management is recommended for goiters with compressive symptom, in aim to improved breathing and swallowing outcomes after thyroidectomy. With careful preoperative testing and thoughtful consideration of the type of anesthesia, including the type of intubation, preparation for surgery can be optimized.

Methimazole-Resistant graves' disease: a case report

Meriem Adel[1], Marwa Chiboub[1, 2], Ons Smairi[1], Manel Jemel[1] & Ines Kammoun[1]
[1]National Institute of Nutrition and Food Technology, Endocrinology, Tunis; [2]Tunisia, Endocrinology, Tunis, Tunisia

Introduction
Graves' disease (GD), the most common cause of hyperthyroidism, is an organ-specific autoimmune disease. Initial treatment of GD is based on antithyroid drugs (ATDs). However, few cases of resistance to ATDs have been described in the literature. Here, we report a GD patient who suffered from resistance to ATDs requiring an early definitive therapy.
Case presentation
A 30-year-old female patient was referred to our institution for management of resistant thyrotoxicosis. She had no significant medical or surgical history. The diagnosis of Graves' disease was established based on clinical signs of thyrotoxicosis, goiter and eye signs. Laboratory findings objective high free thyroxine (FT4) concentrations, low TSH concentration and positive levels of TSH receptor autoantibody. Initial treatment involved prescribing 1 mg of Methimazole and 1 mg of Propranolol. However, despite good compliance, FT4 levels remained elevated for few months. Corticosteroid therapy at a dose of 30 mg of prednisolone was added for one month but thyroid function tests remained unchanged. Therefore, the patient was given 3 boluses of 1 mg of Solumedrol per day in combination with Methimazole 40 mg/d. seven days later, FT4 levels decreased to 39.8 pmol/l. In the presence of a FT4 level close to the normal range, the patient underwent definitive treatment. She received 15 mCi of radioactive iodine. The biological control one month after radioiodine therapy revealed a normal level of FT4 with decreasing clinical signs.
Discussion
For many years, ATDs have been the primary treatment for Graves' disease due to their ability to swiftly achieve euthyroidism with a lower likelihood of progressing to permanent hypothyroidism compared to alternative therapies. The occurrence of resistance to ATDs is uncommon, and the mechanisms behind such resistance remain unclear due to limited cases. Potential etiologies encompass malabsorption, elevated metabolism, drug antibodies, and irregularities in the intrathyroidal accumulation or action of the drugs. The approach to handling resistance to ATDs is not yet clearly defined. Alternative approaches have been suggested for such situations, including Lugol's solution, lithium carbonate, cholestyramine, and plasma exchange. These aim to achieve prompt euthyroidism before administering definitive treatment.
Conclusion
Managing resistance to ATDs in GD remains a complex issue due to the lack of well-defined diagnostic methods and established secure treatment approaches.

The role of one stop clinic to support patients with thyroid eye disease (TED)

Keiko Carter[1], Bashir Mahamud[2], Mohammad Saleki[3], Ayan Mohamed[4], Furhana Hussein[5], Catherine Man Yan Cheung[6] & Gideon Mlawa[7]
[1]Queen's Hospital, Endocrine and Diabetes Department, Romford, United Kingdom; [2]Queen's Hospital, Acute Medicine, Romford, United Kingdom; [3]Queen's Hospital, Endocrine and Diabetes, Romford, United Kingdom; [4]Queen's Hospital, United Kingdom; [5]Queen's Hospital, Endocrine and Diabetes, United Kingdom; [6]Queen's Hospital, Romford, United Kingdom; [7]Queen's Hospital, Endocrine and Diabetes, Acute Medicine, Romford, United Kingdom

Background
The causes of thyrotoxicosis include hot and Graves disease. Graves' disease can be associated with Graves eye disease, and thus have a psychological impact on the patient. The treatment of thyrotoxicosis includes medical therapy, surgical therapy, and radioiodine treatment. Treatment of thyroid eye disease includes both medical and surgical therapy in a multidisciplinary setting. Medical treatment using steroids may worsen hyperglycaemia in patients with existing diabetes. Steroid-induced

hyperglycaemia is not uncommon. Baseline HBA1C, fasting glucose, and regular monitoring for hyperglycaemia are required in patients on steroids.
Aims
- To establish BM monitoring patterns on non-diabetic patients with thyroid eye disease receiving steroids.
- To establish whether management corresponds with national guidance.
- To develop a consensual pathway for thyroid eye disease patients requiring steroids
- To present a retrospective study in the management of thyroid eye disease in the acute setting

Methods
- Retrospective study/audit using clinic letters and patients notes
- Baseline Fasting glucose done- 100%
- Baseline HBA1C done 100%
- Follow-up fasting glucose and HBA1C done 100%

Results
- 8 Patients analysed were identified.
- 7 patients had their baseline HBA1 checked,
- 50% had their HBA1C months after starting the steroids and
- 62% had their HBA1C checked after finishing the treatment

Discussion
- Treatment of thyroid eye disease includes both medical and surgical therapy in a multidisciplinary setting.
- Medical treatment using steroids may worsen hyperglycaemia in patients with existing diabetes. Steroid-induced hyperglycaemia is not uncommon.
- Baseline HBA1C, fasting glucose, and regular monitoring for hyperglycaemia are required in patients on steroids.
- At present no structured MDT approach to managing these patients. A 'One Stop Shop' with ophthalmology & endocrinology to manage these patients

Unmasking graves' disease: navigating the complexities of diagnosis, treatment, and beyond

Raida Ben Salah[1], Siddiqa Soomauroo[2], Faten Hadjkacem[2], Abdelmuhaymen Missaoui[2], Ahmad Ridwaan Auckburally[3], Wiem Feki[3], Mouna Mnif[2], Sameh Marzouk[1], Mohamed Abid[2], Nabila Rekik[2] & Zouheir Bahloul[1]
[1]Hedi Chaker University Hospital, Department of Internal Medicine, Sfax, Tunisia; [2]Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia; [3]Hedi Chaker University Hospital, Department of Radiology, Sfax, Tunisia

Introduction
Graves' disease (GD), an autoimmune disorder predominantly impacting the thyroid gland, can extend its effects to various organs, such as the eyes and skin. It stands as the leading cause of hyperthyroidism. It is defined by the pathognomonic combination of thyrotoxicosis, goitre and exophthalmos. The aim of this study was to identify the characteristics of GD.
Patients and Methods
A retrospective study involving 31 patients with primary hyperthyroidism was conducted.
Results
We enrolled 29 patients with overt hyperthyroidism, among which 19 was diagnosed with GD. There were 10 men and 9 women. The mean age at diagnosis was 35.5 years. Weight loss and tremor were the most predominant symptoms noted in 64.5% and 58% of cases respectively. In all patients, we found a goitre, while exophthalmos was found in only 11 patients. The mean TSH level was 0.14 µUI/l. The mean free T4 level was 54.68 pmol/l. The TSH-receptor antibodies were positive in all cases. Dyslipidaemia, poorly controlled diabetes and anaemia were observed in 9 patients each. All patients were treated with a beta-adrenergic blocker. Corticosteroid therapy was initiated in 2 patients who had malignant Graves' orbitopathy. Eleven patients were treated with only antithyroid drug (ATD) and 17 with radioactive-iodine treatment (RAI). RAI was used after failure of or intolerance to ATD in 9 patients and a second course of RAI was indicated in 2 patients. Only one patient had a total thyroidectomy, indicated because of resistance to ATD, poor socioeconomic conditions, association with type 1 diabetes mellitus and the patient's young age. Neutropenia secondary to ATD, requiring discontinuation of this treatment and recourse to RAI was observed in one patient. The outcome was considered favourable in 18 patients, with clinical and biological euthyroidism and improvement of the complications caused by the hyperthyroidism itself or by its treatment. One patient died.
Conclusion
GD is a systemic condition that impacts various organs, presenting with diverse symptoms. The optimal management involves a collaborative approach by an interprofessional healthcare team. While antithyroid drugs can control symptoms, they don't provide a cure, resulting in common relapses. Radioactive iodine is often the preferred approach to address the condition. Hyperthyroidism poses significant short and long-term health risks, emphasizing the importance of early recognition and timely intervention.

Ultrasound assessment of thyroid gland size in young healthy men in the Minsk city

Elena Brutskaya-Stempkovskaya[1], Alena Yurenia[2], Volha Shyshko[1, 2], Ulyana Vauchankova[1] & Vladislav Dembski[1]
[1]Belarusian State medical University, Belarus; [2]Minsk City Clinical Endocrinology Center, Belarus

Background
Normal thyroid size varies across populations depending on age and gender. The results of assessing the normal size of the thyroid gland in young healthy men in Belarus population have not been published yet.
Materials and methods
A retrospective cross-sectional study was conducted. We studied 138 men 18-28 years old without endocrine pathology who applied to the Minsk City Clinical Endocrinology Center in 2023. The aim of the study is to establish the normal size of the thyroid gland among healthy young men. The study included patients with normal echogenicity of the thyroid gland, without increased thyroid blood flow, without a severe disturbance of the echostructure (cyst-like formations with a diameter of less than 5 mm were assessed as normal). Patients with cervical lymphadenopathy were excluded from the study. Statistical processing of the results was carried out using the Statistica 10 program (StatSoft, USA).
Examination
thyroid ultrasound, TSH, FT4, ATPO, height, weight, BMI.
Results
Average age was 21.9±2.42 years, height was 180 (175-186) sm, weight was 78 (64-95) kg, BMI was 22.1 (19.6-24.4) kg/cm^2. TSH level was detected 3.14±1.01 µIU/ml, FT4 – 17.1 (14.9-20.1) pmol/l, ATPO -13.9 (7.3-22.1) IU/ml. The average volume of the right lobe was 5.45±2.13 cm^3, the left lobe of the thyroid gland was 5.39±1.74 cm^3. The width of the isthmus was 2.4 (2.1-2.7) cm. Minimum registered total thyroid volume was 4.1 cm^3, maximum registered total thyroid volume was 25, 4 cm^3. The total thyroid volume was recorded 10.7 (6.7-17.9) cm^3.
Conclusion
As a result of the study, the total thyroid volume was recorded as 10.7 (6.7-17.9) cm^3 in young healthy men 18-28 years old without a history of endocrine diseases in the city of Minsk.

Ultrasound thyroid size in young healthy women in the minsk city

Elena Brutskaya-Stempkovskaya[1], Ihar Tarasik[2], Katsiaryna Dziachko[2], Volha Bohdan[1], Anastasiya Tubolets[1], Mikhail Vasiliuchak[1] & Aliona Mikhailava[1]
[1]Belarusian State medical University; [2]Minsk Clinical Consulting and Diagnostic Center, Belarus

Normal thyroid size in women varies between populations, and depends on the age. The results of assessing the normal size of the thyroid gland in young healthy fertile women in Belarus population have not been published yet.
Materials and methods
A retrospective cross-sectional study was conducted. We studied 122 fertile women 18-44 years old without endocrine pathology who applied to the Minsk Clinical Consultative and Diagnostic Center in 2023. The aim of the study is to establish the normal size of the thyroid gland among healthy young women. The study included patients with normal echogenicity of the thyroid gland, without increased thyroid blood flow, without a severe disturbance of the echostructure (cyst-like formations with a diameter of less than 5 mm were assessed as normal). Patients with cervical lymphadenopathy were excluded from the study. Statistical processing of the results was carried out using the Statistica 10 program (StatSoft, USA).
Examination
thyroid ultrasound, TSH, FT4, ATPO, height, weight, BMI.
Results
Average age was 32.0±7.25 years, height was 166 (162-170) sm, weight was 64 (56-73) kg, BMI was 22.4 (19.2-24.7) kg/cm^2. TSH level was detected 2.15 (1.46 -

3.04) μIU/ml, FT4 – 16.3 (15.2-18.8) pmol/l, ATPO -18.0 (11.8- 31.6) IU/ml. The average volume of the right lobe was 5.1 ± 1.69 cm^3, the left lobe of the thyroid gland was 5.5 ± 1.86 cm^3. The width of the isthmus was 2.5 (2.0-2.9) cm. Minimum registered total thyroid volume was 3.4 cm3, maximum registered total thyroid volume was 25, 2 cm^3. The total thyroid volume was recorded 9.7 ±3.13 cm^3. Frequency range 5-95% was detected 5.8-16.4 cm^3.
Conclusion
The result of the study demonstrated the total thyroid volume was recorded 5.8-16.4 cm^3 as normal in young healthy fertile women 18-44 years old without a history of endocrine diseases in the city of Minsk

Subclinical hyperthyroidism: exploring etiologies, clinical profiles and outcomes

Baltagi Myriam[1], Sawsen Essayeh[2], Imen Rojbi[2], Ibtissem Ben Nacef[2], Sabrine Mekni[2], Rihab Laamouri[2] & Karima Khiari[2]
[1]Tunisia, Endocrinology, Tunisia; [2]

Introduction
Subclinical hyperthyroidism (SH) is defined by normal thyroid hormone levels and reduced thyroid-stimulating hormone (TSH) concentration. It still raises intriguing questions about its clinical impact, management and outcomes. The aim of our study was to determine the underlying etiologies of SH, its clinical features and its outcomes in Tunisian patients.
Methods
We conducted a retrospective study at Charles Nicolle Hospital, including 46 patients with subclinical hyperthyroidism. Clinical data and paraclinical parameters were collected for analysis.
Results
The mean age of patients was 67 ± 8 years, with a female predominance (26women against20 men). Patients were managing health conditions, including 60% with type 2 diabetes, 42% with hypertension, 56% with dyslipidemia, and 8% with coronopathy. The majority of diagnoses (49%) for subclinical hyperthyroidism were incidental, discovered through routine medical analyses. Hashitoxicosis emerged as the most prevalent etiology, accounting for 32%, followed by Graves' disease at 21%, and multinodular goiter at 5%. In the majority of cases, the therapeutic decision involved a conservative approach, opting to monitor patients without initiating treatment. SH resolved spontaneously in 35% of cases.
Conclusion
In summary, our study emphasizes the importance of individualized approaches in addressing this condition, considering its varied etiologies and the potential for spontaneous resolution. Wait-and-See approach can be an interesting therapeutic alternative when hashitoxicosis is the suspected cause.

Radiation thyroiditis after radioactive iodine treatment

Hatice AKSU[1], Yaşar Aydoğmuş[1], Narin Nasiroğlu imga[1], Nazim Coşkun[2], Hüsniye Başer[3], Oya Topaloğlu[4], Reyhan Ersoy[3] & Bekir Çakir[3]
[1]Ankara City Hospital, Endocrinoloogy and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Nuclear Medicine, Ankara, Turkey; [3]Ankara Yildirim Beyazit University Faculty of Medicine, Endocrinoloogy and Metabolism, Ankara, Turkey; [4]Ankara Yildirim Beyazit University Faculty of Medicine, Ankara, Turkey

Radioactive iodine therapy (RAI) is a treatment method used to in cases of Graves' disease(GD), toxic multinodular guatr and solitary toxic nodüle and residual tissue after thyroidectomy or in the treatment of metastases capable of capturing iodine. The biological basis of the treatment is the inhibition of follicle cell functions. Side effects such as thyroid swelling, radiation thyroiditis and sialadenitis are rare. Radiation thyroiditis tends to occur within two weeks after RAI administration and is generally asymptomatic in most patients. Approximately % 1-5 of patients with GD develop radiation thyroiditis after RAI treatment. Radiation causes ınflammation that develops as a result of exposure of a large residual tissue to a high radiation dose may cause tenderness in the thyroid tissue or neck, erythema and edema, pain when swallowing, rarely airway obstruction, and in some patients, a thyrotoxic state. Symptoms generally begin 1-10 days after treatment. Pain and tenderness in the thyroid and neck area are mild and disappear within 3-7 days. There may be a temporary hyperthyroidism attack at this time. Mild symptoms are usually relieved with non-steroidal anti-inflammatory drugs. In more severe cases, corticosteroid treatment (30 mg/day prednisone) provides rapid relief of symptoms. In case of thyroid storm, symptoms can be controlled with corticosteroids, if severe adrenergic symptoms are accompanied by beta blockers and if necessary antithyroid drugs. Here we will present a case of radiation tyroditis developing after Graves Diseaes(GD). A 71-year-old patient with a diagnosis of Graves' disease was treated with 20 mcı radioactive iodine due to elevated liver function tests under antithyroid drug therapy. 1 week after radioactive iodine treatment, she was admitted to our outpatient clinic with complaints of pain in the throat and difficulty swallowing. Thyrotoxicosis was detected in the tests. Oral cavity looked natural and sensivity was detected in the neck area. No respiratory distress was detected. Newyl developed tracheal stenosis was detected on the cervical graphy. Color doppler pattern 3 and edema in the thyroid gland was detected on the ultrasonography. The patient 's complaıns were primarily evaluated as thyroiditis secondary to radıoactive iodine treatment. The patient was started on oral methylprednisolone sodıum succinate, non-steroidal anti-inflamatory and betablocker treatment. The patient's complaints regressed under treatment. In conclusion, radiation thyroiditis is a complication of RAI for the treatment of GD and may cause morbidity. Radiation thyroiditis should be suspected as the etiology of patients presenting with neck pain and difficulty swallowing immediately after RAI.

A spontaneous remission of Hashimoto's thyroiditis

Oumeyma Trimeche[1], Bilel Ben Amor[1], Ekram Hajji[1], Matiem Souissi[1], Ines Bayar[1], Sana Abid[1], Héla Marmouch[1], Hanene Sayadi[1] & Inès Khochteli[1]
[1]Fattouma Bourguiba University hospital, Monastir, Tunisia

Introduction
Hashimoto's thyroiditis (HT) is one of the most frequent endocrine diseases worldwide that is typically irreversible. Herein we report the case of a woman who had spontaneous remission of hypothyroidism while discussing the potential mechanisms underlying this unusual evolution.
Case report
T.C. is a 44-year-old woman with no familial history of thyroid diseases nor autoimmune conditions. She has no particular personal medical history. She consulted our Endocrinology department the first time in September 2021, with clinical signs suggestive of hypothyroidism such as asthenia, chronic constipation, myxedema and alopecia. Hormonal evaluation confirmed the diagnosis of primary hypothyroidism: elevated Thyroid stimulating hormone (TSH = 206 μui/ml) and low thyroxine (FT4 = 2.29 pmol/l). Thus, she was put on 100 μg per day of Levothyroxine. Her cervical echography showed hypotrophic gland with normal vascularization. Her anti thyroperoxidase antibodies were elevated 120 ui/ml (normal < 50) as well as her anti TSH receptor antibodies > 40 UI/l (normal < 1.8). She initially reported resolution of her symptoms. Shortly after, her TSH began to fall. As a result, her levothyroxine dose was diminished until completely stopping it after two years. On last check up, she was asymptomatic, had a TSH of 0.14 μui/ml and an FT4 of 10.3 pmol/l. Intriguingly, her anti TSH receptor became negative. Ultrasound was normal at last control.
Discussion
There are some hypotheses that can explain this intriguing phenomenon: cessation of medications susceptible of inducing hypothyroidism, high iodine exposure and disappearance of blocking anti TSH receptor antibodies, which in our case seems the most plausible cause.

Recurrence of papillary microcarcinoma after 7 years of surgical treatment

Tamar Shervashidze[1], Rusudan Kvanchakhadze[2], Irakli Phagava[1], Liana Jashi[3], Khatuna Chakvetadze[4] & Badri Gvadzabia[5]
[1]David Abuladze Georgian Italian Clinic, Endocrinology, Tbilisi, Georgia; [2]David Aghmashenebeli University of Georgia, Tbilisi, Georgia; [3]Batumi Shota Rustaveli State University, batumi, Georgia; [4]EVEX Kutaisi Emergency Referral Hospital, kutaisi, Georgia; [5]National Institute of Endocrinology, Tbilisi, Georgia

Background
Papillary microcarcinoma (PMC) of the thyroid is defined as papillary thyroid carcinoma (PTC) measuring ≤1 cm., Survival after surgery for papillary thyroid microcarcinoma is greater than 99%. The chances of a recurrence of thyroid cancer after surgery are between 2-4%.
Case Presentation
9 years old boy was consulted by an endocrinologist in 2012. 6-5-1 mm thyroid nodule revealed. Thyroid antibodies and thyroid hormones were in normal ranges. He was administered 100 mg of iodine supplementation. An ultrasound examination of the thyroid gland was performed once in 6 months. In 2016, the isoechoic nodule of 9 x 6 mm, with microcalcifications was determined. FNA was performed-papillary carcinoma was detected. A total thyroidectomy was planned. Histomorphological examination of the postoperative material confirmed the presence of papillary microcarcinoma Radioiodine therapy was not performed. Thyroglobulin level was within the desired range after surgery and annually <0.2 ng/ml 2016-2021. Thyroid hormone levels were maintained within the recommended target range of 0.5-2.0 ng/ml. In 2023 an increase in TG, anti-TG, and the presence of pretracheal lymph nodes with reduced echogenicity were detected. An aspiration biopsy with cytological examination of the lymph node was performed - a secondary lesion of papillary carcinoma. On June 9, 2023, the patient underwent reoperation and radioiodine therapy.
Conclusions
After total thyroidectomy, long-term follow-up was conducted for more than 5 years with positive results. Nevertheless, in the process of observation, a tendency of TG increase was revealed, not within the limits of the recommendations >1 ng/ml, which did not indicate the risk of disease recurrence. However, with additional studies conducted, tumor metastasis was discovered and excised in time

Deep cervical lymph node metastasis of thyroid cancer: a case report

Houas Jihene[1], Heyfa Belhadj-Miled[1], Monia Ghammam[1], El Ghali Wassim[2], Malika El Omri[1], Abir Meherzi[1], Mouna Bellakhdhar[1], Yosra Hasni El Abed[3], Wassim Kermani[1] & Mohamed Abdelkafi[1]
[1]Farhat Hached Hospital, ENT Department, Sousse, Tunisia; [2]Department of Anaesthesia, Sousse, Tunisia; [3]Department of Endocrinology, Sousse, Tunisia

Introduction
Follicular thyroid cancer is the second most common differentiated thyroid cancer and accounts for approximately 10–15% of all thyroid cancers. It tends to invade blood vessels and metastasise by haematogenous spread to distant sites, most commonly to the bones and lungs. The incidence of distant metastasis in follicular thyroid cancer has been reported as 6–20%. Metastases to the retropharyngeal lymph nodes are extremely rare. the aim of this work is to document a rare case of retropharyngeal metastasis from a follicular carcinoma of the thyroid and to describe its evolutionary characteristics.
Materials and Methods
We present the case of a patient who underwent surgery at our ENT department for a follicular carcinoma of the thyroid, with the discovery of a voluminous retropharyngeal metastasis during follow-up.
Observation
We report the case of a 60-year-old woman followed for thyroid goiter, clinically and biologically euthyroid. Ultrasound revealed a multinodular goiter without suggestive signs of malignancy. The patient underwent total thyroidectomy due to dysphagia. The final pathological examination confirmed a follicular carcinoma of the right lobe of the thyroid classified as T3NoM0. Additional radioactive iodine therapy was indicated. The course was marked by the appearance, six months later, of nodal metastases in the IIA and IIB chain with thrombosis of the right internal jugular vein. The patient underwent a right radical neck dissection. During follow-up, an increase in serum thyroglobulin levels was noted despite adequate radioiodine therapy. Clinical examination revealed no abnormalities. A cervical ultrasound returned normal results. A CT scan revealed a large right retropharyngeal mass measuring 4 cm, suggestive of retropharyngeal lymph node metastasis associated with a costal bone metastasis. The patient passed away one month later.
Conclusion
The incidence of distant metastasis after total thyroidectomy for thyroid cancer is between 7% and 23%. Although rare, retropharyngeal lymph node metastasis should be considered during the follow-up of thyroid carcinomas.

New case of papillary thyreoglossal cyst carcinoma, in the absence of clear guidelines, what should be do?

El Jadi Hamza[1] & Moustaghit Imane[2]
[1]Oued Eddahab Military, Endocrinology and Metabolic Diseases, Agadir, Morocco; [2]Oued Eddahab Military, Endocrinology and Metabolic Diseases, Agadir, Morocco

Thyroglossal tract cyst carcinoma (TTC) is a rare pathological situation, The challenge is mainly in the surgical management. We report a new case of papillary TTC in a 51 year old female patient, not suspected preoperatively and confirmed postoperatively by histological analysis of the resected specimen. The therapeutic strategy was completed by a total thyroidectomy with adjuvant treatment with radioactive iodine and hormone restraint therapy. The outcome was favorable after 7 years of follow-up. The incidence of TTC carcinoma is unknown, probably in the order of 1%. Since Brentano's first description in 1911, only about 300 cases have been published, mostly as case reports or small serie. The papillary type is the most common and is found in about 83% of cases. The other types are mixed papillary-vesicular carcinomas (8%), squamous cell carcinomas (6%), a few cases of Hûrthle cell, vesicular, anaplastic and squamous cell carcinomas. No cases of medullary carcinoma have been described. In the absence of clear guidelines, the management of TTC depends on the clinical situation and the experience of the treating team. TTC carcinoma is a rare entity with an overall good prognosis. Its management is still a matter of debate between those who are satisfied with excision of the cyst and others who opt for a more aggressive treatment. In all cases, it is necessary to stratify the risk of recurrence in order to identify the modalities of subsequent follow-up. With this work, we add a new observation of a rare carcinoma with the expectation that further studies will be done to standardize the therapeutic procedure and improve the prognosis.

Specificities of papillary thyroid carcinoma in males

Neni Dezoumbe[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital, Endocrinology, Diabetology, Metabolic Diseases, and Nutrition, Casablanca, Morocco

Introduction
Thyroid cancers in males are rare forms characterized by their aggressiveness and frequent association with locoregional or distant metastases. Objective To describe the clinical and biological characteristics of papillary thyroid carcinomas in male subjects.
Materials and Methods
We conducted a descriptive cross-sectional study involving all male patients followed for papillary thyroid carcinoma at the endocrinology department of Ibn Rochd University Hospital in Casablanca from 1986 to 2023. Univariate statistical analysis was performed for all variables using Excel 2017.
Results
The male gender accounted for 45 patients, representing a prevalence of 4.4%. The mean age was 50 years, with a history of familial thyroid neoplasia in 6.6% of cases. The most common presenting complaint was multi-heteronodular goiter in 45% of cases. The average tumor size was (0.2–6.2 cm). All patients underwent total thyroidectomy, with lymph node dissection performed in 20% of cases. Radioiodine therapy was indicated in 59% of patients. Papillary carcinoma was the histological type in all cases, classified as high risk in 51.4% of cases. Follow-up revealed 25% locoregional recurrences and distant metastasis (pulmonary) in 5% of patients. Prognosis was significantly correlated with tumor size and locoregional or distant metastases at the time of diagnosis.
Discussion
Thyroid cancers in male subjects are rare and aggressive forms. Their major prognostic impact influences subsequent management, as reported in the literature.

Toxic adenoma in a patient with hashimoto's thyroiditis. a case report and review of the literature

Marjeta Kermaj[1], Ana Selaj[1], Violeta Hoxha[1], Klodiana Poshi[1], Dorina Ylli[1] & Agron Ylli[1]
[1]UHC " Mother Tereza", Endocrinology, Tirana, Albania

Introduction
Thyroid nodules are common in Hashimoto's Thyroiditis (HT) patients. They are usually hypo-functioning or "cold" areas on the scan. Presentation as a functioning "nodule" is extremely unusual. Warner reported the first case of Hashimoto's thyroiditis and hot nodule in 1971. This rare condition has been previously reported in a few cases too. We present a 55-year-old woman with toxic adenoma and Hashimoto's Thyroiditis with local compressive signs.
Case report
The patient presents in outpatient consultations with difficulty in breathing and swallowing for 3 months and an enlarged thyroid gland. Physical examination: Mild signs of hyperthyroidism. Enlarged thyroid gland. Laboratory tests: TSH 0.019 (0.3-4.5) and Ft3, Ft4 twice the normal values. Anti TPO 208.14 IU/ml (<5.5) Calcitonin = 0.50 (<6.4), Anti TG = 218.5 (<115). WBC = 7.1 k/ul (4 - 10.5), Neutrophils = 3.7 k/ul (1.6-7.56), ALT= 28 U/l (<55), AST= 21 U/l (5-34). Thyroid ultrasonography: The entire left lobe had increased dimensions, occupied by a nodule with cystic degeneration inside with dimensions over 60 mm, that displaces the trachea to the right. The right lobe was reduced in size and had bilateral reactive laterocervical lymph nodes. Thyroid Schinti scan with tc99m showed a hot nodule occupying the entire left lobe of the thyroid with a total uptake of 4.6% (0.35-3.65), with inhibition of the right lobe. Ct scan neck with contrast iv, showed: The left lobe of the thyroid with increased dimensions, transformed into a nodular structure with necrotic degeneration inside, and dimensions of 66×62 mm, extending to the jugular fossa with displacement of the trachea to the right and compressing it. It was concluded that the diagnosis was toxic Adenoma with local compressive signs in a patient with Hashimoto's Thyroiditis. Under treatment with methimazole 1 mg 2×1 tablets for 6 weeks, TSH, Ft4, and Ft3 were within normal range. Because of compressive signs, the patient performed a total thyroidectomy and the biopsy showed: chronic lymphocytic thyroiditis.
Conclusion
Our case confirms that Toxic adenoma can be associated with Hashimoto's Thyroiditis. Schinti scans with Tc99m help determine the function of nodules and the decision for definitive treatment.

Intrathyroidal CMT with high level of calcitonin

Miruna-Alicia Ungureanu[1], Ramona Dobre[1, 2], Andreea Manole[1], Anca Andrei[1], Iulia-Florentina Burcea[1, 2], Dan Octavian Alexandrescu[1] & Catalina Poiana[1, 2]
[1]National Institute of Endocrinology "C.I. Parhon"; [2]University of Medicine and Pharmacy "Carol Davila"

Introduction
Medullary thyroid carcinoma (MTC) is defined as a rare neuroendocrine tumor originated from the parafollicular C cells of the thyroid, noted for the ability of secreting calcitonin and other peptides. MTC poses a high risk of mortality if left untreated as the tumoral cells can invade nearby tissues, lymph nodes, lymphatic or blood vessels and, ultimately, other organs. Calcitonin is key in the evaluation and treatment protocol as its basal serum levels tend to be proportional with the tumor size and the extent of metastasis. Thus, targeted surgical treatment holds an important role in the therapeutic management of this disease. We present the case of a patient with low suspicion of MTC but with high suspicion of distant metastatic disease due to increased levels of serum calcitonin.
Clinical case
A 34 years old male patient, with a previous history of a 'cold' thyroid nodule in the left thyroid lobe and a serum calcitonin level of 1025 pg/ml with no significant clinical signs discovered during examination. Thyroid ultrasound described a solitary, hypoechoic, irregular macronodule in the left thyroid lobe with no suspicious lymph nodes. The family history was negative for MTC or MEN-related diseases. Fine needle aspiration biopsy confirmed the diagnosis and calcitonin wash-out level was higher than 200000 pg/ml, serum CEA levels of 56.56 ng/ml. Screening for primary hyperparathyroidism, pheochromocytoma and ectopic Cushing's syndrome was negative. Germline RET mutation is awaited. The high level of calcitonin imposed additional imaging like cervical, thorax and abdominal computed tomography which revealed no evidence of local invasion, secondary lesions. The therapeutic decision was based on calcitonin levels and involved complete removal of the thyroid along with extensive prophylactic bilateral cervical lymph node dissection (central and lateral compartments). The results of the histopathological exam confirmed the diagnosis of CMT in the thyroid nodule but no affected lymph nodes. Seven days after surgery, the patients serum calcitonin levels dropped significantly to 4.35 pg/ml, with the CEA levels lowered to 29.13 pmol/l.
Conclusion
An optimistic prognosis of a patient with MTC is usually rare. Although an agreement on the subject of prophylactic lymph node dissections in the absence of secondary lesions does not exist, ultimately, the only chance of increasing the survival rate remains surgery. In this particular case with very high levels of calcitonin of an intrathyroidal CMT, a rapidly declining level of calcitonin after one-week post-surgery offers early evidence of remission.

A foreign body of the thyroid gland

Yuriy Aleksandrov[1] & Vasiliy Semikov[2]
[1]Yaroslavl State Medical University, Surgery, Yaroslavl, Russian Federation; [2]I.M. Sechenov First Moscow State Medical University, Surgery, Moscow, Russian Federation

Patient R., 66 years old. Diagnosis: A foreign body of the thyroid gland. Anamnesis: On 01.12.2023, I ate fish. After swallowing a piece of fish, I felt discomfort in the neck area, a feeling of a foreign body appeared. On 02.12.2023, she turned to an otolaryngologist. During laryngoscopy, it was found that the fish bone stuck into the wall of the esophagus at the level of the larynx. During endoscopic removal, the bone broke off. It was possible to extract a fragment up to 2 cm long. The patient was allowed to go home. The patient had a feeling of a foreign body. The patient performed a CT scan of the neck organs. It was found that a foreign body passed through the wall of the esophagus into the right lobe of the thyroid gland. The length of the formation is 25 mm, the width is 2 mm. The patient was hospitalized in the thoracic department of the regional clinic. In FGDS, damage to the esophageal mucosa has not been established, and no foreign body has been detected. CT scan did not reveal signs of mediastinitis. On 13.12.2023, the patient was discharged with recommendations to contact a specialized center. Treatment at a specialized center on 12/18/2023: the patient's condition is satisfactory, laboratory parameters are normal. A control ultrasound revealed an inflammatory reaction around a foreign body of the thyroid gland with the threat of purulent strumitis and mediastinitis. The patient is hospitalized. A control ultrasound revealed a pronounced migration of a foreign body (up to 1 mm) towards the vascular bundle of the neck on the right. The distance from the acute end of the foreign body to the carotid artery on the right was 2 mm. On 12/19/2023, an operation was performed: removal of a foreign body of the thyroid gland and soft tissues of the neck. During the revision, it was found that the foreign body migrated to soft tissues, while there was a pronounced scarring process involving the thyroid gland and neck muscles associated with tissue damage by the sharp end of the foreign body and local bleeding. Intraoperative ultrasound was used in the search for a foreign body. The foreign body (fish bone 25 mm) was completely removed, and the patient received antibiotics in the postoperative period. The patient was discharged from the hospital for 5 days in a satisfactory condition.

Heterogeneous clinical outcomes in two separate cases of advanced differentiated thyroid cancers

Massimiliano Mazza[1], Chiara Parazzoli[1], Vittoria Favero[1, 2], Carioni Emanuela[1], Alberto Falchetti[1], Erika Grossrubatscher[1], Bendetta Zampetti[1], Iacopo Chiodini[1, 2] & Paolo Dalino Ciaramella[1]
[1]Ospedale Niguarda Ca' Granda, Milan (Italy), Endocrinology Unit; [2]Department of Biotechnology and Translational Medicine, University of Milan, Milan (Italy)

Background
Among differentiated thyroid cancers, follicular thyroid carcinoma (FTC) is the second most prevalent, representing 10-15% of cases. Histopathological features, tumour size, multifocality, presence of lymphnode metastasis at diagnosis are the most impacting features affecting clinical outcome. Tumour microenvironment (TME) may have an important ancillary role for disease progression. We present two cases of FTC with biochemical and structural persistence of disease, with different clinical outcomes and timing of disease progression.
Case report
Case 1 In November 2008, an 81-year-old male underwent total thyroidectomy for a FTC measuring 6 cm with capsular invasion. A 100 mCi radioactive iodine therapy (RAI) was administered. Whole-body scintigraphy (WBS) revealed radioiodine hyperaccumulations in both lung fields, leading to multiple RAI sessions (cumulative dose of 700 mCi). In 2014, after a fourth RAI, WBS highlighted small focal hyperaccumulations in the left lung field. In 2015 at

SPECT, a small hyperaccumulation projecting to the liver was observed. In 2021, computed tomography (CT), showed the growth of the hepatic lesion, which was surgically removed. Six months later, multiple subpleural pulmonary nodules were revealed at CT. The patient refused tyrosine kinase inhibitor treatment. Over a 14-year follow-up period, the patient enjoyed a satisfactory quality of life until June 2023 when an uncontrolled disease progression, with bone and cerebral metastasis, led to a fatal outcome. Case 2 In March 2017, a 70-year-old female underwent total thyroidectomy, diagnosed at biopsy as a Hurthle cell carcinoma, followed by 100mCi RAI treatment. In 2018 a thyroid ultrasound identified a cervical anechoic nodule, negative on WBS. Thyroglobulin levels exhibited a consistent increase. A thorax CT scan revealed pulmonary nodules, inactive at WBS. At FDG-PET scan hypercaptation was observable in thyroidal (compatible with residual disease), paratracheal and paraesofageal region. Patient started lenvatinib at low-dose due to poor compliance, systemic adverse effects and low body weight (46 kg). Over a four-year follow-up period, the patient exhibited an unexpected rapid disease progression with a fatal outcome (pulmonary, hepatic and pancreatic metastases).
Conclusions
Patients with FTC may have indolent persistence of disease for several years with an unexpected rapid progression of disease, independent from the histotype and disease extension at diagnosis. These observations suggest a possible role of the TME in influencing the disease outcomes. Future research on the TME complex interactions and its effects on disease outcome, is warranted. This would allow for a more nuanced approach, potentially modulating the TME and improve treatment outcomes.

Debulking surgery in locally advanced papillary thyroid carcinoma

Laura García García[1], M. Isabel Gutiérrez Giner[1], Ángel Luis Sánchez Álvarez[1], Ana Tejera Hernández[1], Jorge Loro Pérez[1] & Magel Fernández Alfonso[1]
[1]Complejo Hospitalario Universitario Insular Materno Infantil, General and Digestive Surgery, Las Palmas de Gran Canaria, Spain

Introduction
Thyroid cancer is the most common endocrine neoplasia, with papillary thyroid carcinoma (PTC) being the subtype that represents 75 - 80% of cases; with an indolent character and a 10-year survival rate greater than 90%. Vascular infiltration is very rare in this type of tumors, which usually spread through the lymphatic route. The treatment of choice continues to be surgery with adjuvant radioiodine based on the risk stratification of recurrence and radiotherapy in very selected cases.
Case Presentation
We present the case of a 78-year-old male patient with a grade III goiter at the expense of the left thyroid lobe with an intrathoracic component and Bethesda IV FNAC, anticoagulated for left jugular vein thrombosis. Presented in a multidisciplinary committee, a total thyroidectomy was decided. During surgery, a 10 cm locally advanced tumor mass was observed that infiltrated the esophagus and was closely adhered to the internal jugular vein. During the process, there is a loss of signal from the recurrent laryngeal nerve (RLN), so the total thyroidectomy is not completed while awaiting the definitive pathological result. The final pathology confirmed infiltrative follicular variant papillary carcinoma with extrathyroidal extension and vascular and lymphatic infiltration (pT3b). Subsequent surgery involved a totalizing right lobectomy and adjuvant 1131 treatment. Follow-up showed increased thyroglobulin, cervical remnants with a left internal jugular vein tumor thrombus, and suspicious lymph nodes in the left compartment ll. An exploratory cervicotomy revealed a large tumor thrombus affecting the entire cervical extension of the left internal jugular vein, requiring resection with spinal nerve preservation. Intraoperatively, a tumor mass infiltrating the pharyngoesophageal junction was observed, necessitating debulking surgery, leaving a small tumor due to the risk of pharyngeal fistula, excision of pathological lymphadenopathy at the level of compartment II. Subsequently, the tumor bed was marked with clips for adjuvant radiotherapy.
Discussion
Surgery remains crucial in managing recurrent thyroid cases unresponsive to radioactive iodine treatment. Locally advanced thyroid neoplasms are rare, requiring individualized management in clinical committees and specialized centers with experienced endocrine surgeons.

Clinical progression and differential diagnosis of an uncommon delayed-onset thyroid eye disease in a patient with graves' disease: a case report

Abdel Mouhaymen MISSAOUI[1], Nadia Charfi[1], Siddiqa Soomauroo[1], Souhir Maalej[1], Rihab Khochtali[1], Mohamed Abid[1] & Nabila Rekik[1]
[1]Hedi Chaker University Hospital, Department of Endocrinology, Sfax

Introduction
Thyroid eye disease (TED) is the major extra-thyroidal manifestation of Graves' disease (GD). The delayed onset of TED after hyperthyroidism resolution and the decline in TRAb levels is a rare occurrence, necessitating the exclusion of other underlying orbital inflammatory diseases.
Case Report
A 59-year-old non-smoking female patient presented with thyrotoxicosis symptoms (fatigue, palpitations, resting tremors) persisting for three months, along with a homogeneous elastic goiter and no orbital abnormalities. Laboratory investigations revealed primary hyperthyroidism (TSH < 0.01 mIU/l; FT4 = 38.7 pmol/l, 1.8xULN), with positive TRAb at 9 IU/ml (3xULN), strongly indicating GD. The patient was treated with methimazole 7.5 mg/day for 11 months, resulting in clinical improvement, normalization of thyroid function, and a decrease in TRAb levels to 3.59 IU/ml. In the 12th month of treatment, bilateral exophthalmos, eyelid retraction, and bilateral diplopia, predominantly affecting the left eye, emerged. The orbitopathy was inactive (activity score 2/7) but severe. Given the favorable clinical, biochemical, and serological evolution of GD, and the absence of smoking, we aimed to exclude underlying orbital inflammatory disease. Immunological investigations ruled out IgG4-related disease and granulomatosis with polyangiitis. Orbital MRI revealed bilateral fusiform swelling with abnormal signal and intense enhancement of the extraocular muscles. Inflammation was primarily located in the left inferior rectus muscle. The insertions of the extraocular muscles on the eyeballs were spared, ruling out idiopathic orbital myositis (IOM). Delayed-onset TED was confirmed, and the patient continued methimazole treatment with a high-dose corticosteroid regimen (6 weekly boluses of 750 mg of methylprednisolone), leading to the resolution of the patient's diplopia.
Discussion
TED is the most common orbital inflammatory condition. Its delayed onset is rare, occurring in 7% of non-smokers and 20% of smoking individuals with GD. Its primary differential diagnosis is IOM. The distinctive features of TED include the presence of thyroid dysfunction, positive TRAb, painless bilateral involvement, and preservation of extraocular muscle insertions on the eyeballs.

Iodine-induced hyperthyroidism after long-term use of povidone-iodine: a report of two cases

Laura Stirane[1, 2, 3], Viktorija Preobrazenska[1, 2], Natalija Fokina[2] & Lauma Jaunozola[2]
[1]University of Latvia; [2]Pauls Stradiņš Clinical University Hospital, Department of Endocrinology, Riga, Latvia; [3]Rezekne Regional Hospital

A 60–year-old male and 24–year-old female presented to the endocrinologist with hyperthyroidism of unknown cause. A 60-year-old male was admitted to the Department of Endocrinology with fatigue, dyspnoea, increased sweating, and anxiety. Hyperthyroidism was diagnosed with TSH < 0.0008 mIU/l [reference range: 0.3500 – 4.9400], FT4 – 4.03 ng/dl [reference range: 0.89 – 1.76] and FT3 – 12.96 [reference range: 2.3-4.2]. The patient had a history of congenital heart disease, myocardial infarction, dilated cardiomyopathy, Cardiac Resynchronisation Therapy with Defibrillator device implantation, aortic valve replacement, and because of progression of chronic heart failure (NYHA class IV) the HeartMate 3 Left Ventricular Assist Device (LVAD) implantation two years ago. A 24-year-old female visited the endocrinologist in an Outpatient clinic. She complained about nausea and vomiting almost every day, fatigue, and hand tremor. The blood test showed hyperthyroidism: TSH < 0.008 mIU/l, FT4 – 4.4 ng/dl and FT3 – 12.49 pg/ml . Since the age of 3, the patient has been diagnosed with Wolff–Parkinson–White syndrome and left ventricular hypertrophy, later repeated episodes of ventricular and supraventricular arrhythmia, including radio-frequency ablation performed at the age of 14. Subsequently Danon disease

was confirmed by genetic testing. At the age of 22 - a cardioverter-defibrillator was implanted due to ventricular tachycardia and because of progression of chronic heart disease (NYHA class IV) the Heart Mate3 LVAD was implanted. Antithyroid antibodies (TSH receptor antibodies, anti-thyroid peroxidase antibodies) were negative in both patients. They had no personal or family history of thyroid disease. Both patients had no exposure to iodine-containing contrast media, Amiodarone, or iodine supplementation over the past two years. Thyroid ultrasound findings were similar for both - mild diffuse changes in the thyroid gland that could be consistent with chronic autoimmune thyroiditis. Thiamazole 30 mg daily was initiated without improvement. The female patient was evaluated to exclude struma ovarii. Possible iodine sources were reviewed again, and it was determined that Povidone-iodine solution was used for the Heart Mate3 LVAD entry point disinfection daily. Povidone-iodine was discontinued for both patients, and Thiamazole therapy 30 mg daily was continued for one more month and then decreased to 10 mg daily. Following this, both patients felt better, their symptoms of hyperthyroidism settled. A gradual improvement and normalization of thyroid hormone tests was observed within two months and Thiamazole was discontinued. We hypothesize that using Povidone-iodine long-term could cause iodine overdose and hyperthyroidism.

Polyglandular autoimmune syndrome

Mariam Khachatryan[1]
[1]Dilanyan Clinic, Endocrinology, Moscow, Russian Federation

Polyglandular autoimmune syndromes (PAS) are rare group of diseases, which characterised by association of two or more autoimmune endocrine disorders in a single patient. Often PAS is combined with autoimmune damage of non-endocrine organs. Type 3 PAS includes combination of autoimmune thyroid disease and other autoimmune conditions. The adrenal cortex is not involved. This type of PAS typically affects middle aged women. The cause is still unclear. In this case study I describe a patient with Hashimoto's thyroiditis, latent autoimmune diabetes in adults, vitiligo, miasthenia gravis. Case study: A 68-year old female presented to the endocrinology outpatient department with complains of high blood glucose level, dropping of one eyelid, weakness in the hands in the last 3 month. She also noticed that antidiabetic drugs were not effective about 2-3 month. The patient had been diagnosed with Hashimoto's thyroiditis about 5 years before, and with diabetes mellitus type 2 about 1 year before. It was suggested as a latent autoimmune diabetes in adults and initiated insulin therapy. Laboratory tests showed high level of acetylcholine receptor antibody, anti-insulin antibody, GADA, IAA, ICA. So patient had diagnosed with PAS type 3. Treatment of PAS type 3 includes lifelong hormone replacement of any glandular failure. It is very important that patients with PAS type 3 are monitored closely to detect any glandular problems early.

Keywords: polyglandular autoimmune syndrome, Hashimoto's thyroiditis, miasthenia gravis, latent autoimmune diabetes in adults.

Thyroid surgery under local anesthesia in a selected group of patients our experience

Md Safi Ullah[1]
[1]Noakhali, Otolaryngology and HNS, Noakhali, Bangladesh

Objective

To find out the safety and fusibility of Thyroid surgery in a selected group of patients under local anesthesia. The aim of the study was to share our experience in case of home and total thyroidectomy in ENT foundation hospital and different clinics of Dhaka, Bangladesh.

Case Study: Materials and Methods

All the patient was admitted to the hospital with clinically significant goiter selected for surgical treatment (2%) xylocaine with adrenaline was used for infiltration anesthesia. Before the operation, the patient had received 1 mg per kg body weight intravenous pethidine slowly Diazepam 1 mg iv. In case of need in a selected group of patients iv ketorolac is sometimes needed.

Result

Haeme thyroidectomy performs there is no remarkable complication (Intra and post-operative) Except 3 cases (three patients postoperative scar two case Reactionary Hemorrhage mean duration of procedure is about 90 minutes The follow-up medical stay was three days. All the patients were in good general condition on the day of discharge from the hospital.

Conclusion

Surgery for thyroid swelling in a selected group of patients may be an alternative where General Anesthesia is not available and in patients contraindicated for medical reasons.

Papillary thyroid carinoma in children: features and management

Ahmed Boukhalfa[1], Salma El hilali[1], Sana Rafi[1], Ghizlane El Mghari[1] & Nawal El Ansari[1]
[1]Mohamed VI University Hospital Center, Marrakech, Morocco, Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Marrakesh, Morocco

Introduction

Differentiated thyroid carcinoma is the most common pediatric endocrine malignancy (0.5–3% of all childhood malignancies) with papillary thyroid carcinoma (PTC) being the most common type. Children have higher rates of cervical lymph node metastases, distant metastasis and recurrence. We report the case of a patient who presented a thyroid nodule whose exploration revealed PTC, to illustrate clinical, ultrasonographic and therapeutic features.

Clinical Case

Nine years-old patient, with no personal history, admitted for thyroid nodule whose evolution dated back 2 years with, on current ultrasound, a right lobar nodule, 28×17 mm (initially 17×17), oval, isoechoic, heterogeneous with multiple scattered micro-calcifications, mixed vascularization classified Eu-tirads 4 with jugulo-carotid and sub-mandibular nodes of sub-centimetric size. Clinically, no signs of dysthyroidism and was hemodynamically and respiratorily stable. Biological thyroidien tests was normal. A thyroid cytopunction revealed a follicular nodule with epithelial atypia of undetermined significance (category III). The child underwent right lobo-isthmectomy with extemporaneous sampling revealing papillary carcinoma, totalization performed with bilateral central lymph node curage In the post-operative period, the child began to experience clincal signs of hypocalcemia; peri-labial tingling, paresthesias, needles with a positive chvosteak sign in the presence of corrected calcemia at 78 mg/l. Intravenous calcium replacement was initiated, followed by oral replacement. Substitutive and inhibitory treatment has been initiated and will be adjusted according to the risk of recurrence. Patient scheduled for iratherapy 131-I* in one month.

Discussion

Children with PTC have shown a significantly higher local and regional recurrence over time when they undergone a loboisthmectomy compared to those who underwent total thyroidectomy. the high rate of multifocality (42–65%) reported in children with differentiated thyroid cancers have influenced others to recommend total thyroidectomy for all children with disease limited to the thyroid (1, 2). In view of the higher rate of cervical metastasis among children, ATA recommends prophylactic central compartment neck dissection (CCND) (1). Higher rates of post-thyroidectomy hypocalcemia among children when compared to adults is well recognized (3). CCND, extrathyroidal extension and the presence of nodal disease in the neck are the reported risk factors. Recurrence rate was significantly reduced when RAI therapy was performed.

Conclusion

PTC in children is characterized by the frequency of cervical and distant lymph node metastases and recurrences after treatment compared with adults, which justifies the use of total thyroid surgery with lymph node dissection followed by iratherapy, thus guaranteeing a better prognosis.

Keywords: PTC, chidren, metastases, total thyroidectomy, iratherapy.

Effect of central obesity indices on ultrasound and fine needle aspiration features of thyroid nodule

Bilal Natiq Nuaman[1, 2], Sanad Asaad Abd Al -Hussein[3], Mohammed Sami Turki[4] & Mahmood Shakir Khudhair[2]
[1]AL-Iraqia University, College of Medicine; [2]Baghdad, Baghdad, Iraq; [3]Najaf, Najaf, Iraq; [4]Hillah, Hillah, Iraq

Background
Obesity and thyroid neoplasia are common endocrinological diseases in the world and Iraq, and risk factors of this cancer are usually unmodifiable but there are some evidences that obesity is associated with increasing prevalence of many malignancies due to proposed pathophysiological mechanisms. Numerous research assessed the connections between thyroid disease outcomes and obesity, but only a small number took TBSRTC into account. The relationship between obesity and TIRADS is briefly discussed in a few published papers, while the great majority of studies investigating this relationship depend on BMI. To the best of my knowledge, no studies have examined the impact of central obesity on thyroid ultrasonography and FNA results in Iraq. Therefore, this study examined the relationship between thyroid FNA results in Iraqi patients and central obesity indicators as waist circumference and waist-height ratio.
Aim of the study
To Examine the effects of indexes of central obesity on cytological abnormalities of thyroid nodule FNA and risk of malignancy. To Assess the effectiveness of central obesity indices in predicting malignant TNs.
Patients and Methods
Patients with suspicious thyroid nodules who performed FNA at the cytology unit of AL Imamain AL-Kadhimain Medical City between October 2022 and April 2023 were considered for this cross-sectional research. who indicated for FNA according to ACR-TIRADS Criteria (grades TR3-TR5) and had Biochemical 'euthyroidism'
Results
There was a significant association between TBSRTC categories and WtC and WtHR categories ($P<0.0001$). But, there was a no significant association between Bethesda classes (benign vs non-benign) and WtC classes (normal vs central obesity) ($P=0.071$), and there was no age or gender difference between benign and non-benign classes, P 0.502, 0.121, respectively. The efficacy of central obesity indices in predicting malignant TNs was assessed using ROC curve analysis, which revealed that the sensitivity, specificity, and AUC of WtHR at a cutoff value of 0.61 were (66.7%, 64.2%, 0.714; respectively), while those for WtC in females were (82.4%, 68.1%, 0.767; respectively) at a cutoff value of 99 cm, and those for WtC in males were (75.0%, 66.7%, 0.646; respectively) at a cutoff value of 105 cm. The sensitivity and specificity of WtHR alone increased to 76.2% and 66% when WtHR and WtC were combined to assess the risk of malignancy.
Conclusion
The TIRADS and BETHSDA categories of TNs are highly correlated with central adiposity indices, particularly in the elderly.

Difficulties in the management of basedow's disease in children: a case study

Rahal Amel[1]
[1]bologhine hospital, endocrinology, algiers, Algeria

Introduction
Graves' disease is a rare and severe condition, affecting mainly younger children. Its appropriate management in children remains a subject of controversy in pediatric endocrinology, and the optimal duration of medical treatment to induce remission of the disease, as well as the indications for alternative therapies, remain to be defined.
Observation
This is a 15-year-old child who presented at the age of 13 years and 10 months with typical clinical signs of Graves' disease associated with exophthalmia. Clinical and paraclinical data led to the diagnosis of Graves' disease. Follow-up was difficult: the patient was noncompliant and took his treatment irregularly. Hyperthyroidism induce: osteopenia and disturbed liver function; exophthalmias without inflammation. Because of non-compliance of treatment, we opt for total thyroidectomy.
Conclusion
Positive diagnosis of Graves' disease in children is often easy, but poses difficulties in management. The well-codified medical treatment is unfortunately often very poorly accepted in children, making the duration of treatment long and often imposing radical treatment in these situations.

EP1220

Euthyroid graves' orbitopathy

Nino Turashvili[1]
[1]High Technology Medical Centre, University Clinic, Tbilisi, Georgia

Background and aims
Graves's disease is associated with specific eye signs that is called as Graves'orbitopathy or ophthalmopathy (GO). GO usually occurs with hyperthyroidism. However it can be sometimes develop several years before the hyperthyroidism. The aim of this presentation is to describe the clinical case of a 48-year-old female patient with euthyroid Graves' orbitopathy.
Case report
A 48-year old woman presented to the clinic with a few weeks history of exophthalmos. She did not report history of thyroid disease. She was not taking any medication and was not a smoker. Her TSH and FT4 - within normal reference ranges: TSH- 1.1 (*n* 0.27-4.2 mIU/l), FT4-1.2 (*n* 0.93-1.7 ng/dl). The level of anti-TSHR was elevated: Anti-TSHR-1.94 (n <1.5 U/l). Ultrasonographically, the volume of the thyroid gland was normal. She was referred to an ophthalmologist. A computed tomography (CT) scan of the orbits showed typical findings of GO. Local therapy measures (artificial tears) and supplementation of selenium was advised for mild case of GO. Currently, the patient is on regular follow-up. She still remains euthyroid.
Conclusion
Graves orbitopathy (GO) usually occurs with hyperthyroidism. However, the patient can sometimes present without thyroid dysfunction in which case it is called euthyroid Graves' orbitopathy.

EP1222

Coexistence of primary hyperparathyroidism and thyroid papillary carcinoma: about two cases

Gorgi Khaoula[1], Lamya Echchad[1], Cheibatta Zakaria[1], Rifai Kaoutar[1], Iraqi Hinde[1] & Gharbi Mohamed El Hassan[1]
[1]Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
Primary hyperparathyroidism represents a commonly encountered endocrine disorder characterized by the dysregulated secretion of parathyroid hormone (PTH), often associated with a parathyroid adenoma. The simultaneous occurrence of primary hyperparathyroidism with non-medullary thyroid carcinoma is infrequent. Our cases bring attention to this atypical connection, emphasizing the unique nature of this rare association.
Cases
In Case 1, a 63-year-old female patient, presenting a history of recurrent bilateral renal lithiasis, was admitted for the management of primary hyperparathyroidism. The localization workup favored a left inferior parathyroid nodule associated with a multiheteronodular goiter classified as Eutirads 5. Subsequent intervention included left lower parathyroidectomy combined with total thyroidectomy. Anatomopathological examination revealed a parathyroid adenoma and identified a thyroid papillary microcarcinoma measuring 0.6 x 0.7 mm Case 2 involves a 66-year-old female patient with chronic renal failure at the dialysis stage, concurrently treated for primary hyperparathyroidism. The localization workup revealed a right parathyroid nodule alongside suspicious multiheteronodular nodules classified as Eutirads 4. The patient underwent total thyroidectomy associated with right parathyroidectomy. Anatomopathological study confirmed a parathyroid adenoma and disclosed a thyroid papillary carcinoma classified as PT1bNxMx.
Discussion & Conclusion
The co-occurrence of non-medullary thyroid carcinoma and hyperparathyroidism is considered rare, and the underlying mechanisms of this association remain inadequately understood. A potential hypothesis suggests a connection rooted in embryological origins and shared genetic factors, possibly exacerbated by elevated parathyroid hormone levels, diminished vitamin D levels, and hypercalcemia, resulting in heightened levels of angiogenic growth factors. While this association is infrequent, it should not be disregarded during the preoperative phase. A thorough acknowledgment of this dual pathology is crucial for ensuring optimal management of both conditions

Assessment of sarcopenia in patients with diabetes mellitus, considering body composition

Elena Makhlina[1], Yana Navmenova[1], Oksana Kononova[1] & Tatiana Mohort[2]
[1]Gomel State Medical University, Chairs Internal Medicine No. 1 with courses in endocrinology and hematology, Gomel, Belarus; [2]Minsk, Endocrinology, Minsk, Belarus

Objective
To assess the features of the manifestation of sarcopenia (SP) in patients with diabetes mellitus (DM), taking into account the body composition.
Materials and study methods
The study included 87 patients with DM (29 men - 33% and 58 women - 67%). The average age of patients was 41.59 ± 11.84 years and duration of diabetes was 12.51 ± 6.39 years. The study included anthropometric measurements: mass body index (BMI), waist circumference (WC), shin circumference (SC). Muscle strength (MS) was determined using hand dynamometry, and muscle function (MF) was assessed using a 4-meter walking speed test. Taking into account WC, patients were divided into 2 groups: the first group ($n=45$) WC less than 80 cm for women and less than 94 cm for men and the second group ($n=42$) with WC exceeding these target parameters taking into account gender. Statistical processing of the data array was performed using the statistical program «Statistica 10.0» (StatSoft, GS35F-5899H). The level $P<0.05$ is considered as a criterion for the statistical confidence of the results.
Study results and discussion
When assessing SP parameters in patients with DM, the groups differed significantly in muscle mass (MM) assessed by SC (SC first group 35.00 [34.00; 36.00]cm, second group 38.00 [37.00; 39.00] cm) and MF (first group 4.00 [4.00; 4.00] points, second group 3.00 [3.00; 4.00] points) $P<0.05$. There were no significant differences in MS between the groups (first group 27.27 [20.50; 37.00] kg, second group 21.00 [18.00; 31.50] kg) $P>0.05$. There was a decrease in MM in 14% of patients in the first group and in 8% of patients in the second group. A decrease in MF prevailed in patients in the second group (62%), while in the first group a decrease in MF was not noted. The decrease in MS prevailed in patients in the second group (first group – 29%, second group – 46% of patients) $P<0.05$.
Conclusions
Decreased MS (46% of patients) in patients with DM, which determines the probability of SP, and decreased MF (62% of patients) were noted in patients with WC and BMI exceeding the target values, and decreased MM prevailed in patients with WC and BMI corresponding to the target normal values.

EP1227

Patient perception of unmet needs for multiple endocrine neoplasia (MEN) in germany

Rosemarie Schubert[1,2], Petra Bruegmann[1,2], Jo Grey[2,3], Johan de Graaf[4], Juliet Fleischer[5], Helga Schmelzer[1], Philipp Drewitz[2] & Ludwig Schaaf[2,6]
[1]Netzwerk Hypophysen - und Nebennierenerkrankungen e.V., Fürth, Germany; [2]European MEN Alliance e.V., München, Germany; [3]The Association for Multiple Endocrine Neoplasia Disorders (AMEND), Tonbridge, Kent, United Kingdom; [4]Nederlandse Hypofyse Stichting, Nijkerk, Netherlands; [5]Ludwig-Maximilians-Universität München, Institut für Statistik, München, Germany; [6]München Klinik Schwabing, München

The German Network for Pituitary and Adrenal Disorders (Netzwerk Hypophysen- und Nebennierenerkrankungen e.V.) conducted a nationwide survey on unmet needs of patients with multiple endocrine neoplasia (MEN) in Germany. The study aimed to identify unmet needs in patient care and quality of life, as well as potential areas for improvement.
Methods
The survey was based on a questionnaire developed by the European MEN Alliance (EMENA) and was distributed by the German Patients' Advocacy Group using the European Commission's EU Survey platform among group members, physicians, and social media. A total of 73 responses were analysed.
Results
Of the responses analysed, 23% ($n=17$) were from patients or their parents and carers aged 39 years or younger, and 77% ($n=56$) were from those aged 40 years or older, of whom 34% were male. 54 cases of MEN1, 10 cases of MEN2A, 6 cases of MEN2B, and 3 cases of MEN4 were included. Just under 50% of all cases were managed by a multidisciplinary team and were not aware of reference centres. The time to diagnosis is rated as too long (30%), psychological help is missing (40%). Approximately one-third of the participants indicate their GP's knowledge of their disease as poor. More than half of the participants rate the communication among the physicians as suboptimal. The involvement of endocrine nurses is not well recognized and is unknown to many (57%). Unmet needs according to patients include biomarkers to predict new tumours or recurrence (28%), more clinical trials (20%), digital tools for quick screening results (18%), faster tests and scans, and self-monitoring of hormones in the blood. It is noteworthy that 60% of the MEN patients are not registered in any research database, despite almost all respondents (93%) being interested in registries. They hope for new knowledge about the disease and treatments. About 45% are not members of a patient group, although meetings with fellow patients are described as important (62%). The results of the survey indicate that German patients generally perceive the quality of medical care to be good. However, there are some unmet needs regarding access to reference centres, research registries and membership of patient organisations. In particular, the access to psychological help and communication between the different doctors involved in the care of MEN patients needs improvement.

EP1228

Primary bilateral macronodular adrenal hyperplasia caused by a novel variant in the ARMC5 gene

Mariana Lopes-Pinto[1], André M Travessa[2,3], Ema Paula Ricca Lacerda Nobre M Caetano[1,3] & Ana Paula Barbosa[1,3]
[1]Unidade Local de Saúde de Santa Maria, Hospital de Santa Maria, Endocrinology Department, Lisbon, Portugal; [2]Unidade Local de Saúde de Santa Maria, Hospital de Santa Maria, Medical Genetics Department, Unidade Local de Saúde de Santa Maria, Hospital de Santa Maria, Lisbon, Portugal, Lisbon, Portugal; [3]Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal, Lisbon, Portugal

Introduction
Primary Bilateral Macronodular Adrenal Hyperplasia (PBMAH) represents <2% of all causes of Cushing's Syndrome (CS). Clinical course is insidious, with adrenal bilateral macronodules and gradual cortisol excess, only rarely presenting with overt CS. The pathophysiology remains unclear in most cases; however, pathogenic variants in the onco-supressor ARMC5 gene are described in 25-50% of PBMAH and may confer a more severe clinical course.
Objectives
To report a new germline variant in the ARMC5 gene associated with PBMAH.
Case Report
A 34-year-old woman presented with exuberant CS phenotype including progressive weight gain, facial hair growth, plethoric face, dorsocervical and supraclavicular fat pads and easy bruising. She had been diagnosed with prediabetes and hypertension. Serum morning cortisol was 46.1 µg/dl (N: 6.2-18) and ACTH was <1 pg/ml. Morning cortisol after 1 mg overnight dexamethasone suppression test was 37.9 µg/dl, 24 h urinary cortisol was 6825 µg/24 h (N:124-581), while salivary cortisol kept circadian rhythm. Androgen and mineralocorticoid hypersecretion were excluded. Androgen and mineralocorticoid hypersecretion were excluded. Adrenal CT scan documented evident bilateral adrenal enlargement with multiple hypodense macronodules that reached a maximum diameter of 67 mm and 49 mm. No aberrant receptors were identified following a stimulation tests protocol. The patient showed good biochemical response to metyrapone and was submitted to unilateral adrenalectomy of the largest adrenal gland. Histopathologic evaluation revealed adrenal cortex macronodular hyperplasia, compatible with the diagnosis of PBMAH. There was an evident clinical response after surgery, with improved well-being, CS phenotype regression and weight loss. Additionally biochemical response with normalization of cortisol levels was achieved. One year after surgery, hydrocortisone replacement was resumed. Given the clinical diagnosis, a Next Generation Sequencing (NGS) panel including the ARMC5 and KDM1A genes was performed, and identified a novel germline variant in heterozygosity in the ARMC5 gene, c.169G>T p. (Gly57), leading to a premature stop codon. This new variant is classified as likely pathogenic. The recurrence risk for offspring is 50%.
Discussion and Conclusions
We report a case of PBMAH with a new germline variant in the ARMC5 gene, c.169G>T p.(Gly57), diagnosed due to overt CS and successfully treated with unilateral adrenalectomy. Genetic assessment of patients with PBMAH and family members may allow an early diagnosis of CS, minimize complications, and contribute to a better management and follow-up of PBMAH patients.

Steroidogenesis inhibitors in mild/subclinical cushing's syndrome: results from a retrospective cohort of patients

Alessandro Bavaresco, Filippo Ceccato, Pierluigi Mazzeo, Martina Lazzara, Giacomo Voltan, Irene Tizianel, Alessandro Mondin & Mattia Barbot
University of Padova, Endocrinology Unit, Padua, Italy

Cushing's syndrome (CS) is a severe disease associated with elevated morbidity and mortality rates, up to four times higher than those of general population. Whether the positive effects of cortisol-lowering medications is widely documented in overt CS cases, its impact on mild or subclinical CS remains unclear since limited clinical investigations have been performed in patients with subclinical hypercortisolism. In this study, we retrospectively analysed clinical data from patients with mild CS treated with either Ketoconazole or Metyrapone. Inclusion criteria were: serum cortisol levels after dexamethasone suppression test >50 nmol/l, slight increase of urinary free cortisol (UFC) levels (<2 times the upper limit of normal) and/or impaired circadian rhythm of cortisol. Our aim was to evaluate the effects of steroidogenesis inhibitors on UFC, late-night salivary cortisol (LNSC), ACTH, metabolic parameters, and blood pressure in these patients. Twenty-five patients (20F and 5 M) met the inclusion criteria, with 12 diagnosed with adrenal CS and 13 with Cushing's Disease. Fifteen patients were treated with Metyrapone and ten with Ketoconazole. Significant reduction in UFC levels were observed after 6 (median [IQR] levels 120 [65 – 162] nmol/24 h, *P* 0, 021) and 12 months of treatment (74 [48 – 146], *P* 0, 008) compared to baseline (178 [116 – 255], along with a reduction in LNSC (baseline 3.7 [3.4 – 5.1] nmol/l, 12 months 2.7 [1.7 – 3.6] *P* 0, 022) and increase in ACTH levels at 12 months (baseline 17.7 [6.7 – 43.8] ng/l, 12 months (33 [7.9 – 58.5], *P* 0, 033). However, metabolic parameters such as glucose, HbA1c, LDL cholesterol, waist circumference and blood pressure did not change over time. The subgroup analysis of patients treated with Metyrapone also showed an improvement of glucose metabolism both at 6 and 12 months. Conversely, patients treated with Ketoconazole did not experience any of these changes. Additionally, we considered patients treated for more than 12 months. Sixteen patients were included, with follow-up period which ranged from 13 to 125 months. We observed a significant reduction in UFC, total cholesterol, LDL (baseline 124 [102.75 – 144.3] mg/dl, last follow-up 87.2 [75.7 – 111.3], *P* 0, 028) and an increase in ACTH levels. To conclude, metyrapone might be considered to control mild/subclinical CS. Although no metabolic effects were observed after 6-12 months of treatment, an improvement in lipid profile was observed in patients treated for a longer period. Further studies are needed to evaluate the metabolic and cardiovascular implications of medical therapy in these patients.

Audit on management of addison's disease in pregnancy

Masato Ahsan[1,2], Emma Bremner[1], Diane Todd[1], Chandrima Roy[1], Miles J Levy[1,2], Shailesh Gohil[1,2] & Narendra Reddy[1,2]
[1]Leicester Royal Infirmary, United Kingdom; [2]University of Leicester, United Kingdom

Background
Primary adrenal insufficiency or Addison's disease (AD) is characterized by glucocorticoid and mineralocorticoid deficiency due to lesion of the adrenal glands through different mechanisms (1). Addison's disease is a risk factor for adverse maternal and neonatal outcomes. Close monitoring is required for these patients during the intrapartum and postpartum periods.(2)
Objective
Retrospective evaluation of the management of Addison's disease in pregnant patients, focusing on adherence to guidelines, monitoring practices, and maternal and fetal outcomes.
Methods
Retrospective data was collected after reviewing medical records of pregnant patients with diagnosed Addison's disease.
Results
$n=7$, mean age of 27, mean BMI at booking 30.5, 100% patients were on Hydrocortisone and Fludrocortisone, All pregnancies were spontaneous, 15% patient had hospital admission with adrenal crisis within one year prior to the pregnancy, 2 patients had miscarriage (at 6th week and 8th week) and both of them prior to first antenatal visit, 70% patient had successful outcome of pregnancy and among them all were reviewed in endocrine antenatal or maternal medicine clinic. None of the patient was reported to have gestational hypertension or pre-eclampsia. Mean Sodium was 137 (lowest 128 and highest 142), Potassium was 4.8 (lowest 4.2 and highest 5.6). Among the 70% pregnancy, all of them reached the term and all had NVD. Labour was induced in 1 patient. Average birthweight of the babies was 2900 grams (highest 3500 gram and lowest 2300 grams). Neonatal seizure or neonatal hypoglycaemia was reported in none of the babies.
Conclusion
This audit highlights the importance of stringent adherence to management protocols for Addison's disease during pregnancy. Pregnant individuals with Addison's disease require ongoing monitoring throughout pregnancy and postpartum by multidisciplinary teams. It is crucial to provide patient education and specialized monitoring to prevent complications arising from inadequate or excessive replacement therapy during this time. Timely referral to hospital services facilitating collaboration between Endocrinology and Obstetrics is essential.

EP1231

Autoimmune endocrinopathies associated with the use of immune checkpoint inhibitors: a clinical case of a combination of isolated secondary adrenal insufficiency and diabetes mellitus

Laura Ebanoidze, Ekaterina Pigarova, Larisa Dzeranova, Elena Przhiyalkovskaya & Lyudmila Ibragimova
Endocrinology research centre, st. Dmitry Ulyanov, 11, Moscow, Russian Federation

Introduction
Endocrinopathies are one of the most common autoimmune adverse events (AIAEs) causing severe toxic complications during the use of checkpoint inhibitor therapy (CPI).
Clinical Case
A patient with complaints of hyperpigmentation of the skin of the back in August 2022 an excisional biopsy was performed and pigmented epithelioid cell melanoma with tumor growth along the resection margin was verified. In December 2022, CT revealed metastases in the right axillary and supraclavicular lymph nodes, the right lung, the right scapula and the right groin area - mts skin melanoma of the back T4aN3M1 b (R1), and therefore therapy with pembrolizumab (a human monoclonal antibody IgG4 kappa that selectively blocks PD-1) was initiated. In August 2023 with manifestations of asthenic syndrome, dyspepsia (nausea, vomiting), an increase in venous blood glucose to 14-16 mmol/l, an endocrinologist at the place of residence diagnosed type 2 diabetes mellitus and recommended taking metformin and glimepiride. Due to the lack of improvement in general well-being the patient was hospitalized to an emergency department with diabetic ketoacidosis where insulin therapy was initiated (insulin glargine 14 units at night, short-acting insulin 3-4 units before main meals) with subsequent stabilization of the condition, but continuous persistence of asthenia and hypotension.. Subsequently, based on low values of ACTH and blood cortisol as well as 24-hour urine cortisol, secondary adrenal insufficiency was identified, for which hydrocortisone was prescribed. Due to the lack of compensation for adrenal insufficiency, the drug was replaced with prednisolone at a dose of 7.5 mg $\rightarrow$ 5 mg/day. Later, due to severe hypotension on either glucocorticoid therapy (BP 80/40 mm Hg), fludrocortisone 0.05 $\rightarrow$ 0.1 mg was added to therapy. In November 2023 during hospitalization in the endocrinology hospital, his lab tests showedlow levels of C-peptide – 0.0035 ng/ml (1.1-4.4), insulin – 1.42 mU/ml (2.6-24.9), absense of antibodies to GAD – 0.2 U/ml (0-10), insulin – 2.68 U/ml (0-10), tyrosine phosphatase <1 U/ml (0-10) and positive islet cell antibodies – 2.6 U/ml (0-1). Insulin therapy was optimized, glycemic levels were stabilized within individual target values. According to hormonal analysis: ACTH – 2.77 pg/ml (7.2-63.3), cortisol – 41.42 nmol/l (171-536). MRI of the brain visualized heterogeneity of the adenohypophysis and the developing "empty" *sella turcica*.
Conclusion
Considering the etiological features of the occurrence of AIAEs during the use of CPI, a multidisciplinary approach is required for comprehensive and effective management of patients, minimizing complications and fully implement the therapeutic potential of this treatment method.

EP1232

Angiogenesis in benign and malignant thyroid pathologies based on the vascular endothelial growth factor (VEGF) and CD34 markers activities

Tamuna Gvianishvili & Liana Gogiashvili

Ivane Javakhishvili Tbilisi State University, Alexandre Natishvili Institute of Morphology, Department of Clinical and Experimental Pathology, Tbilisi, Georgia

Angiogenesis is critical for tumor growth and metastatic spread. Vascular Endothelial Growth Factor (VEGF) is the most potent inducer of neovascularization, and its increased expression is associated with worse clinical outcome in many diseases. The aim of our work was to evaluate the dynamics of VEGF and CD34 molecular morphology with Follicular Epithelial Dysplasia (FED) in Thyroid neoplasm and autoimmune pathology. These markers allow accuracy distinguishing between pseudoneoplastic hypertrophy (Graves' disease) and neoplasia (Papillary Thyroid Carcinoma (PTC)). 36 patients in equal amounts were evaluated: Hashimoto's Thyroiditis (HT) ($n=12$), Graves' disease ($n=12$), PTC ($n=12$), which had undergone total thyroidectomy or lobectomy. Immunohistochemical reaction with VEGF-138 and CD34 antibody (Leica Novocastra, UK) and routine H&E diagnostic treatment were used. As a result, molecular analysis using data, obtained from Immunohistochemistry, VEGF expression was markedly lower in Graves' disease and HT, than in PTC. But there was no significant association between CD34 expression and thyroid pathology variants. Consequently, incidence of FED correlate with VEGF activity rate. Based on the above mentioned observation, neovascularization/angiogenesis play a crucial role for the growth and metastatic spread of neoplasms and is comparable to each other. We hypothesize that the thyroid tumors in early stage of carcinogenesis (precursor lesion) is characterized by well-developed vasculo- and angiogenesis and became secondary objective of our research.

DOI: 10.1530/endoabs.99.EP1232

EP1233

Features of pregnancy after simultaneous pancreas-kidney transplantation in patient with type 1 diabetes mellitus (clinical case)

Madina Yevloyeva, Darya Savitskaya, Anastasia Severina, Natalia Trubitsyna & Minara Shamkhalova
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
Simultaneous pancreas-kidney transplantation (SPKT) is the best way to restore normoglycemia and renal function in patients with type 1 diabetes mellitus (T1D) and end-stage renal disease (ESRD). Pregnant patients after SPKT are a high-risk group for adverse events/loss fetal and transplantation organs. These risks are significantly reduced due to pregnancy planning, regular monitoring of the woman and fetus condition with timely correction of immunosuppressive therapy, maintaining blood pressure (BP) and glycemia, choosing the optimal birth time, mode of delivery.
Case Description
A 34-years-old woman with T1D (for 25 years) and ESRD underwent successful SPKT in 2021 in preparation for pregnancy. Graft function was preserved during treatment in endocrinology hospital in 2022: HbA1c = 5.6%, estimated glomerular filtration rate 80.9 ml/min, normoalbuminuria. All necessary conditions for successful planned pregnancy outcome were discussed. A transplantologist adjusted immunosuppressive therapy: mycophenolic acid was replaced by azathioprine (teratogenic effect), the patient continued taking methylprednisolone and tacrolimus (his concentration was maintained within the target values). A 16-week pregnant patient was admitted to an endocrinologic hospital because of BP episodic elevating up to 160/90 mmHg in 2023. The transplanted kidney function corresponded to stage 3a microalbuminuric CKD. Blood glucose levels was found to be higher than the target values for pregnant women during diet therapy (HbA1c = 5.6%, glycemia range: 4.6-9.3 mmol/l). Insulin (glargine) therapy was recommended due to failure to achieve the glycemic targets, which injections were refused by the patient. BP stabilized by optimal methyldopa dose selection. Glycemic target were ensured by diet therapy in the future. A 34-week pregnant patient was hospitalized in a nephrology ward because of increased creatinine level (175 μmol/l). After consultation with transplantologist it was decreased to 140 μmol/l due to reduction of the tacrolimus dose. A cesarean section was performed during the planned hospitalization to the maternity hospital at 38 weeks of pregnancy. The child birth weight was 3320 g, height - 52 cm, Apgar score 8-8 points. Creatinine, urea and blood glucose values of mother and child were normal in the postnatal period.
Conclusion
Pregnancy management in patients after SPKT should begin at the planning stage with the correction of immunosuppressive therapy and careful monitoring graft function. Such patients should be monitored by a multidisciplinary team (endocrinologist, nephrologist, obstetrician, transplantologist) in order to ensure a favorable pregnancy and delivery course with minimization of potential risks for mother and child. The success of these measures proves the experience of our patient.

EP1234

Patient with MEN1 gene deletion and the classic triad of MEN-1 components

Rustam Salimkhanov[1], Victoria Vishnyakova[1], Ekaterina Kim[1], Anastasia Lavreniuk[1], Anna Eremkina[1], Timofei Vizerov[2], Marina Utkina[1] & Natalia Mokrysheva[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Research Centre for Medical Genetics, Moscow, Russian Federation

Introduction
Multiple endocrine neoplasia syndrome type 1 (MEN-1) is an autosomal dominant disorder caused by germline mutations in the *MEN1* gene encoding menin. *MEN1* mutations are mainly represented by deletions/insertions, nonsense, splice site or missense mutations and can be detected by DNA sequencing. MEN-1 generally includes parathyroid, adenohypophysis, and pancreatoduodenal neuroendocrine tumors.
Clinical Case
Patient S., 26-years-old female, admitted with morbid obesity (BMI – 49, 5 kg/m^2), weakness, vertigo, high blood pressure and irregular menstrual cycle. Primary hyperparathyroidism (PHPT) was diagnosed at 23 (2020): PTH – 481.6 pg/ml (15-65), $Ca_{adj.}$ – 3.0 mmol/l (2.15-2.55). The patient underwent selective parathyroidectomy (histologic confirmation of adenoma) with postoperative PTH and blood Ca normalization. Three years later, laboratory tests revealed PHPT relapse: PTH – 158.0 pg/ml (15-65) with a high-normal $Ca_{adj.}$ – 2.55 mmol/l (2.15-2.55), normophosphatemia – 0.8 mmol/l (0.74-1.52), normocalciuria – 5, 65 mmol/d (2.5-8.0). Screening for PHPT complications excluded nephrocalcinosis/nephrolithiasis, gastric and duodenal ulcer disease. DXA showed decreased bone mineral density in L_{1-4} below age-expected values: -2.9 SD (Z-score). Imaging techniques (US;^{99m}Tc-sestamibi scintigraphy with SPECT-CT) visualized left upper, right lower and upper abnormal parathyroid glands (PGs) (maximum size 1.6x0.85x0.5 cm) in typical locations. In 2023, S. had a surgical removal of three altered PGs with remission achievement. Histological analysis verified hyperplasia and adenoma. Therapy after discharge included alfacalcidol and Ca supplements. We diagnosed the patient with hyperprolactinemia – 1526 mEd/l (64-365). Brain MRI revealed an endosellar pituitary microadenoma (6x8 mm). Dopamine receptor agonist therapy was prescribed. Laboratory tests showed hypergastrinemia – 3283.0 pg/ml (13.0-115.0), chromogranin A elevation –34.6 nmol/l (<3.00). Contrast-enhanced CT scan detected multiple pancreatoduodenal tumors (maximum size 2.0x2.0x2.0 cm) with focal SSTR2 overexpression at PET-CT with ^{68}Ga-DOTA-TATE, confirming its neuroendocrine origin. Considering clinical findings genetic analysis was performed identifying mutation in the *MEN1* (an extended deletion in the heterozygous state of HG38:chr:11 chromosome with approximate boundaries 64804062-64810384 and p. 6322 bp, including 2-10 exons of the *MEN1* gene (NM 130799.2). We used chromosomal microarray analysis as a reference method: microdeletion in chromosome 11 (67901 base pairs), imbalance region genes – *MEN1*, *MAP4K2*, *CDC42BPG*, *EHD1*.
Conclusions
There is currently no conclusive data on the genotype-phenotype correlation of MEN-1. Small or large deletions of the *MEN1* gene are rare and have been described previously as pathogenic. Deletions of other genes are also of interest. Presumably they may affect the clinical manifestations of the disease.

Use of bidirectional Mendelian randomization to unveil the mutual associations of Helicobacter pylori infection and autoimmune thyroid diseases

Kai Wang & Qinnan Zhang
Shanghai Fifth People's Hospital, Fudan University, Department of Endocrinology, Shanghai

Previous observational studies found associations between *Helicobacter pylori* infection and autoimmune thyroid diseases (AITDs), but the causal nature of this association is still uncertain. We investigated the causal effect of 6 crucial antibodies against *H. pylori* on AITDs using a bidirectional Mendelian randomization (MR). We found anti-*H. pylori* OMP significantly increased the

risk of hyperthyroidism and Graves' disease (GD). In addition, our reverse MR analysis indicated hyperthyroidism could increase the levels of CagA and OMP antibodies. We also observed causal roles of GD on anti-*H. pylori* OMP. Our analyses indicate the mutual effects of *H. pylori* infection and AITDs, suggesting the existence of a gut-thyroid axis. These results also provide evidence of the bidirectional causal association between anti-*H. pylori* OMP with hyperthyroidism and GD, resulting in a vicious circle.

Insufficient bone mineralization to sustain mechanical load of weight in obese boys: a cross-sectional study

fabienne Emeriau, Amsellemn Jager Jessica, Bouhours-Nouet Natacha, Donzeau Aurelie, Rouleau Stephanie, Rerat Solene, Labarre Emmanuelle, Levaillant Lucie & Regis Coutant
Angers University Hospital Center, Angers, France

Context
The increase in bone mineral content (BMC) and density (BMD) measured by dual-energy X-ray absorptiometry (DXA) in obese children may not sustain the mechanical load associated with weight, and the factors influencing bone mineralization are not well known.
Objective
We described bone mineralization in overweight- obese (ow/ob) and lean (non-ow/non-ob) boys in relation to body composition.
Methods
Cross-sectional study in the Pediatric Endocrinology Unit of Angers University Hospital. Two-hundred-forty-nine ow/ob boys aged 8-18 underwent DXA and insulin, testosterone, and IGF-1 measurements. Bone mineralization was compared with data obtained from 301 lean boys of similar age and height from the NHANES study from 2011 to 2015, using the same DXA model. Path analyses were performed to evaluate the factors associated with total body less head (TBLH) BMC.
Results
The mean age and height-adjusted difference in TBLH-BMC between obese and lean boys was 241 ± 20 g/cm^2. Each 1 kg/m^2 increase in BMI was associated with $+39 \pm 6$ g of TBLH-BMC in lean subjects vs. $+25 \pm 3$ g in obese subjects ($P < 0.05$). Each 1 kg/m^2 increase in lean BMI (LBMI) was associated with $+78 \pm 5$ g of TBLH-BMC in lean and obese boys, and each 1 kg/m^2 increase in fat mass index (FMI) was associated with a decrease of 9 ± 3 g of TBLH-BMC. These findings suggest that the rise in TBLH-BMC observed in obese boys cannot sustain the increased mechanical load associated with weight. The Path analyses for TBLH-BMC Z-score in lean boys shows that TBLH-BMC Z-score was directly influenced by LBMI and height Z-scores (positively) and indirectly influenced by testosterone, FMI, and height Z-scores (positively, mediated through LBMI Z-score). And the path analyses for TBLH-BMC Z-score in obese boys shows that TBLH-BMC Z-score was directly influenced by LBMI and height Z-scores (positively) and indirectly influenced by insulin, height Z-scores (positively, mediated through LBMI Z-score), indirectly influenced by IGF-1, testosterone, and insulin Z-scores (positively, mediated through height and LBMI Z- scores). Finally, FMI Z-score indirectly influenced TBLH-BMC Z-score both positively (through LBMI Z-score) and negatively (through its negative impact on IGF-1 and testosterone Z-scores).
Conclusion
Bone mineralization in obese children and adolescents, although increased in response to the increased mechanical load of weight, did not follow the same positive relationship with BMI as that observed in lean boys. Lean body mass, had a similar positive relationship with bone mineralization in obese and lean boys, whereas fat mass had a negative impact.

Therapeutic options in the control of refractory hypercalcemia due recurrent parathyroid carcinoma: a case series

Olga Spasskaya, Ekaterina Kim, Rustam Salimkhanov, Anastasiia Lavreniuk, Anna Eremkina & Natalia Mokrysheva
Endocrinology Research Centre

Introduction
Parathyroid carcinoma (PC) is one of the rarest malignant endocrine neoplasms (0.005% of all oncological diseases). PC relapses in 40-60% cases. The severity of the disease is determined by life-threatening hypercalcemia. Surgery is the gold treatment standard of primary tumors and distant metastases, but if it is contraindicated there are few options to control life-threatening hypercalcemia.
Case 1
A 36-year-old-woman with a recurrent parathyroid carcinoma (PC) after multiple surgeries was admitted with symptoms of hypercalcemic crisis. Laboratory test revealed severe hypercalcemia - 4.62 mmol/l (2.15-2.55), elevated PTH - 265 pmol/l (2.0-9.4), hypophosphatemia - 0.58 mmol/l (0.74-1.52) while taking zoledronic acid 4 mg/month for 11 months and cinacalcet 90 mg/day (further dose titration lead to dyspepsia). The PET-CT with 18-FDG showed metastases in both lungs, pleura, multiple bones and liver. Due to ineffectiveness of previous therapy, we initiated denosumab 120 mg/28 days with a significant clinical and laboratory improvement. 3 months later Ca adj. was 2.6 mmol/l without cinacalcet therapy.
Case 2
A 70-year-old woman with a PC relapse and distant lung metastases complaining of muscle weakness, adynamia, bone pain and hoarseness was hospitalized in our Centre. Laboratory examination showed hypercalcemia - 4, 04 mmol/l, increased PTH - 1148 pg/ml and low eGFR (CKD-EPI) - 32 ml\min\1.73 m^2. We initiated infusion therapy, cinacalcet and denosumab 60 mg with the achievement of normocalcemia - Ca adj. 2.26 mmol/l on the 14th day. She was discharged under cinacalcet 60 mg/day. 6 months later she was admitted again with symptomatic hypercalcemia - Ca adj. 4, 13 mmol/l and reduced eGFR (CKD-EPI) - 27 ml/min/1.73 m^2. We started infusion therapy, titrated cinacalcet to 90 mg/day and provided injection of denosumab 60 mg. 7 days after Ca adj. was 2.9 mmol/l, eGFR (CKD-EPI) - 42 ml/min/1.73 m^2. Failure to achieve significant calcemia reduction we prescribed denosumab 120 mg/28 days with cinacalcet titration to 120 mg/day under regular laboratory follow-up
Conclusion
Managing a recurrent PC is challenging. Denosumab is a therapy of choice in bisphosphonate/calcimimetics refractory hypercalcemia and low eGFR.

Characteristics of prolactin macroadenomas:a cross-sectional analytical study of 40 cases

Farah Ayechi[1], Hanene Sayadi[1], sana abid[1], Raoua Naouar[1], Ghassen Belkahla[2], Atef Ben Nsir[2], Bilel Ben Amor[1], Ekram Hajji[1], Ines Bayar[1], Héla Marmouch[1], Inès Khochteli[1], Mahdi Darmoul[2] & Gema Martinez Tames[3]
[4]Fattouma Bourguiba Hospital, endocrinology and internal medicine department, monastir; [2]Fattouma Bourguiba Hospital, Neurosurgery department, monastir; [3]Hospital Valle del Nalon, Servicio de Endocrinología y Nutrición, Spain

Introduction
Macroprolactinoma is a rare pathology often considered benign. However, its singularity lies in its potential to become highly invasive, threatening both functional and vital prognosis by infiltrating surrounding structures.
Patients and methods
We conducted a monocentric, cross-sectional, analytical study of patients followed for confirmed prolactinoma at the endocrinology-internal medicine and neurosurgery departments of the Fattouma Bourguiba University Hospital, Monastir, from January2000 to March2022.
Results
Our study population comprised 24men and 16women (sex ratio (M/F)1.5) with a mean age at diagnosis of 41 ± 15.3 years. Men were significantly older than women ($P < 0.001$). The mean time to diagnosis was 1.9 ± 0.68 years. The main circumstances of discovery were: headache (47.5%), visual disorders (65%), galactorrhea (22.5%), menstrual cycle disorders (50% of women) and erectile dysfunctio (41.66% of men). The clinical signs most frequently encountered in both sexes were headache (70%), reduced visual acuity (60%) and visual field impairment (65%). In women, galactorrhea-amenorrhea syndrome was the most frequent clinical sign: galactorrhea was noted in 75% of patients, and secondary amenorrhea was present in 56.25% of cases. In men, erectile dysfunction (58.33%) and decreased libido (33.33%) were the most common signs. Median prolactinemia was 399 ng/ml[291.4 - 1075] and mean tumor size was estimated at 28.25 ± 11.85 mm. Extra-sellar extension was observed in 82.5% of cases, with invasion of the cavernous sinus in 62.5% of our patients. In our series, macroprolactinoma was complicated by pituitary deficiency in 85% of patients, involving the gonadotropic axis in 72.5% of cases. The metabolic impact showed the presence of: overweight or obesity (55%), prediabetes (15%), unrecognized diabetes (2.5%), hypertriglyceridemia (7.5%)and hypercholesterolemia (27.5%). Treatment with dopaminergic agonists resulted in tumor reduction and disappearance in 77.5% and 15% of cases respectively, and normalization of

serum PRL levels in 65% of cases. Complete remission was achieved in 15% of our patients, more frequently in women than in men, with a statistically significant difference ($P=0.01$). At the end of our study, we noted a similar serum PRL concentration whatever the type of treatment received, and an absence of significant difference between the mean rate of tumor reduction in the case of surgical treatment compared with that of medical treatment ($P=0.2$). Among the factors associated with the use of surgery found in our work, only initial tumour size was correlated with surgical treatment.
Conclusion
Macroprolactinoma is a rare and potentially serious disease. Prolonged and regular multidisciplinary collaboration is essential for optimal management of these patients. Thus, a multicentric study and the creation of a national registry are needed to better codify the management of this pathology.

Symptomatic hypocalcemia and hypomagnesemia in a 72 year-old woman, chronic user of pantoprazole

Alba Hernandez-Lazaro[1], Ricardo Jose de Leon-Durango[2], Borja Santana-Ojeda[2], Inmaculada Molinero-Marcos[2], Carmen Acosta-Calero[3], Claudia Arnas-Leon[2,4], Agnieszka Kuzior[4], Paula Gonzalez-Diaz[5], Maria del Pino Perez-Garcia[6] & Francisco Javier Martinez Martin[2,4]
[1]Parc Taulí University Hospital, Endocrinology & Nutrition, Sabadell, Spain; [2]University Hospital of Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [3]University Hospital of Gran Canaria Dr. Negrín, Cardiology, Las Palmas de Gran Canaria, Spain; [4]Hospitales San Roque, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [5]University Hospital of Gran Canaria Dr. Negrín, Emergency Medicine, Las Palmas de Gran Canaria, Spain; [6]Centro de Salud El Calero, Family & Community Medicine, Telde, Gran Canaria, Spain

Introduction and Objectives
Proton-pump inhibitors (PPI) are some of the most commonly prescribed drugs, and they are generally well tolerated. However, their long-term use has been associated with adverse effects such as acute interstitial nephritis, Clostridium difficile infection. pneumonia, and (controversially) bone fractures, cardiovascular disease and dementia. The acidification of the intestinal milieu may interfere with TRMP6-mediated active absorption of magnesium in the intestinal mucosa. There have been several reports of symptomatic, even life-threatening (because of severe arrhythmia) hypomagnesemia associated with chronic use of PPIs. We hereby report a case of symptomatic hypocalcemia and hypomagnesemia in a patient which was resolved after switching pantoprazole to famotidine, in order to raise awareness about this uncommon adverse effect.
Methods
Review of the patient's clinical records and of the relevant literature
Results
A 72 year old woman with history of obesity, hiatal hernia and gastroesophageal reflux, chronically treated with pantoprazole (>3 years) was admitted in the hospital emergency room with tingling and paresthesia in both arms and hands after an episode of acute gastroenteritis with vomiting and diarrhoea; Mild hypocalcemia (7.9 mg/dl) and severe hypomagnesemia (0.6 mg/dl) were detected, but her EKG showed no significant anomalies. Intravenous magnesium sulphate was administered and the patient's symptoms were alleviated. She was discharged with calcium, magnesium and cholecalciferol supplements and referred to our Endocrinology clinic, after one month with new lab tests. The patient reported fatigue and occasional cramps and numbness in both hands but the Trousseau and Chvostek tests were negative. Plasma calcium, phosphate, PTH and calcifediol were normal but magnesium remained low (0.9 mg/dl) in spite of reported good compliance with the supplements and no new episodes of vomiting and diarrhoea. In a 24-h urine collection, calciuria was normal but magnesiuria was low. PPI-related hypomagnesemia with secondary hypocalcemia was suspected; the patient was switched from pantoprazole 40 mg to famotidine 20 mg daily. In the follow up visit after 3 months there were no symptoms and lab tests were normal; calcium, vitamin D and magnesium supplements were withdrawn.
Conclusions
Severe symptomatic hypomagnesemia is an uncommon adverse effect associated with the chronic use of PPIs, and it is resistant to the use of oral magnesium supplements. PPIs are probably overused, and deprescription should be considered in chronic users unless there is a clear justification. H2 blockers can be used as an alternative to PPIs if needed.

Exploring experiences of patients with adrenal insufficiency (AI) using parenteral hydrocortisone injection device to manage adrenal crisis: a qualitative interview study

Aldons Chua[1,2], William Drake[1], Heather Yoeli[2], Patrick Oyibo[2], Umesh Dashora[3], David Till[3], Martin Cartwright[2] & Sofia Llahana[2]
[1]St Bartholomew's Hospital, Endocrinology, London, United Kingdom; [2]City, University of London, London, United Kingdom; [3]East Sussex Healthcare NHS Trust, Hastings, United Kingdom

Background
Adrenal Insufficiency (AI) is an inadequate production of cortisol hormone from the adrenal glands. The most common form is secondary AI (suppression of the hypothalamic-pituitary-adrenal axis), with a prevalence of approximately 300 cases per million. Patients with AI require lifelong corticosteroid replacement, which poses a risk of a life-threatening adrenal crisis (AC) event. AC presents with low blood pressure, hypoglycaemia and even loss of consciousness. This causes a significant burden, not just to families but also to the healthcare system. To prevent AC-related complications and even death, patients with AI need an urgent hydrocortisone 100 mg intramuscular injection. The United Kingdom (UK) Society for Endocrinology released an updated clinical guidance in 2016, including a new emergency steroid alert card. "Patient education" is also emphasised as an essential tool. However, studies showed that up to 50% of AC-related hospitalisations are preventable with effective patient self-management. However, numerous studies still report barriers to effective patient self-management during AC.
Objective
This study aimed to explore experiences of patients with adrenal insufficiency (AI) during an adrenal crisis (AC), and to identify barriers and enablers on the use of hydrocortisone injection device in self managing AC.
Methods
This is a qualitative study using 1:1 semi-structured interview. Participants were recruited through patient advisory groups (Addison's Disease Self-help Group and the Pituitary Foundation) in the UK. Eligible participants were interviewed via Microsoft Teams online platform, transcribed verbatim and analysed using thematic analysis with NVivo software.
Results
Twelve White European females from various geographical locations in the UK, with confirmed diagnosis of secondary/tertiary AI participated. All participants possess an emergency hydrocortisone injection and report at least one AC episode per year. Only one participant successfully self-injected hydrocortisone. Participants reported self-management during AC is mainly affected by complexity of the disease. But, over time, understanding and confidence developed. Challenges with the use of hydrocortisone injection have been highlighted and compared to other modalities i.e., EpiPens and insulin pens. The current tools and training were beneficial to most participants, but some find the teaching session confusing. Concerns were also raised on healthcare professional's lack of understanding in managing AC, especially in emergency departments. With the support available, i.e., next of kin, participants were able to manage AC at home.
Conclusion
This study highlights the need for an easier-to-prepare hydrocortisone injection device and more structured teaching provision not just for patients, but also for health care professionals.

Graves' disease following subacute thyroiditis: a rare occurrence

Nergis Basmacı & Seda Hanife Oguz
Hacettepe University School of Medicine, Endocrinology and Metabolism, Ankara, Turkey

Background
Subacute thyroiditis (SAT) is typically a self-limiting condition, with patients usually returning to normal thyroid function after healing. However, very rarely, Graves' disease (GD) may develop following SAT.
Case presentation
A 50-year-old female patient presented to an outside internal medicine outpatient clinic with anterior neck pain, fatigue, and subclinical fever symptoms. Her medical history included a diagnosis of psoriatic arthritis and she was receiving weekly methotrexate along with folate replacement. Firstly, the patient was given oral antibiotics that failed to relieve the symptoms. Laboratory tests revealed thyrotoxicosis [TSH: 0.096 uIU/ml (0.38-5.33 uIU/ml), fT4: 28.6 pmol/l (7.8-14.4 pmol/l), fT3: 7.9 pmol/l (3.8-6 pmol/l)]; and elevated acute phase reactants

[eritrocyte sedimentation rate (ESR): 28 (0-20), C-reactive protein (CRP): 48 mg/l (0-5 mg/l)]. Both anti-thyroglobulin (Anti-Tg Ab, 602 IU/ml (0-40 IU/ml), and anti-thyroid peroxidase antibodies (Anti-TPO Ab, 28 IU/ml (0-9 IU/ml) were positive, while the thyroid stimulating immunoglobulin (TSI) was undetectable. She was then consulted to endocrinology outpatient clinic. On physical examination, she had a diffuse tender goiter and no symptoms of orbitopathy. Ultrasonographic examination revealed enlargement in the thyroid gland, and patchy heterogenous areas with decreased vascularization on color Doppler imaging, consistent with SAT. Treatment with methylprednisolone 16 mg/day was initiated, which led to instant symptom relief. The dosage was gradually reduced and the medication was eventually discontinued after 4 weeks. One month after cessation of treatment, thyroid function tests were normal. However, after an additional 2 months, the patient presented with complaints of anterior neck pain, palpitations, sweating and hair loss. Thyroid examination revealed mild tenderness, and thyroid function tests showed subclinical hyperthyroidism (TSH: 0.2 mIU/l, fT_4: 14.5 pmol/l, fT_3: 5.4 pmol/l). Both ESR and CRP levels were in normal range. However, TSI level was 1 IU/l (<0.1 IU/l), inciting a suspicion of GD. A thyroid scintigraphy was performed which demonstrated diffuse radioisotope uptake with reduced counting time. In addition, increased vascularity was observed on color Doppler imaging. The patient was therefore diagnosed with GD following SAT.
Conclusions
This case highlights the unusual onset of GD following subacute SAT. Although the pathogenic pathways have yet to be uncovered, the inflammatory environment of SAT might trigger an immunological response, resulting in the onset of GD. Clinicians must be mindful for GD in individuals with persistent hyperthyroidism after SAT remission, especially in patients with a history of other autoinflammatory disorders, as in our case.

Clinicopathological features of inflamed rathkes cleft cysts: a case series

Annabelle Hayes[1,2], Julia Low[2], Nicholas Shoung[2], Sebastain Fung[2] & Ann McCormack[1,2,3]
[1]UNSW Sydney, School of Medicine, Sydney, Australia; [2]St Vincent's Hospital Sydney, Darlinghurst, Australia; [3]Garvan Institute of Medical Research, Darlinghurst, Australia

Background
Rathkes cleft cysts (RCC) are present in up to 20% of autopsy studies but only a minority necessitate surgical treatment[1]. Inflammation of the RCC wall may act a trigger for disease progression, resulting in development of clinical symptoms and prompting investigation and surgical management[2,3]. The significance of inflammation of RCC is thought to be three-fold: the development of classical symptoms including headache, visual disturbance or pituitary hormone disturbance, secondly, a predisposition to rupture or apoplexy, and thirdly, it is thought to increase rate of RCC recurrence[1].
Objective
To review and characterize clinical presentation, histological and radiological findings in a series of patients with inflamed RCC.
Methods
We conducted a retrospective case series of 25 cases of RCC, which had undergone surgical management between April 2016 and November 2022. Histopathology and radiology were independently reviewed by neuropathologist and neuroradiologist, and case notes were reviewed for clinical and biochemical data.
Results
25 cases were reviewed: 19 demonstrated inflammation of either the RCC cyst epithelium ($n=10$), cyst wall ($n=17$) (Rathkes cystitis) or anterior pituitary (adenohypophysitis) ($n=10$), 6 cases were not inflamed; mean age was 47 years (± 19 years); 72% were female, consistent with literature. Preoperative features included pituitary dysfunction (64%), headache (64%), visual disturbance (20%) and polyuria/polydipsia (4%). Most (67%) patients experienced symptoms for less than 1 year. Four patients presented with apoplexy. Headache was present in 90% of patients with adenohypophysitis vs 47% cases without pituitary involvement ($P=0.027$) and all 9 cases where adenohypophysitis was chronic. Pituitary dysfunction was not associated with cystitis (69% vs 67% p=ns) or adenohypophysitis (44% vs 33% P=ns). Rathkes cystitis was associated with loss of posterior bright spot (71% vs 14% $P=0.013$).
Conclusion
Headache but not pituitary dysfunction was associated with adenohypophyseal inflammation. A trend of increasing headache prevalence was seen with increasing degree of inflammatory infiltrate within RCC.

Severe spontaneous long-lasting hypoglycaemia. Differential diagnostic challenges thorough a case report

Gergő Csitári[1], Bettina Varga[1] & Gábor Simonyi[1,2]
[1]DBC-SZIEOK, Metabolic Center, Budapest; [2]Szent Imre University Teaching Hospital, Metabolic Center, Budapest, Hungary

In our presentation we would like to demonstrate a complex case with severe spontaneous long-lasting hypoglycaemic episodes that were observed for more than 48-hours. Later the continuous parenteral glucose need was promptly ceased. A 78-years-old hypertensive non-diabetic patient came to our hospital with hypoglycaemic coma. His unconsciousness were cured prehospitally by parenteral glucose replacement. However hypoglycaemic comas (GCS 1-2-1) were observed several times in the ER and upon admission so he were treated by intravenous glucose perfusor. In the first 24-hours he needed 420 grams (!) of glucose intravenously to avoid unconsciousness and to maintain the patient's blood glucose level around 3-4 mmol/l. Unsuppressed, moreover elevated serum insulin and C-peptide levels were measured simultaneously with the hypoglycaemic episodes. Our patient was in good physical condition, he was neither obese nor malnourished. He negated any alcohol and antidiabetic drug consumptions despite multiple interrogations. His wife had T2DM but she was on fix dose combination of metformin and vildagliptin. Staging CT and abdominal MRI scans did not revealed any obvious malignancy nor insulinoma or any GEP-NET-like alteration. On the third observational day our patient's parenteral glucose need started to decreased and later it ceased. Therefore a casualty of sulfonylurea abuse was clinically assumed, so we sent blood and urine samples to the laboratory of toxicology for sulfonylurea derivates. The findings showed 87, 5 ng/ml gliclazide in the blood and traces of gliclazide from the urine with liquid chromatography and tandem mass spectrometry which could also be an artefact. Once we received these results we asked again the patient and his family whether they had ever taken gliclazide on its marketed brand names. Then they confirmed that they had gliclazide in their home, although it was prescribed only for his wife's peri-contrast media days despite metformin and they proved that only those 4 pills were missing. Thus, we dared to perform a 72-hours fasting test which ended with a negative result, consequently the likelihood of insulinoma finally could be excluded. We asked the family to keep the above mentioned unnecessary drug far away from our patient and from his wife to avoid similar accidents. The patient was discharged but he needs further urologic and cardiologic follow up due to elevated PSA levels and sinus bradycardia with left bundle branch block.

Improvement in albumin excretion in patients with type 2 diabetes mellitus labelled as metformin-intolerant after rechallenge with extender-release metformin

Jennifer Maria Perez-Rivero[1], Alba Hernandez-Lazaro[2], Ricardo Jose de Leon-Durango[3], Carlos Rios-Gomez[3], Borja Santana-Ojeda[3], Inmaculada Molinero-Marcos[3], Claudia Arnas-Leon[3,4], Carmen Acosta-Calero[5], Agnieszka Kuzior[4] & Francisco Javier Martinez Martin[3,4]
[1]Centro Salud Escaleritas, Family & Community Medicine, Las Palmas de Gran Canaria, Spain; [2]Parc Taulí University Hospital, Endocrinology & Nutrition, Sabadell, Spain; [3]University Hospital of Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [4]Hospitales Universitarios San Roque, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [5]University Hospital of Gran Canaria Dr. Negrín, Cardiology, Las Palmas de Gran Canaria, Spain

Introduction and Objective
Metformin is still a mainstay of treatment in patients with type 2 diabetes mellitus (T2DM), but in 10-25% of them there are persistent gastrointestinal disturbances that worsen their quality of life, lead to poor compliance and treatment withdrawal, and ultimately result in worse health outcomes. Extended-Release Metformin (XRM) is much better tolerated, and since 2005 is recommended in the

well-respected British NICE guidelines for the treatment of T2DM in patients with gastrointestinal disturbances related to the use of metformin. However in Spain XRM was not available until 2022, after the expiration of the patent of sitagliptin, when a generic combination of XRM/sitagliptin (1000/50 mg) became available, while monocomponent XRM is still not available. We undertook to study whether in patients with T2DM, labeled as metformin-intolerant and treated with a DPP4 inhibitor but insufficiently controlled, the switch from the DPP4 inhibitor to the XRM/sitagliptin combination could improve their glycemic control and renal function.
Design & Method
Patients with T2MD, with HbA1c $>7\%$ but $<9\%$; estimated GFR >45 ml/min/1.73 m^2, labeled as metformin-intolerant and treated with full dose of a DPP4 inhibitor were recruited and, after informed consent, switched to XRM/sitagliptin 100/50 mg beginning with one daily pill, and after one month increasing the dose to 2 daily pills if there were no significant tolerance issues. Fasting glycaemia, HbA1C, estimated GFR (CKD-EPI equation) and albumin/-creatinine ratio in a morning urine sample were measured before and 3-4 months after the switch. As albumin/creatinine values are not distributed normally, they are given as median (interquartile range) and compared by Mann-Whitney's U test
Results
72 such patients were recruited; 12 did not tolerate the combination, 8 tolerated only one pill, and 52 tolerated both pills. Fasting glucose was reduced from 175 ± 34 to 129 ± 23 mg/dl ($P<0.05$) with one pill and to 121 ± 21 ($P<0.01$) with 2 pills. HbA1c was reduced from 8.3 ± 1.0 to $7.7\pm0.8\%$ ($P<0.05$) with one pill and to 7.4 ± 0. GFR was unchanged: 57 ± 16 to 59 ± 16 ml/min/1.73 m^2 7. Albumin/creatinine quotient was reduced from 39 (17-78) to 29 (14-66) mg/gr ($P=0.029$). There was a significant positive correlation between albumin/creatinine change and HbA1C change (Spearman's rho: 0.47, $P<0.001$).
Conclusions
The switch from DPP4 inhibitor to the XRM-sitagliptin combination was well tolerated in a large majority of the patients, improved significantly the glycemic control and reduced urinary albumin excretion; this reduction seems to be partly driven by the improvement in glycemic control.

Cutaneous lymphoid hyperplasia in a male patient with type 3 polyglandular autoimmune syndrome - a rare association

Daniel Cosma[1], Horatiu Silaghi[2] & Cristina Alina Silaghi[3]
[4]Horezu City Hospital, Diabetes, Nutrition and Metabolic Diseases Outpatient Clinic, Horezu, Romania; [2"]Iuliu Hatieganu" University of Medicine and Pharmacy, 5th Department of Surgery, Cluj-Napoca, Romania; [3"]Iuliu Hatieganu" University of Medicine and Pharmacy, Endocrinology Department, Cluj, Romania

Cutaneous lymphoid hyperplasia (CLH) is a spectrum of benign conditions characterized by reactive B- and T-cell cutaneous lymphocytic infiltrates. The most common presentation of reactive CLH is as a solitary red skin papule, nodule, or plaque but 10–15% of patients present with more generalized or multifocal skin lesions. A 40-year old male, initially diagnosed with type 1 diabetes mellitus (DM), with a family history of autoimmune thyroid disease, vitiligo and type 2 DM, asked transfer to our service for specific treatment and monitoring. Based on detailed personal history, labs exams (positive antibodies and normal C-peptide value) and clinical evolution, the diagnosis was changed to latent autoimmune diabetes of the adult (LADA) in the context of a polyglandular autoimmune syndrome type 3 by association with vitiligo and Hashimoto thyroiditis. The physical examination revealed a round erythematous lesion on the right shoulder with positive Darier sign (sugestive for a mastocytoma), localized prurit after stimulation, 3 other circular lesions on the abdomen and telangiectasia on the epigastric area. The patient was directed to a university hematology center for further investigations, where the CHL diagnosis was established based on the tryptase and β-2 microglobulin within normal values, lack of the pAsp816Val mutation and the histopathological examination. Despite denying the diagnosis of systemic mastocytosis, the patient received treatment with an antihistamine agent and sodium cromoglycate with progressive titration up to 10 capsules/day with some improvements in gastrointestinal and urinary symptoms. The antihyperglycemic therapy consists of Metformin and basal insulin. To our knowledge, this is the first case of CLH in a patient with type 3 polyglandular autoimmune syndrome composed of LADA, Hashimoto thyroiditis and vitiligo.

Insights into beckwith-wiedemann syndrome: exploring the clinical spectrum and tumor surveillance in four case reports

Denisa-Isabella Tănasie[1], Elena Braha[2], Camelia Procopiuc[2], Aura-Madalina Boboc[1,2], Carmen Iordachescu[2], Adriana Padure[2] & Iuliana Gherlan[1,2]
[1]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [2]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania

Introduction
Beckwith-Wiedemann Syndrome (BWS), a genetic imprinting disorder linked to 11p15, showcases overgrowth traits, including macrosomia, macroglossia, and abdominal wall defects. Characterized by specific genotype-phenotype correlations and recognized as a cancer predisposition syndrome (nephroblastoma, hepatoblastoma, neuroblastoma and adrenocortical carcinoma), our four case reports provide insights into varied clinical presentations.
Case reports
Case 1: a 1-year and 4-month-old boy conceived through *in vitro* fertilization was diagnosed with BWS at 11 months. MLPA detected maternal hypomethylation (11p15-IC2). Notable physical features include macroglossia and a forehead flat hemangioma. Literature supports a 10-fold BWS risk with assisted-reproduction-technology, potentially indicating milder phenotype (Carli D *et al*, 22). Case 2: We examine a 2-year and 6-month-old girl with suspected BWS identified prenatally due to macroglossia, omphalocele, and polyhydramnios. At 1-day old, she underwent surgical intervention for omphalocele. BWS was confirmed at 6 months through MLPA, revealing the same submolecular type as in case 1 (IC2-LoM). Case 3: We introduce a 2-year and 7-month-old girl. Neonatally, the phenotypic features, with macroglossia, transient hypoglycemia and ear lobe creases raised suspicion of BWS. By 1 year and 6 months, she had surgical reduction for macroglossia, and, over time, the diastasis of the rectus abdominis resolved spontaneously. At 2 years, an orthopedic exam revealed a leg length discrepancy, suggesting shoe lift usage. The patient's clinical score is 7 points, exceeding the diagnostic threshold for BWS without molecular confirmation (Brioude *et al*., 18). Case 4: a 1-year and 3-month-old girl presented with neonatal hypoglycemia and hyperinsulinism (elevated insulin and C-peptide levels). Central adrenal insufficiency (low cortisol, lower normal range ACTH) was treated with hydrocortisone. An early ultrasound revealed a left adrenal tumor that later resolved, likely due to adrenal hemorrhage. Genetic tests, including WES and MLPA, showed no evidence of congenital hyperinsulinism or BWS-associated deletions/duplications. Like case 3, the clinical score is 7 points (including macroglossia, ear pits), negating a need for molecular confirmation. Repeated suprarenal ultrasound demonstrated no tumor formations on both sides. In all four cases, the tumor screening consists of serum alpha-fetoprotein (AFP) levels and abdominal ultrasound every three months, were within normal limits. IC2-LoM, found in 2 of our cases is associated with the lowest tumor risk, being the most frequent.
Conclusion
Given the complex genetics and diverse phenotypes associated with BWS, a multidisciplinary team approach is essential. This collaborative effort aims to coordinate various aspects of care throughout childhood, particularly highlighting the need for tumor surveillance.

EP1247

Sociodemographic and socioeconomic factors of patients with adrenal insufficiency and their influence on glucocorticoid dosage and the occurrence of adrenal crisis

Milena Haase[1], Peter Kropp[2], Catharina Bullmann[3] & Birgit Harbeck[1,3]
[1]University Medical Center Hamburg-Eppendorf, III. Department of Medicine, Hamburg, Germany; [2]University of Rostock, Institute for Medical Psychology and Medical Sociology, Rostock, Germany; [3]MVZ Amedes Experts, Endocrinology, Hamburg, Germany

Introduction
Patients with primary, secondary or tertial adrenal insufficiency are usually treated with a glucocorticoid substitution therapy adjusting dosages to align with the circadian rhythm. Despite those attempts, finding the correct dosage individually seems challenging, influenced not only by the complexity of circadian rhythms but also by various other factors. Approximately 6-8% of adrenal insufficiency patients still experience adrenal crises every year, which is associated with an increased mortality. While it is known that social circumstances significantly impact disease development, the current therapy primarily focuses on glucocorticoid substitution, which makes it necessary to

implement a different approach in therapy considering physiological and sociodemographic factors.
Material and Methods
Patients with primary, secondary or tertial adrenal insufficiency were included in the study. They were handed out questionnaires to collect demographic data, quality of life, symptoms of depression and anxiety as well as social integrity and social support data. The data analysis was conducted using Excel and SPSS.
Results
61 participants (77% females, 23% males) with primary (47.5%), secondary (47.5%), or tertiary (4.9%) adrenal insufficiency took part in this study.. The results indicate lower health-related quality of life in adrenal insufficiency patients compared to the normative sample. The collected data from the sum of the questionnaires, in particular SCL90-R, SF-36 and AddiQol, suggest a significant correlation between lower health-related quality of life, respectively depressive symptoms, and increased occurrence of adrenal crises. For better comparability, the analysis included not only the overall number of experienced adrenal crises but also the number of crises within the last year. There was no observed correlation concerning individual glucocorticoid dosage.
Conclusions
The study underscores ongoing challenges faced in the therapy of adrenal insufficiency. The results of our study confirm a networthy association between lower health-related quality of life, including depressive symptoms and inadequate social support, and an increased incidence of adrenal crises. Although glucocorticoid dosage didn't show a significant correlation, improving social conditions may reduce substitution requirements and adrenal crises frequency, which could have a positive impact on overall well-being and disease outcomes. This study highlights the importance of considering socioeconomic and sociodemographic factors in treatment of adrenal insufficiency.

Primary aldosteronism in patient with autosomal dominant polycystic kidney diseases: diagnostic and therapeutic challenge

Kammoun Fatma[1], Ibtissem Ben Nacef[1], Sabrine Mekni[1], Sawsen Essayeh[1], Rihab Laamouri[1], Werfili Mariem[2], Mchirgui Nadia[1], Karima Khiari[1] & Imen Rojbi[1]
[1]Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia; [2]Charles Nicolle Hospital, Laboratory of Renal Pathology LR00SP01, Tunis, Tunisia

Introduction
Hypertension is often associated with autosomal dominant polycystic kidney disease (ADPKD). The pathogenesis of hypertension is complex, including intrarenal activation of the renin-angiotensin-aldosterone system (RAAS), arterial stiffness endothelial dysfunction, increased sympathetic nervous system activity and endothelin-1 secretion. However a secondary cause of hypertension should be suspected in presence of hypokaliemia and resistant hypertension.
Case report
A 51-year-old woman with a 30-year history of ADPKD was admitted to our hospital because of inadequate control of blood pressure. She had a family history of polycystic kidney disease, with an affected father and brother. The patient was diagnosed with hypertension secondary to ADPKD at the age of 35, she received treatment with betablockers, calcium blockers and angiotensin converting enzyme inhibitor. At physical examination the blood pressure was 160/100 mm Hg (no difference between arms); heart rate was 70 beats/min and body mass index was 28.48 kg/m^2. Laboratory findings revealed mild hypokalemia 3.4 mmol/l with inappropriate kaliuresis 53, mmol/24H, increased serum creatinine at 110 umol/l with an estimated glomerular filtration rate (GFr) : 50 ml/min. After therapeutic adjustement, management of hypokalemia and normal salt diet, endocrine evaluation revealed high plasma aldosterone concentration at 583 pg/ml $>$200 pg/ml, suppressed plasma renin activity, aldosterone/renin ratio of 74, 36 $>$23 confirmed the diagnosis of primary aldosteronism (PA). Abdominal computer tomography (CT) without contrast revealed an adenoma in the left adrenal gland of 13 mm. The surgical excision of the adenoma was considered but it was excluded due to the difficult surgical approach, and therefore the patient started spironolactone (a mineralocorticoid-receptor blocker) at 50 mg once daily. After medical treatement, the patient's blood pressure normalized (120/80 mmHg) as did her serum potassium level (4.0 mmol/l) without impairment of kidney function.
Discussion
The diagnosis of primary aldosteronism in a patient with polycystic kidney disease is challenging because: the renal cysts may obscure an adrenal adenoma; polycystic kidney disease itself is often complicated by hypertension and hypokalemia can be obscured by renal insufficiency. The association of ADPKD and PA is rare but once the coexistence of hypokalemia and resistant hypertension is identified in ADPKD patients, a secondary cause of hypertension should be considered, like PA.

Prevalence and characterization of sexual dysfunctions in male patients with hyperprolactinemia in a national registry

Antonio De Fraia[1], Elisa Maseroli[2], Emilia Sbardella[3], Cristina de Angelis[1], Marianna Minnetti[3], Renata Simone Auriemma[1], Rita Indirli[4], Caterina Golinelli[5], Angelo Cignarelli[6], Linda Vignozzi[2], Giovanni Corona[7], Andrea Isidori[3] & Rosario Pivonello[1]
[1]Università Federico II di Napoli, Naples, Italy, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia ed Andrologia, Unità di Andrologia e Medicina della Riproduzione, Sessualità e Affermazione di Genere (Fertisexcares), Italy; [2]Università di Firenze, Florence, Italy, Dipartimento di Scienze Sperimentali Cliniche e Biomediche "Mario Serio"; [3]Università La Sapienza di Roma, Rome, Italy, Dipartimento di Medicina Sperimentale; [4]University of Milan, Milan, Italy, Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy - Department of Clinical Sciences and Community Health; [5]University of Modena and Reggio Emilia, Modena (Italy), Department of Biomedical, Metabolic and Neural Sciences; [6]Università degli Studi di Bari "Aldo Moro", Dipartimento di Medicina di Precisione e Rigenerativa e Area Jonica - (DiMePRe-J);[7]AUSL di Bologna, U.O. di Endocrinologia e Malattie del Ricambio Ospedale Maggiore Bellaria, AUSL di Bologna, U.O. di Endocrinologia e Malattie del Ricambio Ospedale Maggiore Bellaria

Hyperprolactinemia is frequently accompanied by sexual dysfunctions, represented by decreased libido, erectile dysfunction and ejaculatory disorders. Moreover, cabergoline (CAB), used for treatment of hyperprolactinemia, is known to influence sexual function. Aim of the study was to evaluate sexual function in males with hyperprolactinemia under medical therapy. Data were retrieved from GONADIS, a national registry on gonadal status and reproductive and psycho-sexual function in patients affected by pituitary and adrenal disorders, promoted by SIAMS–SIE–AME. Twenty-three male patients aged 25-76 yrs (median age: 49 yrs) with diagnosis of hyperprolactinemia and on therapy with CAB were evaluated. Pharmacological anamnesis, hormonal parameters and standardized questionnaires investigating sexual function (SIEDY, Androtest, IIEF-15, PEDT, MHQ and BDI) were assessed; the cohort was then stratified in "uncontrolled" and "controlled" patients, the latter defined by PRL $<$16, 5 ng/ml. In overall cohort, 12/23 (52.2%) reached disease control. In overall cohort CAB dose negatively correlated with MHQ-A (r=-0. 652; P=0. 016), MHQ-O (r=-0, 0615; P=0, 025), MHQ-S (r=-0.618; P=0.024), MHQ-D (r=-0.561; P=0, 046) and MHQ-I (r=-0.600; P=0.030) score. In patients with uncontrolled disease, CAB dose positively correlated with IIEF-15 overall satisfaction domain score (r=0.829; $P<0.021$) and PRL level negatively correlated with IIEF-15 intercourse satisfaction domain score (r=-0.811; $P<0.027$); in patients with controlled disease, CAB dose negatively correlated with MHQ-S (r=-0.788; $P<0.028$) and MHQ-H (r=-0.716; $P<0.03$) score. Our study highlighted that in patients with uncontrolled disease, a worse disease control (i.e. higher PRL levels), is associated with a worse intercourse satisfaction, and that CAB treatment positively impacts on overall satisfaction; this should encourage a tighter disease control by increasing CAB dose. In controlled disease, CAB dose positively impacts on somatization and hysteria traits, which might contribute to general and sexual health. This happens regardless of PRL levels, suggesting that it might be due to its dopaminergic properties.

Scienze Sperimentali Cliniche e Biomediche “Mario Serio”, florence; [4]Endocrinology Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy - Department of Clinical Sciences and Community Health, bologna

The potential independent role of growth hormone (GH) excess in sexual dysfunction of acromegalic male patients is poorly characterized. The aim of the current study was to evaluate the sexual function, in adult males with acromegaly, stratifying the cohort in “uncontrolled” and “controlled” disease. Data were retrieved from GONADIS, a national registry on gonadal status and reproductive and psycho-sexual function in patients affected by pituitary and adrenal disorders, promoted by SIAMS - SIE - AME. Sixty male acromegalic patients aged 18-73 yrs (mean age: 51.4 $\pm$13.4 yrs) were evaluated. In the overall cohort, 34/60 (56.6%) patients had reached disease control; 10/23 (43.4%) had ED at IIEF, 26/34 (76.4%) BPH, 17/37 (45.9%) varicocele, 7/37 (18.9%) testis hypotrophy, 17/47 (36.1%) hypotestosteronemia. Controlled disease patients had significantly higher age ($P=0.021$), disease duration ($P=0.003$), IIEF-15 total score ($P=0.011$), IIEF-erectile function (IIEF-EF) ($P=0.008$), IIEF-orgasmic function (IIEF-OF) ($P=0.021$), IIEF-Sexual desire (IIEF-SD) ($P=0.006$) and IIEF-Overall satisfaction (IIEF-OS) ($P=0.012$), and lower serum levels of insulin ($P=0.022$), HOMA index ($P=0.046$), glycated hemoglobin ($P=0.013$), IGF-1 ($P<0.001$) and GH ($P<0.001$). Controlled disease patients had a lower prevalence of ED ($P=0.001$). Correlation analysis in overall cohort highlighted that IIEF-EF score negatively correlated with free anxiety (MHQ-A) ($r=-0.470$; $P=0.015$) and depression (MHQ-D) ($r=-0.503$; $P=0.009$) traits, serum IGF-1 levels ($r=-0.308$; $P=0.025$); IIEF-OF ($r=-0.460$; $P=0.031$), IIEF-SD ($r=-0.542$; $P=0.009$) and IIEF-OS ($r=-0.515$; $P=0.014$) scores negatively correlated with serum IGF-1 levels. SIEDY scale 1 score correlated positively with age ($r=0.386$; $P=0.02$) and negatively with Peak Systolic Velocity at penile-US ($r=-0.423$; $P=0.016$). Linear regression analysis with age, testosterone, IGF-1, MHQ-A and MHQ-D scores as independent variables failed to identify a main independent predictor of IIEF-EF score.

EP1251

Nearly asymptomatic hypophosphatasia: a clinical case report

Ekaterina Pigarova[1,2], Aurika Asanova[1,2], Elizaveta Drachuk[1,2] & Larisa Dzeranova[1,2]
[1,2]Endocrinology Research Centre, Moscow, Russia

Introduction
Hypophosphatasia is a group of inherited disorders characterized by the impaired mineralization of bones and/or teeth and low serum alkaline phosphatase (ALP) activity. It is caused by a mutation in the ALPL gene encoding the isoenzyme of ALP resulting in a loss of function. Since an early age of onset is usually associated with a more severe disease, and a late age – with a mild course of the disease, the manifestation of the disorder ranges from a life-threatening condition occurring at birth, characterized by severely impaired bone mineralization and seizures, to young adults with premature tooth loss without other symptoms. Relatively little data is available on the prevalence and clinical features of hypophosphatasia in adults.
Clinical case
An 18-year-old female (weight 56 kg, height 160 cm, BMI 21.9) with complaints of weakness, pain in the legs and joints, darkening in the eyes. Development in childhood and adolescence proceeded without any special features. Considers herself sick since the age of 16, when swelling and tenderness of the left ankle and knee joints appeared without x-ray changes. At the same time, the patient was diagnosed with infectious mononucleosis, after which she noted an increase in general weakness, periodic increases in body temperature to 37.2 0C, loss of appetite, pain in the bones and joints. CRP, ASLO, RF – negative, biochemical indicators, parameters of bone and calcium-phosphorus metabolism were normal except for the detected decrease in ALP to 13-15 U/l (40-150) and a pronounced deficiency of vitamin D - 9 ng/ml (30-100). The diagnosis of hypophosphatasia was confirmed: a pathogenic nucleotide variant *chr1:21563115C>A* was detected in a heterozygous state in the ALPL gene. According to DEXA of the whole body, BMD, taking into account the skull, corresponds to the age norm: -0.5 SD (Z-criterion);BMD excluding the skull corresponds to the age norm: -0.7 SD. According to lateral morphometry, no data were obtained for vertebral deformities and compression fractures. Teeth, hair, nails without any features. A detailed collection of family history revealed similar symptoms of joint pain in the mother with a decrease in ALP to 20 U/l (35-105).
Conclusions
Despite low ALP activity the patient does not demonstrate the typical clinical indications of hypophosphatasia, as evidenced by the absence of manifestations in the mother. The observed symptoms could possibly be the result of mononucleosis. Other genetic, epigenetic, or non-genetic factors influencing illness progression may explain circumstances where it is difficult to demonstrate a link between a pathology’s genotype and phenotype.

Diagnosis of adult GHD: new diagnostic tests

Kevin Yuen
Phoenix, Neuroendocrinology and Neurosurgery, Phoenix, United States

Although diminished height velocity and short stature are important clinical markers to consider testing for GHD in children, the signs and symptoms of GHD are not always so apparent in adults. Furthermore, quality of life and metabolic health are often impacted in adults with GHD; thus, making an accurate diagnosis is important so that appropriate GH replacement therapy can be offered to these patients. However, the diagnostic work up of adult GHD can be challenging and made more complicated by the episodic and pulsatile nature of endogenous GH secretion, concurrently modified by age, gender, and body mass index. Hence, GH stimulation testing is required to establish the diagnosis, and should only be considered if there is a clinical suspicion of GHD and the intention to treat if the diagnosis is confirmed. One or more GH stimulation tests may be required, but existing methods of testing can be inaccurate, difficult to perform, and imprecise. Furthermore, there are caveats when interpreting test results including individual patient factors, differences in peak GH cut-offs (by age and test) and testing time points. For now, the insulin tolerance test (ITT) remains the gold standard test, while the glucagon stimulation test is its reasonable alternative. Following its validation against the ITT, together with its safety, reproducibility and good patient tolerability, the macimorelin test gained approval in the US in December 2017 but its use was limited due to its cost and its distribution in the US was discontinued in May 2023. In Europe, macimorelin (renamed ghryvelin) was approved in January 2019 becoming the newest diagnostic test for adult GHD. Cost withstanding, given the ease of conducting this test and good patient tolerability, the oral macimorelin test has the potential of becoming the preferred GH stimulation test for diagnosing adult GHD in Europe.

Exploring the relationship between metabolic dysfunction-associated steatotic liver disease and osteoporosis

Marin Pecani[1,2], Marzia Miglionico[1], Michele Mallamace[3], Gabriele Angeloni[3], Antonia Barbitta[3], Stefania Basili[4] & Paola Andreozzi[3]
[1]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [2]Sapienza University of Rome; [3]Sapienza University of Rome, Policlinico Umberto I University Hospital, Rome, Italy; [4]Sapienza University of Rome, Department of Translational and Precision Medicine, Roma, Italy

Background and aims
Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) and Osteoporosis are two silent prevalent metabolic conditions. MASLD involves fat accumulation in the liver, along with at least one of five specified cardiometabolic criteria, while excluding other liver diseases or secondary causes. Osteoporosis is a systemic skeletal condition characterised by reduced bone mass, leading to increased fracture risk. The relationship between MASLD and decreased bone mineral density remains uncertain. Therefore, this study aims to explore the association of bone mineral density in patients with and without MASLD.
Methods
Subject’s demographics, medical history, and laboratory test findings were collected. MASLD diagnosis was done according to the new consensus statement definition and the guidelines outlined by EASL–EASD–EASO. Dual-energy X-ray absorptiometry (DEXA) was used to evaluate bone mineral density (BMD), and Osteoporosis diagnosis followed the criteria outlined by World Health Organization (WHO). Statistical analysis was performed, with significance determined for P values <0.05.
Results
106 consecutive individuals were investigated for osteoporosis. The study population had a mean age of 63.55 years and consisted of 83 (78.3%) females

and 23 (21, 7%) males. Osteoporosis was identified in 26 (24.5%) patients, while osteopenia and vertebral fracture were present in 54 (50.9%) and 10 (9.4%) patients respectively. Hypertension was the most prevalent condition, affecting 70 (66%) individuals, followed by dyslipidemia in 53 (50%), impaired fasting glucose 19 (17.9%) and type 2 diabetes 14 (13.2%). MASLD was present in 43 patients (40.6%). When comparing individuals with MASLD to those without MASLD, no statistically significant differences were found in age ($P=0.865$), gender ($P=0.285$), smoking status ($P=0.143$), hypertension ($P=0.503$), dyslipidemia ($P=0.166$), or impaired fasting glucose ($P=0.237$). However, there were statistically significant differences between the two groups observed in type 2 diabetes prevalence ($P=0.012$), Body Mass Index (BMI) ($p<0.001$), and Vitamin D levels ($P=0.008$). There were no significant differences between the two groups regarding osteoporosis ($P=0.106$), osteopenia ($P=0.665$), and vertebral fracture ($P=0.178$).

Conclusion

Individuals with MASLD showed reduced levels of vitamin D, increased body mass index, and higher type 2 diabetes prevalence than those without MASLD. However, this study did not reveal an increased association between MASLD and conditions like osteoporosis, osteopenia, or vertebral fractures.

Etiological profile of young diabetes mellitus in south indian population

Sadishkumar Kamalanathan[1], Kg Rashmi[1], Jayaprakash Sahoo[1], Dukhabandhu Naik[1], Jabasteen J[2], Aaron Chapla[2] & Nihal Thomas[2]
[1]JIPMER, Endocrinology, Puducherry, India; [2]CMC, Endocrinology, Vellore, India

Background & objective

In contrast to Caucasians of European origin, the aetiology of diabetes mellitus (DM) in young adults in other ethnic groups, including Indians is likely to be heterogeneous and difficult to determine. This study was undertaken to determine the aetiology of DM in the young South Indian population.

Methods

In this ambispective study, 144 South Indian young-onset diabetes (age at onset 12-35 years; duration <5 years) were studied. Diabetes secondary to steroid intake, gestational diabetes and secondary to endocrine diseases like acromegaly, and Cushing's disease were excluded. Fasting and post-prandial plasma glucose, fasting lipid profile, fasting and stimulated C-peptide, islet cell antibodies ICAs [glutamic acid decarboxylase 65 (GADA), tyrosine phosphatase (IA-2Ab) and zinc transporter-8 (ZnT8Ab)] and pancreatic imaging using abdominal radiography was performed in all patients. Clinically suspected MODY subjects were subjected to targeted next generation sequencing for 13 MODY genes.

Results

The prevalence of type 2 diabetes (T2DM) and type 1 diabetes (T1DM) was 59.02% (85/144) and 29.16% (42/144) respectively, followed by fibrocalculous pancreatic diabetes (2.77%). Other rare types included MODY (2.08%), ketosis-prone type 2 DM (2.08%), diabetes secondary to lipodystrophy (1.38%), syndromic diabetes (1.38%), diabetes secondary to pancreatic disease (2.08%). The median (IQR) fasting c-peptide was 1.83(1.3, 2.62) vs 0.27(0.023, 0.66) ng/ml [$P<0.0001$] while stimulated C-peptide was 4.38(2.82, 5.95) vs 0.43(0.093, 1.55) ng/ml[$P<0.0001$] in T2DM and T1DM respectively. ICA was positive in 73.80% of T1DM and 5.8% of T2DM. Among T1DM subjects, the ICA positivity for GADA, IA-2Ab and ZnT8Ab was 61.90% (26/42), 21.42% (9/42) and 1.66% (7/42) respectively. GADA+ IA-2Ab positivity was found in 7.14%, and GADA+ZnT8Ab positivity was found in 9.52%. and only one T1DM subject was found to be positive for IA-2Ab+ZnT8Ab. For diagnosis of T1DM, the addition of IA-2Ab increased the yield in three subjects, while ZnT8 didn't add to the yield. MODY was diagnosed in 2.08% (3/144) subjects, one subject was positive for a novel heterozygous ABCC8 (NM_000352.6): c.1591A>G. *P* (Thr531Ala) gene missense variant with unknown significance. Other two MODY subjects were positive for heterozygous ABCC8 (NM_000352.6): c.917G>A p. (Arg306His) gene missense mutation and a rare heterozygous PDX1 (NM_00209.4): c.670G>A *P* (Glu224Lys) gene variant with unknown significance respectively.

Conclusion

The aetiology of diabetes in young adults was heterogeneous, with T2DM more common than T1DM. Testing for islet antibodies and C-peptide along with targeted genetic testing in this age group helps in the correct etiological diagnosis of diabetes.

A case of langerhans cell histiocytosis accompanying hypothalamus, mastoid bone and liver involvement

Saadet Acar, Berrin Çetinarslan, Zeynep Cantürk, Alev Selek, Emre Gezer, Damla Köksalan, Özlem Alkan & Fatma Öktem
Kocaeli Üniversitesi Tıp Fakültesi, Endocrinology and Metabolic Diseases, Kocaeli, Turkey

Introduction

Langerhans cell histiocytosis (LCH) is a multisystem neoplastic disease with primarily bone and skin involvement. Although its pathogenesis is still not fully understood, LCH lesions contain clonal CD 207+ dendritic cells with the frequently identified BRAF V600E mutation and an inflammatory component. Although isolated central nervous system involvement is extremely rare, a common site of involvement is the hypothalamic-pituitary axis.

Case

A 35-year-old female patient applied to us with complaints of headache, excessive water retention, vomiting, weakness and amenorrhea in the last two months. There was no additional disease in his medical history other than hyperlipidemia. There was no history of previous surgery or head trauma. On physical examination, there was a fluctuating disorientation in place and time. The patient had panhypopituitarism and hypernatremia at the time of admission. It was determined that the patient, who was subjected to water restriction, had central diabetes insipidus. Contrast-enhanced cranial MRI revealed 19x10x17 mm a mass in the hypothalamus and diffuse contrast enhancement. PET-CT showed increased FDG uptake in the pituitary locus (SUV-max: 19.4), posterior of the left mastoid (SUV-max: 12.4) and hepatıc segment 8 (SUV-max 8.4). Temporal MRI showed mass lesions extending to the petrous sinus with signal characteristics similar to hypothalamic lesions. Liver dynamic MRI showed T2A hyperintense lesions with progressive contrast enhancement, the largest of which was 12 mm in diameter in the subcapsular area of segment 8. Thereupon, the patient underwent mastoid and liver biopsy. The biopsy result showed widespread monocyte infiltration with acidophilic cytoplasm and stained pozitifly with S100 and CD1a. The patient was referred to the oncology clinic for treatment.

Conclusions

Multisystemic diseases such as Langerhans cell histiocytosis should be considered in the differential diagnosis of patients with a hypothalamic mass, and other systemic involvements should also be investigated.

Factors associated with high glycemic variability in adolescents with type 1 diabetes

Faten Mahjoub, Ines Bani, Nadia Ben Amor, Ramla Mizouri & Jamoussi Henda
Institut De Nutrition, Tunis, Tunisia

Factors associated with high glucose variability in patients with type 1 diabetes

High glycemic variability is recognized as a risk factor for degenerative complications and hypoglycemia. The factors affecting glycemic variability in diabetic patients need to be clarified. Our aim was to determine factors associated with high GV in adolescents patients with type 1 diabetes.

Method

This is a cross-sectional analytical study, conducted at the National Institute of Nutrition in Tunis during the year 2022, including adolescents with type 1 diabetes, who underwent continuous glucose monitoring for 6 days. We analyzed the continuous glucose monitoring CGM data for each patient and we calculated the coefficient of variability (CV)by dividing the SD by the mean glucose and multiplying by 100 to get a percentage.

Results

Our study included 90 patients with type 1 diabetes, of which 53 are girls and 37 are boys. The average age was $16.6\pm2.$, and the mean duration of diabetes was 6.7 ± 3.5 years. The average CV was $40\pm12\%$, and 62, 2% of patients had a CV greater than 36%. The age of patients, and duration of diabetes were positively correlated with CV ($P=0.001$ and $P=0.002$ respectively), however, age at onset of diabetes was negatively correlated with CV ($r=-0.3$; $P=0.004$). Patients with higher glycemic variability took significantly higher doses of basal insulin ($P=0.03$). Patients on insulin analogues had a significantly lower CV than patients on NPH insulin ($P=0,\ 021$). A significant association was observed between the presence of lipodystrophy and a cv $>36\%$ ($P=0,\ 024$). However, no statistically significant relationship was found between the presence of autoimmune diseases such as adrenal insufficiency, celiac disease and hypothyroidism) and glycemic variability.

Conclusion
Several factors are involved in the genesis of glycemic variability in type 1 diabetics. Recognizing these factors enables us to act on modifiable factors to limit glycemic variability.

«Is there disparity in gestational diabetes care in Switzerland?»

Nina Kägi-Braun[1], Kutz Alexander[2] & Löf Marie[1]
[1]Karolinska Institute, Sweden; [2]KSA Kantonsspital Aarau, Aarau, Switzerland

Background
Lifestyle interventions as well as pharmacological therapy are strong measures to prevent adverse pregnancy and birth outcomes in women with gestational diabetes (GDM). Social determinants of health and consequent health disparities can affect a successful GDM management. This includes inequality in health care and education quality, economic stability as well as environmental factors. However, in high-income countries, these social determinants of health have rarely been studied even though gestational diabetes prevalences as well as social inequities are a rising health care problem.
Aim
Therefore, our aim is to investigate whether the association between GDM and adverse maternal outcomes is modified by insurance classes, regional area, or citizenship.
Methods
This is a population-based retrospective cohort study, using Swiss claims data from the Federal Statistical Office from January 2012 to December 2021. All delivery hospitalisations in Swiss hospitals were included and stratified according to maternal gestational diabetes status. The primary endpoint is a composite endpoint of adverse pregnancy (hypertensive disorders), delivery (induction of labor, instrumental or surgical delivery, obstetric traumata, other complications) and puerperal (infections, venous complications, other complications) outcomes defined by ICD-10 and CHOP codes. Secondary outcomes are the single components of the primary outcome.
Results
Of the identified 850, 414 delivery hospitalisations between 2012 and 2021, 7.3% of the pregnancies were affected by GDM. Women with GDM were more likely to be publicly insured, more often born outside of Switzerland and lived more often in a region with a high urban population. GDM patients had higher risk of an adverse obstetric outcome overall (OR 1.14, 95% CI 1.12-1.16). This association remained stable in the citizenship or insurance status subgroups but not in the regional area subgroup where we found a more pronounced association in women living in a canton with higher proportion of rural population (rural canton OR 1.18, 95% CI 1.14-1.23 vs urban canton OR 1.12, 95% CI 1.11-1.15, *P* for interaction 0.043).
Conclusion
We found no evidence for health disparity in relation to insurance status and citizenship in Switzerland. If there is no treatment inequality or if these variables are not adequate proxies for health disparities remains unknown. The finding that women from a more rural canton were at higher risk for GDM-related outcomes might be of importance in further improving nation-wide GDM care.

Atypical manifestation of parathyroid carcinoma in patient with RET and CYP24A1 mutations: a case report

Aurika Asanova, Ekaterina Kim, Anna Eremkina, Ekaterina Pigarova & Natalia Mokrysheva
Endocrinology Research Centre, Moscow, Russia

Introduction
Parathyroid carcinoma (PC) is one of the rarest endocrine malignancies. Most PCs are sporadic, sometimes occurring in the framework of familial primary hyperparathyroidism (PHPT). PHPT due to PC is usually characterized by significantly increased PTH levels, severe hypercalcemia, larger tumor size and a higher incidence of disease complications.
Clinical case
A 56-year-old male C. presented with an accidental formation at the posterior contour of the right thyroid gland lobe 10x9x9 mm according to US in 2017 (correlated with ST scan). Mineral metabolism parameters were assessed for the first time after a year: PTH 13.67 pmol/l (1.6-6.9), hypercalcemia - Ca 2.86 mmol/l (2.12-2.6), *P* and daily calciuria were not determined. PHPT complications included recurrent urolithiasis (first manifesting at age 25), osteopenia in L1-L4 (-2.2 SD T-score). C. did not notice loss of height, gastric and duodenal ulcers. There was no family history. In 2019 the patient underwent selective parathyroidectomy followed by mild asymptomatic hypocalcemia (Ca 2.15 mmol/l). At discharging he was prescribed cholecalciferol 2000 IU. Histological examination revealed atypical parathyroid tumor (APT) with fibrous bands, hemorrhages and foci suspicious for capsular invasion. After immunohistochemistry (IHC) the diagnosis was reclassified as PC based on capsular invasion and the presence of tumor cells in the surrounding fatty tissue. Ki-67 was 9%, there was positive parafibromin expression. Regular follow-up confirmed normocalcemia and PTH within the reference ranges. We recommended gene panel sequencing associated with hereditary forms of PHPT that revealed heterozygous mutations with uncertain significance variants: in the *RET (c.3052C>T:p.L1018F)* and *CYP24A1 (c.37G>A:p.A13T)* genes. The patient is currently in remission of the disease. DEXA scans showed positive dynamics in the BMD (L1-L4 -1 SD) There are no clinical symptoms of MEN2 syndrome. Liquid chromatography–mass spectrometry did not reveal any changes in the vitamin D metabolites similar to *CYP24A1* mutation.
Conclusions
Patients with solid masses near the typical location of the parathyroid glands should be examined for PTH and Ca. Morphological diagnosis of ATP requires additional IHC. In the present case the mild clinical course of PC and tumor's small size are noteworthy. The identified mutations with unknown pathogenicity are also of particular interest because they have not been previously described in patients with PC.

EP1259

Langerhans cell histiocytosis presenting spinal cord compression after diabetes insipidus diagnosis: a case report

Zeliha Yarar[1] & Hülya Kaynak[2]
[1]Tokat State Hospital, Department of Endocrinology and Metabolism, Tokat, Turkey; [2]Meram Faculty of Medicine, Necmettin Erbakan University, Department of Endocrinology and Metabolism, Konya, Turkey

Introduction
Langerhans cell histiocytosis (LCH) is a proliferative disease that origins from dentritic cell family. LCH most commonly affects bones and skin, but it can also involve the other systems and organs. Lytic bone lesions are the most common findings in LCH, LCH can involve any bone; the most common sites are skull and femur. In rare case, lytic osseous lesions occur in the spine. Diabetes insipidus (DI) is the most frequent endocrine abnormality associated with LCH and it can occur prior to, concomitant with or after the diagnosis of LCH. Here, we report a rare case of LCH at spinal vertebra in an adult patient with present neurological deficits.
Case Report
A 33-year-old woman presented with 3 months history of back pain, weakness in the lower extremities and unable to walk for 2 days. She had no history of fever, weight loss. The patient's medical history was unremarkable for trauma or other bone diseases. Three years before admission, the patient was diagnosed with central DI and desmopressin treatment was started. The etiologic cause of DI could not be found. On physical examinations, she rated the back pain as visual analogue scale 8 and localized tenderness over the C7-T1 spinous process was showed. Muscle strength in lower limbs was slightly decreased (3-4/5). Pathological reflexes were negative for both legs. And there were no sensory abnormalities. Her body temperature was normal, and there was no inflammatory focus in other systems. Laboratory tests including blood cell count, serum electrolytes, renal and liver function tests, erythrocyte sedimentation rate, and C-reactive protein did not reveal any abnormalities. Computed tomography showed a defined osteolytic lesion involving the the vertebral body C7, T1 and L2. Magnetic resonance imaging revealed a continuous enhancing epidural lesion located C7-T1 level with spinal cord compression. Because of motor weakness, and cord compression, the patient underwent posterior laminectomy. Histopathological examination showed that neoplastic cells which were positive for S-100, CD 68 and CD-1a. These features confirmed the diagnosis of LCH. After surgery, the patient showed a progressive improvement in motor function. The patient underwent chemotherapy with prednisolone and vinblastine.
Conclusion
We reported a rare case of adult spinal LCH with epidural involvement and neurological compression. The patient was treated succesfully vertebral resection and chemotherapy. Although extremely rare, LCH should be considered when there are epidural lesions with spinal cord compression in adults and it can be seen years after DI diagnosis.

Papillary thyroid carcinoma revealed by toxic goiter: a case report

Hajar Azagouagh, Karimi Meryem, Talbi Dounia, Sebbar Ghizlane, Rifai Kaoutar, Iraqi Hind & Mohamed Elhassan Gharbi
Chu Ibn Sina, Endocrinology, Rabat, Morocco

Introduction
A toxic goiter is a goiter that functions autonomously, causing hypersecretion of thyroid hormones, and is almost always benign. We report here the case of a toxic goiter that revealed the presence of papillary thyroid carcinoma.
Observation
Patient aged 68, with a history of arterial hypertension, followed for hyperthyroidism on a toxic goitre, with a thyroid scintigraphy showing an enlarged thyroid gland with intense uptake on the right side, an ultrasound scan showed a multiheteronodular goiter with nodules classified EUTIRADS 3 and 5. Antithyroid antibodies were negative, which led to her being put on TSA and beta-blockers, and the patient underwent surgery after euthyroidism. Pathological examination revealed an invasive variant vesicular papillary carcinoma of the right lobe of the thyroid measuring 1.5 cm long, with the presence of vascular emboli, and an invasive variant vesicular papillary microcarcinoma of the left lobe of the thyroid measuring 0.5 cm long, with the presence of vascular emboli. The tumour was classified as PT2NxMx at intermediate risk of recurrence. Iratherapy was considered and the patient was put on hormone replacement therapy with l. Thyroxine.
Discussion and conclusion
Differentiated thyroid carcinoma usually occurs in euthyroidism. The association of papillary thyroid carcinoma with hyperthyroidism is exceptional. The prevalence of this association varies from 0.2 to 8.3%. This has led to widely adopted recommendations by several expert groups not to perform cytopuncture on these lesions. Our case has shown that the risk of malignancy in toxic goitres is not zero, hence the need to resort to cytopuncture in the presence of elements in favour of malignancy.

Liver injury after I131 administration

Irina Tica
"Ovidius" Faculty of Medicine, Constanta, Romania, IInd Medical Department, Constanta, Romania

Hepatic effects of I131 administration in endocrine disorders are not mentioned in drug's recipe and are rarely described in medical literature. We present the case of a 32 years old woman who was admitted and investigated for myalgias, arthralgias, asthenia and elevated transaminases (ALAT = 482.22 UI/l). The patient was diagnosed in 2022 with autoimmune thyroiditis and a dominant nodule (TIRADS 4) in the right lobe. Thyroidectomy was performed in 2023 and multifocal, partially incapsulated papillary carcinoma was detected. Three months after thyroidectomy, a dosage of 30 mCi of I131 was administered. Five months after thyroidectomy, the patient was admitted for the previous symptoms. After multiple and extensive investigations, using the Roussel Uclaf Causality Assessment Method scaler, the diagnosis of drug (I131) induced liver injury was considered. After conventional hepatoprotective treatment failed to improve patient's status, corticoid treatment was used, with a benefic outcome. Even if liver injury is not cited as an adverse effect of I131 administration, it must be taken into consideration. The manifestations start after a long time (3-6 weeks) post-exposure and they do not respond to conventional hepatoprotective treatment but to corticotherapy.

Clinical and biochemical characteristics of pheochromocytoma

Anna Lugovskaya & Irena Ilovayskaya
Moscow Regional Research and Clinical Institute, Department of Neuroendocrine Diseases, Moscow, Russian Federation

Introduction
Pheochromocytomas (PCCs) or adrenal paragangliomas are neuroendocrine non-epithelial catecholamine-producing tumors with a wide range of cardiovascular, metabolic, neurological manifestations, which may complicate the early diagnosis of the disease in some cases.
Materials and methods
We analyzed data from 89 patients (58 women, 31 men, median age 52 years) with histologically and immunohistochemically verified PCCs including 4 patients with bilateral PCCs.
Results
The most common symptom was hypertension which was observed in 78 (85%) patients including 67 (73%) patients with paroxysmal hypertension, and 11 (12%) patients with sustained hypertension. Median blood pressure (BP) was 200/107mm Hg, the majority (75%) of patients had BP grade III (ESH/ESC 2018). Episodes of tachycardia were observed in 34 (37%) patients. The other most common symptoms were headaches ($n = 47$, 51%), pain in the lumbar region ($n = 20$, 22%) and sweating ($n = 16$, 17%). According to biochemical data, mixed type of secretion predominated (59%), noradrenergic type (25%) and adrenergic type (8%) were rare. Interestingly, we did not observe catecholamine hypersecretion in 8% cases patients despite the subsequent verification of PCCs. Perhaps they had dopamine type of secretion which is currently not available in routine clinical practice. We could not find any obvious correlation between hypertension course and biochemical catecholamine profile. According to CT data of PCCs, the size varied from 1.5 cm to 20 cm (median 4.75), native density - from +9HU to +96HU (median +39HU). Lesion's size was >4 cm in most of the patients (75%), however, CT-density <+10HU was a more accurate marker of pheochromocytoma.
Conclusion
In our cohort of patients, BP grade III (ESH/ESC 2018) predominated regardless of the type of catecholamine secretion. We could not find any obvious correlation between hypertension course and biochemical catecholamine profile. The absence of catecholamine hypersecretion does not exclude the presence of pheochromocytoma in patients with arterial hypertension and an adrenal tumor. Pheochromocytoma should be considered in adrenal lesions of high native CT-density.

Nutritional status in patients with eating disorders after hospital admission

Delia Lavinia Marginean, Carmen Zurera Gomez, María Ángeles Gálvez, Ángel Rebollo-Román & Concepción Muñoz
Hospital Reina Sofía, Endocrinología y Nutrición, Córdoba, Spain

Introduction
Eating disorders (ED) are prevalent psychiatric conditions with significant nutritional implications, posing a risk of life-threatening illness for patients. The chronic and recurrent nature of these disorders, along with normal laboratory test results, present challenges in their management and ongoing monitoring, which typically focuses on weight changes. Techniques like determining the phase angle using bioimpedance analysis or conducting functional muscle tests such as dynamometry can be valuable for monitoring the progression of these patients.
Objective
To evaluate changes in anthropometric measures (weight and body mass index), muscle function and body composition in patients with ED after hospital admission.
Methods
Patients with at least one hospital admission in the last three years. Anthropometric data, bioimpedance and dynamometry data were collected. Statistical analyses were performed with SPSS version 25.
Results
Eighteen cases were included, 100% women with a mean age of 24 + 7.15 years. Anthropometric data at admission: weight 40.59 + 6.17 kg and BMI 14.70 + 1.45 kg/m^2. The 61.1% presented low phase angle (<5.5º). Dynamometry on admission: right arm 20.62 + 4.99 kg and left arm 19.27 + 6.35 kg. After 33.16 + 27.58 days of admission, a significant increase in weight was observed with a mean at discharge of 44.14 + 6.42 kg ($P < 0.05$) and BMI of 16.18 + 1.78 kg/m^2 ($P < 0.05$). At discharge, 55.6% continued with low phase angle. Improvements in functional muscle testing were observed, with right arm dynamometry of 23.71 + 5.00 kg ($P = 0.11$) and left arm dynamometry of 22.24 + 4.91 kg ($P = 0.22$) not significant.
Conclusions
The study population did not show significant alterations or improvements in the analytical parameters after admission, which is consistent with findings in the literature. These findings are more commonly observed in other eating disorders such as bulimia nervosa. Additionally, the phase angle did not exhibit significant improvement after admission, despite being previously reported by other authors. However, dynamometry did show improvement, even though the baseline values were not pathological. This study suggests that BMI and weight are sensitive parameters for determining the timing of admission and confirming the clinical stability of the patients.

Results of bariatric surgery in a third level hospital in the last 5 years

Eduardo Torrecillas del Castillo, Mercedes Peinado Ruiz, María del Castillo Tous Romero, Reyes Rave García, Eduardo Domínguez-Adame Lanuza, Juan Manuel Cáceres Salazar & María Asunción Martínez Brocca
Hospital Universitario Virgen Macarena, Sevilla, Spain

Aim
Describing bariatric surgery (BS) interventions in our center in the last five years, complications and effectiviness in weight loss and resolution of comorbities.
Methodology
Prospective descriptive study on a cohort of people who underwent BS surgery at Virgen Macarena University Hospital, a tertiary hospital of the Public Health System of Andalusia, between January 2018 and May 2023. Patients who underwent revision surgery with a first previous surgery were excluded. Description of demographic characteristics, complications, weight evolution, comorbidities associated with obesity (diabetes, arterial hypertension and OSA) and their remission after BS up to two years later. Quality criteria based on AEC and SECO recommendations.
Results
217 patients, average age 46.55 years, 156 women (71.9%) Median follow-up time between surgery and last check-up 19.8 months. Most common surgery: vertical sleeve gastrectomy (77.88%), 21.66% gastric bypass. Surgery complications: early complications 23 cases (10.6%), 1 death (0.46%). Reintervention before 30 days 5.06%. Revision surgery: 5.52%, GERD most common cause. Initial average weight 140.7 kg (SDS 23.42). Initial BMI 51.36 kg/m^2, 14.5% weight loss in preparation for surgery. Average weight after one year 83.97 kg (SDS 14.10). Average weight after 2 years 83.29 (SDS 14.77), loss of 40.8% of weight and 79.2% of excess overweight. Average weight after 5 years 87.5 kg (SDS 14.5), weight loss of 37.8%. Comorbidities before BS: Diabetes mellitus (DM) 64 (29.5%), prediabetes 28 (12.9%). Average oral drugs for + GLP1a 2.01 (70.3% of patients with GLP1 analogues). 13 patients with insulin (20.6%, 64 IU/day on average, SDS 40.55). Arterial hypertension (AHT) 113 cases (52.1%), average number of drugs for control 2.03. OSA with CPAP 126 patients (58.1%). After BS: DM remission 69.8%. Insulinization 3 patients (1.38%), 12.55 IU/day on average (SDS 12.14). Cessation of aGLP1 in 97.77%. AHT remission 68.1%. Withdrawal of CPAP in patients with OSA 49.2%.
Conclusions
We observed good initial weight loss data, highlighting a high percentage of loss in the preoperative period and maintenance of the percentage obtained after the intervention. Sleeve vertical gastrectomy was the most used technique. The percentage of remission of comorbidities after BS is high two years after surgery. Greater follow-up is needed to evaluate definitive data on weight loss, medium-long term complications, evolution of comorbidities, need to reintroduce drugs due to comorbidities and revision surgery.

Diagnostic challenges: suspected adrenal myeloid sarcoma

Kouloud Hachani[1], Sabrine Mekni[1,2], Sawsen Essayeh[1,2], Rihab Laamouri[1], Meriem Werfelli[1], Nadia Mchirgui[1], Karima Khiari[1], Imen Rojbi[1,2] & Ibtissem Ben Nacef[1,2]
[1]Charles Nicolle Hospital, Tunis, Tunisia; [2]Laboratory of Renal Pathology LR00SP01, Tunis, Tunisia

Introduction
Myeloid sarcoma is a rare etiology of adrenal tumors, with both diagnostic and therapeutic difficulties. This clinical case highlights the diagnostic challenges inherent in the coexistence of these two pathologies, underscoring the complexity of their management.
Case report
We present the case of a 40-year-old woman with a history of polycystic ovary syndrome since her youth. She was referred to our department to explore adrenal incidentaloma as a CT scan of the abdomen showed a 55 × 49 mm heterogeneous adrenal mass with a density of 35 HU. Investigations revealed a suspicious, non-secreting mass, with morning cortisol levels after a 1-mg overnight dexamethasone suppression test at 22 nmol/l and normal Urinary metanephrins and normetanepherins, testosterone and SDHEA levels. Clinicobiological assessments and CT chest-abdomen-pelvis excluded metastasis from another cancer. The patient was referred to the urology department for total adrenalectomy, but she developed (2month later) bicytopenia, presenting with anemia at 5 g/dl and thrombocytopenia at 50, 000 / microliter. Faced with the hematological emergency, surgery and biopsy could not be performed, and the patient was referred to the hematology department. The diagnosis of acute myeloid leukemia was established, and the patient underwent chemotherapy (protocol combining intensive induction chemotherapy, and consolidation treatment). The course was marked by a significant decrease in adrenal tumor size by 47% in the adrenal CT scan follow up. Given this evidence, the most probable diagnosis appears to be myeloid sarcoma of the adrenal gland.
Conclusion
Myeloid sarcoma can develop before the onset of acute myeloid leukemia (Aml), concurrently with AMl, or during Aml relapse. Its localization in various organs is possible, however, adrenal localization remains rare. Diagnosis can be concluded by clinical and evolutive evidence, but definitive confirmation always relies on histopathology.

EP1266

LHX4 mutation: new perspective

Stefania Munari, Rebecca Vitella, Rossella Gaudino & Franco Antoniazzi
Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy

Background
Growth is a multifactorial trait, in which about 80% are determined by genetic factors. The pituitary plays a central role and some of the transcription factors can be involved in isolated or combined deficits: they orchestrate the ontogeny of the gland, maintain the differentiated state and mediate the coordinated expression of specific cell type. Among them, *LHX4* mutations can manifest as a combined pituitary hormone deficiency and are associated with an ectopic posterior pituitary and/or a sella turcica defect. Its mutations are associated with variable expressivity and incomplete penetrance.
Case presentation
We describe a patient with growth failure. Regular pregnancy without problems reported at prenatal ultrasounds. Term-born: weight 3040g (-1.1 SDS), length 48 cm (-1.5 SDS), head circumference 33 cm (-1.5 SDS). No dysmorphisms. At the age of three, sleep apneas are reported with an obstructive sleep apnea syndrome (OSAS) with central predominant component of mild degree at the polysomnography. At the age of four, we evidenced a growth slowdown (height -2.7 SDS, with TH -1, 2 SDS). We excluded celiac disease, hypothyroidism, GH deficiency (GHD), chromosomopathy and *SHOX* gene alteration. Bone age was delayed by about 1 year. Due to persistence of growth failure, we performed a genetic analysis that revealed a mutation in the *LHX4* gene c.250C>T p.(Arg84Cys), which was subsequently detected in the father (final height 168 cm). No other deficits in pituitary hormone function were found. The brain MRI showed no abnormalities in the hypothalamic-pituitary region nor other encephalic defects were detected. At the age of 6, 8, we started a trial therapy with rhGH 27 mg/kg/day, but due to behavior disorder (anger outbursts) and the lack of improvement in growth rate with the therapy the treatment was suspended after 6 months.
Conclusions
Our patient has a mutation that is already described as putative, but he doesn't present the typical clinical features: he doesn't have any pituitary deficit nor any alteration at the brain MRI. His short stature can't be explained by a GHD, moreover the trial treatment with rhGH didn't work. Further studies are needed to elucidate the relationship between short stature and the *LHX4* mutation. The central OSAS could be related to the *LHX4* mutation since studies on mice demonstrated a ventral motor neuron defect that impair respiratory movements, associated whit lung hypoplasia. This could be a possible manifestation in humans which let us widen the clinical manifestation associated with such mutation.

The influence of hyperglycemia on clinical and biochemical parameters in patients with acute myocardial infarction

Mehriban Rizaeva[1] & Zulaykho Shamansurova[2,3]
[1]Bukhara State Medical Institute, Endocrinology, Bukhara, Uzbekistan; [2]Central Asian University Medical School, Endocrinology, Tashkent, Uzbekistan; [3]Institute of Biophysics and Biochemistry at the NUUz, Metabolomics, Tashkent, Uzbekistan

Introduction
Hyperglycemia is often elevated in patients with acute myocardial infarction (AMI) and is a prognostic indicator. According to a number of researchers, the risk differs between women and men. The purpose of our study was to study the effect of hyperglycemia on clinical and biochemical parameters in men and women with AMI.

Materials and methods
The study was conducted on 92 patients admitted to the intensive care unit of the cardiology center in Bukhara. Of these, 65% are men and 35% are women, aged from 42 to 84 years. Among them, 16 patients had a history of type 2 diabetes. All subjects were measured for BMI, SBP, DBP, general blood count, urine test, glycemia, HbA1c, ALT, AST, blood urea and creatinine levels, and coagulation parameters according to a coagulogram.
Results
The results showed that AMI was more common in men (1.78 times) compared to women, while the increase in glycemia was observed in women by 1.87 times higher compared to the group of men. BMI, SBP, DBP, and blood biochemical parameters did not differ significantly in the group of men and women. However, the dependence on glycemia assessed by correlation showed an average correlation between BMI in the group of men with normoglycemia, while in women this relationship was positive in both the group with normoglycemia and hyperglycemia. A positive correlation was found between the parameters of SBP, leukocytes, blood platelets, with proteinuria, prothrombin index, D-dimer. Interestingly, a positive correlation with glycemia was detected with both normo- and hyperglycemia; there was a weak correlation with BDNF levels.
Conclusions
AMI is more common in men than in women. At the same time, clinical and laboratory parameters did not differ significantly. A correlation was found with BMI, SBP, blood leukocyte level, blood D-dimer, and a weak correlation was noted with blood BDNF level, which suggests their consideration as prognostic criteria for the prognosis of AMI.

Using a SGLT2 inhibitor does not modify the efficacy and tolerability of extended-release metformin in patients with type 2 diabetes

Borja Santana-Ojeda[1], Alba Hernandez-Lazaro[2], Ricardo Jose de Leon-Durango[1], Inmaculada Molinero-Marcos[1], Agnieszka Kuzior[3], Claudia Arnas-Leon[1,3], Jennifer Maria Perez-Rivero[4], Marta Martin-Perez[5], Paula Gonzalez-Diaz[6] & Francisco Javier Martinez Martin[1,3]
[1]University Hospital of Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [2]Parc Taulí University Hospital, Endocrinology & Nutrition, Sabadell, Spain; [3]Clinica San Roque, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [4]Centro Salud Escaleritas, Family & Community Medicine, Las Palmas de Gran Canaria, Spain; [5]Clínica Cajal, Family & Community Medicine, Las Palmas de Gran Canaria, Spain; [6]University Hospital of Gran Canaria Dr. Negrín, Emergency Medicine, Las Palmas de Gran Canaria, Spain

Introduction and Objectives
The tolerance of extended-release metformin (XRM) is superior to that of conventional metformin. XRM is recently available in Spain as a fixed combination with sitagliptin, but not in monotherapy. There are no data yet on how additional antidiabetic treatment can modify the effects of the XRM/sitagliptin combination. After assessing the efficacy and tolerability of XRM/sitagliptin in patients with T2DM labelled as metformin-intolerant and treated with a DPP4 inhibitor (DPP4i), we performed additional analyses in order to assess if additional treatment could modify these results.
Patients and Methods
Consecutive patients with T2DM, HbA1c $>7\%$ and GFR (CKD-EPI) >45 mL/min/1.73m^2 labelled as metformin-intolerant due to gastrointestinal symptoms, and treated with a DPP4i were switched to the 50 mg sitagliptin plus 1000 mg XRM combination, taking 1 pill daily in the first month and afterwards 2 pills if the tolerance was good. Tolerance data were obtained by questionnaire in the follow-up visit. All Included patients granted informed consent.
Results
29 patients previously treated with SGLT2i (17 with empagliflozin, 8 with dapagliflozin and 4 with canagliflozin) could be pooled and analyzed vs. 43 not treated with any SGLT2i. No patient was treated with metformin (due to assumed intolerance); all were treated with DPP4i (by protocol) but none with a GLP-1ra (due to incompatibility with iDPP4); 5 patients were treated with insulin, 4 with gliclazide, 3 with repaglinide and 3 with pioglitazone; these drugs were unsuitable for analysis due to sample size. There were no significant differences for the reductions in fasting glycemia (without SGLT2i: 36 ± 16 mg/dl with 1 pill, 45 ± 17 mg/dl with 2 pills; with SGLT2i 32 ± 16 mg/dl with 1 pill, 40 ± 13 mg/dl with 2 pills) or in HbA1c (without SGLT2i: $0.64\pm0.30\%$ with 1 pill, $0.95\pm0.32\%$ with 2 pills; with SGLT2i $0.59\pm0.28\%$ mg/dl with 1 pill, $0.91\pm0.30\%$ with 2 pills) induced by the switch from DPP4i to XRM/sitagliptin in patients with vs. without previous SGLT2i treatment. There were also no significant differences for tolerance: without SGLT2i: 8 patients (18.6%) did not tolerate the rechallenge, and 5 (11.6%) tolerated only 1 pill; with SGLT2i, 4 (13.8%) did not tolerate, and 3 (10.3%) tolerated only 1 pill.
Conclusions
A large majority of the patients with T2DM labelled as metformin-intolerant and treated with DPP4i tolerated XRM/sitagliptin, and their fasting blood glucose and HbA1c significantly improved. The concomitant use of iSGLT2i did not modify these results. Other antidiabetic treatments could not be meaningfully analyzed.

Rechallenge with extended-release metformin in patients with type 2 diabetes labelled as metformin-intolerant: satisfaction and its determinants

Ricardo Jose de Leon-Durango[1], Alba Hernandez-Lazaro[2], Carlos Rios-Gomez[1], Borja Santana-Ojeda[1], Inmaculada Molinero-Marcos[1], Agnieszka Kuzior[3], Claudia Arnas-Leon[1], Jennifer Maria Perez-Rivero[4], Debora Maria Garcia-Alamo[5] & Francisco Javier Martinez Martin[1,3]
[1]University Hospital of Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [2]Parc Taulí University Hospital, Endocrinology & Nutrition, Sabadell, Spain; [3]Clinica San Roque, Endocrinology & Nutrition, Las Palmas de Gran Canaria; [4]Centro Salud Escaleritas, Family & Community Medicine, Las Palmas de Gran Canaria, Spain; [5]Hospital Virgen Macarena, Laboral Medicine, Sevilla, Spain

Introduction and Objectives
Extended-release metformin (XRM) is recently available in Spain as a fixed combination with sitagliptin, but not in monotherapy. Its tolerance is clearly superior to that of conventional metformin, and since 2005 the NICE guidelines for type 2 diabetes mellitus (T2DM) recommend its use in patients with metformin-caused gastrointestinal disturbances. We assessed the efficacy and tolerability of XRM/sitagliptin in patients with T2DM previously labelled as metformin-intolerant and treated with a DPP4 inhibitor (DPP4i), and additionally analyzed the data for patient satisfaction.
Patients and Methods
Consecutive patients with T2DM, HbA1c $>7\%$ and GFR (CKD-EPI) >45 mL/min/1.73m^2 labelled as metformin-intolerant due to gastrointestinal symptoms, and treated with a DPP4i were switched to the 50 mg sitagliptin plus 1000 mg XRM combination, taking 1 pill daily in the first month and afterwards 2 pills if the tolerance was good. The mean reductions in HbA1c were 0.6% with 1 pill and 0.9% with 2 pills (both $P<0.01$). The patients were contacted for a short web-based questionnaire in order to assess their satisfaction with the switch from DPP4i to the XRM/sitagliptin combination. This was categorically expressed choosing one of 5 icons conventionally considered as representing "very poor, poor, fair, good or very good" satisfaction (Likert scale); there was also an option for "no opinion". Tolerance data were obtained by questionnaire in the follow-up visit. All Included patients granted informed consent.
Results
Satisfaction data could be obtained from 70 of a total 72 patients, 62 through the web, 5 by phone and 3 presentially, but the questioner was never the prescribing physician. 39 (55.7%) of the patients reported "very good" satisfaction, 14 (20.0%) "good" satisfaction, 9 (12.6%) "fair" satisfaction, 4 (5.7%) "poor" satisfaction, 2 (2.9%) "very poor" satisfaction, and 2 (2.9%) reported no opinion. 51 patients (73%) tolerated 2 tablets of XRM/sitagliptin (1000/50 mg); 8 (11%) tolerated 1 tablet and 11 (16%) did not tolerate any. A backwards stepwise logistic regression identified the lack of adverse effects as the only independent predictor of "good" or "very good" satisfaction, while the changes in HbA1c, fasting glucose, body weight, etc. did not predict satisfaction.
Conclusions
A large majority of the patients with T2DM labelled as metformin-intolerant and treated with a DPP4i tolerated the XRM/sitagliptin combination. Patient satisfaction with the switch was high, with 3/4 of them reporting it as "good" or "very good", and was driven by the absence of adverse effects.

Should acromegaly disease activity be considered while using anti-diabetic treatment among patients with acromegaly and diabetes?

Adnan Zaina[1] & Kassem Sameer[2]

[1]Bar-Ilan University, Azrieli Faculty of Medicine, Division of Endocrinology and Metabolism, Israel; [2]Technion - Israel Institute of Technology, Haifa, Israel

Management of type 2 diabetes (T2DM) has advanced since introducing sodium-glucose co-transporter 2 inhibitors (SGLT2i) with their protective cardiovascular and renal effects. However, in acromegaly patients with diabetes, the SGLT2i class is less attractive among endocrinologists because of the increased risk of diabetic ketoacidosis (DKA), and the use of incretin-based therapy as second-line treatment after metformin is more considered. This review aims to discuss the role of SGLT2i in diabetes management in acromegaly.
Methods
A comprehensive Medline/PubMed and Embase search was performed between 2012-2022 using the terms acromegaly and diabetes, SGLT2i in acromegaly, DKA in patients with acromegaly with and without SGLT2i use.
Results
Database evidence regarding the use of SGLT2i in acromegaly patients with diabetes is scanty. Previously reported data disclosed that in most cases, DKA was not related to SGLT2i, and this complication was reported as a presenting manifestation in most patients with uncontrolled acromegaly and diabetes. It is worth mentioning that GH and IGF-1 levels were markedly elevated in all reported cases of developed DKA. In contrast, in our previously reported data, the use of SGLT2i in controlled acromegaly was safe and without adverse events. Therefore, in this review, we consider acromegaly disease activity an essential criterion in the proposed algorithm for diabetes management in acromegaly patients, particularly when considering treatment with SGLT2i.
Conclusion
We recommend using SGLT2i among patients with controlled acromegaly and diabetes, following the T2DM recommendation guidelines. However, SGLT2i could be considered cautiously among partially controlled acromegaly patients and not recommended in poorly controlled patients. In these cases, incretin-based therapy is more favorable for patients, at least until the availability of future studies demonstrating SGLT2i safety also in this context.

The short and long-term potential negative effects of thyroxine therapy in children and adolescents

Ashraf Soliman, Nada Alaaraj, Noor Hamed, Shayma Mohamed & Fawzia Alyafei
Hamad General Hospital, Doha, Qatar

Introduction
This review aims to systematically analyze and summarize the findings from research articles regarding the potential short-term and long-term side effects of L-thyroxine therapy in children and adolescents. The selection criteria for the studies included their focus on the negative effects of thyroxine therapy related to thyroid health, cognitive function, cardiovascular health, bone health, and cancer risk in pediatric populations.
Results of the Review
Summary of Research Findings on Thyroxine Therapy, Thyroid Health, and Associated Risks in Children and Adolescents

(Abstract EP1271)

Study Focus	Findings	Authors	Year
Neurocognitive Function in Hypothyroidism	Short-term thyroxine therapy did not significantly affect neuropsychological function in children with compensated hypothyroidism.	Aijaz *et al.*	2006
Cardiovascular Side Effects of Thyroxine Therapy	Potential adverse effects include shortening of systolic time intervals, increased frequency of atrial premature beats, and possible left ventricular hypertrophy, manageable with appropriate dosage adjustments.	Bartalena, Bogazzi, & Martino	1996
Bone Health in Long-term Thyroxine Therapy	Long-term use of thyroxine can affect bone density and mass, mitigable with careful monitoring.	Bartalena, Bogazzi, & Martino	1996
Thyroxine Therapy in Down Syndrome	Thyroxine treatment improved growth and potentially development in Down syndrome children with congenital hypothyroidism.	van Trotsenburg *et al.*	2005
Cognitive and Behavioral Outcomes in Juvenile Hypothyroidism	Mild behavioral symptoms and poorer school achievement may occur in children treated with L-thyroxine for juvenile acquired hypothyroidism.	Rovet, Daneman, & Bailey	1993
Autoimmune Hyperthyroidism Characteristics	Prepubertal children are more severely affected at presentation and require longer therapy for remission.	Shulman *et al.*	1997
Thyroid Cancer Outcome after Chernobyl	Favorable responses to radioiodine therapy in Chernobyl-exposed Belarusian children and adolescents with thyroid cancer.	Reiners *et al.*	2013
Thyroid Cancer Risk and Serum TSH	Increased thyroid cancer risk in children especially vulnerable to ionizing radiation.	Ron *et al.*	1995
Neurocognitive Functions in Subclinical Hypothyroidism	Impacts on attention in children and adolescents with subclinical hypothyroidism.	Ergür *et al.*	2012
Thyroxine Therapy in Nodular Goiter	L-thyroxine treatment associated with decreased frequency of papillary thyroid cancer in nodular goiter patients.	Fiore *et al.*	2010

Conclusions
The review highlights that while thyroxine therapy is crucial for the management of hypothyroidism and associated conditions in pediatric populations, careful consideration is necessary to mitigate potential adverse effects. These include, but are not limited to, cardiovascular side effects, impacts on bone health, cognitive function, and growth. The findings underscore the importance of tailored and monitored thyroxine therapy in children and adolescents to balance therapeutic benefits against potential risks.

Dilated cardiomyopathy: an unusual revelation of autoimmune hypothyroidism; case report

Ikrame Qasdi, Hasna Ouirar, Kaoutar Elmoatamid, Fatima Toulali, Kaoutar Rifai, Iraqi Hinde & Mohamed Elhassan Gharbi
Ibn Sina University hospital, Endocrinologie et maladies métaboliques, rabat, Morocco

Introduction
The occurrence of Dilated Cardiomyopathy (DCM) and hypothyroidism induced systolic dysfunction is rare, especially when it presents as an initial manifestation of hypothyroidism Case We report the case of a 57-year-old patient, a known chronic smoker, who was admitted to the emergency department reporting asthenia, NYHA class III dyspnea, cardiac angina, and periorbital oedema. The ECG reveals a regular rhythm at 50 bpm and diffuse low voltage with firstdegree atrioventricular block. Biologically, the initial assessment showed normal renal and hepatic function. TSH was elevated at 228 mIU/l, T4 was low, and anti-TPO and anti-TG were significantly positive. Cervical ultrasound findings pointed towards a pseudo-nodular thyroid indicative of thyroiditis, along with features of bi-ventricular dilated cardiomyopathy presenting moderate left ventricular dysfunction and an ejection fraction of 45% on echocardiography. The Coronary angiography yielded normal results, while cardiac MRI revealed dilated cardiomyopathy with a dilated left ventricle. The patient underwent heart failure management, with a stepwise introduction of thyroid hormone replacement therapy using L-thyroxine, leading to a favorable clinical, biological, and radiological progression
Discussion
Dilated cardiomyopathy is a weakening and stretching of the heart muscle, resulting in a diminished capacity for effective blood pumping. Although it can have diverse factors, such as genetic causes, viral infections, and metabolic issues, it can also have an association with thyroid disorders, including hypothyroidism. Treating hypothyroidism can enhance cardiac function gradually in numerous cases.

When an ectopic and hyperfunctional thyroid nodule appears 2 decades after subtotal thyroidectomy: A case report

Hasna Ouirar, Ikrame Qasdi, Caimae Zouna, Amal Riad, Kaoutar Elmoatamid, Fatima Toulali, Ghizlane Sabbar, Kaoutar Rifai, Iraqi Hinde & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Endocrinology and Metabolic Diseases, Rabat, Morocco

Introduction
A toxic thyroid nodule refers to a nodule that functions autonomously, causing an overabundance of thyroid hormones. It is generally considered non-malignant. Making a decision regarding surgery in hyperthyroid patients necessitates the accurate localization of the toxic region. Here we report a case of an intrathoracic toxic thyroid nodule causing hyperthyroidism with a normally functioning cervical thyroid nodule.
Case
A 63 year-old female underwent subtotal thyroidectomy in 2000 for a multinodular goiter with preservation of the upper left pole, and postoperative course was marked by permanent hypoparathyroidism requiring replacement therapy. The pathological examination revealed a benign condition. Subsequently, in 2019, a toxic nodule developed and was treated with radioiodine therapy without improvement. Confronted with ongoing clinical and biochemical hyperthyroidism, Ultrasonographic assessment of thyroid bed showed an isoechoic left nodule measuring 17×13 mm. Thyroid scintigraphy employing 99m technetium displayed intense and heterogeneous uptake projecting into the anterior and middle mediastinum. Cervico-thoracic CT imaging disclosed a mediastinal lesion, indicating a possible ectopic thyroid nodule. The patient was treated with graded doses of Carbimazole, but partial response was provided. A left lobectomy and removal of an intrathoracic goiter were performed. Results of the histopathological evaluation are currently being processed
Discussion
Radionuclide scintigraphy is valuable in confirming suspected or clinically evident thyroid tissue that is extending into mediastinum. The possibility of the existence of external thyroidal tissue should be kept in mind in such suspicious cases. Intrathoracic goiters are generally considered an indication for surgery; radioiodine therapy remains a choice for those who cannot be operable because of advanced systemic disease or other reasons.

From high dose Insulin therapy to dual oral therapy: recovery from glucotoxicity after acute pancreatitis and severe ketoacidotic hyperglycaemia

Hassan Al Sahaf[1], Lama AlMahrous[2] & Azmi Mohammed[3,4]
[1]Johns Hopkins Aramco Healthcare Dhahran, Dhahran, Saudi Arabia; [2]Johns Hopkins Aramco Healthcare Dhahran, Internal Medicine, Dhahran, Saudi Arabia; [3]Johns Hopkins Aramco Healthcare Dhahran, Endocrinology, Dhahran, Saudi Arabia; [4]County Durham and Darlington NHS Foundation Trust, United Kingdom

Significant hyperglycaemia suppresses beta cell replication and cell cycle progression. Acute beta cell failure is caused by several mechanisms involving oxidative and endoplasmic stress leading to DNA damage response (collectively termed glucotoxicity) [(1)]. Short-term glycaemic control unmasks the regenerative potential of beta cells, leading to recovery and potentially weaning off Insulin therapy [(1, 2, 3)]. We present a case of a 62-year-old woman with type 2 diabetes mellitus for four years, on metformin (2g daily) and Empagliflozin (25 mg daily), who presented with acute abdomen secondary to acute pancreatitis, severe ketotic hyperglycaemia (glucose 477 mg/dl) and acidaemia (pH: 7.31, anion gap 20 mEq/l). She was managed medically with intravenous insulin infusion and IV therapy, then converted to multiple daily injections (MDI). Her laboratory results indicated high lipase; low C-peptide coupled with high glucose. CT abdomen was unremarkable apart from signs of pancreatitis. Following stabilization over a few days in the hospital, she was discharged on glargine, meticulously adjusted to 42 units daily, and NovoRapid up to a maximum of 16 units with meals. Empagliflozin was initially suspended for a few weeks to mitigate the risk of rebound ketonemia. Over the subsequent eight weeks, a methodical reduction in her insulin doses was pursued until the need for MDI was eliminated. HbA1c 4.85% was achieved without troublesome hypoglycaemia on glucose monitoring with Freestyle libre (2). Presently, her diabetes is managed effectively with metformin and Empagliflozin 10 mg daily. This case highlights the complex risks of glucotoxicity stemming from severe hyperglycaemia that causes acute beta cell failure. Acute pancreatitis exacerbated insulin deficiency in this case. SGLT2 inhibitors increased the risk of ketonemia due to pronounced insulin deficiency and resistance. They can also lead to dehydration through glucosuria, hinder ketone elimination, heighten the glucagon-to-insulin ratio, and promote ketogenesis [(4)]. Interestingly, the effects of glucotoxicity were reversible following 6-8 weeks in a normoglycemic setting with adequate Insulin therapy, illustrating the potential for beta-cell functional recovery, eventually leading to insulin therapy cessation. In conclusion, this narrative underscores the criticality of recognizing and addressing glucotoxicity in patients with type 2 diabetes who may present with acute pancreatitis. It illustrates the importance of vigilant management strategies, including short-term insulin therapy, to reverse the adverse effects of glucotoxicity.

Graves' disease associated with primary biliary cholangitis: a case report

Karimi Meryem, Hajar Azagouagh, Hasna Ouirar, Rifai Kaoutar, Iraqi Hind & Mohamed Elhassan Gharbi
Ibn Sina Rabat, Endocrinology, Rabat, Morocco

Introduction
Graves' disease is an autoimmune thyroid disease that is frequently associated with other autoimmune diseases. In our case, we report a rare association with primary biliary cholangitis.
Case report
A 38-year-old patient, with no particular medical history, has been followed for Graves' disease for 14 years, initially treated with carbimazole with poor therapeutic compliance and irregular follow-up. The evolution was marked by the onset of cutaneous-mucosal jaundice. Laboratory tests showed hepatic cholestasis with cytolysis and pancytopenia, persisting after discontinuation of treatment. Hepatic ultrasound was unremarkable. Liver biopsy confirmed primary biliary cholangitis. The patient was started on ursodeoxycholic acid with rapid medical preparation for definitive treatment.
Discussion and Conclusion
The disturbance of liver function tests in Graves' disease may be correlated with thyrotoxicosis or secondary to treatment with synthetic antithyroid drugs, or it may be due to primary biliary cholangitis, which should always be considered in cases of hepatic cholestasis.

EP1276

A rare association between cushing's disease and primary biliary cirrhosis: about a case report

Arige Abid, Bchir Najla, Annam Benchhida, Yosra Abderrahim, Dorra Dorraelguiche, Zouaoui Chadia & Haroun Ouertani
Tunis Military Hospital, Endocrinologie, Tunis, Tunisia

Introduction
Cushing's disease is a rare disorder caused by the hypersecretion of corticosteroids. Primary biliary cirrhosis (PBC) is a chronic autoimmune cholestatic hepatopathy characterized by destruction of the bile ducts and the presence of m^2-type anti-mitchondrial antibodies. We report a rare association between cushing's disease and primary biliary cirrhosis.
Observation
The patient was 38 years old, with recent history of diabetes and dyslipidemia, was admitted to our department of endocrinology for suspicion of a Cushing syndrome. The physical examination showed facial erythrosis, filling of the supra-scalvicular hollows, presence of a buffalo hump and facio-truncular fat distribution but not catabolic signs. Diagnosis of ACTH-dependent cushing's syndrome biologically was made on the basis of lack of plasma cortisol response to low dexamethasone suppression test at 516 nmol/l (above 50 nmol/l), and high ACTH value at 69.4 confirmed by a second assessment at 100 pg/ml. High-dose Dexamethasone Suppression test cortisol level decrease greater than 50% after 8 mg of dexamethasone (from 728 to 315 nmol/l), suggesting Cushing disease. Pituitary MRI showed a 6 mm micro-adenoma. She underwent a transphenoidal adenomectomy with post operative remission. Moreover, the biological work -up showed cytolysis at 1.5 time the upper limit with cholestasis. Viral serologies and autoimmune antibodies were carried out, showing positive anti-mitochondrial m^2 ACs and negative viral serologies. Abdominal ultrasound revealed no abnormalities. A liver biopsy was performed, showing epithelioid granulomas with neoductular proliferation, confirming the diagnosis. The patient was treated by ursalvan,
Conclusion
Cushing's syndrome has been associated in the literature to several liver diseases, hepatic steatosis being the most common. coexistance between cushing's disease and primary biliary cirrhosis (PBC) is uncommon and has been little reported Common physiopathology must be investigated.

EP1277

Heterozygous type 1 familial hypercholesterolemia patient with a rare LDL receptor mutation and the efficacy of evolocumab in the management of consequent hyperlipidemia

Olivera Boskovic[1] & Edina Hubanic[2]
[1]Clinical Center of Montenegro, Endocrinology, Podgorica, Montenegro; [2]Bijelo Polje, General Hospital-Internal medicine department, Bijelo Polje

Heterozygous (monoallelic) familial hypercholesterolemia (HeFH) is a monogenic disorder that affects one in 300 people. The majority of cases of FH are caused by inherited mutations in the LDLR gene, which encodes the LDLR. Less commonly, the heterozygous FH phenotype can be caused by mutations in other genes, specifically PCSK9, which encodes proprotein convertase subtilisin/kexin type 9. As many as 30% of patients do not survive their first myocardial infarction (MI). We present a HeFH patient with a rare mutation of LDLr. A 67-year-old woman with FH has been treated for the past 30 years with statins in the maximum tolerated dose. Last 10 years, on Rosuvastatin 40 mg, and cholesterol absorption inhibitor Ezetimibe 10 mg. Her past history revealed that she underwent percutaneous coronary interventions (PCI) with stent implantation on the left anterior descending artery 15 years ago and carotid endarterectomy. Her family history included premature coronary artery disease: her brother had MI in his forties, required the placement of 3 bypasses. Both daughters have FH. For determining the presence of a hetero or homozygous form of FH for the purpose of applying appropriate therapy, molecular genetic diagnostics using Next Generation Sequencing method was conducted. The analysis included all coding sequences (exons) and boundary exon/intron sequences in genes defined according to phenotypic characteristic present in the patient. The clinical target encompassed nine genes in the panel for FH. The conducted analysis revealed the presence of a likely pathogenic heterozygous variant in the LDLr gene c.858C > A, p. (Ser286Arg), NM 000527.5. This variant has an expected allelic frequency of 0.0028%. Following the results, she became eligible for treatment with a PCSK9 inhibitor, and she was approved for adjuvant biweekly treatment with Repatha® (evolocumab) 140 mg. Follow-up results showed a reduction: total cholesterol from 4.93 to 3.9 mmol/l; and LDL-C from 2.59 to 1.48 mmol/l. Treatment with PCSK9 inhibitor was combined with Rosuvastatin 20 mg and Ezetimibe 10 mg daily. We confirm the observations that, in compound heterozygous HeFH patients who receive stable background lipid-lowering treatment and do not undergo apheresis, biweekly treatment with evolocumab 140 mg was well tolerated and significantly reduced LDL-C.

Introduction and Objectives
The prevalence of prediabetes in the adult Spanish population is close to 15%. People with prediabetes are not only at high risk of developing T2DM but also at high cardiovascular risk. Several drugs, including metformin, glitazones, GLP-1RAs and SGLT2is have been found to reduce the incidence of diabetes in this population, but none is currently licensed with this indication. In particular α-glucosidase inhibitors such as acarbose have been shown to significantly reduce the risk of progression to T2DM but also the risk of developing hypertension and major cardiovascular events (STOP-NIDDM trial). The white mulberry (Morus Alba) leaf contains 1-deoxynojirimycin, a powerful α-glucosidase inhibitor. A novel neutraceutical based on Reducose, a patented standardized white mulberry leaf extract, containing also fenugreek, inulin, Lactiplantibacillus plantarum A14, chromium, zinc and niacin (for better efficacy and tolerance) has been developed for the treatment of prediabetes. We undertook an open trial to validate the tolerability and efficacy of this nutraceutical including markers of cardiovascular and metabolic risk.
Methods
We are actively recruiting adult subjects with prediabetes, excluding those with morbid obesity, concomitant serious diseases, alcoholism, addictions, present or planned pregnancy. After obtaining baseline anthropometry and lab tests and giving informed consent, they take a pill of the nutraceutical daily before lunch with a glass of water. Follow- up visits are scheduled after 3-4 and 6-7 months. Presently we have 15 subjects who have completed the first follow-up visit for this preliminary analysis. The targets are: estimated 10-year cardiovascular risk (SCORE2), lipid profile, systolic BP, BMI, fasting glucose and insulin, HOMA2-IR and tolerability (questionnaire). Stats were made by paired t-test.
Results
In 15 subjects (2/3 women, age 54.2 ± 6.6 years, 20% active smokers), the SCORE2 changed from to 4.09 ± 1.98 to 3.63 ± 1.83% ($P = 0.002$); cHDL from 46.5 ± 9.5 to 49.1 ± 8.9 mg/dl ($P = 0.002$), triglycerides from 183.6 ± 59.4 to 155.9 ± 52.8 mg/dl ($P = 0.009$); SBP from 138.1 ± 16.1 to 131.7 ± 13.4 mmHg ($P = 0.002$); HOMA2-IR from 1.42 ± 0.32 to 1.19 ± 0.17 ($P = 0.029$); fasting glucose from 105.5 ± 11.9 to 99.5 ± 7.7 mg/dl ($P = 0.015$); fasting insulin from 10.6 ± 2.4 to 8.89 ± 1, 31 μU/ml ($P = 0.028$); HbA1c from 6.07 ± 0.28 to 5.93 ± 0.24% ($P = 0.023$). Total cholesterol, cLDL and IMC did not change significantly. There were no serious tolerability issues and no patient has withdrawn from the study so far.
Conclusions
These are very preliminary but promising results for the novel neutraceutical with significant reductions both for cardiovascular and for metabolic risk.

EP1279

A rapid and concise dual-mode aptasensor for ultrasensitive detection of 17β-estradiol

Fengfeng Zhao
Zhongda Hospital, School of Medicine, Southeast University, Center of Clinical Laboratory Medicine, Nanjing, China

Objective
Pollution of endocrine disrupting chemicals has become a global issue. As one of the hormonally active compounds, 17β-estradiol produces the strongest estrogenic effect when it enters the organism exogenously including food intakes, bringing potential harmfulness such as malfunction of the endocrine system. Therefore, in order to assure food safety and avoid potential risks of 17β-estradiol to humans, it is of great significance to develop rapid, sensitive and selective approaches for the detection of 17β-estradiol in food matrices.
Method
Molecular recognition elements are valuable tools for rapidly and selectively binding to target proteins. Aptamers, commonly referred to as chemical antibodies, are one such category of molecular recognition elements, exhibiting several advantages such as smaller size, stability, cost-effectiveness, easy modification, low immunogenicity, and scalability for production. As a result, aptasensors combined with diverse detection technologies offer a promising alternative for the detection of clinical biomarkers across various sample types, enabling rapid and direct analysis. A developed freezing method has proven to be remarkably simple and efficient through gold nanoparticles (AuNPs) functionalized with thiolated DNA and poly (A)-tagged DNA. When the AuNPs are coated with polymers and DNA sequences, aggregation of AuNPs becomes reversible after freezing and thawing. Building upon this freezing-directed approach, the bioprobes based on AuNPs have been successfully implemented in a variety of detection systems, including colorimetric, fluorescence, and lateral flow assays. Inspired by this, we propose and demonstrate a rapid and concise dual-mode aptasensor (named RCPA) for reliable detection of 17β-estradiol.
Result
The RCPA strategy shows ultrahigh sensitivity to 17β-estradiol determination due to high binding affinity of aptamers, with the limit of detection of 0.018 ng/ml. The total detection time of 17β-estradiol in milk or serum is less than 30 min with small sample consumption (about 50 μ L) due to the rapid magnetic separation of apt@MNP. In addition, the proposed biosensor exhibits a high specificity for 17β-estradiol quantitative detection. On the other hand, the freeze-thaw mode provides a visual and concise detection method.
Conclusion
Therefore, this work provides a promising and concise strategy to rapid and ultrasensitive detection of 17β-estradiol for broader patients and more urgent cases.

Relation between hormonal and metabolic status in persons affected by the chnpp accident with parathyroid disordres

Valeriia Praporschikova[1], Irina Muraviova[1,2] & Dmytro Afanasyev[1,2]
[1]SI «National Research Center for Radiation Medicine of the NAMS of Ukraine», Radiation Endocrinology, Kyiv, Ukraine; [2], Kyiv, Ukraine

Objective
assessment of endocrine system profile featuring hormonal and metabolic parameters in persons affected by the ChNPP accident with parathyroid disorders.
Methods and results
Patients treated in the Department of Radiation Endocrinology in 2019-2020 were selected ($n=150$) by the method of blind sampling in accordance with the study objective. Study sample included the 100 subjects (50% females, 50% males) were affected by the ChNPP accident. The comparison group included 50 patients (55% males, 45% females) not exposed to ionizing radiation. The age of study subjects ranged from 37 to 75 years with 60.2 ± 9.8 years in average. Incidence of parathyroid hyperplasia among persons affected by the ChNPP accident was in twice higher vs the comparison group (41% and 20% respectively) against the background of the same serum level of vitamin 25(OH)D. Average level of parathyroid hormone among the ChNPP accident patients with parathyroid hyperplasia was significantly higher vs. the comparison group (57.2 ± 2.87 and 31.88 ± 4.82 respectively, $P<0.05$). Mean level of vitamin 25(OH)D in subjects with parathyroid hyperplasia was significantly lower than in cases of no such a disorder (14.36 ± 2.31 and 28.32 ± 6.48 respectively, $P<0.05$). Relationships between the hormones and metabolic profile using the correlation- regression analysis showed a significant negative effect of secondary hyperparathyroidism on comorbid conditions, namely the endocrine component of arterial hypertension, dyslipidemia, osteopenia and metabolic syndrome. Using multivariate analysis, a reliable relationship was established between the vitamin 25(OH)D deficiency and astheno-neurotic, anxiety-depressive syndromes ($F=83.811$; $P=0.0001$), autoimmune thyroiditis, hypothyroidism ($F=8.1802$; $P=0.0001$), type 2 diabetes mellitus and metabolic syndrome ($F=16.428$; $P=0.0001$). Also the multivariate analysis provided a reliable confirmation of the negative impact of hyperparathyroidism on arterial hypertension and arrhythmia ($F=8.8469$; $P=0.0007$), osteopenia ($F=16.208$; $P=0.0001$).
Conclusions
Secondary hyperparathyroidism has a negative effect on the course of concomitant endocrine disorders and comorbid conditions.

Temporal and masseter muscle evaluation by MRI provides information on muscle mass and quality in acromegaly patients

Angelo Milioto[1,2], Giuliana Corica[1,2], Federica Nista[3], Claudia Campana[2], Anna Arecco[2], Lorenzo Mattioli[2], Lorenzo Belluscio[2], Diego Ferone[1,2], Alberto Tagliafico[3,4] & Federico Gatto[1]
[1]Endocrinology Unit, IRCCS Ospedale Policlinico San Martino, Genoa, Italy; [2]Endocrinology Unit, Department of Internal Medicine and Medical Specialties (DIMI) and Centre of Excellence for Biomedical Research (CEBR), University of Genova, Genoa, Italy; [3]Radiology Section, Department of Health Sciences (DISSAL), University of Genova, Genoa, Italy; [4]Department of Radiology, IRCCS Ospedale Policlinico San Martino, Genoa, Italy

The impact of GH/IGF-1 levels on skeletal muscle in patients with acromegaly is still matter of debate. Recently, temporal (TMT) and masseter muscle thickness (MMT) have emerged as reliable indicators of muscle mass, as well as patients' functional status/prognosis in various clinical context – especially in the oncologic setting. This study aims to investigate the potential correlations between TMT/MMT and patients' demographic and clinical characteristics. A retrospective longitudinal analysis was conducted at a single tertiary center for pituitary diseases. Sixty-nine patients diagnosed with acromegaly, each with at least one brain/sella turcica MRI scan and matched clinical data, were included. The primary outcomes assessed were TMT, MMT, and muscle fatty infiltration (evaluated using the modified Goutailler score) at baseline (69 MRIs) and over time (total of 182 MRIs). The median time between first to last available MRI was 49 months. Results revealed that, at baseline, males had significantly higher TMT and MMT compared to females ($P=0.001$ and $P=0.016$, respectively). A direct association between TMT and MMT was observed (β 0.508, $P<0.001$). TMT was positively correlated with IGF-1 ×ULN ($P=0.047$), while MMT showed positive correlations with IGF-1 ×ULN ($P=0.001$), patient weight ($P=0.015$), and height ($P=0.006$). The presence of hypogonadism or impaired glucose metabolism did not significantly correlate with TMT or MMT. No significant difference in TMT and MMT has been observed when comparing patients with active cancers, with cancers in remission, and those with a negative clinical history for malignancies. Considering all available MRIs, sex and IGF-1 ×ULN emerged as significant determinants of both TMT and MMT in multivariable analysis (female sex: β -0.345/-0.426, $P<0.001$; IGF-1 ×ULN: β 0.257/0.328, $P<0.001$). Patients defined at risk of sarcopenia - by sex-specific TMT cut-offs – had IGF-1 ×ULN levels significantly lower compared to individuals classified as having normal muscle status ($P=0.016$). At longitudinal evaluation, patients with uncontrolled acromegaly at baseline exhibited a significant reduction in MMT over time ($P=0.044$). Notably, considerable fatty infiltration was observed in 34-37% of MRIs, with age identified as the main determinant (temporal muscle: OR 1.665; $P=0.013$; masseter: OR 1.793; $P=0.009$). In conclusion, male patients with higher IGF-1 values demonstrated thicker temporal and masseter muscles, indicative of greater muscle mass compared to other patients.

Estimation of thyroid diseases in type 1 DM women living in iodine deficiency region

Mushtariy Makhkamova[1], Mukima Karimova[1], Nigora Ibragimova[2], Muhammadrasul Muhammadsiddikov[1] & Zulaykho Shamansurova[3,4]
[1]Fergana Medical Institute of Public Health, Endocrinology, Fergana, Uzbekistan; [2]Fergana Regional Endocrinologic Dispensary, Endocrinology, Fergana, Uzbekistan; [3]Central Asian University Medical School, Endocrinology, Tashkent, Uzbekistan; [4]Institute of Biophysics and Biochemistry at the NUUz, Metabolomics, Tashkent, Uzbekistan

Iodine deficiency diseases are one of the wide problems seen in the geografically iodine deficiency regions and associated with a large number of people. The goal of our investigation was study of frequency of the thyroid diseases in women with type 1 Diabetes Mellitus (DM1) whose living in Ferghana valley, the iodine deficiency region of Uzbekistan.
Materials and methods
In 120 female patients in age from 18^h to 36 years old with type 1 diabetes blood glucose, HbA1c, TSH, free T4, antiTPO level were measured, thyroid glands were palpated and ultrasound were performed.
Results
Thyroid gland enlargement were found at palpation in all observed woman, with DM1 and in 92.5% without DM1. Estimation of thyroid status showed euthyroidism in 58% DM1 group and 85% without DM, hypothyroidism were registered in 42% woman with DM1 and 15% without DM1. Thyroid glands ultrasound showed in DM1 group 5% woman had nodular, 3.3% mixed goiter and 20% had autoimmune thyroiditis. In group without DM1 nodular goiter were detected in 2.5%, mixed in 3% and autoimmune thyroiditis in 10% woman. In case of nodular and mixed goiter ultrasound results clissified by TIRADS showed 55% TIRADS 1 and 2, 45% TIRADS 3, 4, 5 in DM1 group, whereas in woman without DM TIRADS 1 and 2 seen in 82% and TIRADS 3 and 4 in 18%.
Conclusion
In woman with DM1 lived in iodine defficiency region thyroid diseases were highly presented as a 2 times more nodular goiter and 2 times more autoimmune thyroiditis. Moreover, mallignancy signs incresed by TIRADS on ultrasound imaging. Effective elimination of Iodine defficiency is important in woman with DM1.

Neurosurgery treatment for macroprolactinomas: a retrospective study

Raoua Naouar[1], Hanene Sayadi[1], Sana Abid[1], Ghassen Belkahla[2], Atef Ben Nsir[2], Bilel Ben Amor[1], Ekram Hajji[1], Ines Bayar[1], Héla Marmouch[1], Inès Khochteli[1], Mahdi Darmoul[2] & Gema Martinez Tames[3]
[1]Fattouma Bourguiba Hospital, Endocrinology and Internal Medicine Department, Monastir, Tunisia;[2]Fattouma Bourguiba Hospital, Neurosurgery Department, Monastir, Tunisia; [3]Hospital Valle Del Nalon, Endocrinology Division, Monastir, Tunisia

Introduction
The management of prolactinomas, whatever their size, is based on medical treatment with dopamine agonists (DA). The latter allows clinical improvement with efficient control of prolactin secretion and tumor growth. Pituitary surgery or radiotherapy are adjuvant therapies in case of neurologic complication or lack of response to DA.
Patients and methods
We conducted a monocentric analytic study of patients followed for confirmed prolactinomas at the endocrinology-internal medicine and neurosurgery departments of the Fattouma Bourguiba University Hospital, Monastir, from January 2000 to March 2022.
Results
Among the factors associated with the necessity for surgery, only initial tumor size was correlated with surgical treatment. Indeed, the average initial tumor size in operated patients was 34.5 ± 8.44 mm versus 26.16 ± 12.19 mm in non-operated patients. However, there was no difference in the normalization of prolactin level (90% versus 93%, $P = 0.4$) nor in the rate of reduction in tumor size in response to surgery compared to those under medical treatment (53% versus 57%, $P = 0.2$).
Conclusion
DA have traditionally been the primary treatment for the majority of prolactinomas, with surgery considered the second line therapy. Complete surgical removal of invasive macroprolactinomas is technically difficult and structural healing is rare and is not without risks. It should be reserved for cases of inadequate response to medical therapy or in cases of emergency.

Table 1. Factors related to the use of pituitary surgery

Factors	Surgical managment $n=10$	p
Gender male	5 (50%)	0.39
Age at diagnosis	38.5 ± 11.78	0.66
Prolactin level (ng/ml)	639.9	0.09
Initial tumor size (mm)	**34.5 ± 8.44**	**0.02**
Pituitary apoplexy	2 (20%)	0.12
Tumor invasion	6 (60%)	0.79
T2-weighted MRI signal		
Hypersignal	8 (80%)	0.35
Hyposignal	1 (10%)	0.23
Isosignal	1 (10%)	0.21

Impact of type 1 Diabetes on growth, puberty onset and retardation

Shakhnoza Babamukhamedova[1] & Zulaykho Shamansurova[1,2]
[1]Central Asian University Medical School, Endocrinology, Tashkent, Uzbekistan; [2]Institute of Biophysics and Biochemistry t the NUUz, Metbolomics, Tashkent, Uzbekistan

Introduction
In some cases pubertal growth and sexual maturation and relating normal physiology can be disturbed and retarded by chronic disease as like Diabetes Mellitus (DM). According to International Diabetes Federation Atlas in 2013 approximately 5, 00, 000 known cases of children with T1DM (0–14 years) worldwide, where 50-60% of cases are diagnosed before the age of 15. Insulin deficiency in T1DM presented with age in childhood and visible peaks at the time of puberty can affected growth and puberty onset delay. We analysed data from literature by compare cases of growth and puberty delay in people with T1DM if there any majority of applicable mechanisms of growth and puberty retardation which are related with disease specific mechanisms.
Material and methods
A case-control study with 20 type 1 Diabetes Mellitus patients, who were 14-18 years old on the other hand 20 healthy age-matched participants were included as a control group. The stage of sexual maturation - Tanner's stage, hormonal profile - follicle-stimulating hormone (FSH), luteinizing hormone (LH), prolactin, and total testosterone measured and the growth parameters, including the weight, height, and BMI respectively for both groups.
Results
The major criteria, its impact on linear growth, development and puberty onset, especially in those with poor glycemic control. T1DM was a cause of retardation of puberty as about one-quarter (25%) of the boys were sexually immature by Tanner's chart (did not reach stage V) comparing with control group, where 90% of volunteers were sexually mature regarding their age. Moreover, prolactin, testosterone, BMI, height and weight parameters were low in diabetic group comparing with control. Authors proposed well known fact the insulin affects central nervous system and involved reproduction. It is tend to be consequences of hypoinsulinemia or delayed release of GnRH, with subsequent delayed release of sex hormones. IGF-1 stimulates growth and puberty, also directly regulates GnRH which was in the decreased range because of hypoinsulinemia. When main risk factors were calculated poor glycemic control, low FSH and LH to cause pubertal and normal growth delay in these patients.
Conclusion
Children and adolescent with T1DM those with poor glycemic control showed remarkably delayed puberty (90%) and lower growth (25%) parameters, also accompanied with lower sex hormones level. Adequate insulin therapy with education should be necessary part of treatment in patients with T1DM.

Diabetes mellitus and endometrial carcinoma: risk factors and etiological links

Zebo Karabaeva[1] & Zulaykho Shamansurova[1,2]
[1]Central Asian University Medical School, Endocrinology, Tashkent, Uzbekistan; [2]Institute of Biophysics and Biochemistry at NUUz, Metabolomics, Tashkent, Uzbekistan

Introduction
Diabetes mellitus (DM) has emerged as a significant global health concern, contributing to increased mortality and complications, thereby adversely affecting overall quality of life. The incrising incidence of DM, particularly type-2 DM (T2DM), correlates with rising rates of various cancers, suggesting a potential direct link between DM and cancer. Mounting evidence suggests DM as a potential contributor to the heightened incidence of endometrial cancer (EC) and underlines its association with poor prognosis. Early intervention with metformin is anticipated to serve as an effective adjuvant alternative for EC, thereby offering new avenues for preventive and therapeutic strategies targeting glucose metabolism. Epidemiological studies affirm hyperglycemia as an independent risk factor for EC development. Patients with DM face a doubled risk of progressing to EC, possibly due to the conducive environment for the growth and invasiveness of EC cells in high-glucose settings. However, the etiological relationship between DM and EC remains unclear, and the precise biological mechanisms linking the two are not well understood. As existing treatments fail to prevent or delay EC progression, exploring early and effective prevention through glucose metabolism interventions holds promise for innovative targeted therapeutic interventions in EC, carrying substantial medical and social value.
Materials and Methods
A comparative analysis was conducted through a systematic search over the past two years, combining and analyzing published data from MEDLINE, EMBASE, PubMed, and Research Gate.
Results
Most epidemiological studies indicate a strong association between EC and T2DM. Analysis of T2DM's impact on cancer risk and mortality reveals a significant increase in both morbidity and mortality for EC. Early-stage DM, aside from T2DM patients, shows a 4.9% increased risk of EC. T1DM is also linked to an elevated risk of EC. Additionally, DM emerges as an independent risk factor for EC mortality. Biological Mechanisms: Increasing evidence suggests that insulin resistance (IR) and hyperinsulinemia, mediated by insulin and insulin-like growth factors, influence endometrial cells and signaling pathways, such as PI3K, MAPK/ERK, and VEGFR, promoting angiogenesis and EC occurrence. Chronic inflammation factors like TNFα, IL-6, and COX-2 contribute to carcinogenesis.
Conclusion
This study enhances the understanding of the complex relationship between DM and EC, offering a global perspective on the effects of DM on EC through various

mechanisms. It emphasizes the clinical application of antidiabetic medications for EC, providing valuable insights for future research and therapeutic strategies.

Epidemiological, clinical, paraclinical, and preoperative complication of primary hyperparathyroidism: a moroccan single center experience

Lamiae Zarraa[1], Rania El Amel[1], Siham Rouf[1,2] & Hanane Latrech[1,2]
[1]Endocrinology-Diabetology and Nutrition Department CHU Mohamed VI, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy Mohammed Premier University Oujda, Morocco, Oujda; [2]Morocco, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy Mohammed Premier University Oujda, Morocco, Oujda

Introduction
Primary hyperparathyroidism is a common endocrinopathy associated with autonomous hypersecretion of PTH by one or more parathyroid glands. This work aims to study the epidemiological, clinical, biological, radiological, and therapeutic profile of primary hyperparathyroidism, as well as its preoperative complications.
Material and methods
A retrospective descriptive study of 50 patients followed at the Endocrinology-Diabetology-Nutrition Department of Mohammed-VI-University-Hospital-Center-Oujda-Morocco for primary hyperparathyroidism. Data were collected from medical records and analyzed using SPSS-V21 software.
Results
The mean age was 55.24 ± 12.9 years, with a clear female predominance in 78% of cases, 79% of whom were menopausal. The circumstances of discovery were dominated by bone pain, recurrent renal lithiasis and abdominal pain, and were fortuitous in only 29% of cases. Biologically, hypercalcemia was found in 84% of cases, with a mean of 127 ± 24 mg/l, and hypercalciuria in 74%. The mean PTH1-84biointact value was 408 ± 586 pg/ml and vitamin D deficiency was observed in 62% of patients. Cervical ultrasonography was carried out in all our patients, localizing the tumor in 88%, thoracic CT objective a medial ectopic parathyroid tumor in 2 cases, and SestaMIBI scintigraphy was performed in nine patients whose cervical ultrasonography failed to localize the parathyroid adenoma. Osteoporosis and renal lithiasis were the main preoperative complications, occurring in 34% and 32% of cases in our series respectively; there was a high prevalence of brown tumours in 18% of cases; 90% of patients underwent surgical treatment, 13% of them complicated by hypocalcemia. Anatomopathological findings were in favor of parathyroid adenoma in 88.6%, parathyroid hyperplasia in 5.8%, and parathyroid carcinoma in 2.9%.
Conclusions
Primary hyperparathyroidism is responsible for altered phosphocalcic metabolism and is a frequent cause of hypercalcemia. Etiologies are dominated by parathyroid adenoma, with a clear female predominance, and treatment is mainly surgical.

EP1288

Hypocalcemia revealing digeorge syndrome: case report

Cheibete Zakaria, Mariem Cheikh & Mohamed Elmoctar
Rabat, Endocrinology, Rabat, Morocco

DiGeorge syndrome is a genetic abnormality caused by a microdeletion of chromosome 22. Chromosome 22q1 1.2 microdeletion was first identified in 1992 [1-3] as the common genetic anomaly associated with a range of conditions previously known as DiGeorge or velocardiofacial syndrome, usually presents later in childhood, often leading to hypernasal speech caused by cleft palate, submucous cleft palate, or velopharyngeal insufficiency. Both disorders share similar clinical features, such as conotruncal heart defects and mildly dysmorphic facial characteristics. The term CATCH 22 (cardiac defect, abnormal facies, thymus hypoplasia, cleft palate, hypocalcemia, and chromosome 22 microdeletion) was coined to encompass both conditions. Usually, the age of diagnosis varies between birth and 16 years. The overall prevalence of DiGeorge's syndrome is 1 in 5950 births. Approximately 13% of patients receive a diagnosis at the age of 15 or older, with most of them being identified through familial genetic studies. In adulthood, the presence of hypocalcemia as a result of pseudohypoparathyroidism (PH) is often the primary indicator of the disorder. Adults with PH typically exhibit developmental delays, psychiatric issues, and cardiac anomalies. Additionally, there may be an increased risk of early-onset Parkinson's disease. The majority of patients experience hypocalcemia (49-80%), which can manifest at any age. Hypocalcemia is caused by PH, which is characterized by congenital parathyroid aplasia or hypoplasia We report in this work the case of a 17-year-old Moroccan male who has a PTH-dependant hypocalcemia revealed by DiGeorge Syndrome. Our aim is to emphasize the importance of considering that chromosome 22q11.2 deletion syndrome is not a rare occurrence and may manifest later in life with such abnormalities.

Leydig cell tumors in a postmenopausal women: case report

Kammoun Fatma[1,2], Sabrine Mekni[1,3], Sawsen Essayeh[3,4], Rihab Laamouri[3,4], Werfili Mariem[3], Mchirgui Nadia[4], Karima Khiari[3,4], Imen Rojbi[3,4] & Ibtissem Ben Nacef[3,4]
[1]Charles Nicolle Hospital, Endocrinology, Tunisia; [2]Charles Nicolle Hospital, Laboratory of Renal Pathology LR00SP01, Tunis; [3]Charles Nicolle Hospital, Laboratory of Renal Pathology LR00SP01, Tunis, Tunisia; [4]Charles Nicolle Hospital, Endocrinology, Tunis, Tunisia

Introduction
Virilizing ovarian tumors (VOT) are a rare cause of hyperandrogenism in postmenopausel women. Leydig cell tumors (LCTs) are rare sex-cord stromal tumors as they account for less than 0, 1 % of all ovarian tumors, and although they occur at any age, approximately one-fourth of them present after menopause. We report a clinical case of Leydig cell tumor in a postmenopausal woman.
Case-report
A 75-year-old woman, with a personnel history of type 2 diabetes mellitus, hypertension, and dyslipidemia presented with sudde nonset of virilization, hirsutism, androgenetic alopecia, and deep voice. On physical examination, she had positive signs of virilization, including temporal balding, coarse hair with a Ferriman-Galleway score of 36. The baseline laboratory values were as follows: DHEA-sulfate 35 µg/dl (normal range 15-220 µg/dl); androstenedione, 525 ng/dl (normal: 20-310 ng/dl); and total testosterone, 3.85 ng/ml (normal 0.03-0.4 ng/ml). On pelvic ultrasound, the patient's right ovary was enlarged but the echostructure was normal and there were no other findings. Pelvic MRI revealed a low-intensity mass in the right ovary measuring 35 mm. The patient underwent exploratory laparotomy with bilateral salpingo-oophorectomy. Histopathologic examination of the resected ovaries revealed a Leydig cell tumor of the right ovary. Six weeks later, her serum testosterone and androstenedione levels, normalized to the normal range for women. Four months after surgery, the patient showed significant improvement in hirsutism and virilization symptoms.
Conclusion
Although LCT is rare and difficult to diagnose biochemically or with imaging studies, androgen-secreting tumors should be considered in postmenopausal women with hyperandrogenism and hirsutism.

Diagnosis of MEN-1 syndrome with multiple tumor locations and a rare genetic mutation

Anastasios Tsitsimpis[1], Kasiani Papadimitriou[1], Vasiliki Papanikolaou[1], Maria Rigana[1], Konstantinos Barkas[2], Konstantinos Nastos[3] & Andromahi Vryonidou[1]
[1]Korgialeneio-Benakeio Red Cross General Hospital, Department of Endocrinology & Metabolism – Center of Diabetes, Athens, Greece; [2]General Hospital "Agios Panteleimon", Neurosurgery Clinic, Athens, Greece; [3]General Hospital "Attikon", 3rd Surgical Clinic, Athens, Greece

Introduction
Most of pituitary adenomas are sporadic, with only 5% of them attributed to genetic mutations and syndromes such as Multiple Endocrine Neoplasia type 1 (MEN-1). However, how easy is it for a doctor to suspect it when there is no known family history?
Case Presentation
A 36-year-old patient with no personal or family history presented to our Endocrine Department reporting intermittent episodes of unconsciousness during the last 48 hours. The episodes lasted a few minutes without preceding aura or postictal phenomena. Biochemical analysis showed Glu = 44 mg/dl, without accompanying symptoms. Brain imaging with CT revealed pathological tissue

within the pituitary fossa with suprasellar and parasellar extension, without evidence of bleeding or optic chiasm compression. Further hormonal and imaging testing of the pituitary revealed a non-functioning adenoma measuring 2.3×3×2 cm on MRI, with concomitant thyrotroph and corticotroph axes deficiency. Despite hydrocortisone replacement therapy, the patient had consistently low fasting morning glucose levels (Glu < 45 mg/dl) with inappropriately high insulin levels (Ins = 9 IU/mmol), without neuroglycopenic symptoms. Prolonged fasting test confirmed endogenous insulin hypersecretion. Abdominal CT described an invasive lesion in the pancreas body. Endoscopic ultrasound identified a 2 cm mass in the uncinate process, a 3 cm mass between the body and the tail, and two smaller (< 1 cm) satellite lesions. Cytology confirmed a pancreatic NET with characteristics of insulinoma. Additionally, biochemical analysis revealed elevated corrected calcium (11.9 mg/dl) and PTH = 238 pg/ml levels, and 25OHD3 < 8 mg/dl, indicating primary hyperparathyroidism. Neck ultrasound confirmed the presence of a parathyroid adenoma measuring 15.4×6.6×8 mm. Based on these findings, the diagnosis of MEN-1 syndrome was established and confirmed by genetic testing, detecting the rare nucleotide change c.467G > A heterozygosity in exon 3 of the MEN-1 gene. PET CT with Ga-68 showed no other lesions. The patient underwent initially transsphenoidal adenectomy and pathology report revealed "a well differentiated endocrine tumor consisting of a population of neoplastic cells expressing hormones (β-FSH, β-LH, PRL), with Ki-67 = 7% and absence of menin expression". Then parathyroidectomy, thyroidectomy, total pancreatectomy, splenectomy, and cholecystectomy took place. Histology revealed parathyroid hyperplasia consistent with MEN-1 and a pancreatic NET G2 with Ki-67 = 5%, well-confined, without peripancreatic lymph node involvement.

Discussion

Many cases may seem to have an obvious diagnosis, but patience and persistence in clinical observation can reveal an underlying rare syndrome, while genetic testing serves as the confirmation. A multidisciplinary approach is crucial for the optimal management of patients with rare diseases.

EP1291

Endocrine disorders associated with prader-willi syndrome: a case report

Mariem Cheikh, Mohamed Elmoctar, Cheibete Zakaria, Diehah Isselmou, Rifai Kaoutar, Hinde Iraqi & Gharbi Mohamedelhassan
Ibn Sina Hospital, Endocrinology, Rabat, Morocco

Introduction

Prader Willi syndrome is a rare and complex genetic disease, with numerous implications on metabolic, endocrine, neurologic systems, with behavior and intellectual difficulties. Many patients with PWS manifest short stature due to growth hormone deficiency. These individuals also present with hypothalamic dysfunction, leading to several endocrinopathies such as hypogonadism, hypothyroidism, central adrenal insufficiency, with reduced bone mineral density. Our case illustrates the value of early genetic diagnosis.

Observation

A 21-year-old patient, diagnosed since the age of 12 with prader willi syndrome, presented with impubirism and severe statural retardation. Investigations revealed GH deficiency, hypogonadotropic hypogonadism complicated by severe osteoporosis and central hypothyroidism. The patient was substituted by l thyroxine and testosterone.

Discussion and conclusion

Prader-Willi syndrome is a complex genetic disorder caused by lack of expression of the paternally inherited chromosome 15q11-q13. Previous epidemiologic studies have estimated the incidence of PWS from 1 in 10, 000 to 1 in 30, 000 live births disorder It is characterized by hypothalamic-pituitary deficiency, severe neonatal hypotonia, early-onset hyperphagia, hypogonadism, mental retardation and morbid obesity, sometimes complicated by diabetes. Children diagnosed with Prader-Willi syndrome should receive GH treatment from 3 to 6 months of age. Several clinical guidelines recommend that thyroid function be assessed at the time of diagnosis of Prader-Willi syndrome, and once a year thereafter. Confirmation of the disease is necessary for early management of endocrinological manifestations, in particular early GH supplementation. Proper management of PWS patients requires a multidisciplinary team approach. It is important for pediatric endocrinologists to be aware of the recommendations for screening and monitoring of variou.

Effectiveness of the transition process in adolescents with chronic endocrinological disorders: experience of the transition clinic in verona, italy

Stefania Munari[1], Rossella Gaudino[2], Sabrina Vantini[2], Alessandro Ferruzzi[2], Thomas Zoller[2], Marta Arrigoni[2], Roberto Castello[2] & Franco Antoniazzi[2]
[1]Azienda Ospedaliera Universitaria Integrata Verona, Pediatria, Verona, Italy; [2]Azienda Ospedaliera Universitaria Integrata Verona, Verona, Italy

Background

Literature data indicate that up to 36.8% of patients with chronic endocrinopathies, occurring in children, abandon follow-up visits in adulthood, with the risk of major long-term consequences for their health. For this reason, it is essential that their transfer to an adult physician takes place through a well-structured transition process in order to ensure continuity of care. With this goal, the Transition Clinic of pediatric endocrine pathologies of AOUI Verona was born in 2010, first in Italy.

Aims

From the analysis of subjects transiting to our clinic from 2010 to 2019, the main objective of this work has been to assess the effectiveness of the transition process by measuring adherence to follow-up visits, experience and satisfaction with the transition process, the perception of their self-management skills and the assessment of the quality of life of these patients.

Subjects and Methods

50 patients with 9 different chronic endocrinopathies were included in this study. Clinical data have been collected through the consultation of medical records. Subjects have been offered an online, anonymous questionnaire. Adherence to follow-up visits was assessed by the detection of the last control visit. Satisfaction with the transition process was measured through an Analog Visual Scale (VAS). Evaluation of the perception of one's own self-management skills and quality of life was carried out through the "On Your own feet – Self-Efficacy Scale" (OYOF-SES) and SF-36®, respectively.

Results

For the first time a drop-out rate of 26% was found, with a significant variability among the individual endocrinological diseases analyzed (from 0% for Turner syndrome and Klinefelter syndrome up to 100% for hypoparathyroidism) and transited properly. 82% of the transited subjects were satisfied with their experience at the Transition Clinic, with a grade 6 (average 7.9 ± 2.4 SD). There was a good capacity for self-management, with high scores obtained at OYOF-SES (average 96.98 ± 13.30 SD). The perceived quality of life is also overall good, except for mental health, which was significantly lower than the reference healthy population.

Conclusions

Despite the improvement in the dropout rate and the results in terms of self-management and quality of life obtained by the Transition Clinic of AOUI in Verona, constant analysis and implementation of individualized transition process are necessary to ensure their optimum effectiveness.

The impact of metabolic and hormonal alterations on sexual and psychological function in women with polycystic ovary syndrome

Nunzia Verde, Federica Sorice, Roberta Scairati, Cristina de Angelis, Francesco Garifalos, Davide Menafra, Antonio de Fraia, Luigi Santella, Alessandro Mazzarella, Renata Simona Auriemma, Annamaria Colao & Rosario Pivonello
Università di Napoli "Federico II", Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia ed Andrologia, Unità di Andrologia e Medicina della Riproduzione, Sessualità e Affermazione di Genere (Fertisexcares), Naples, Italy

The current study evaluated the impact of metabolic and hormonal alterations on sexual and psychological function in women with Polycystic Ovary Syndrome (PCOS). Fifty consecutive women aged 24.16 ± 5.97 years with a diagnosis of PCOS were recruited; metabolic and hormonal parameters were measured and questionnaires related to sexual function (Female Sexual Function Index-FSFI) and psychological traits (Middlesex Hospital Questionnaire-MHQ, Body Uneasiness Test A and B-BUT A and B)were administered. Correlation analysis was performed by Spearman test, intragroup comparison by Mann-Whitney test. Mean FSFI total score was 12.5 ± 26.6 with a prevalence of sexual dysfunction of 34%. Anxiety was detected in 76%, phobia in 50%, obsession in 42%, somatization in 50%, depersonalization in 84%, and hysteria in 66% of patients.

Body image concern positively correlated with BMI and Waist Circumference (WC) ($P=0.031$; $P=0.022$) and depersonalization positively correlated with WC ($P=0.035$). Positive Symptom Distress Index-PSDI positively correlated with Ferriman-Gallwey score ($P=0.016$). FSFI total score ($P=0.009$; $P=0.019$), desire ($P=0.017$; $P=0.049$), arousal ($P=0.012$; $P=0.028$), lubrication ($P=0.011$; $P=0.022$), orgasm ($P=0.03$; $P=0.008$) and satisfaction ($P=0.013$; $P=0.016$) negatively correlated with insulin and HOMA-IR. Positive Symptom Total-PST positively correlated with insulin ($P=0.015$). Global Severity Index-GSI ($P=0.048$), weight phobia ($P=0.04$), thighs ($P=0.0443$) and legs ($P=0.008$) negatively correlated with prolactin levels. Pathological somatization ($P=0.011$), body image concern ($P=0.036$), WC ($P<0.0001$), Hip Circumference-HC ($P<0.0001$), insulin ($P=0.012$) and HOMA-IR ($P=0.003$) were significantly worse in overweight/obese($n=25$), compared to normal-weight($n=23$) patients; no difference in any of assessed parameters was detected based on the presence/absence of insulin resistance. The results of the current study highlighted that sexual and psychological function of PCOS patients might be negatively influenced by insulin resistance and that higher PRL levels were associated with reduced body satisfaction. The underlying mechanism might rely in the known negative impact of insulin resistance on clitoral vascular flow, namely increased vascular flow resistance. A timely and individualized therapy is necessary not only for the resolution of **metabolic** complications but also to improve **psycho-sexual** health of patients affected by PCOS.

EP1294

Population characteristics of thyroid carcinoma in children and adolescents living in conditions of iodine deficiency in the republic of uzbekistan

Shakhlo Muratova & Madina Sattorova[1,1]
Republican Specialized Scientific and Practical Medical Center of Endocrinology named after Academician Y.Kh. Turakulov, Tashkent

Introduction
Thyroid cancer (TC) is a rare disease in childhood, with an incidence of 0.2 to 5 cases per million per year or higher [Neiva F., 2012, Tuli G, 2023]. The incidence of malignancy among thyroid nodules in children is about 16%, which is about three times higher than in adults [Vaisman F., 2011, Yeker R.M., 2022]. Lymph node metastases (40–80%) and distant metastases (25%) are also much more common in the pediatric population [Zirilli G., 2018, Thomas JK., 2021]. One of the important factors for the high risk of TC is iodine deficiency, which persists in Uzbekistan, although thanks to ongoing prevention, its prevalence has decreased by more than 2.5 times over the past 20 years [Ismailov S.I., 2018].
Objective
To assess the incidence of TC in children and adolescents based on admission to a tertiary hospital in the Republic of Uzbekistan.
Materials and methods
A retrospective study of 13, 509 medical histories and outpatient records of children and adolescents who received outpatient and inpatient treatment at the clinic of the RSSPMCE named after Academician Y.Kh. Turakulov for the period from 2016 to 2022 was conducted.
Results
During this period, 27 children with TC were identified, of which 24 were girls (89%) and 3 boys (11%), the gender distribution was 8.1:1. The average age was 17.5 ± 2.7 years. TC was most common among school-age patients (44.4%), in second place - among university students (26%), then among lyceum students (14.8%), college (11.1%), and among working people (3.7%). In all children, palpation revealed grade 2 goiter, with 66.7% (18) of children diagnosed with nodular goiter, and 33.3% (9) with multinodular goiter. Total thyroidectomy was performed in 75% (18) of cases, subtotal - 16.7% (4), and 2 patients underwent hemithyroidectomy (8.3%). Histological examination of native thyroid tissue in all children we studied revealed differentiated TC; papillary TC was diagnosed 2 times more often than follicular carcinoma. There were no cases of medullary and anaplastic TC. Radioiodine ablation with I131 was performed in only 20.8% of children.
Conclusion
TC remains a pressing and little-studied problem. Most often, children are diagnosed with papillary TC with a solid euthyroid node in adolescence, while in girls it is detected 8 times more often. The average TI-RADS values in children with TC according to ultrasound data are 4.2 ± 0.2, histological examination data are 4.14 ± 0.34 according to Bethesda. Further population-based prospective studies of TC in the pediatric population are necessary.

Evaluation of body image and eating behavior disorders in pregnant women

Yosra Hasni[1,2], Wiem Saafi[1,2], Aya Mlayah[3], Hamza Elfekih[1,2], Syrine Chelly[2,4], Meriem Ghardallou[2,5] & Latifa Lassoued[2,4]
[1]Hospital F. Hached, endocrinology, Sousse, Tunisia; [2]Ibn El Jazzar Medical Faculty of Sousse, Sousse, Tunisia; [3]College Science And Technology Health De Sousse, Sousse, Tunisia; [4]Hospital F. Hached, gynecology, Sousse, Tunisia; [5]Hospital F. Hached, epidemiology, Sousse, Tunisia

Introduction
During pregnancy, women experience various physiological changes that can impact them psychologically. Lifestyle modifications such as eating behaviors and physical activity during this period are major determinants of pregnancy outcomes, child development, and maternal health. Also, body transformations during this period could reactivate concerns regarding body image and introduce anxiety, body dissatisfaction, and eating behavior issues. The aim of our study was to assess the relationship between body image and eating behaviors in pregnant women.
Methods
We conducted a cross-sectional study that involved 194 pregnant women. We administered a questionnaire to explore their sociodemographic characteristics, gynecological-obstetric history, and current pregnancy. In addition, we assessed the nutritional status of these women using the FIGO checklist, evaluated their body image using the BAQ, and screened for eating disorders using the SCOFF tool.
Results
Our study found that 95.5% of the participants had an unhealthy diet that required further revision with a nutritionist. Among pregnant women, 66.5% consumed fruits and vegetables in moderation, while whole foods were the least consumed. More than half (58.8%) of the women in our study consumed pastries five times a week. The mean score for the Body Attitude Questionnaire (BAQ) was 140.7 ± 17, with scores ranging from 87 to 200. Additionally, 32% of the women were found to be at risk of developing an eating disorder based on the results of the SCOFF. Although there was no significant association between the SCOFF and the BAQ, the SCOFF was positively correlated with some subscales of the BAQ.
Conclusion
Our results stress the need for evaluating the nutritional status of pregnant women and monitoring their psychological well-being to address the risk of developing eating disorders.

Case report: acute intestinal pseudo-obstruction as a rare complication of pheochromocytoma

Yi Yi Aung, Ching Man Li & Sherif Ghieth
University Hospitals Plymouth Trust, Department of Endocrinology and Diabetes, Plymouth, United Kingdom

Phaeochromocytoma is a rare tumour of the adrenal gland medulla characterized by excess catecholamine release. Classic presentation includes paroxysms of hypertension and adrenergic symptoms such as headache, sweating, shortness of breath, and tachycardia. In severe cases, patients might develop hypertensive crises and cardiomyopathy. We present a case of intestinal pseudo-obstruction as a rare complication of phaeochromocytoma which responded only to surgical resection of the tumour. A 76-year-old lady presented to A&E with progressive shortness of breath, chest discomfort, and collapse following a new introduction of a beta blocker. Initial assessment revealed tachypnoea, low oxygen saturation, and high blood pressure. CT pulmonary angiogram ruled out pulmonary but picked up incidental 8-cm right adrenal lesion, highly suspicious for phaeochromocytoma. Further imaging with CT thorax, abdomen and pelvis and raised urinary metanephrines confirmed non-metastatic phaeochromocytoma diagnosis. During admission, Doxazosin was titrated up to the maximum dose; however, blood pressure remained uncontrolled while she started to develop symptoms of bowel obstruction. CT abdomen revealed non-mechanical small bowel obstruction which confirmed paralytic ileus diagnosis. She was put on NBM and moved to ICU for IV Phentolamine infusion; however, paralytic ileus continued to deteriorate. Accordingly, she underwent urgent laparoscopic right adrenalectomy which managed to resolve paralytic ileus and allowed her to

gradually stop antihypertensive medications. In conclusion, this case sheds light on rare complications of phaeochromocytoma, including intestinal pseudo-obstruction, that should be assessed in acute presentations.

The efficacy of pasireotide treatment in invasive crooke's cell corticotropinoma – case report

Katarzyna Maliszewska[1], Anna Poplawska-Kita[2], Aleksandra Januszewska-Gilis[3], Przemyslaw Witek[4], Tomasz Lyson[2] & Adam Kretowski[1]
[1]Madical University of Bialystok, Department of Endocrinology, Diabetology and Internal Medicine, Bialystok, Poland; [2]Madical University of Bialystok, Department of Neurosurgery with Department of Interventional Neurology, Bialystok, Poland; [3]Jagiellonian University Medical College, Cracow, Poland, Department of Endocrinology, Cracow, Poland; [4]Warsaw Medical University, Warsaw, Poland, Department of Internal Medicine, Endocrinology and Diabetology, Warsaw, Poland

Introduction
Crooke's cell adenomas (CCA) are a rare type of pituitary neoplasm, associated with Cushing's disease. They are characterised by accumulation of perinuclear cytokeratin filaments, appearing distinctly hyaline in hematoxylin and eosin (HE) staining (Crooke's hyaline change). Due to their rarity, the management and treatment remain a challenge.
Clinical case
A 33-year-old male patient, presented sudden visual impairment, no signs of Cushing's disease were reported. The pituitary MRI revealed a 51×29×32mm macroadenoma within sella turcica, penetrating into the cavernous sinus, suprasellar region and the third ventricle with compression of the optic chiasm. Two months after the initial diagnosis, the typical hypercortisolemia symptoms (sudden weight gain, striae and hypertension) occurred. The laboratory results showed high ACTH concentrations (230pg/ml), loss of circadian cortisol rhythm, elevated urinary free cortisol excretion (UFC 675 mg/24 h), and lack of cortisol inhibition after 1 mg of dexamethasone. The patient underwent transsphenoidal surgery, the mass was partially (~50%) removed (diameters of mass 19x14x12mm in MRI) without normalisation of ACTH and UFC. After the post operation period, gradual increases of cortisol hormones and tumor mass progression were observed. After analyzing the risk associated with reoperation or possible radiation therapy, the decision was made to start with conservative treatment. Regarding the presence of functional Cushing disease, long-acting pasireotide administered once monthly was introduced, with the initial dose of 10 mg with gradual titration to 30 mg. However, the normalisation of ACTH and UFC after 6 months of treatment was not achieved. For the next 6 months osilodrostat (1 mg twice a day) was added to the therapy simultaneous with pasireotide 30 mg each month. In imaging data, a year after the pharmacology therapy, the slight progression in tumor size was detected (diameters of mass 22x15x20mm). Another attempt at transnasal resection was made, but no complete resection was achieved. Postoperatively the normalisation of UFC was observed with persistent slight increase of ACTH concentration (150pg/ml). Histologically, the tumour was described as densely granulated adenoma, Ki-67 labeling index was low; surprisingly no Crooke hyaline change was detected. Again, the therapy of pasireotide was restarted with stabilisation of the disease (UFC in normal laboratory range 54.6 mg/24 h and slight increase of ACTH concentration 135pg/ml) after one year of observation.
Conclusion
CCA is a rare pituitary adenoma that should receive significant attention. Pasireotide could be considered as a second or third line treatment in CCA. However, further studies of the effectiveness of such treatment are required.

Primary hyperparathyroidism secondary to parathyroid carcinoma in a 53 year-old male presenting with lassitude, constipation and bone pains: a case report

Rhoda Mae Pableo & Donnah Bless Lumanlan-Mosqueda
Brokenshire Medical Center, Internal Medicine, Davao City, Philippines

Parathyroid carcinoma is a rare (<1-5%) cause of primary hyperparathyroidism (pHPT) marked by excessive parathyroid hormone secretion leading to hypercalcemia. The prevalence rate of parathyroid carcinoma is 0.005% among all malignancies which has a slow and indolent course. A 53 year old male presented with lassitude, constipation, and bone pains which are common but non-specific symptoms. Diagnostic examination showed ionized calcium of 2.16mmol/l, nephrolithiasis, elevated creatinine and shortened QT interval. Intact PTH (iPTH) is elevated at 177.57 pg/ml with normal thyroid function tests. Hypercalcemia was managed with hydration and diuretics. Imaging revealed a hypoechoic mass posterior to the thyroid gland. Sestamibi scan showed increased tracer accumulation almost occupying the entire right lobe. Right inferior parathyroidectomy with right thyroid lobectomy was done wherein biopsy revealed parathyroid carcinoma. Post-operative iPTH showed a significant decline (>50%) from baseline at 39.91 pg/ml indicating complete removal of the abnormal hyperfunctioning parathyroid gland. Succeeding iPTH and serum calcium showed a decreasing trend alongside improving signs and symptoms. Although parathyroid carcinoma is rare, its manifestations as a result of hypercalcemia is common. Given that the best chance for treatment success is with a complete en-bloc resection, early diagnosis is imperative for treatment success and prolonged disease-free survival.

Unraveling the link: polycythemia and hyperparathyroidism - a case report

Sulmaaz Qamar[1] & Bernard Khoo[1,2]
[1]Royal Free Hospital, United Kingdom; [2]University College London, United Kingdom

Introduction
This case report explores the intricate relationship between polycythemia and hyperparathyroidism in a 42-year-old male, shedding light on the resolution of polycythemia following surgical intervention for PTH-dependent hypercalcemia. Despite the absence of symptomatic nephrolithiasis or renal failure, the patient's DXA scan revealed osteoporosis, prompting a deeper investigation into the complex interplay between these two conditions.
Methods
Comprehensive diagnostics, including ultrasound and SPECT scans, identified a 3.4 cm parathyroid adenoma. Initial pharmacological interventions with Colecalciferol and Cinacalcet escalated, revealing a Cinacalcet dosage of 60 mg BD. Notably, the patient remained asymptomatic, presenting an intriguing clinical paradox.
Results
The excision of the right inferior parathyroid adenoma yielded more than a resolution of hypercalcemia. Postoperatively, the patient experienced a marked normalization of blood calcium levels and the unexpected resolution of polycythemia. Histological examination confirmed a solid cystic parathyroid adenoma with no malignancy, emphasizing the unique relationship between these two conditions.
Discussion
This case challenges existing paradigms, raising whether polycythemia may be an underrecognized consequence of hyperparathyroidism. Literature suggests an association between polycythemia and parathyroid carcinoma; however, the absence of malignancy, in this case, prompts consideration of broader factors influencing the resolution of polycythemia.
Follow-up and Management
Subsequent clinic assessments three months postoperatively revealed successful recovery and resolution of pins and needles. Cinacalcet was discontinued due to the normalization of blood calcium and PTH levels. The unexpected resolution of polycythemia underscores the importance of continuous monitoring and further research into the incidence and mechanisms of this phenomenon.
Conclusion
This case highlights the successful management of PTH-dependent hypercalcemia and emphasizes the need for heightened awareness of the potential relationship between hyperparathyroidism and polycythemia. Further studies are warranted to elucidate the intricate connections between these conditions and their impact on patient outcomes.

Thyroid cyst infected with capnocytophaga canimorsus

Sinead Cadogan[1] & Siobhán McQuaid[1,2]
[1]The Mater Misericordiae University Hospital, Department of Endocrinology, Ireland; [2]University College Dublin, School of Medicine, Dublin, Ireland

Infected thyroid cysts are a rare complication of the thyroid gland, with haematogenous spread from a distal site of infection believed to be one mechanism of infection. We report the case of a patient who presented with an infected thyroid cyst due to Capnocytophaga canimorsus bacteraemia after sustaining a dog bite on her hand. A 37-year-old female presented to the Emergency Department with a five-day history of fevers, neck pain, and a rapidly enlarging neck swelling. The patient reported a dog bite on her right hand two days prior. Physical examination revealed temperature of 39.2°C, tachycardia, and a 3 cm tender mass in the left thyroid lobe. Laboratory investigations demonstrated leukocytosis (white blood cell count: 16.6×10^9/l) and elevated C-reactive protein (160 m g/l). Thyroid Ultrasound revealed a 3.1 cm left lobe cyst which demonstrated vascularity, and an overall multinodular appearance to the left lobe. The thyroid cyst was aspirated, and the fluid culture grew gram negative bacillus. Subsequent PCR testing confirmed this as Capnocytophaga canimorsus. The infected thyroid cyst was attributed to haematogenous spread of bacteria. Following a two week course of ceftriaxone and metronidazole, the patient's condition improved, with resolution of fever and normalisation of inflammatory markers. Capnocytophaga canimorsus is a gram-negative bacterium and an oral commensal in dogs, and occasionally causes serious infections in humans. To our knowledge, this is the first case report of an infected thyroid cyst due to capnocytophaga canimorsus.

Autoimmune polyglandular syndrome type 2: a clinical case of a rare combination of primary adrenal insufficiency and latent autoimmune diabetes in adults

Ilana Katsobashvili, Laura Ebanoidze, Ivan Golodnikov, Larisa Dzeranova, Ekaterina Pigarova & Tatyana Nikonova
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
According to statistical data, the combination of chronic adrenal insufficiency and diabetes mellitus is the rarest among patients with autoimmune polyglandular syndrome type 2 (APS-2).
Clinical Case
In 2017, a 32-year-old patient B. with excess body weight manifested type 2 diabetes mellitus with typical clinical symptoms of carbohydrate metabolism disorder. Metformin and gliclazide were recommended. After a viral pneumonia episode with hospitalization in the intensive care unit in December 2022, the patient experienced pronounced weakness, nausea, hypotension, and weight loss. During outpatient examination for worsening general well-being, a sharp increase in ACTH and a decrease in blood cortisol were detected for the first time. In May 2023, the patient was urgently hospitalized in the endocrinology department, where primary adrenal insufficiency was diagnosed based on hormonal studies (morning blood cortisol – 94 nmol/l, ACTH – 1250 pg/ml). Hydrocortisone 10 mg in the morning/evening and fludrocortisone 0.1 mg/day were prescribed. Due to organizational difficulties, mineralocorticoid therapy was not administered. Due to decompensated carbohydrate metabolism (HbA1c - 19%), the patient was switched to basal-bolus insulin therapy (Protaphane 8 IU in the morning, 6 IU in the evening, Biosulin R 4 IU before main meals). In November 2023, during hospitalization in an endocrinological ward, considering a low C-peptide level of 0.501 ng/ml (1.1-4.4), antibodies to GAD >2000 U/ml (0-10), insulin – 6.38 U/ml (0-10), and tyrosine phosphatase <1 U/ml (0-10), latent autoimmune diabetes in adults (LADA) was confirmed in combination with other criteria (age >35 years, being on oral hypoglycemic therapy for >6 months). Hormonal studies revealed morning ACTH - 1044 pg/ml (7.2-63.3) and morning cortisol - 45.5 nmol/l (171-536). The hydrocortisone regimen was adjusted to 10 mg in the morning, 5 mg at 13:00, and 5 mg at 18:00. Data indicating mineralocorticoid deficiency were obtained: sodium - 133.7 mmol/l (136-145), potassium - 4.09 mmol/l (3.5-5.1), renin - 75.95 mU/l (2.8-39.9), and fludrocortisone 0.1 mg/day was initiated. To exclude celiac disease, antibodies to gliadin IgA were taken, yielding 2.79 U/ml (0-12). Upon admission, HbA1c was 14%, and insulin therapy was optimized: insulin degludec 100 U/ml 12 IU at 22:00, insulin aspart 6 IU before main meals, stabilizing glycemic indicators within individual target ranges.
Conclusion
The clinical manifestations of APS-2 underscore the complex nature of the interplay between autoimmune and metabolic disorders necessitating an interdisciplinary approach in the timely diagnosis and treatment of this syndrome.

EP1302

Denosumab, immobility and calcium dysregulation

Raisa Minhas & Asjid Qureshi
Northwick Park Hospital, Diabetes & Endocrinology, London, United Kingdom

Case Summary
We report a case of a 79 yr old female with multiple co-morbidities including diabetes mellitus, hypertension, recurrent TIAs, CABG (2015), HfpEF and osteoporosis. Following treatment for the latter with Denosumab 60 mg, the patient developed hypocalcaemia (1.87 -2.13 mmol/l) with appropriately raised PTH (7.2 - 457.4 pmol/l). Her 25 hydroxy vitamin D level was 99 nmol/l. Her hypocalcaemia was managed with alfacalcidol and intravenous and then oral calcium supplements. Over a period of 4 months, these were withdrawn, and the patient maintained a normal calcium off supplements for 1 month. The patient then developed sepsis requiring prolonged admission to ITU for 33 days. During this period of her inpatient stay, she developed hypercalcemia (2.60-3.24 mmol/l) with a suppressed PTH. Her serum ACE and electrophoresis were normal. Her PET-CT scan demonstrated no evidence of malignancy. Her hypercalcaemia was suspected to be secondary to immobility and possibly rebound hypercalcemia after the discontinuation of denosumab. Treatment was with rehydration and bisphosphonates following which her calcium normalized. Immobilization is a recognized cause of hypercalcaemia. This is associated with a suppressed PTH, as in our case. Its onset is usually in 4 to 6 weeks after the precipitating injury/immobilization and calcium levels are usually no higher than 2.99 mmol/l?????. Severe hypercalcemia with levels $>$ 4.31 mmol/l, have been rarely described in the literature. Risk factors included prolonged inpatient stay (e.g. 6 months), sepsis (inflammatory cytokines accelerate osteoclastic resorption), chronic kidney disease stage 4, ITU stay, young age, spinal cord injury????. Rebound hypercacalcemia after discontinuing Denosumab has also been described in the literature. So far 6 cases have been reported amongst which 4 have been reported in pediatric population. Such cases are also associated with suppressed PTH levels, as in our case. Its onset is usually in 7 weeks to 6 months after discontinuing this drug and the severity of hypercalcaemia ranges between 2.5 to 3.79 mmol/l in adults. The mechanism may involve rebound osteoclast activity. Gradual tapering of denosumab dosage or prophylactic administration of bisphosphonates may prevent such cases. The management options for hypercaclaemia due to these two causes include hydration, bisphosphonates, corticosteroids, calcitonin, etc. Others have suggested that in severe cases, repeated use of bisphosphonates or reinjection of denosumab may be required to repress the surge of calcium released into the circulation.

The effect of teriparatide on bone density in osteoporotic patients with hiv infection

Eleni Palioura[1], Eleni Herolidi[1], Nikolaos Kalogeris[1], Alexandros Dermentzoglou[1], Maria Katsafyloudi[1], Alexandros Konidaris[1], Georgios Tsekes[2], Maria Chini[2] & Andromahi Vryonidou[1]
[1]Korgialenio Benakio, Hellenic Red Cross Hospital, Department of Endocrinology and Diabetes Center, Athens; [2]Korgialenio Benakio, Hellenic Red Cross Hospital, Department Infectious Diseases, Athens, Greece

Introduction
HIV infection has been associated with bone loss and increased frequency of bone fractures. The main pathogenetic mechanisms involve the direct effect of the virus and the HIV-induced inflammatory cytokines on bone metabolism, the effect of antiretroviral therapy (cART) *per se* and the frequently coexisting nutritional disorders and hypogonadism, further accelerating bone loss. Bisphosphonates remain the first-line treatment for these patients. Limited data are available for the safety and efficacy of denosumab while the effect of teriparatide is largely unknow in this population with only one case report described in literature.

Aim
To study the effectiveness and safety of teriparatide in osteoporotic patients with HIV infection.
Methods
This is a 36-month follow-up study. Subcutaneous teriparatide 20 mg was administered once daily for 24 months in three patients (two females and one male aged 68, 54 και 33 years, respectively). In two patients teriparatide was administered after vertebral fractures while on bisphosphonates therapy whereas in the third the agent was initiated after completing a 10-year treatment with risedronate. All patients received adequate calcium and vitamin D supplementation. Laboratory and imaging evaluation with DEXA of lumbar spine (L1-L4) and hip were performed before treatment initiation, at 24, and at 36 months. All patients had well controlled HIV infection (CD4 cell count >500 cells/ μl; undetectable viral load) under cART including tenofovir alafenamide.
Results
At 24 months a significant increase in BMD was observed in the lumbar spine (L2-L4) in all three patients: in the two females [percentage increase 9.4 and 18.4, respectively] and in the male [percentage increase 11.4], while a moderate increase was documented in total hip only in one female and the male [percentage increase 2.2 and 3.2, respectively]. At 36 months, thus one year since completing teriparatide treatment, two patients (68-year-old female and the male) showed further increase in bone density, especially in the lumbar spine (L2-L4) [percentage increase 11 and 3.1, respectively] and to a lesser extent in the total hip in the female [percentage increase 6.9]. CD4 cell count and viral load remained unaffected throughout the study. Additionally, none of the patients developed hypercalcemia during the treatment period, nor did they present any other biochemical or hormonal disturbances.
Conclusions
Teriparatide administration in osteoporotic patients with HIV infection, after bisphosphonate failure, seems to have a favorable impact on bone density. Further studies are needed to confirm the long-term effectiveness and safety of teriparatide in this population.

Efficacy and side effects of subcutaneous pasireotide alone or in combination with cabergoline in patients with cushing's disease whithout postoperative remission

Alev Selek, Nurgül Demir, Berrin Çetinarslan, Zeynep Cantürk, Emre Gezer, Mehmet Sözen, Damla Köksalan, Özlem Alkan, Saadet Acar & Fatma Öktem
kocaeli university, endocrinology, Kocaeli

Pasireotide is a second-generation, multireceptor-targeted somatostatin receptor ligand and is approved for the treatment of patients with Cushing's Didease (CD) for whom surgery has failed or is not an option. This retrospective single center study aims to report the efficacy, side effects and follow-up of the treatment with pasireotide alone or in combination with cabergoline in patients without remission after transsphenoidal surgery. Among 187 patients with CD, 15 patients, who did not achieve post operative remission and on pasireotide tretment, were enrolled to the study. Demographic data, comorbid diseases and clinical status of the patients before pasireotide treatment were shown on table 1. The mean pasireotide treatment duration was 15±13 months. UFC normalization was seen in 10 (67%) patients in 12 months, 2 patients discontinue the treatment <6 months because of drug intolerance (gastrointestinal disturbance and hypoglycemia) and 3 patients were unresponsive. Among 10 patients with normalization of UFC, 3 had remission and stopped medication after three years (2 had radiosurgery before, one not), one patient had treatment escape after 3 years and 6 of them are still on medication. New onset diabetes was seen in two cases (13%) however deterioration of glycemic control was seen in 3 (50%) of the diabetic patients. Cholelithiasis was seen in one patient. Clinical prognostic factors were also evaluated between pasireotide responsive and nonresponsive groups; all the factors were similar between groups probably due to small sample size (table 2). Pasireotide is an effective treatment in patients without surgical remission. Approximately half of the patients in our study were successfully treated with pasireotide alone or in combination with cabergoline without severe side effects. Radiosurgery is another treatment choice and pasireotide is also a good option until the effect of radiosurgery appears.

Table 1.

12 female (80%)	Mean age was 43 ±15 years
9 macroadenoma (60%)	Mean follow-up was 80 ±58 months
6 overt diabetes mellitus (40%) 5 prediabetes (33%)	Mean tumor size was 14.6 ±11.8 mm
6 2 or more operations (40%)	Mean pretreatment kortizol was 17.6 ±5.8 mg/dl

Diabetes as a consequence of chronic calcifying pancreatitis: case report

Ikrame Qasdi, Hasna Ouirar, Amal Riad, Caimae Zouna, Fatima Toulali, Ghizlane Sabbar, Kaoutar Rifai, Iraqi Hinde & Mohamed Elhassan Gharbi
Ibn Sina University hospital, Endocrinology and Metabolic Diseases, rabat

Introduction
Diabetes stemming from pancreatic causes constitutes 0.5% of diabetes cases (1–2). It is defined as 'other specific types of diabetes resulting from exocrine pancreas impairment.' Through this case report, we elucidate the distinctive clinical features of chronic calcifying pancreatitis-related diabetes.
Case report
A 31-year-old male with a diabetic family history and a history of occasional alcohol consumption, is presenting with exocrine pancreatic insufficiency for the last 9 months. Characterized by diffuse abdominal pain, malabsorption-type diarrhea, concomitant onset of cardinal symptoms, and a weight loss of 14 kg over a year. Diabetes was revealed during the weight loss investigation. Clinical examination showed epigastric tenderness on palpation, capillary blood glucose at 5.9 g/l without ketonuria. Biochemically, fasting blood glucose was 2.5 g/l, eGFR at 123ml/min, HbA1c at 16.4g/dl, along with hepatic cytolysis and cholestasis. The infectious panel yielded negative results. The diagnosis of Chronic Calcifying Pancreatitis (CCP) was considered due to clinical and biological manifestations of exocrine insufficiency, weight loss, diabetes, and morphological findings. Notably, the pancreatic CT scan indicated a predominantly atrophic appearance of the entire pancreas with numerous micro and macro calcifications, along with dilation of the common bile duct and intrahepatic bile ducts, and findings consistent with calcifying pancreatitis without signs of glandular necrosis on magnetic resonance cholangiopancreatographic (MRCP). Given the indications of insulin deficiency, the patient was placed on insulin therapy using a basal-bolus strategy, and pancreatic enzyme supplementation was introduced. There were no manifestations of macroangiopathy or microangiopathy.
Discussion
Diagnosis of pancreatic diabetes is frequently delayed, with a notably higher occurrence in chronic calcifying pancreatitis. It should be considered in the presence of early signs of insulin deficiency

Changes in gut microbiota and arginine metabolic rates in patients with type 1 diabetes

Yelena Aghajanova[1,1], Arthur Melkonyan[1], Nina Alchujyan[2], Bayburdyan Gayane[1], Lusine Arakelyan[1], Sona Hakobyan[1], Zara Gevorgyan[1], Naira Zohrabyan[1], Margarita Hovhannisyan[2], Armine Mnatsakanyan[3] & Anna Vardanyan[1]
[1]Yerevan State Medical University, Endocrinology, Yerevan; [2]H. Bunyatyan Institute of Biochemistry NAS RA, Department of Pathological Biochemistry and Radioisotope Methods, Yerevan; [3]«Nork» Infectious Diseases Clinical Hospital, Clinical Laboratory, Yerevan

Introduction
Type 1 diabetes (T1DM) is one of the most frequent autoimmune and metabolic disorders in childhood and youth, developing due to autoimmune destruction of β-cells, which leads to an absolute insulin deficiency. Accumulating data suggest that gut microbiota (GM) may contribute to the pathogenesis of diabetes influencing the immune response, in which arginine-metabolizing enzymes are involved, particularly arginase. We examined the connection between GM and cytoplasmic and mitochondrial arginase isoforms (AI and AII respectively) in the leukocytes of patients with T1DM.

Materials/Methods
All patients were recruited at the Muratsan University Hospital, Endocrinology Department, Yerevan. Microbiota was examined in feces of participants in the clinical laboratory of «Nork» infectious diseases hospital. Fasting venous blood was taken into 3.8% sodium citrate anticoagulant, mixed with 6% dextran, and leukocytes were isolated by conventional procedures, then the leukocyte cytoplasmic and mitochondrial fractions were prepared by differential centrifugation. Arginase assay was based on the accumulation of L-ornithine produced by arginase in the reaction mixture during 1 hour incubation and determined by means ninhydrin. Measurement of the nitric oxide stable metabolites in protein-free samples was performed using Griess-Ilosvay reagent.
Results
Number of E.coli, Bifidobacterium spp., Lactobacillus spp. were drastically decreased with a concomitant increase in that of Candida albicans, and a manifestation of Staphilococcus aureus was also observed in T1DM, which may compete with the gut beneficial bacteria. E.coli plays a protector role for GM, whereas clinical cultures of C.albicans has detrimental effects causing desquamation of small fragments peptidoglycan layers of cell wall and total destruction of the cytoplasm in lactobacilli. Changes in GM were associated with 1.3 and 1.5 fold increase in the activity of cytoplasmic and mitochondrial arginase isoforms in newly-diagnosed T1DM patients and 1.6 and 1.7 fold increase in patients with duration of T1DM more than 1 year. Simultaneously, in the same groups, statistically significant decline in the number of NO metabolites was observed. Arginase is known to contribute to decreased availability of L-Arginine in the organism, and particularly to nitric oxide synthase that may cause a subsequent reduction of NOS/NO production attributed to the pathological processes associated with diabetes.
Conclusions
Quantitative and qualitative changes in the content of GM in T1DM patients were recorded, which were associated with arginine metabolism intracellular changes in immune response involved leucocytes. Arginase isoforms stimulation in cytoplasme and mitochondrias of leucocytes in T1DM patients was revealed, associated with a decrease in nitrates level, which indicates the involvement of these processes in pathogenesis of the disease.

Hypocalcemia revealing digeorge syndrome: case report

Mariem Cheikh, Cheibete Zakaria, Mohamed Mokhtar, Kaoutar Rifai, Iraqi Hinde & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Endocrinology Department, Rabat, Morocco

Introduction
DiGeorge syndrome is a genetic abnormality caused by a microdeletion of chromosome 22. Chromosome 22q1 1.2 microdeletion was first identified in 1992 as the common genetic anomaly associated with a range of conditions previously known as DiGeorge or velocardiofacial syndrome.
Case report
A 17-year-old Moroccan male was mildly mentally challenged and had seizures from the age of 9 years. He had dysmorphic facial features, and mild tortuosity of the vessels of the retina but no hemorrhage or exudates. The clinical examination found the presence of a hydrocele, Chvostek's and and Trousseau's signs were positive. Corrected calcemia was at 68 mgl/l, Urea was at 0, 21 g/l, creatinine at 8 mg/l, albumine 45 g/l, PTH was at 8 pg/ml A CT scan of the head showed Farh syndrome. Echocardiogram showed an interventricular septal defect with no aortic arch abnormalities. The diagnosis of DiGeorge's syndrome was suspected based on mental retardation, seizures, the dysmorphic facial features and cardiac abnormalities and the biochemical findings of hypoparathyroidism and hypocalcemia.
Discussion
The overall prevalence of DiGeorge's syndrome is 1 in 5950 births. It usually presents later in childhood, often leading to hypernasal speech caused by cleft palate, submucous cleft palate, or velopharyngeal insufficiency. Both disorders share similar clinical features, such as conotruncal heart defects and mildly dysmorphic facial characteristics. Approximately 13% of patients receive a diagnosis at the age of 15 or older, with most of them being identified through familial genetic studies. In adulthood, the presence of hypocalcemia as a result of pseudohypoparathyroidism (PH) is often the primary indicator of the disorder. Adults with PH typically exhibit developmental delays, psychiatric issues, and cardiac anomalies. Additionally, there may be an increased risk of early-onset Parkinson's disease. The majority of patients experience hypocalcemia (49-80%), which can manifest at any age. Hypocalcemia is caused by PH, which is characterized by congenital parathyroid aplasia or hypoplasia
Conclusion
This case highlights the diagnostic complexity of hypocalcemia in a setting of multiple potential etiologic factors. It emphasizes the importance of considering that chromosome 22q11.2 deletion syndrome is not a rare occurrence and may manifest later in life, ought to prompt healthcare providers to request genetic testing regardless of the individual's age.

Thyroid replacement therapy with liquid levothyroxine as an alternative for patients with gastrointestinal absorption problems

Eduardo Torrecillas del Castillo, Mercedes Peinado Ruiz, Pablo Rodriguez de Vera, Alberto Torres Cuadro, Clara García Socorro, María Asunción Martínez Brocca & Tomás Martín Hernández
Hospital universitario virgen macarena, Sevilla, Spain

Aim
Illustrating a case series of two patients with levothyroxine malabsorption and suboptimal control of the thyroid profile who experienced a significant improvement after switching to liquid levothyroxine.
Material and Methods
Case saries of two patients who were attended in monographic thyroid pathology consultations at Virgen Macarena University Hospital.
Results
Case 1: a 46-year-old female patient who had multinodular goitre detected incidentally by CT. Her personal history included Crohn's disease, ileocecectomy in 2007. No treatment. A thyroid ultrasound was performed, showing TIRADS4 nodule, on which FNA was performed with suspected papillary carcinoma. A total thyroidectomy was performed. Postoperative control showed Thyrotropin (TSH) levels 39.30 IU/ml and free-thyroxine(FT4) levels 0.75 ng/dl. Non-specific symptoms were reported. The patient required multiple dose readjustments with difficulty in achieving optimal control, requiring up to 300 mg/day of levothyroxine, with level variations, compatible with both treatment deficit and iatrogenic hyperthyroidism. A change to liquid levothyroxine was proposed. the next follow-up visit the laboratory tests showed a thyroid profile within target range: TSH 1.46 IU/ml; FT4 1.32 ng/dl; FT3 2.44pg/ml, dose of 200 mg/day. Case2: a 32-year-old primigravida patient who was unable to adjust her thyroid replacement levels despite progressive increases in the dose of oral levothyroxine. Her personal history included a total thyroidectomy for a papillary thyroid carcinoma that showed excellent control for 10 years with oral levothyroxine 200 mg/day. She reported symptoms of nausea and vomiting from the fourth week of gestation, which had worsened the last few days, leading to a weight loss of 2 kg. She reported muscle fatigue and generalised weakness in the last month. Laboratory tests were normal. Foetal follow-up and obstetric check-ups presented within normal limits. The thyroid profile showed TSH 58 IU/ml; FT4 0.36 ng/dl. A loss of muscle strength of 4/5 was observed on physical examination. Stretch reflexes slightly elongated. No thyroid remnants on cervical ultrasound. Based on these findings and the thyroid hormone levels, a clinical assessment of hypothyroidism secondary to thyroid hormone malabsorption was made, replacing levothyroxine tablets by liquid thyroxine at a dose of 2.3 mg/kg/24h, with thyroid hormone levels returning to normal and fatigue and muscle weakness also subsiding.
Conclusions
There are a significant number of patients who do not achieve an adequate response to oral levothyroxine therapy due to problems in its absorption, with negative consequences on the patient's well-being. Liquid levothyroxine could help this group of patients achieve more stable TSH values, improving their quality of life and reducing the risk of iatrogenic hyperthyroidism.

Malignant pheochromocytoma unmasked by paralyzing sciatic symptoms: a case report

Hasna Ouirar, Caimae Zouna, Ikrame Qasdi, Kaoutar Elmoatamid, Fatima Toulali, Ghizlane Sabbar, Kaoutar Rifai, Iraqi Hinde & Mohamed Elhassan Gharbi
Ibn Sina University Hospital, Endocrinology and Metabolic Diseases, Rabat, Morocco

Introduction
Developing in the adrenal medulla's chromaffin cells, pheochromocytoma (PC) is an infrequent tumor Illustrating the instance of a patient diagnosed with malignant adrenal pheochromocytoma (PCM) following the onset of paralyzing sciatic pain

Case
A 60-year-old patient managing hypertension with triple therapy and type 2 diabetes using metformin and insulin glargine. The patient sought emergency care due to recurrent and disabling sciatic pain progressing to paraplegia. Concurrent constitutional symptoms, significant weight loss, and anorexia prompted a lumbar spine MRI, revealing spinal cord compression with an L3 fracture, and a concurrent 88mm adrenal mass, as further confirmed by an abdominopelvic CT scan. Secretory biochemical analysis indicated a significant increase in plasma Normetanephrines, measuring 116 times the normal level, while Metanephrines remained within the normal range. An 18F-FDG PET scan performed for staging purposes confirmed the hypermetabolic adrenal mass and identified a vertebral tumor extension with comparable features to the adrenal tumor. Surgical intervention has been advised after medical preparation.
Discussion
A neuroendocrine tumor, pheochromocytoma, is an infrequent condition marked by excessive catecholamine secretion. Malignancy is noted in 10% of cases, determined by metastases in tissues lacking chromaffin cells. It has a hereditary component in 40% of cases and in order to provide the best care, a coordinated, multidisciplinary approach is imperative

Somatotropinoma masked by morbid obesity: a case report

Anastasia Averkina[1,2], Raisat Guseinova[1,2], Manushak Rafaelyan[1,2], Olga Vasukova[1,2], Elena Andreeva[2], Ekaterina Pigarova[2], Vilen Azizyan[2], Ekaterina Bondarenko[2], Daria Kopytina[2] & Natalia Mokrysheva[2]
[1]Endocrinology Research Center, Center for the Treatment and Prevention of Metabolic Diseases and Obesity, Moscow, Russian Federation; [2]Endocrinology Research Center, Moscow, Russian Federation

Introduction
Acromegaly can be asymptomatic for a long time and morbid obesity can mask typical clinical signs (facial disfigurement, large hands and feet) and even severe disorders, such as hypopituitarism, cardiomyopathy, respiratory dysfunction, sleep apnea, atherosclerosis, endothelial dysfunction, arthropathy, prediabetes/-diabetes, dyslipidemia and mineral dysmetabolism. Menstrual irregularity and infertility combined with headaches are among the earliest issues a patient both with acromegaly and obesity might experience. This trio could be a clue for a diagnostic search for acromegaly long before obvious clinical manifestation.
Case Report
36 years old women was referred to endocrinologist, specialised in Obesity and Metabolism, by gynecologist due to infertility, stagnation of body weight at 120 kg (BMI 43 kg/m^2, max body weight was 160 kg at the age of 23), fatigue, headaches, episodes of high blood pressure up to 140/100 mm Hg and striae on the body. There were no changes in apperence typical for acromegaly. 2 years ago, an MRI scan was performed for headaches and delayed menstrual cycle investigation and a pituitary microadenoma was suspected. Hyperprolactinemia 628 mU/l (94-557) was detected, but after a single dose of cabergoline (0.125 mg) the cycle was restored and remained regular, patient discontinued the therapy. IGF-1 level was high = 364-428 ng/ml (78-311) and suppression of GH during the OGTT was inadequate (0-30-60-90-120 min – 2.2-1.1-2.0-2.3-3.1 ng/ml). Endogenous hypercortisolism was excluded (cortisol after the 1 mg overnight dexamethasone suppression test was 19 nmol/l). Prolactin was within a normal range (470 mU/l). Neither hypopituitarism nor glucose or mineral metabolism disorders (including hyperparathyroidism) were found. A patient underwent a transsphenoidal surgery for an endo-infrasellar pituitary microadenoma (7.5×6×8.8 mm). Histology showed a neoplasm of a solid structure from cells with basophilic cytoplasm; the immunohistochemical study revealed cytoplasmic expression of CAM5.2, pronounced expression of somatotropic hormone and focal weak expression of prolactin. Patient was biochemically in remission 6 month after surgery with no signs of hypopituitarism. Restoration of ovulatory ovarian cycles and regression of adipose mass resulted in clinical improvement and the occurrence of pregnancy.
Conclusion
This case report highlights a necessity to evaluate pituitary function in patients with morbid obesity and reproductive dysfunction, especially in presence of regular headaches. The application of a described multidisciplinary approach led to the timely verification of the underlying «asymptomatic» acromegaly and enabled us to prevent the development of complications and improve patient's quality of life.

High levels of serum prolactin associated with antipsychotic use: Should we be concerned? About two cases

Emna Mraihi[1], Imen Rojbi[1,2], Sabrine Mekni[1,2], Sawsen Essayeh[1,2], Rihab Laamouri[1], Meriem Werfelli[1], Karima Khiari[1] & Ibtissem Ben Nacef[1,2]
[1]Charles Nicolle Hospital, Tunis, Tunisia; [2]Laboratory of renal pathology (LR00SP01), Tunis, Tunisia

Introduction
Antipsychotic-induced hyperprolactinemia is a prevalent hindering condition that is often overlooked. It is responsible for several significant consequences that alter the patients' therapeutic compliance and quality of life. It can be a debilitating condition that warrants routine assessment and careful management through well-structured protocols.
Case details
We report the case of two patients treated with antipsychotics:
-The first one was a 25-year-old female with a personal history of chronic psychosis grafted onto mental disability treated with risperidone 2 mg per day. She presented with hyperprolactinemia (serum prolactin = 277 ng/ml) associated with secondary amenorrhea and galactorrhea.
-The second female patient was 31-year-old with a personal history of schizophrenia stabilized on both clozapine 100 mg per day and amisulpride 400 mg per day presented with hyperprolactinemia (serum prolactin = 168 ng/ml) associated as well with secondary amenorrhea. Neither patient exhibited signs of tumor syndrome. We ruled out, first, any active pregnancy. Then we measured serum thyroid stimulating hormone that came back in the normal range excluding, thus, primary hypothyroidism. Both patients had no renal insufficiency Pituitary MRIs were lastly conducted to rule out prolactinomas or tumors causing the 'Stalk effect'. A bone density test was performed to evaluate the long-term effect of hyperprolactinemia on the bone mass and showed no signs of osteopenia/osteoporosis. Since drug switch or discontinuation, as well as dose reduction, were not possible we aimed for hormone replacement therapy with estrogen.
Conclusion
Antipsychotic-induced hyperprolactinemia is a widespread endocrine disorder that can typically range from 25 to 100 ng/ml. Levels above 100 ng/ml can be observed and need further evaluation to rule out lactotroph tumors. Its approaches are controversial and numerous clinical trials are still being conducted.

Improvement of blood pressure in patients with type 2 diabetes, labelled as metformin-intolerant when rechallenged with extended-release metformin

Agnieszka Kuzior[1], Jennifer Maria Perez-Rivero[2], Claudia Arnas-Leon[1], Alba Hernandez-Lazaro[3], Ricardo Jose de Leon-Durango[4], Borja Santana-Ojeda[4], Inmaculada Molinero Marcos[4], Carmen Acosta-Calero[5], Maria del Pino Perez-Garcia[6] & Francisco Javier Martinez Martin[1, 4]
[1]Hospitales Universitarios San Roque, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [2]Centro Salud Escaleritas, Family & Community Medicine, Las Palmas de Gran Canaria, Spain; [3]Parc Taulí University Hospital, Endocrinology & Nutrition, Sabadell, Spain; [4]University Hospital of Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [5]University Hospital of Gran Canaria Dr. Negrín, Cardiology, Las Palmas de Gran Canaria, Spain; [6]Centro de Salud El Calero, Family & Community Medicine, Telde, Gran Canaria, Spain

Introduction and Objective
Extended-release metformin has much better gastrointestinal tolerability than conventional (immediate release)metformin and according to the UK NICE guidelines should be offered to patients who have gastrointestinal tolerance issues with conventional metformin. We rechallenged patients with T2DM labelled as metformin-intolerant and treated with a DPP4i with a single-pill combination (SPC) of extended release metformin and sitagliptin (1000/50 mg) in order to assess its tolerability. We retrospectively calculated the cardiovascular risk of our patients at baseline and after 3-4 months on treatment with this SPC with the SCORE2-Diabetes calculator, and assessed the changes in office blood pressure.
Design & Methods
Consecutive patients with T2DM, HbA1c >7% but < 9% and eGFR (CKD-EPI) >45 ml/min/1.73m^2 labelled as metformin-intolerant due to gastrointestinal symptoms, and treated with a DPP4i were switched to the mentioned SPC, taking 1 pill daily in the first month and afterwards 2 pills if the tolerance was good. Additional antidiabetic medication, if any, was unchanged; however, lifestyle, antihypertensive and cholesterol-lowering medication were adjusted according to

current guidelines. Tolerance data were obtained by questionnaire in the follow-up visit. Calculations were done by intention to treat.
Results
We applied the SCORE2-Diabetes in 72 patients (45 women, aged 55±8 years, 7.5±3.2 years since the diagnosis of T2DM), of which 52 tolerated 2 tablets, 8 tolerated 1 tablet and 12 did not tolerate any. After 3-4 months of treatment, systolic office blood pressure was reduced from 147.3±21.2 to 131.8±18.9 mmHg ($P<0.001$); diastolic office blood pressure was reduced from 92.8±16.3 to 81.8±15.7 mmHg ($P<0.001$). The number of patients at target (<130/80 mmHg) changed from 14 (19.1%) to 33 (48.5%), $P=0.0011$ The baseline CV risk (major event in the next 10 years) was estimated as 12.8±2.3%; 7 (10.3%) patients were classified as intermediate risk, 46 (67.6%) as high risk and 15 (22.1%) as very high risk patients. After 3-4 months of treatment the 10-year CV risk was reduced to 10.3±1.8% ($P<0.001$); 27 (39.7%) patients were classified as intermediate risk, 34 (50%) as high risk and 7 (10.3%) as very high risk patients ($P<0.001$).
Conclusions
A large majority of the patients tolerated the rechallenge; their blood pressure and cardiovascular risk were significantly reduced. These changes must be considered as multifactorial, as in most patients there were additional interventions in lifestyle, antihypertensive and cholesterol-lowering drugs.

EP1313

Papillary thyroid microcarcinoma revealed during surgical treatment of squamous cell carcinoma of the larynx

Karimi Meryem, Hajar Azagouagh, Talbi Dounia, Rifai Kaoutar, Iraqi Hind & Mohamed Elhassan Gharbi
Ibn Sina Rabat, Endocrinology, Rabat, Morocco

Introduction
The association of thyroid carcinoma with squamous cell carcinoma of the larynx is very rare, with few clinical cases reported in the literature.
Case report
We report the case of a 63-year-old patient with no significant medical history who presented with progressive dysphonia. Fiberoptic examination revealed a budding lesion. CT scan showed a tumor process centered on the right vocal cord, with negative extension findings. The patient underwent right laryngectomy with hemithyroidectomy and right recurrent laryngeal nerve dissection. Histopathological examination revealed two foci of well-defined, non-encapsulated, 3mm each, papillary microcarcinoma of the thyroid, vesicular variant, with no metastatic lymph nodes found in the totalization and central lymph node dissection. The patient was classified as low risk of recurrence. Subsequently, the patient received radiotherapy/chemotherapy as part of the management of the squamous cell carcinoma and was started on suppressive therapy with l-thyroxine.
Discussion and Conclusion
Surgical treatment of squamous cell carcinoma of the larynx is an unusual circumstance for the discovery of thyroid cancer, most often representing a histological surprise. According to the literature, there is no well-established therapeutic protocol, but the prognosis is closely linked to upper aerodigestive tract cancer.

Characteristics of ferritin status in patients with NAFLD and insulin resistance

Olha Kozak, Ihor Hospodarskyy & Oksana Prokopchuk
Ternopil National Medical University, Highter nursing education and clinical immunology, Ternopil, Ukraine

Introduction
Non-alcoholic fatty liver disease (NAFLD) is one of the most prevalent pathologies in the modern world. Despite the prevalence of this pathology, it continues to be studied, with new facts and mysteries about this diagnosis emerging. One such aspect is the impact of NAFLD on serum ferritin levels.
Aim
To investigate whether NAFLD affects serum ferritin levels in patients with insulin resistance.
Materials and Methods
To explore this topic, we examined 19 patients with NAFLD and insulin resistance, who were treated at the Ternopil regional central hospital (Group 1). The control group consisted of 16 patients with NAFLD but without nsulin resistance and without pathologies that could directly affect serum ferritin levels (Group 2). All patients underwent medical examinations. For comprehensive research, we conducted general clinical analyses (complete blood count, urinalysis, biochemical blood analysis) and instrumental studies (ultrasound, elastography, ECG). Special examination methods were also performed, including analyses of serum ferritin levels. The combination of these studies allowed us to confirm NAFLD and Insulin resistance in patients of the first group and exclude it in patients of the control group.
Results
When comparing the results of the control group (2) and the examined group (1), we identified certain patterns and peculiarities. Among the patients in the control group (2), the serum ferritin level was normal in 8 patients (50%), decreased in 5 patients (31.25%), and elevated in 2 patients (12.5%). In group 1 (patients with NAFLD), the distribution of results was as follows: the serum ferritin level corresponded to the norm in 7 patients (36.8%), was decreased in 2 patients (10.52%), and was elevated in 10 patients (52.63%). Thus, comparing the percentage ratio of data between group 1 and group 2 (control group), a clear pattern of elevated serum ferritin levels in the majority of NAFLD patients with Insulin resistance was evident.
Conclusions
According to the aforementioned results, we can assert that the presence of NAFLD and Insulin resistance is one of the factors influencing the elevation of serum ferritin levels in patients. This issue requires further and deeper investigation.

Renal cell carcinoma, solitary fibrous tumor and papillary thyroid carcinoma: an exceptional association

Elloumi Yesmine, Mrabet Houcem ElOmma, Ayadi Younes, Ayadi Mariem, Boubaker Fadia, Lassoued Najoua, Zantour Baha, Alaya Wafa & Med Habib Sfar
Hospital of Taher Sfar

Introduction
The solitary fibrous tumor is a rare spindle cell neoplasm, originally described in the pleural cavity. However, it can occur in other locations. Multiple primary cancers are a rare entity and their incidence is described at 5.5%. We report a case associating three neoplasms: a renal cell carcinoma, a mediastinal solitary fibrous tumor and a papillary thyroid cancer.
Obervation
We report the case of a 38 year old patient with no particular medical history, who presented a cough with fever. Chest scan showed a voluminous 10 cm mass in the upper mediastinum adhering to the upper lobe of the lung along with an incidental left mediorenal mass of 9 cm extending to the hilum. The patient underwent surgery: Resection of the lung mass with an enlarged left nephrectomy. Anatomopathological examination showed a mediastinal solitary fibrous tumor and a chromophobe renal cell carcinoma. Ten years later, the patient consulted for a cervical mass. Ultrasound showed suspicious cervical adenopathies along with a right mediolobar thyroid nodule of complex appearance measuring 17*13mm graded Eutirads 4. The patient underwent a total thyroidectomy. The histological examination showed a bifocal papillary carcinoma of the right thyroid lobe. The first one measures 1.7 cm, non-encapsulated and infiltrates the peri-thyroid adipose tissue and the 2nd nodule measures 0.1 cm, non-encapsulated and non-infiltrating along with lymph nodes metastases.
Conclusion
The association between renal cell carcinoma, mediastinal solitary fibrous tumor and papillary thyroid carcinoma wasn't described before in the literature. The coexistence of several neoplasms is rare. Common genetic and environmental risk factors seem to be involved in many cases. Multiplicity itself is not necessarily a poor prognostic factor. The role of genetic study is essential to codify these different diseases into a syndromic approach.

Clinical case of idiopathic osteoporosis associated with pregnancy

Ilana Katsobashvili, Laura Ebanoidze, Ekaterina Pigarova, Larisa Dzeranova & Svetlana Vorotnikova
Endocrinology Research Centre, Moscow, Russian Federation

Introduction
According to published data, pregnancy-associated osteoporosis is a rare disease, the pathophysiology of which is currently not fully explored.
Clinical case
In 2014, a 27 year-old patient B. after the first childbirth, pain appeared in the lumbosacral spine, for which a course of physical therapy was carried out with a short-term positive effect. In 2016 after the second childbirth, pains increased; according to the results of further examination, severe osteoporosis was revealed. According to densitometry (DXA) - the maximum decrease in bone mineral density (BMD) according to the Z-score in L_1-L_4 до -3.7 SD; MRI visualized compression fractures of the vertebral bodies $Th_{5,\ 8,\ 10}$. Later, vitamin D deficiency was verified (8.0 ng/ml), and colecalciferol was recommended to take 6000 IU/day in combination with calcium citrate and carbonate 500 mg/day, followed by ibandronic acid 150 mg once a month. In December 2019, MRI revealed new compression fractures of the vertebral bodies (Th_6 - 60%, Th_7 - 40%, Th_{11} - 40%). In order to exclude contraindications to the prescription of anabolic therapy, a blood test for the M-gradient was performed, followed by hematologist and oncologist consultation; multiple myeloma was not found. In this connection, in 2020 Teriparatide 20 mg subcutaneously daily was initiated, after 18 months the patient was transferred to zoledronic acid infusion. During hospitalization in the endocrinology hospital in December 2023, secondary hyperparathyroidism was diagnosed due to the use of bisphosphonates and insufficient calcium intake: PTH – 76.86 pg/ml (15-65), Ca adj. – 2.1 mmol/l (2.15-2.55). Therapy with calcium carbonate + calcium lactogluconate 1000 mg/day was recommended, the dose of colecalciferol is adjusted to 3000 IU daily. According to DXA, positive dynamics were noted - BMD was within the age norm ($L_{1\text{-}4}$ -1.2 SD; in the femur and radius: -1.3 SD and -1.2 SD, respectively).
Conclusion
The described case confirms the relevance of timely identification of risk factors and emphasizes the need to develop a personalized approach to the diagnosis and treatment of osteoporosis associated with pregnancy.

Concomitant multiple myeloma in a patient with primary hyperparathyroidism

Anna Somogyi[1], Eszter Berta[2], Inez Lengyel[3], László Váróczy[4], Endre Nagy[2] & Miklos Bodor[2]
[1]Faculty of Medicine, University of Debrecen, Endocrinology, Debrecen, Hungary; [2]Faculty of Medicine, University of Debrecen, Department of Endocrinology, Debrecen, Hungary; [3]Doctoral School of Health Sciences, University of Debrecen, Debrecen, Hungary; [4]Faculty of Medicine, University of Debrecen, Division of Hematology, Department of Internal Medicine, Debrecen, Hungary

Introduction
Primary hyperparathyroidism (PHPT) is one of the most common causes of non-neoplastic hypercalcemia with characteristically increased or inappropriately normal plasma parathyroid hormone (PTH) levels. Hypercalcemia is also a significant feature of patients with multiple myeloma (MM), and a pathogenetic link is presumed between the two diseases, strengthened by preclinical data. Only limited number of case reports of concomitant PHPT and MM are available in the literature.
Case report
A 58-year-old male patient was referred to the Department of Endocrinology, University of Debrecen, in 2022 with fatigue and hypercalcemia. His PTH was in the normal range and a 15×7 mm lesion was depicted by ultrasound in the region of left parathyroid gland. Imaging with technetium 99m-pertechnetate/technetium 99m-MIBI subtraction scintigraphy and with single photon emission tomography affirmed the suspected localization of parathyroid adenoma, PTH level became slightly elevated. After the surgical removal of the parathyroid adenoma histology affirmed benign lesion, and hypercalcemia persisted accompanied by normal PTH (se calcium 2.95 mmol/l, PTH 2.4 pmol/l). Nuclear imaging was repeated, and the results excluded the existence of another parathyroid adenoma, therefore we started to evaluate the opportunity of a concomitant neoplasia. Hyperproteinemia was also detected, and hematology workup started which confirmed the diagnosis of first stage IgG-kappa type multiple myeloma without typical lytic bone lesions. Since there is increasing evidence that monoclonal gammopathies are more common in patients with PHPT, a search for multiple underlying causes of uncontrollable hypercalcemia should be performed.

Hypocalcemia revealing digeorge syndrome: case report

Zakaria Cheibete[1], Mariem Cheikh & Mohamed Elmoctar
Ibn Sina University Hospital, Endocrinology, Rabat, Morocco

Introduction
DiGeorge syndrome is a genetic abnormality caused by a microdeletion of chromosome 22. Chromosome 22q1 1.2 microdeletion was first identified in 1992 as the common genetic anomaly associated with a range of conditions previously known as DiGeorge or velocardiofacial syndrome.
Case report
A 17-year-old Moroccan male was mildly mentally challenged and had seizures from the age of 9 years. He had dysmorphic facial features, and mild tortuosity of the vessels of the retina but no hemorrhage or exudates. The clinical examination found the presence of a hydrocele, Chvostek's and and Trousseau's signs were positive. Corrected calcemia was at 68 mgl/l, Urea was at 0, 21 g/l, creatinine at 8 mg/l, albumine 45 g/l, PTH was at 8 pg/ml A CT scan of the head showed Farh syndrome. Echocardiogram showed an interventricular septal defect with no aortic arch abnormalities. The diagnosis of DiGeorge's syndrome was suspected based on mental retardation, seizures, the dysmorphic facial features and cardiac abnormalities and the biochemical findings of hypoparathyroidism and hypocalcemia.
Discussion
The overall prevalence of DiGeorge's syndrome is 1 in 5950 births. It usually presents later in childhood, often leading to hypernasal speech caused by cleft palate, submucous cleft palate, or velopharyngeal insufficiency. Both disorders share similar clinical features, such as conotruncal heart defects and mildly dysmorphic facial characteristics. Approximately 13% of patients receive a diagnosis at the age of 15 or older, with most of them being identified through familial genetic studies. In adulthood, the presence of hypocalcemia as a result of pseudohypoparathyroidism (PH) is often the primary indicator of the disorder. Adults with PH typically exhibit developmental delays, psychiatric issues, and cardiac anomalies. Additionally, there may be an increased risk of early-onset Parkinson's disease. The majority of patients experience hypocalcemia (49-80%), which can manifest at any age. Hypocalcemia is caused by PH, which is characterized by congenital parathyroid aplasia or hypoplasia
Conclusion
This case highlights the diagnostic complexity of hypocalcemia in a setting of multiple potential etiologic factors. It emphasizes the importance of considering that chromosome 22q11.2 deletion syndrome is not a rare occurrence and may manifest later in life, ought to prompt healthcare providers to request genetic testing regardless of the individual's age.

EP1319

Peculiar case of post-gastrectomy noninsulinoma pancreatogenous hypoglycemic syndrome

Saša Ilić[1], Bojana Popovic[1,2], Drasko Gostiljac[1,2], Gordana Milic[1,2], Sandra Pekic Djurdjevic[1,2], Dragana Miljic[1,2], Masa Ristic[1] & Vesna Dimitrijevic Sreckovic[1,2]
[1]Clinic for endocrinology, diabetes and metabolic diseases, University Clinical Center of Serbia, Serbia; [2]University of Belgrade - Faculty of Medicine, Beograd, Serbia

For the diagnosis of hyperinsulinemic hypoglycemia (HH), it is necessary that in symptomatic hypoglycemia in the fasting test the insulin/glucose ratio is >0.3, or that in spontaneous hypoglycemia there are C-peptide >0.6 nmol/l and insulin >3.0 mIU/ml. It is a well-known fact about the increasing frequency of hypoglycemia after bariatric surgery (estimated up to 30% of patients), mostly within the Dumping syndrome, but the frequency of occurrence of noninsulinoma pancreatogenous hypoglycemia (NIPHS) after gastrectomy is still unknown. A 55-year-old female patient was referred to an endocrinologist due to hypoglycemia with neuroglycopenia and a positive Whipple triad – minimal home-measured glycemia was 1.9 mmol/l. Malnutrition dominates among the physical findings, with a BMI of 15 kg/m^2. Namely, 4 years ago, she was operated on because of gastric carcinoma (gastrectomy, lymphadenectomy, omentectomy, and right-sided hemicolectomy have been done), and during her follow up there were no signs of recurrence of the disease and/or dissemination. During the endocrinology examination, daily hypoglycemias were in the range of 2.0-2.7 mmol/l, during which was observed significant insulinemia (24.4-50.9 mIU/l) and C-peptide (1.4-2.8 nmol/l), During 5h oral glucose tolerance test and mixed meal test, HH was recorded. Radiological diagnostics (CT, MRI) ruled out the existence of a focal lesion in the pancreas. The response of counterregulatory hormones in repeated spontaneous hypoglycemia was blunted, which is why an

insulin tolerance test was performed: cortisol 86...61...100...119...99.9 nmol/l, PRL 377...290...227...195...180 mIU/l, HGH 0.5...1.0... 2.5...0.4...0.5 mIU/l – showing hypopituitarism. MRI showed no focal changes in the sellar region, but there were two aneurysms of the internal carotid artery slightly compressing the pituitary. Throughout the examination, the patient used megestrol for appetite stimulation. After excluding megestrol, normal baseline values of stress hormones were verified, and an adequate spike of cortisol was recorded in the ACTH test. Despite compliance with the diet, HH continued. Trial therapy with fast-acting octreotide was accompanied by significant hyperglycemia, so it was replaced with diazoxide, and with a daily dose of 175 mg, a satisfactory therapeutic response was achieved. HH in gastrectomy patients is a rarity and the most of published literature is in the form of case reports. In our patient, we speculate that during the post-gastrectomy period, she developed functional gastrointestinal hormonal adaptation and secondary nesidioblastosis (NIPHS). Hypopituitarism in our patient was observed as a transient and described side effect of megestrol, but close monitoring was continued due to aneurysms in the sellar region.

***in vitro* study of 17-beta-estradiol effects on a renal cancer cell line**

Lucrezia Rossi, Maria Rosaria Ambrosio & Maria Chiara Zatelli
Ospedale Universitario Sant'Anna di Cona, Section of Endocrinology, Department of Medical Sciences, University of Ferrara, Ferrara, Italy, Ferrara, Italy

Introduction
Renal carcinomas (RCs) are the most common kidney cancers, and their prognosis is affected by many factors; 5-year survival rate is >90% in patients with small tumors confined to the kidney. RC makes up 2-3% of cancers in adults aged between 50 and 70 years; in particular, the incidence in men is higher than women, 66.7 vs 33.3% of the cases, respectively.
Aim
RC incidence is twice as high in men as in women. This difference could suggest that estrogens may play a role in influencing a lower RC incidence in women. The aim of this study is to evaluate the effects of 17-β-estradiol (E2) on renal cancer cell proliferation *in vitro*.
Materials and methods
Experiments were performed with the HEK293 cells, a RC cell line, transfected with the pBIND-ERα Vector, containing the gene for the estrogen receptor. Cells were incubated for 48 and 72 hours with increasing E2 concentrations and proliferation was assessed by cell counting.
Results
We found that E2 concentrations in the range 1, 5 - 100 mM (*phase 1*) were killing the cells, being 1 mM E2 the maximum tolerated concentration, with a reduction in cell viability of 33%. E2 concentrations in the range 1, 5 - 100 μM (*phase 2*) significantly reduced viable cell number by 20%.
Conclusions
In *phase 1*, RC cells were exposed to high E2 concentrations, mimicking those of a woman in the peak of childbearing age (15-45 years). Conversely, in *phase 2*, RC cells were exposed to very low doses, mimicking those of a menopausal woman and/or a man. These results suggest a potential protective role of E2 towards RC.
Disclosure of interest: None declared.

Possible concurrence of primary aldosteronism with cushing's disease: a case report

Diana Becheanu, Adina Mariana Ghemigian, Laura Stanescu, Bianca Bucur, Eugenyia Petrova & Andra Cocolos
Parhon Institute, Bucharest, Romania

Resistant hypertension of endocrine cause can make for a challenging diagnosis but it certainly is a very important one.
Case report
We present the case of a 65 year old male patient with a history of arterial hypertension and hypokalemia for the past 10 years, for which he was prescribed a combination of alpha and beta blockers, calcium channel blockers, angiotensin receptor blockers (ARBs), loop diuretic, and spironolactone. The lack of response to this treatment suggested a possible endocrine cause and he was admitted to our clinic for further investigation. The blood biochemistry confirmed the hypokalemia (2, 9 mmol/l) and the endocrine panel showed high normal aldosterone levels (145 pg/ml), suppressed renin (0, 96 pg/ml) with an aldosterone/renin ratio (ARR) of 15, 1 ng/dl, and normal levels of metanephrines and normetanephrines. Additionally, we tested the serum cortisol and ACTH and performed 1 mg overnight dexamethasone test and 2 mg two-day dexamethasone test with lack of suppression with a slight increase of the blood pressure after the latter. Rising the spironolactone dose did manage to normalize the potassium levels, but the blood pressure remained high. The abdominal CT scan revealed bilateral macronodular adrenal hyperplasia and the pituitary MRI a micro-adenoma thus indicating that further investigations, such as adrenal venous sampling (AVS) and inferior petrosal sinus sampling could be needed in order to establish a correct diagnosis and treatment plan.
Conclusions
When facing with a patient with severe secondary hypertension it is important to search thoroughly for the endocrine imbalance since the results can sometimes be misleading and disorders could concur.

Primary hyperparathyroidism meets vascular malformation: a tale of intriguing coexistence

Ait Kassi Nada[1], Kouira Hiba[2,2], Issouani Jade[2] & Guerboub Ahmed Anas[2]
[1]Mohamed V Military Hospital, Endocrinology, Morocco; [2]Mohamed V Military Hospital, Endocrinology, Rabat, Morocco

Introduction and importance
Primary hyperparathyroidism is a prevalent source of hypercalcemia, predominantly attributed to a solitary adenoma in 80-85% of cases. Progress in imaging techniques has enhanced the accurate preoperative identification and targeted removal of hyperfunctional parathyroids in primary hyperparathyroidism (PHPT). The amalgamation of imaging methods or a "dual" approach, when congruent, enhances the precision of adenoma localization. Surgery remains the sole curative intervention for pHPT. The surgical approach must be carefully chosen to ensure optimal cure while minimizing dissection and associated morbidity.
Case presentation
We report the case of a 62-year-old female with a history of well-controlled hypertension on dual therapy and a history of cholecystectomy. She was admitted for the management of primary hyperparathyroidism, biochemically confirmed with a corrected calcium level of 110 mg/l, a phosphorus level of 22 mg/l, a PTH level 3.7 times the normal range, and elevated 24-hour urine calcium. As part of the impact assessment, we identified osteoporosis. In the localization assessment, cervical ultrasound revealed a right parathyroid adenoma with a distinctive aspect involving the carotid artery. Initially, we conducted a MIBI scintigraphy, which did not reveal any abnormalities, followed by a cervicothoracic CT scan that did not show evidence of a parathyroid adenoma. *In situ* echoguided PTH measurement returned high at 1 335 000 pg/ml. A PET scan with F-choline was performed, confirming a parathyroid adenoma adjacent to the lower pole of the right thyroid lobe. Additionally, an angioscan was conducted for a more comprehensive characterization of the carotid artery, indicating a right common carotid dolichoartery.
Conclusion
Surgery stands as the optimal course of treatment for our patient; nevertheless, the presence of this vascular malformation requires a thorough evaluation of the risk-benefit profile to recommend a suitable therapeutic strategy. Our patient's case will undergo review in a multidisciplinary team meeting to formulate an optimal management plan.

Quality of life improvement associated with the rechallenge with extended-release metformin in patients with type 2 diabetes labelled as metformin-intolerant

Inmaculada Molinero-Marcos[1], Alba Hernandez-Lazaro[2], Ricardo Jose de Leon-Durango[1], Carlos Rios-Gomez[1], Borja Santana Ojeda[1], Agnieszka Kuzior[3], Claudia Arnas-Leon[1, 3], Jennifer Maria Perez-Rivero[4], Maria del Pino Perez-Garcia[5] & Francisco Javier Martinez Martin[1, 3]
[1]University Hospital of Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [2]Parc Taulí University Hospital, Endocrinology & Nutrition, Sabadell, Spain; [3]Clinica San Roque, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [4]Centro Salud Escaleritas, Family & Community Medicine, Las Palmas de Gran

Canaria, Spain; [5]Centro de Salud El Calero, Family & Community Medicine, El Calero, Spain

Introduction and Objectives
The tolerability of extended-release metformin (XRM) is clearly superior to that of conventional metformin, with the potential to improve patient compliance, effectiveness and outcomes. Since 2005 the NICE guidelines for type 2 diabetes mellitus (T2DM) recommend its use in patients with metformin-caused gastrointestinal disturbances. XRM is recently available in Spain as a fixed combination with sitagliptin, but not in monotherapy. We assessed the efficacy and tolerability of XRM/sitagliptin in patients with T2DM previously labeled as metformin-intolerant and treated with a DPP4 inhibitor (DPP4i), and additionally analyzed the data for quality of life before and after the switch.
Patients and Methods
Consecutive patients with T2DM, HbA1c $>7\%$ and GFR (CKD-EPI) >45 ml/min/1.73m^2 labelled as metformin-intolerant due to gastrointestinal symptoms, and treated with a DPP4i were switched to the 50 mg sitagliptin plus 1000 mg XRM combination, taking 1 pill daily in the first month and afterwards 2 pills if the tolerance was good. Tolerance data were obtained by questionnaire in the follow-up visit. Quality of life was assessed by the well-validated questionnaire EuroQol-5D-3L on health-related quality of life, before the onset of treatment and again after 3-4 months on treatment. The questionnaire consists of 5 triple-answer questions (on mobility, personal care, daily activities, pain or discomfort, and anxiety or depression), and a visual analogue scale (VAS) or "thermometer" for health. All Included patients granted informed consent.
Results
69 of a total 72 patients completed the EuroQol-5D-3L before and after the switch from DPP4i to XRM/sitagliptin. The questionnaire was never administered to the patients by their prescribing physicians. The Quality of life score increased from 0.759 ± 0.121 to 0.866 ± 0.130; this change was driven mainly by the pain/discomfort score. The VAS score increased from 68.3 ± 13.8 to 82.5 ± 15.5 (both $P<0.01$). The reductions in fasting plasma glucose were 36 mg/dl with 1 pill of XRM/sitagliptin (1000/50 mg), and 44 mg/dl with 2 pills, and the reductions in HbA1c were 0.6% with 1 pill and 0.9% with 2 pills (all $P<0.01$). 51 patients (74%) tolerated 2 pills, 8 (12%) tolerated 1 tablet and 10 (14%) did not tolerate any.
Conclusions
A large majority of the patients with T2DM labelled as metformin-intolerant and treated with an DPP4i tolerated the XRM/sitagliptin combination, and their glycemic control was significantly improved The switch from DPP4i to the XRM/sitagliptn combination was associated with increased quality of life, particularly in relationship with decreased pain and discomfort.

EP1324

Endocrine osteoporosis: report of a series of cases

Essafi Mohammed Amine[1], Aynaou Hayat[1] & Salhi Houda[2]
[1]Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition. Hassan II University Hospital Center, Fez, Morocco; [2]Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition. Hassan II University Hospital Center, Morocco

Background and aims
Endocrine osteoporosis should be uncommon in contemporary times due to improved early diagnosis of endocrinopathies. Our objective is to analyze the osteodensitometric profiles of patients under endocrinopathy care.
Methods
A cross-sectional study of patients followed for endocrinopathies at the Endocrinology Department of the Hassan II University Hospital of Fez, spanning from the beginning of January 2016 to January 2022. Exclusion criteria encompassed patients receiving treatment for inflammatory rheumatism and those under care for systemic diseases. Analysis was conducted using SPSS26 software.
Results
A total of 83 patients diagnosed with endocrinopathy underwent Bone Mineral Density (BMD) assessment. The average age was 35.77 years, and a majority were female (73.49%). Primary and secondary amenorrhea were the predominant reasons for consultation, accounting for 37.35% of cases. 15.66% of the cases exhibited normal osteodensitometry, while 84.34% displayed abnormal Bone Mineral Density (BMD), with 34.94% diagnosed with osteoporosis and 49.40% with osteopenia. The identification of BMD issues, primarily osteoporosis and osteopenia, occurred in 87.14% of cases subsequent to the detection of the endocrinopathy. Hypogonadism prevailed among endocrinopathies, accounting for 71.08% of cases. Hyperparathyroidism constituted 19.28%, endogenous hypercorticism at 6.02%, and acromegaly at 3.62%. Osteoporosis was more commonly observed in the spine, occurring in 26.3% of cases with an average T-score of -2.88 ± 0.85. In the femur, osteopenia was present in 25.6%, while osteoporosis was noted in 8.64%, with a mean T-score of -1.46 ± 1.02. All patients underwent treatment for the underlying cause of their endocrinopathy along with adopting hygienic-dietary measures. Anti-osteoporotic treatment, primarily bisphosphonates, was prescribed in 34.94%. Regarding the follow-up, only 34.94% managed to undergo a follow-up Bone Mineral Density (BMD) assessment, and in every instance, there was an enhancement observed in T-scores.
Conclusions
This study underscores the notable occurrence of osteoporosis and osteopenia among patients undergoing treatment for endocrine disorders. Consequently, it emphasizes the necessity to systematically assess bone health in any endocrinopathy that may lead to rheumatological complications. Additionally, it highlights the importance of a thorough etiological investigation, aiming to identify an underlying endocrine pathology before the onset of osteoporosis or osteopenia.

Special case: giant invasive macroprolactinoma complicated by cerebrospinal fluid rhinorrhea and meningoencephalitis

Gema Martinez Tames[1], Sana Abid[2], Hanene Sayadi[2], Farah Ayechi[2], Raoua Naouar[2], Ghassen Belkahla[3], Atef Ben Nsir[3], Bilel Ben Amor[2], Ekram Hajji[2], Ines Bayar[2], Héla Marmouch[2], Inès Khochteli[2], Mahdi Darmoul[3] & Gema Martinez Tames[1]
[1]Hospital Valle del Nalon, Servicio de Endocrinología y Nutrición, Spain; [2]Fattouma Bourguiba Hospital, endocrinology and internal medicine department, monastir; [3]Fattouma Bourguiba Hospital, Neurosurgery department, monastir

Introduction
Prolactinomas are the most commun secreting adenomas of the pituitary gland. They are classified according to their sizes into microprolactinomas (<10mm long axis) and macroprolactinoma ($>=10$mm long axis). According to studies its prevalence is approximately 3.5-5 for 100000 inhabitants. The diagnosis is made by the blood prolactin assay as well as the pituitary magnetic resonance imaging (MRI) which is the radiological reference exam to evaluate the dimensions of the adenoma. The severity of these tumors mainly depends on their size.
Methods
we conducted a monocenter cross-sectional analytical study including 40 patients with confirmed prolactinoma followed in the Endocrinology Diabetology and neurosurgery departments of the Fattouma Bourguiba Hospital of Monastir during the period from January 2000 to march 2022.
Results
A 30-years-old patient with no medical history was reffered to our department for exploration of a pituitary macroadenoma. The circumstances of discovery were the onset of headaches with progressive decrease of visual acuity and bilateral amputation of the visual field for which he consulted an ophtalmologist. A brain CT revealed a sellar and parasellar tumor with hormonal assessment of hyperprolactinemia at 258ng/ml. The diagnosis of macroprolactinoma was made on the basis of hyperprolactinemia confirmed twice (258 and 296 ng/ml) and the presence on pituitary MRI of a macroadenoma measuring 25*26*40mm with extrasellar extension. The patient was treated with cabergoline withe a dose up to 2 mg/week. The evolution was marked bay the regression of the tumor size on the MRI in a year but we noticed the appearance of a cerebrospinal rhinorrhea complicated by pneumococcal meningoencephalitis for which he recieved an appropriate antibiotic therapy with a good clinical and biological progress. The pituitary scan showed the presence of a sphenoidal gap with lysis of sellar turcica. After that, the patient underwent transphenoidal surgery with biopsy of the adenomatous tissue and multilayer repair of the breach. The post operative evolution was simple with rhinorrhea drying up. The pathological and immunohistochimical study showed a lactotroph pituitary adenoma. The further evolution was marked by improvment of headaches and visual disturbances with a partial tumor response and biological remission under cabergoline 1 mg/week.
Conclusion
Prolonged and regular multidisciplinary collaboration seems to be essential for optimizing the management of these patients with endocrine, ophtalmological, neurosurgical, and radiological evaluation at initial diagnosis and throughout follow-up.

Pasireotide induced diabetic ketoacidosis in a patient with secondary diabetes with acromegaly

Nishchil Patel[1,2] & Daniel Flanagan[1]
[1]University Hospital Plymouth NHS Trust, Endocrinology and Diabetes, Plymouth, United Kingdom; [2]University Hospital Plymouth, Endocrinology and Diabetes, Plymouth, United Kingdom

Background
We report this interesting case of worsening diabetes and diabetes ketoacidosis in a young male with acromegaly who was commenced on Pasireotide treatment.
Case Report
This 30 years gentleman was diagnosed with Acromegaly in April 2015. He underwent trans- sphenoidal surgery in January 2016 with significant residual tumour post-surgery. His IGF1 remained elevated and was unresponsive to Lanreotide. He was commenced on adjuvant therapy with Pasireotide, in early 2017 under the Novartis clinical trial. He was also found to have partial hypopituitarism, and required hydrocortisone and testosterone replacement. He was found to have elevated HbA1c- 55 mmol/mol in April 2016. He was initiated on Metformin and Sitagliptin treatment along with lifestyle and dietary advice. Two months after commencement of Pasereotide, he was admitted with an episode of severe diabetic ketoacidosis (DKA) with no other obvious precipitant. His HbA1c at the time was 75 mmol/mol. Basal bolus regime of insulin was commenced along with Metformin. His HbA1c improved over time with insulin treatment and regular diabetes team input.
Conclusion
Pasereotide is a novel multi-receptor-targeted somatostatin receptor ligand used in therapy for acromegaly. It has been associated with hyperglycemia and DKA in patient with Acromegaly and Cushing's disease. The hyperglycemia is attributed to reduced insulin secretion and incretin response. This case highlights the need for closer monitoring of HbA1c and glycaemic control in patients with acromegaly and diabetes, and more so for those on Pasireotide therapy.

Early gestational diabetes vs late gestational diabetes: are there any differences?

Leire Garaizabal Azkue[1], Ihintza Larrañaga Unanue[1], María Magdalena Arteaga Ossa[2], Ainhoa Etxaniz Cerezo[1], Celia Bravo Ansorena[1] & Maite Unamuno Lecuona[2]
[1]Mendaroko ospitalea, Mendaro, Spain; [2]Hospital Alto Deba - Osakidetza, Arrasate, Spain

Whether frequency of complications during pregnancy increases when gestational diabetes (GD) is diagnosed early (<24 weeks) compared to late (>24 w) is not fully define. Observational studies suggest fasting glucose values (>92 mg/dl) during the first trimester are associated with adverse perinatal outcomes.
Objectives
describe the characteristics of pregnant women with GD, the frequency of complications during pregnancy and delivery and assess the differences between early and late diagnosis of GD.
Material and methods
Retrospective study of 70 women with GD diagnosed between 2022 and 2023 in two second level hospitals. We described demographic, anthropometric and clinical data, and compared obstetric-perinatal outcomes according to whether GD was early or late.
Results
Of all women, 64.3% were non-European (North Africa 28.6%, South America 22.9% and Pakistan 10%), mean age of 34 ± 5.74 years. 42.9% had early GD. The reasons for 1st trimester screening were BMI, previous GD and age (42.8%, 31.42% and 28.6%, respectively). The mean BMI of the early GD group was 31.91 kg/m^2 vs 28.64 kg/m^2 in the late group ($P=0.003$) and 1st trimester fasting glucose and O'Sullivan score were higher in the early group (98.93 mg/dl vs 89.88 mg/dl ($P=$NS) and 197 mg/dl vs 171 mg/dl $P<0.001$). Insulin was required in 47.1% of the sample, the majority in the early group (18/30 vs 15/40 ($P=$NS)). Only 5/18 were insulinised in the 1st trimester, 15 in the 2nd and 13 in the 3rd trimester. There were differences in the need for insulin according to origin: 60% of non-European vs 24% of Europeans ($P=0.004$). Regarding delivery, 8 patients had a preterm birth: 15% on the late group vs 6.6% on the early group ($P=$NS). Of all new-borns, 9 had neonatal hypoglycaemia, without differences between clusters. Hypoglycaemia was not related to prematurity, macrosomia or small for gestational age (SGA). 37% had complications during pregnancy ($P=$NS), being pre-eclampsia/HT the most frequent (12.9%). Large for gestational age (LGA) new-borns were higher in the early GD group (26.6% vs 17.5%, $P=$NS).
Conclusions
- In our setting, early diagnosed GD does not increase the frequency of obstetric complications, although there is a higher rate of LGA new-borns. It would be necessary to assess differences according to the degree of GD control.
- Basal glycaemia in first trimester was higher in the early GD cluster. It is necessary to evaluate it as a risk factor for the development of GD.

Latvian health professionals' knowledge of diabetes mellitus and safe driving: a survey

Katrīna Elīna Bērziņa[1] & Ingvars Rasa[2]
[1]Rīga Stradiņs University, Faculty of Medicine, Rīga, Latvia; [2]Riga East Clinical University Hospital, Outpatient, Rīga, Latvia

Background
Hypoglycemia refers to blood glucose levels dropping below 4.0 mmol/l, which can cause dizziness and confusion in those with diabetes. In severe cases, patients may experience seizures, vision problems, and cognitive impairment. It is unsafe to drive while in this state of mind. Health professionals (HP) must possess the necessary expertise to educate patients on this matter and ensure their safety.
Aims
The current study aimed to investigate HP's endocrinologists, internists, and family physicians' understanding of diabetes mellitus (DM) and safe driving practices.
Methods
The survey was conducted from 2022 to January 2024, with a total of 140 respondents. HP in Latvia received a 17-question original, anonymous questionnaire. IBM SPSS 29.0 was used to analyze the results.
Results
HP's mean age was 48.1 ± 15.4 years. 86.4% ($n=121$) of the respondents were females. Of the respondents, 9.3% ($n=13$) were endocrinologists, and 90.7% ($n=127$) were internists or general practitioners. HP work experience ranged from 1 to 55 years. 15% ($n=21$) did not believe that DM is a risk factor for car accidents. Of those 85% ($n=119$) who believed that DM is a risk factor, 66.4% ($n=79$) educated their DM patient about safe driving. 97% ($n=136$) consider frequent and severe episodes of hypoglycaemias to be a contraindication for driving, but only 39% ($n=53$) of them had advised their DM patients not to drive. 88.6% ($n=124$) believed that not recognizing hypoglycaemia is a contra-indication for driving, but only 38.7% ($n=48$) recommended that DM patients measure their blood glucose levels before driving. Information materials on hypoglycaemia and safe driving were not available at the workplace of 80% ($n=112$) of respondents, but 62.5% ($n=70$) of them discussed the topic of diabetes and safe driving. Of the 20% ($n=28$) who had informational materials in the workplace, 82.1% ($n=23$) discussed the topic of diabetes and safe driving. Only 33.6% ($n=38$) of respondents knew that blood glucose levels below 4.0 mmol/l are unsafe for driving.
Conclusions
Less than half of health professionals educate DM patients about safe driving despite their knowledge of the increased risks associated with diabetes mellitus. Healthcare providers must receive education about DM and safe driving to inform their patients better.

A case of HARS2-related perrault's syndrome

Amina Al-Qaysi, Yuyu Kyaw & Janan AlAjaimi
Buckinghamshire Healthcare NHS Trust, United Kingdom

Introduction
Amenorrhea is a frequent cause of Endocrinology clinic attendances. While causes like menopause, thyroid disorders and hyperprolactinemia are common, less common aetiologies need to be considered, especially the inherited ones that could affect a patient's family. Identifying rare conditions requires constant vigilance, as well as clinical experience and the knowledge of the diagnostic criteria.
Case report
We report the case of a 39-year-old female that attended our Endocrinology clinic for secondary amenorrhea since the age of 29 years and hypergonadotropic

hypogonadism due to premature ovarian failure. Her parents are first cousins, she has also married her first cousin whose parents are distant cousins. She was diagnosed with bilateral sensorineural hearing loss at the age of five years requiring cochlear implant, and her son suffered from autistic spectrum disorder and bilateral sensorineural hearing loss at a young age as well. Perrault's Syndrome was highly suspected, and genetic testing revealed two alterations in the HARS2 gene which is linked to Perrault's syndrome. She was found to have small ovaries on ultrasound and bone densitometry revealed normal bone density. The Clinical Genetics team is arranging genetic counselling and testing for her family.
Conclusion
Perrault's syndrome is a rare condition that is inherited in an autosomal recessive pattern, resulting in ovarian dysgenesis and bilateral sensorineural hearing loss. The spectrum of this condition also includes cerebellar ataxia, motor-sensory peripheral neuropathy, and learning difficulties. The management of these cases includes the management of its manifestations, with no available treatments or gene therapy yet. Identifying carriers of autosomal recessive disorders within families is crucial for understanding the likelihood of passing on the condition to future generations.

Primary hyperparathyroidism related to mediastinal ectopic parathyroid adenoma: about 2 cases

Lamiae Zarraa[1], Siham Rouf[1,2] & Hanane Latrech[1,2]
[1]Endocrinology-Diabetology and Nutrition Department Chu Mohamed VI, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy Mohammed Premier University Oujda, Morocco, Oujda; [2]Morocco, Laboratory of Epidemiology, Clinical Research and Public Health, Faculty of Medicine and Pharmacy Mohammed Premier University Oujda, Morocco, Oujda

Introduction
Primary hyperparathyroidism is a frequent endocrinopathy characterized by a disorder of phosphocalcic metabolism related to an inappropriate secretion of parathyroid hormone (PTH). Parathyroid adenoma can be located ectopically and represents a particular diagnostic and therapeutic challenge. We report 2 clinical cases of ectopic parathyroid adenoma in mediastinal location.
Observations
Case 1: A 47-year-old patient without any pathological history consulted for paresthesias associated with diffuse joint pain predominantly in the shoulders. The biological assessment revealed hypercalcemia at 146 mg/l, and hypophosphatemia with hypercalciuria at 323 mg/24h. The diagnosis of primary hyperparathyroidism was confirmed by a biointact PTH 1-84 assay at 925 pg/ml on an ectopic parathyroid adenoma located in the upper mediastinum which became intensely and heterogeneously enlarged after injection of PDC measuring 44*20 mm. This nodule insinuated itself into the later-aortic-cava. The management was first medical obtaining normocalcemia followed by surgical treatment with a low cervical approach, the postoperative course was simple and the anatomopathological study was in favor of a benign parathyroid adenoma without signs of malignancy.
Cas 2: This is a 59-year-old patient with recurrent renal lithiasis, the etiological finding revealed hypercalcemia at 120 mg/l on a primary hyperparathyroidism with a bio-intact PTH level at 414 pg/ml, and the cervical ultrasound localized a left posteroinferior parathyroid adenoma, the patient was operated and the anatomopathological study concluded to a parathyroid adenoma. Postoperatively, hyperparathormonemia with hypercalcemia was noted, hence the indication of parathyroid scintigraphy which revealed the presence of a mediastinal parathyroid adenoma, the patient refused the surgical treatment and she was put under medical treatment by calcimimetic (Mimpara) with a favorable clinical and biological evolution, especially of the calcemia.
Discussion-Conclusion
Primal hyperparathyroidism is a frequent pathology that requires a topographic diagnosis to rectify surgery when indicated. Ectopic parathyroid adenoma is a rare entity and the advent of new radiological techniques including parathyroid scintigraphy has allowed the topographic diagnosis of this entity.

Diabetes and depression -a cyrculus vitiosus: case report

Snjezana Popovic Pejicic[1,2], Nina Pejicic[1,2], Valentina Soldat Stankovic[1,2], Gabrijela Malesevic[1,2] & Anja Jankovic Pejicic[3]
[1]University of Banja Luka, Faculty of Medicine, Banja Luka, Bosnia and Herzegovina, Banja Luka; [2]University Clinical Center of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina, Banja Luka, Bosnia and Herzegovina; [3]Medical University of Vienna, Wien, Austria

Introduction and aim
Depression has a strong impact on psychosocial as well as medical outcomes in patients with diabetes. Consequently, depression treatment in diabetes is also aimed at improvement of glycemic control and reduction of diabetes complications and mortality risk.. Up to now, no single treatment that consistently leads to better medical outcomes in patients with both depression and diabetes has been clearly identified.
Matherial and methods
Patient was a 61 year old male worker, married. He has low educational and socioeconomic status and has been treated for type 2 diabetes with oral antidiabetics for 10 years. The predictors of depression were longer duration of diabetes, low social support and unemployment. Due to high glycemic values in daily profile and HbA1c 9.8% for the past 3 months, intensified insulin therapy was started, but was not regularly monitored. Fifteen days before he was admitted to the Clinic for Psychiatry, University Clinical Center of the Republic of Srpska, he became irritable, overwhelming, troubled by small things, complained of malaise, loss of energy and strength. On admission the following symptoms are present psychiatric interview was done; psychological, somatic and neurological status;routine laboratory tests with the daily glycemic profile and HbA1c; EEG; psychological testing; Beck's Depression Assessment Scale showed score of 57.
Results
Because of high glycaemic levels endocrinologist was adjusted insulin and antihypertensive therapy. Psychiatric condition stabilized on applied treatment and improvement of glycoregulation. The score on Beck's scale was reduced to 12, and he was discharged with recommendations for follow ups with endocrinologists and psychiatrists. Selective serotonin reuptake inhibitors, antipsychotics in low doses, anxiolytic and psychotherapy was used. Treatment according to endocrinologist's suggestion Structured education program "Düsseldorf model" After structured education HbA1c levels decreased by 1.8% after 6 months (9, 8 to 8, 0%) and by 1.2% after 12 months, compared to initial levels (9, 8 to 8, 6%) The score on Beck's scale was reduced from 57 to 12, and patient was discharged with recommendations for follow ups with endocrinologists and psychiatrists.
Conclusion
It could be concluded that presence of depression is likely predictor of poor metabolic control of diabetes. Structured education program is efficient in improving glycaemic control in patients with type 2 diabetes. It motivates patients in achieving better glycaemia control. There is a decline in motivation after 12 months resulting in glycoregulation impairment and need for re-education at least once a year.

A case of combined PTH-dependent and PTH-independent hypercalcemia

Larisa Danilova, Galina Korolenko, Irina Bourko, Maxim Lushchyk & Alexei Ramanouski
Institute for Advanced Training and Retraining of Healthcare Personnel, Belarusian State Medical University, Endocrinology, Minsk, Belarus

Patient D., 74 years old, suffering from type 2 diabetes mellitus, was urgently taken to hospital No. 10 in Minsk with complaints of weakness, nausea and dry mouth. On admission glycemia was 26 mmol/l. Laboratory examinations revealed elevated levels of urea - 34.5 mmol/l, creatinine - 238.2 μmol/l, calcium - 3.12 mmol/l, extremely low levels of vitamin D - 4.8 ng/ml, high levels of parathyroid hormone - 101.3 pg/ml. The laboratory ratio of calcium and parathyroid hormone was assessed as parathyroid hormone-dependent hypercalcemia. An ultrasound examination of the thyroid and parathyroid glands did not reveal any pathological formations. No focus of high uptake of the Te99m MIBI around the parathyroid gland was also identified. Clinical diagnosis: primary hyperparathyroidism in the absence of visualization of the source of parathyroid hormone production. Severe vitamin D deficiency. Type 2 diabetes. Arterial hypertension grade 2. Nephropathy of combined origin. CKD C4 (eGFR 29.4 ml/min/1.73 m^2). She was discharged for outpatient treatment after calcium values normalized. After 3 weeks, the patient was again admitted with complaints of severe general weakness, thirst, frequent urination, nausea, vomiting and dizziness. Extremely high values of total calcium were noted – 4.26 mmol/l. The condition was regarded as the onset of a hypercalcemic crisis. Conservative therapy did not lead to normalization of serum calcium. New ultrasound examination of right parathyroid gland revealed a hypoechoic formation 21.5*7.8*11.3 mm similar to

a parathyroid adenoma, in the thickness of the left lobe - an isoechoic node measuring 12.2*14.0*18.6 mm and altered lymph nodes in the supraclavicular areas. A trephine biopsy of the cervical lymph node was performed, and sarcoid-type granulomas were identified. During surgery, the altered lower parathyroid gland on the right and the left lobe of the thyroid gland were removed. By the evening after surgery the level of calcium in serum decreased to 2.32 mmol/l; after 10 days, the level of calcium was above 3 mmol/l with a steady increase to 3.96 mmol/l, while the level of parathyroid hormone decreased. A diagnosis of sarcoidosis was made. The patient received methylprednisolone at a dose of 32 mg daily. A day after starting methylprednisolone, calcium levels gradually began to decrease. In the presented clinical case, a thorough analysis of clinical, laboratory and instrumental data revealed a rare combination of parathyroid hormone-dependent and parathyroid hormone-independent hypercalcemia. The patient was diagnosed with primary hyperparathyroidism and sarcoidosis with involvement of the mediastinal and cervical lymph nodes.

EP1333

A case report of a patient with severe postoperative hypoparathyroidism

Marina Milotić, Daniela Fabris Vitković, Mariza Babarović-Jurišić, Aleksandra Blagonić, Manuela Ferjančić & Marina Milotic
General Hospital Pula, Endocrinology and Diabetology, Pula, Croatia

Beckgrounds and aims
The most common cause of hypoparathyroidism is postoperative, i.e., after thyroid, parathyroid, or radical neck surgery due to neoplasms, and is most often transient, whether continuous or even intermittent. The incidence of permanent hypoparathyroidism ranges from 0.8 to 3.0% in patients after total thyroidectomy. In this case report, we will present a patient with a severe form of postoperative hypoparathyroidism refractory to standard treatment regimens.
Methods
A 49-year-old patient underwent total thyroidectomy due to recurrent hyperthyroidism and diffuse goiter. Postoperatively, she received levothyroxine, cholecalciferol, and calcium carbonate. Two months after the procedure, the patient complained of tingling in her hands, feet, and face and spasms of the esophagus. Since then, lower values have been constantly observed in the findings of total and ionized Ca with immeasurably low PTH. The dose of drugs was gradually increased (cholecalciferol: 25 000 IU once a week; calcitriol: up to 4.5 mg; calcium carbonate: up to 6 g; magnesium citrate: 300–400 mg per day) with frequent applications of calcium gluconate infusion, without improvement. Since rhPTH (l-84) is not available in our country, we started with subcutaneous administration of teriparatide with a gradual increase in the dose up to 3x20 mg per day, but without improvement. After reviewing the literature, we decided to use teriparatide via an insulin pump.
Results
After the introduction of the catheter-less pump, the serum Ca values quickly normalized, and during the following 3 months, they were maintained at reference values with a stable dose of teriparatide (24 mg/24 h). On January 5 2023, the patient switched to a catheter pump, and since then, large oscillations of serum Ca have been monitored again with symptoms of hypocalcemia and the need for constant correction of the teriparatide dose. On April 28 2023, she switches again to a catheter-less pump with stabilization of the general condition and the dose of teriparatide (18 mg/24 h).
Conclusions
Although chronic postoperative hypoparathyroidism rarely occurs, in most cases it is easily resolved with the use of vitamin D and calcium supplements. In a small number of patients, it is necessary to apply replacement therapy with a parathormone analogue. In our case, the patient stabilized only after continuous use of teriparatide via an insulin pump.

Severe hypomagnesemia: outpatient management in endocrinology and nutrition unit

Ana María Moyano-Sánchez[1], Ángel Rebollo-Román[1], Mª Carmen Serrano Laguna[1], Alfonso Jesús Calañas Continente[1], Maria José Molina[1] & Maria Angeles Galvez Moreno[1]
[1]Hospital Universitario Reina Sofia, Endocrinology And Nutrition Unit, Córdoba, Spain

Magnesium disorders are common in clinical practice. Hypomagnesemia is seen in inherited disorders, with excessive gastrointestinal or renal losses and due to medications. Replacement of magnesium can be challenging, with oral replacement strategies being generally more effective at slowly replacing body storages and intravenous (iv) replacement being more effective at treating life-threatening and severe cases of hypomagnesemia.
Objective, material and methods
To analyze clinical history and evolution of a group of patients with severe hypomagnesemia who received treatment with iv magnesium in the Endocrinology and Nutrition day hospital center of a tertiary hospital during 2023.
Results
7 patients. 5 men. Mean age: 62.6 years. Follow-up 40.9 months. Hypomagnesemia causes: - Short intestine syndrome (5), etiology: Crohn disease (3), surgery complications (1) and radical enteritis (1). - Chronic diarrhea syndrome with Gitelman syndrome (1). - Malabsortion syndrome post bariatric surgery (1). No diagnosis of severe hypomagnesemia due to pharmacology causes. 3/7 with ileostomy. Two patients received additional treatment with iv suerotherapy weekly. One received domiciliary daily suerotherapy through PICC. 3/7 with chronic renal disease. 4/7 chronic consumers of PPIs at start of follow-up. 3/7 maintained it at the end of follow-up as part of high debit ileostomy treatment. 2/7 went to the emergency department during follow-up for neurological complications in the form of vegetative symptoms followed by distal paresthesias and dizziness. The most frequent frequency of infusion was once a week, except for one patient who received iv magnesium infusion every 4 days. As for the amount of magnesium administered, the mean was 585 mg iv per week, with a maximum of 900 mg iv per week and a minimum of 300 mg iv every 15 days. All patients received oral supplementation with magnesium, on average 745 mg/day. 5/7 received oral calcium supplementation, mean 960 mg/day. 3/7 were receiving oral potassium supplementation, mean 2400 mg/day. Magnesium levels improving during the follow-up (initial compared to last visit) [0.91 vs 1, 44 mg/dl (t -3.17 p.019)]. 3/7 treated with oral nutritional supplements because of malnutrition (GLIM criteria). No significant changes in weight and BMI during follow-up.
Conclusions
In our series, the pathology that led to treatment with iv magnesium and high-dose oral supplementation was mainly due to digestive and malabsorption causes. Close monitoring, as well as joint treatment with iv magnesium and high-dose oral supplementation, achieved significant improvements in magnesium blood levels in our sample.

Adipsic central diabetes insipidus as a result of neurosarcoidosis

Radmila Milosheska[1], Ivana Mickovski[1,2] & Daniela Buklioska Ilievska[2,3]
[1]General City Hospital "8th September", Endocrinology, diabetes and metabolic disease, Skopje, Macedonia; [2]Faculty of Medical Sciences, Goce Delcev University Stip, Stip, Macedonia; [3]General City Hospital "8th September", Pulmonology and Allergology, Skopje, Macedonia

Background
Sarcoidosis is a multisystemic disease, the cause of which has not yet been determined. It's characterized by the appearance of granulomas, which typically target the lungs, the lymphatic system and in rare cases, around 5-15%, changes in the nervous system are observed. Neurosarcoidosis leads to hypothalamus-pituitary axis dysfunction and the most common clinical manifestation is the onset of central diabetes insipidus.
Case report
We present the case of a 46-year-old female patient with neurosarcoidosis and changes in the hypothalamus-pituitary axis and clinical manifestation of hypopituitarism, along with a non-typical presentation of central diabetes insipidus. The diagnosis of neurosarcoidosis has not been confirmed with a biopsy due to its high risk and difficulty to access. However, according to the CT and MRI results and the clinical presentation, an intensive hormone replacement therapy was administered to reduce the clinical symptoms. What is notable about this case is the diagnosis for central diabetes insipidus, which could not be confirmed based on the clinical characteristics because of the absence of polydipsia and polyuria, as well as with the classic water deprivation test because of persistent hypernatremia, which was confirmed by excluding other potential causes of hypernatremia.
Conclusion
Neurosarcoidosis has a rich clinical presentation and is a challenge when it comes to diagnosis and treatment, particularly with patients with disorders in the hypothalamus-pituitary axis and non-typical adipsic central diabetes insipidus.
Keywords: neurosarcoidosis, central diabetes insipidus, hypernatremia

An uncommon cause of high gonadotropins and testosterone in a 53-year-old male

Maria Mathiopoulou, Maria Iris Romay, Anna Mavromanoli, Martin Bucher & Roger Schneiter
University Hospital of Zürich, Zürich, Switzerland

A 53-year-old male was referred to the endocrinology outpatient clinic due to elevated levels of gonadotropins and testosterone (LH 11.7 IU/l, reference range 1.7-8.6 IU/l; FSH 17.7 IU/l, reference range 1.5-12.4 IU/l; testosterone 40.9 nmol/l, reference range 6.68-25.70 nmol/l; free testosterone 712.7 pmol/l, reference range 163-473 pmol/l) noted during an annual urologic check-up. No spermiogram was performed, and testicular ultrasound showed no abnormalities. The patient reported no physical complaints other than chronic fatigue and reduced energy since experiencing an occupational burnout 2 years ago. He was not on any medications but regularly consumed Withania somnifera (Ashwagandha) and Tinospora cordifolia. These herbs are commonly used in alternative medicine to alleviate anxiety, stress, and fatigue. MRI imaging showed no signs of pituitary lesions. Despite discontinuation of the herbal remedies, gonadotropin and testosterone levels remained elevated even after 3 months. Withania somnifera contains substances such as steroid lactones, phytosterols, and alkaloids. Phytosterols, resembling cholesterol, can serve as precursors to steroid hormone synthesis. According to the Memorial Sloan Kettering Cancer Center database, Withania somnifera may increase testosterone levels for this reason, as demonstrated in a randomized, double-blind, placebo-controlled study. The cause of elevated gonadotropins remained unclear and requires further investigation. Tinospora cordifolia also contains phytosterols, but data on its effect on steroid hormone synthesis is limited to animal models. Although no definitive effect on steroid hormone synthesis has been proven, it cannot be excluded. Determining a causal relationship between drug use and observed adverse drug reactions involves intrinsic evidence (temporal relationship with drug exposure, dechallenge and rechallenge if applicable, exclusion of other causes, pathophysiological plausibility) and extrinsic evidence (well-documented comparable cases in drug information, pharmacovigilance databases, systematic clinical or epidemiological studies, and possibly case reports). In this case, a clear temporal relationship was observed between the intake of herbal remedies and elevated testosterone levels. Other likely causes were ruled out, and the pathophysiology involving phytosterols as steroid hormone precursors is plausible. The absence of intrinsic evidence is due to the lack of a positive dechallenge, as gonadotropin and testosterone levels remained high after discontinuation. However, extrinsic evidence from a randomized, double-blind, placebo-controlled study, although rare for alternative remedies, supports the conclusion that hypergonadotropic hypergonadism may be caused by Withania somnifera.

Sarcoidosis and hypothalamohypophyseal insufficiency: a case report

Hajar Azagouagh, Talbi Dounia, Karimi Meryem, Sebbar Ghizlane, Rifai Kaoutar, Iraqi Hind & Mohamed Elhassan Gharbi
Chu Ibn Sina, Endocrinology, Rabat

Introduction
Sarcoidosis is a multisystem inflammatory disease. Hypothalamic-pituitary involvement in sarcoidosis is rare and poorly described. We report here a case of pituitary insufficiency during sarcoidosis disease.
Observation
Patient aged 49 years, followed for systemic sarcoidosis with cutaneous, pulmonary and ocular tropism for 7 years, admitted for exploration of a severe polyuro-polydipsic syndrome with four nocturnal awakenings, questioning revealed secondary amenorrhea for 2 years, and physical examination found signs of intra- and extra-cellular dehydration. After eliminating the obvious causes of polyuro-polydypsic syndrome, namely diabetes mellitus and hypercalcemia, the diagnosis of diabetes insipidus was made in view of a low urinary osmolarity of 122 mosmol/l and a plasma osmolarity of 289 mosmol/l. A hormonal workup showed corticotropic, thyrotropic and gonadotropic insufficiency, and a hypothalamic-pituitary MRI revealed a hypothalamic sarcoid granuloma. We put the patient on a vasopressin test, and retained the diagnosis of central diabetes insipidus in view of the improvement in the polyuro-polydipsic syndrome and the increase in urinary osmolarity to 580 mosmol/24h. Therapeutically, our patient was put on hormone replacement therapy and vasopressin spray with a good clinical and biological evolution.
Discussion and conclusion
Neurosarcoidosis affects 5-26% of sarcoidosis patients. Hypothalamohypophyseal involvement is exceptional. It accounts for 0.5% of sarcoidosis cases, MRI provides diagnostic support in cases of clinical suspicion. The most common endocrine disorders are diabetes insipidus and hyperprolactinemia, thyrotropic insufficiency and, to a lesser degree, hypogonadism, hence the need to screen for hypothalamic-pituitary involvement in the presence of systemic sarcoidosis.

Rethinking how we classify pituitary tumours: insights from a serious case of prolactinoma

Waiel Bashari[1,2] & Azmi Mohammed[2]
[1]Addenbrooke's Hospital, Endocrinology, Cambridge, United Kingdom; [2]Sudan Pituitary Foundation, Endocrinology, Khartoum, Sudan

Prolactinomas are a common type of pituitary tumours, making up about 40% of these tumours in total, with an estimated occurrence of 40-50 people per 100, 000. They are more common in women, especially during their reproductive years, but they can affect anyone at any age. Although most prolactinomas are small and respond well to treatment, around 2-10% are aggressive, growing into nearby areas like the cavernous sinus or sphenoid bone. The World Health Organisation's 2017 guidelines classify pituitary tumours based on various factors, aiming to improve diagnosis, treatment, and research. However, these guidelines might not always capture the severity of certain tumours, as seen in our case of an aggressive prolactinoma that led to a patient's death.
Case presentation
We present a 22-year-old male who was admitted with visual bilateral field loss and was found to have a large pituitary lesion with a serum prolactin that is 65000 my/l. A working diagnosis of macroprlactinoma was made and he was treated with an escalated dose of cabergoline, with concomitant replacement of partial anterior pituitary hormone deficiency. After a few months of treatment his tumour had reduced and the vision improved, however, a phase of tumour re-growth took place with complete resistance to dopamine agonist therapy. The tumour invaded the skull base and grew outside his mouth in as short a period as 3 months. Despite efforts for maximum DA dose escalation (reaching 1-2 mg/day) and debulking surgery followed by radiotherapy, his health had deteriorated rapidly and he developed tumour infection and became unfit for chemotherapy options (e.g., temozolamide). He unfortunately succumbed to a cranial infection shortly after that. Although his tumour had not metastasised, it was treatment resistant and locally aggressive, which then led to his death. This case illustrates the need for a more nuanced approach to classifying prolactinomas, especially aggressive ones in young males. It suggests that factors like local tumour invasion should be given more standing in the classification, similar to how other cancers are evaluated (e.g., TNM classification). This could help in better understanding and treating these aggressive tumours.

EP1339

Pediatric pituitary microadenomas: a spectrum of clinical presentations and therapeutic responses"

Noor Hamed, Nada Alaaraj, Shayma Mohamed, Fawzia Alyafei & Ashraf Soliman
Hamad General Hospital, Doha, Qatar

Pituitary microadenomas in children and adolescents are relatively rare, accounting for a small percentage of pediatric endocrine disorders. These benign tumors often present a diagnostic challenge due to their subtle and variable clinical manifestations at this young age. We present clinical and lab data of 5 children with pituitary microadenoma. Case 1: A 12-year-old female with a history of short stature and slow growth velocity was diagnosed with a small pituitary microadenoma. Despite the presence of this lesion, her growth hormone stimulation test was suboptimal, and MRI imaging showed a slightly smaller pituitary gland. Treatment with somatropin led to a significant improvement in height. Case 2: This case involves a 12-year-old female with recurrent headaches, vomiting, dizziness, blurring of vision, early menarche, and recent amenorrhea. MRI confirmed a pituitary microadenoma. She exhibited signs of hormonal imbalances, including elevated ACTH, cortisol, and prolactin levels, suggesting a complex endocrine interaction. Case 3: A 12.4-year-old girl with a history of headaches and fatigue, and a family history of hypothyroidism, was found to have central hypothyroidism and a pituitary microadenoma. Despite levothyroxine treatment, her growth velocity remained low, and her final height was significantly below the mid-parental height. Case 4: This 7-year 10-month-old girl presented with premature thelarche and pubarche. An MRI revealed a

Case	Age	Sex	Clinical Manifestations	Lab Data	MRI Data	Treatment
1	12 years	Female	Short stature, slow growth velocity	WtSDS: -2.22, HtSDS: -2.6, GV: 4 cm/year, IGF1 SDS: -1.81, GHST peak: 5.2 mcg/L	Slightly smaller pituitary gland, microadenoma (2.2 x 2 mm)	Somatropin 0.035 mg/kg/day
2	12 years	Female	Recurrent headaches, vomiting, dizziness, blurring of vision, early menarche, recent amenorrhea	BMISDS: 2.5, Advanced bone age, High HOMA IR, ACTH: 69.5pg/ml, Cortisol: 492nmol/l, Prolactin: 477mIU/L, IGF1SDS: 1.8	Normal height pituitary gland, microadenoma (4.7 x 4.9 x 5.3 mm)	Planned for GH suppression test, pelvic US, salivary cortisol
3	12.4 years	Female	Headaches, fatigability, central hypothyroidism	Low FT4: 11.7pmol/l, TSH: 2.8pmol/l, Negative thyroid autoantibodies, IGF1 SDS: -1.28, GHST peak: 6.7 mcg/L	Globular pituitary gland, microadenoma (2 x 9 x 5 mm)	Levothyroxine 50 mcg daily
4	7 years 10 months	Female	Premature thelarche, pubarche, accelerated growth	Advanced bone age, LH: 8.7 IU/L, FSH: 6.5 IU/L, Estradiol: 130 pmol/L, IGF1: 531.0 ug/L	Microadenoma (3.3 mm diameter)	GnRH analogue monthly injections
5	2.8 years	Female	Premature thelarche, accelerated growth	LH: 0.8 basal, 9 peak, FSH: 2.8 basal, 57 peak, Estradiol: 202, IGF1SDS: +3.1, Bone age: 3.5 years	Microadenoma (3.4 x 2 mm)	Triptorelin

microadenoma in the anterior lobe of the pituitary. Her case was complicated by advanced bone age and elevated hormone levels, indicating early pubertal development. She was treated with GnRH analogue injections. Case 5: A 2.8-year-old girl presented with premature thelarche and accelerated growth. Her hormonal profile and advanced bone age suggested early pubertal changes, and MRI confirmed a pituitary microadenoma. She started on triptorelin for management. Clinical and Lab data of the five cases of pituitary microadenoma

Conclusion

These cases collectively demonstrate the diverse presentations of pituitary microadenomas in pediatrics, ranging from growth disturbances to early pubertal changes. The importance of a comprehensive endocrine evaluation and individualized treatment approach in managing these patients is emphasized. The outcomes varied, reflecting the complexity of pituitary disorders in pediatric populations.

Features of diagnosis and treatment of fulminant hypercortisolism due to ACTH-producing pheochromocytoma: a clinical case

Laura Ebanoidze, Ekaterina Pigarova, Dmitry Beltsevich, Anastasia Sheve, Larisa Dzeranova, Ivan Sitkin, Natalya Tarbaeva, Angelina Khairieva, Michail Degtyarev & Ekaterina Bondarenko
Endocrinology Research centre, Neuroendocrinology, Moscow

Introduction

Statistical data show that in the etiological structure of ACTH-ectopic syndrome pheochromocytoma occupies one of the last places in terms of frequency of occurrence (from 2.8 to 5.6%) Its manifestations such as adrenal mass with ACTH-dependent hypercortisolism lead to significant difficulties in establishing the correct diagnosis.

Clinical Case

A patient with clinical manifestations of hypercortisolism underwent laboratory testing in October 2022: evening saliva cortisol - 220.6 nmol/l (0.5-9.65), evening serum cortisol -1548 nmol/l (64-327), 24-hour urine cortisol -12332.25 nmol/day (100-379); ACTH evening -204.1 pg/ml (2-25.5), morning -313.4 pg/ml (7.2-63.3). Brain MRI with contrast enhancement revealed a microadenoma (3×3.5 mm) in the posterior part of the adenohypophysis. A concomitant search for the source of ACTH ectopia was carried out. According to the abdomen CT: a lesion of the left adrenal gland measuring 37×30×46 mm, a malignant phenotype with a density of 42/49/69/60 HU (active/arterial/venous/delayed phases). Thebilateral selective sampling from the lower petrosal sinuses revealed the absence of thegradient of ACTH secretion (maximum on the right - 1.15; on the left - 1.10). SPECT-CT of the abdominal cavity in the left adrenal gland revealed a formation of soft tissue density measuring 39×30×49 mm, accumulating 99Tc-tectrotide, which confirmed moderately increased expression of somatostatin receptors. Thus, the data obtained supported the extrapituitary genesis of ACTH-dependent hypercortisolism due to pheochromocytoma which was confirmed by 24h-urine analysis - metanephrine - 1122.9 mg/day (25-312), normetanephrine - 1039.11 mg/day (35-445). Taking into account the rate of disease progression, a somatostatin analog (lanreotide autogel 120 mg s.c.) was administered once - without a significant decrease in ACTH secretion (from 313 pg/ml to 243 pg/ml). Ketoconazole 600 mg/day was also prescribed - no effect on 24-hour urine cortisol levels (>35.000 nmol/day). Treatment for complications of hypercortisolism was also initiated. Due to profound hypokalemia (up to 1.9 mmol/l), spironolactone 300 mg/day + kalium chloride 1200 mg were added to therapy. In view of newly diagnosed diabetes due to hypercortisolism, insulin therapy was initiated according. In November 2022 left-side adrenalectomy was performed with preliminary preparation of the α-adrenergic blocker doxazosin with dose escalation to 4 mg/day. Morphological examination revealed pheochromocytoma; immunohistochemistry verified intense expression of chromogranin A and ACTH by pheochromocytoma cells.

Conclusion

Considering the rarity of the described pathology, correct diagnostic tactics make it possible to reliably establish a diagnosis and provide timely medical care before the development of life-threatening cortisol- and adrenaline-mediated complications.

Autoimmune polyendocrinopathy type 2 associated with celiac disease: a case report

Hajar Azagouagh[1], Karimi Meryem[1], Talbi Dounia[1], Sebbar Ghizlane[1], Rifai Kaoutar[2], Iraqi Hind[1] & Mohamed Elhassan Gharbi[1]
[1]Chu Ibn Sina, Endocrinology, Rabat; [2]Chu Ibn Sina, Endocrinology, Rabat

Introduction

Autoimmune polyendocrinopathies (AEP) are rare diseases defined by the presence of at least two endocrine deficiencies linked to an autoimmune mechanism, sometimes with an associated non-endocrine autoimmune disease. Autoimmune polyendocrinopathy type 2 is a more common syndrome, appearing mainly in adults.

Observation

We report the case of a 27-year-old patient, admitted for management of acute inaugural adrenal decompensation, with a history of celiac disease since childhood on a gluten-free diet. Clinically, the patient presented with vomiting and abdominal pain, evolving in a context of altered general condition and melanoderma with slate patches on the inner sides of the cheeks. A blood ionogram showed hyperkalemia at 6.4 mmol/l with hyponatremia at 111mmol/l. We started the patient on hydrocortisone hemisuccinate with intravenous rehydration. Biological investigations revealed low 8-hour plasma cortisol with high ACTH, high anti-21 hydroxylase antibodies, high anti-TPO antibodies with normal TSH, and glycated hemoglobin at 6.3% with positive anti-GAD antibodies. The diagnosis of type 2 AEP was accepted. Treatment consisted of hormone replacement for adrenal insufficiency, with strict monitoring of blood glucose levels and patient education.

Discussion and conclusion

AEP-II combines several autoimmune pathologies, including Addison's disease and autoimmune thyroid disease (Schmidt's syndrome) and/or type 1 diabetes (Carpenter's syndrome). Adrenal insufficiency is the initial manifestation in 50% of AEP-II cases, appearing at the same time as diabetes or thyroid damage in 20% of cases, and occurring after the other manifestations in 30% of cases. Other endocrine components of the syndrome may include primary ovarian failure, rarely testicular failure, and autoimmune hypophysitis. Non-endocrine autoimmune manifestations are polymorphous, dominated by Biermer's disease, vitiligo, celiac disease, rheumatoid arthritis and inflammatory bowel disease. The age of onset of AEP-II varies widely, from childhood to late adulthood, usually between 20 and 40. Celiac disease has become one of the most common diseases in the world. It may be part of a multiple autoimmune disorder. This makes it necessary to screen celiac patients for other autoimmune diseases, in particular Addison's disease.

Mayer-rokitansky-kuster-hauser syndrome: a cause of primary amenorrhea not to be ignored !

Talbi Dounia, Qasdi Ikrame & Guerboub Ahmed Anas
Mohammed V Military Hospital, endocrinology, Morocco

Introduction
Mayer-Rokitansky-Küster-Hauser (MRKH) syndrome is a rare congenital cause of primary amenorrhea, characterized by aplasia of the vagina with or without concurrent uterine and/or cervical aplasia. MRKH syndrome has a heavy psychological impact, and requires multidisciplinary management.
Case Report
A 17-year-old female patient presented for exploration of a primary amenorrhea. Her medical history was significant for recurrent urinary tract infections. Her physical exam was notable for Tanner stage IV pubic hair and Tanner stage V breast development, normal external female genitalia. The hormonal profile was normal with estradiol at 137 pg/ml and the karyotype was 46, XX. A pelvic magnetic resonance imaging revealed an aplastic, blind-ending vaginal canal without an identifiable cervix or uterus. Bilateral ovaries were visualized with normal morphology. The rectum, urinary bladder, kidneys were normal in appearance.
Discussion and Conclusion
Mayer-Rokitansky-Küster-Hauser (MRKH) syndrome is characterized by a physiological development of the secondary sexual characters and by a normal female karyotype 46 XX, but with a congenital aplasia of the uterus and of two/third superior parts of upper vagina. MRKH syndrome is divided into two subtypes: type I and the less-frequent type II (MURCS). 2D/3D ultrasound (US) remains the first-line examination for diagnosing this syndrome, but MRI is more sesitive and specific, and remains the gold standard for accurate diagnosis, with a view to optimal management. The etiology of MRKH, unfortunately, remains unclear. The majority of cases appear to be sporadic; however, rising accounts of familial cases with an autosomal dominant mode of inheritance complicated by an incomplete penetrance and variable expressivity are noted in the literature. In cases involving type II MURCS, disturbances during gastrulation can affect the migration and differentiation of the mesoderm, leading to defects involving the paraxial mesoderm (cervical vertebrae), intermediate mesoderm (urogenital structures), and lateral plate mesoderm (limb defects). Treatment for MRKH depends on your goals and symptoms. There are surgical and nonsurgical treatment options, including vaginoplasty, vaginal dilation and a uterine transplant requiring multidisciplinary management.

Ovarian steroid cell tumor: a case report

Mohamed Elmoctar, Mariem Cheikh, Cheibete Zakaria, Rifai Kaoutar, Hinde Iraqi & Mohamedlhassan Gharbi
Ibn Sina Hôpital, Endocrinology, Rabat, Morocco

Introduction
Ovarian steroid cell tumors are very rare, and are endowed with steroid-secreting capacity. Most often, they are virilizing. Ovarian steroid cell tumours NOS, even if are rare, should be considered in any case of hyperandrogenism and excluded if elevated androgens levels are present. Our case illustrates this exceptional entity.
Case report
A 47-year-old female presented with virilism associated with severe hirsutism, frontotemporal baldness and muscular and clitoral hypertrophy. Biological work-up revealed an increase in androgens (total testosteronemia 12.75 ng/ml), with no associated hypercorticism. Pelvic MRI showed a suspicious left ovarian mass classified as ORADS5 The patient underwent left adnexectomy. Anatomopathological examination concluded that the ovarian stroma was a steroid cell tumour. Post-operative management was straightforward and the patient was placed under observation.
Discussion and conclusion
Steroid cell tumors are defined as ovarian neoplasms composed of cells secreting steroid hormones and represent less than 0.1% of ovarian tumors.... They generally occur in adults, with an average age at diagnosis of 47. In 50% of cases, they are virilizing tumors. They may be non-secreting, causing hyperestrogenism or, more rarely, Cushing's syndrome. They are generally benign, but the potential for malignancy is not negligible, given well-defined histological criteria. Good ovarian imaging is essential in the assessment of hyperandrogenism without associated adrenal abnormalities. Treatment is usually surgical. Complementary therapies are required once malignancy has been confirmed.

Causal relationship between rheumatoid arthritis and hypothyroid state in young females in iodine deficiency area

Diyora Kurambaeva[1], Zulaykho Shamansurova[1,2] & Maftunakhon Burkhanova[3]
[1]Central Asian University Medical School, Endocrinology, Tashkent, Uzbekistan; [2]Institute of Biophysics and Biochemistry at the NUUz, Metabolomics, Tashkent, Uzbekistan; [3]Queen's University, Department of Health Sciences, Kingston, Canada

Introduction
In hypothyroidism bone turnover and osteoclastic resorption will be reduced which also aggravates Rheumatoid arthritis (RA) symptoms. In the literature shown data about relationship between RA and thyroid dysfunction. We aimed to discuss some possible causes and triggers that interplay in both conditions based on data from the literature.
Material and methods
Data analysis was done using the systematic search performed in PubMed, MEDLINE, Scopus, Web of Science database of the articles published during the past 5 years related to RA and thyroid disorders. Main factors to consider were age, gender, cortisol, TSH, T4, T3, anti-TPO.
Results
Combined data from 250 patients with RA were checked for thyroid dysfunction and anti-TPO positivity. Thyroid dysfunction were found in 84 (33.9%), in which 60 (24.2%) cases have prior history of thyroid diseases. Anti-TPO was positive in 77 (32.0%) cases. The frequency of AITD was 52 (21.5%) in cases. The autoimmune Hashimoto's thyroiditis was 2.77 times more common in RA patients than in those without RA. It was reported that occurrence of thyroid pathology in Rheumatoid Arthritis patients is 34%, while specifically the range of Hashimoto's Thyroiditis is 13, 5%. 75% of RA patients were women from 20-39 years and the incidence of hypothyroidism in this group were 3.6 times greater than men had. Tumor necrosis factor-α and interleukin-6, that involved in inflammatory process in RA can exacerbate the dyslipidemia in hypothyroidism. Inflammation leads to deteriorated lipid profiles and low HDL levels. Interestingly, antithyroglobulin antibodies were found in synovial fluid of 34 from 54 patients with Rheumatoid Arthritis. Steroid therapy can lead to hypothyroid state, increasing TSH and inhibiting T4 to T3 conversion. Endocrine changes in young women (puberty, pregnancy, childbirth, and abortion) considered as a risk factors.
Conclusion
Understanding the link between RA and thyroid dysfunction will be helpful in primary prevention, early detection, management, and diminishing further complications of these interconnected diseases in patients at risk. RA patients should be screened for thyroid diseases. Patients with thyroid diseases with increasing of thyroid autoantibody level, in particular Hashimoto's thyroiditis should be screened for other autoimmune conditions, such as RA.

EP1345

Third nerve palsy spontaneously resolved in diabetic patient

Imen Zone[1], Aida Jallouli[1], Mona Rekik[1], Meriem Sahli[1], Faten Haj Kacem Akid[2], Nabila Mejdoub[3] & Trigui Amira[1]
[1]Habib Bourguiba Hospital., Department of Ophtalmology, Tunisia; [2]Hedi Chaker Hospital, Department of Endocrinology, Tunisia; [3]Hedi Chaker Hospital, Department of Ophtalmology, Tunisia

Introduction
We report a case of pupil sparing third nerve palsy caused by diabetes.
Case Presentation
A 68-year-old woman consulted for acute left upper lid ptosis appeared since 2 days ago. The patient complained of blurred vision and periorbital pain. No history of head trauma or infection was reported. The patient has been diagnosed with type II diabetes mellitus and arterial hypertension since 15 years. Ophthalmological examination revealed complete left ptosis, reactive pupillary reflex with deficient elevation, and adduction. The best-corrected visual acuity was 4/10 in both eyes. Anterior segment examination revealed bilateral cataract. Fundus examination didn't show any signs of diabetic retinopathy. Neurological examination was normal. Brain magnetic imaging was unremarkable without intracranial mass lesions and acute infarction. Blood analyses showed hyperglycemia (320 mg/dl) and elevated glycated hemoglobin (11.7%) without other anomalies. A complete recovery of ptosis was achieved after 3 weeks of blood sugar control with control of other cardiovascular risk factors The diagnosis of diabetic third nerve palsy was made.
Discussion
Diabetic third nerve palsy is the most frequent complication of nerve palsy in diabetic patients. The incidence of nerve palsy increases with the duration of the disease, uncontrolled glucose levels and age of the patient. The main etiology is microvascular cranial nerve palsy with high vascular risk factors such as smoking, hypertension, hypercholesterolemia. Third nerve palsy is frequently incomplete with ptosis, divergence of the affected eye, and paralysis eye movements such as adduction, elevation, and lowering without pupil involvement. Full recovery generally takes place at 6 months of follow up. Recurrences of third nerve palsy or other ocular motor nerve is possible.

An uncommon manifestation of a common problem

Muhammad Shoaib Zaidi[1,2]
[1]King Saud University Medical City, Internal medicine, Riyadh, Saudi Arabia; [2]King Saud University Medical City, Internal Medicine, Riyadh, Saudi Arabia

Background
The commonest etiology for the chronic kidney disease and end-stage renal disease, universally, is diabetes. Although, the histology of the kidney is the gold standard for diagnosing diabetic kidney disease, but in common practice it's usually diagnosed clinically and through laboratory testing.
Clinical Case
43 yrs old Saudi house-wife was admitted on the 7th of February, 2024 with 5 months history of progressive pitting pedal edema, facial puffiness, followed by dyspnea (NYHA-III), orthopnea, paroxysmal nocturnal dyspnea and frothy urine for 1 month, prior to the admission. She had a past medical history of long-term Type 2 diabetes and Chronic liver disease (HBV+). Systemic review-weight gain and anorexia. Family history unremarkable. No allergies or addictions. She also developed acute diarrhea during the admission. On evaluation, the patient was found to have the following issues: 1-Diabetic kidney disease (anasarca with moderate ascites+, hypoalbuminemia [S.albumin 26 (39.7-49.4 g/l)], S. Creatinine 140(45-84umol/l), Albuminuria (Albumin/Creatinine-2541(0-30 mg/g), CBC (Hb% 95(12-16 g/l, MCV 86.6fl, TLC and PLTs normal), HbA1c 8.7%, US abdomen (normal liver, spleen, portal vein & kidneys, moderate ascites and right pleural effusion), ascitic tap (serum-ascitic albumin gradient 0.8 g/l) and renal biopsy showed Class III DM nephropathy (classification 2010), with secondary focal segmental glomerulosclerosis 2- Right renal vein thrombosis with poor right renal perfusion (US proven) 3- Clostridium-difficile colitis (toxin+on stool testing. Other important investigations- Hepatitis B core and e Abs +, HBV PCR 159 IU/ml, Auto-immune workup negative. Serum immune electrophoresis-polyclonal gammopathy, Transthoracic Echo-mild concentric left ventricular hypertrophy with normal LV systolic function, moderate pericardial and left pleural effusions, US pelvis-anterior sub-serosal fibroid (2.7 × 2.9 cms)
Results
The patient was managed with moderate protein intake, diuretics, oxygen, fluid restriction, therapeutic abdominal paracentesis, apixaban,, angiotensin receptor and calcium channel blockers, atorvastatin, dapagliflozin, linagliptin and basal-bolus insulin. Her condition got stabilized and was advised follow-ups in the nephrology, hepatology and gynecology clinics.
Conclusions
Our case taught us that one should never assume the heavy proteinuria in diabetes to be related to diabetic nephropathy, until the secondary causes have been excluded. The value of the tissue biopsy in arriving at the precise diagnosis, cannot be overemphasized.

DOI: 10.1530/endoabs.99.EP1346

EP1347

Frequency of major clinical syndromes in patients with drug-induced liver injury

Oksana Prokopchuk[1,2], Svitlana Danchak[1,2], Ihor Hospodarskyy[1,2], Olha Kozak[1,2] & Nadiia Gavryliuk[1,2]
[1]Ukraine, Ternopil, Ternopil; [2]I. Horbachevsky Ternopil National Medical University

Drug-induced liver injury (DILI) today is a global problem in modern gastroenterology and is increasingly common worldwide, demanding focused attention and in-depth study, particularly in terms of recognizing the major clinical syndromes. These often complicate the course of DILI and as a result, its correction.
Objective
To investigate the frequency of major clinical syndromes in patients with DILI during chemotherapy with normal and excess body weight.
Materials and methods.
A total of 123 patients with DILI without signs of cirrhosis and concomitant liver and biliary tract pathology, aged 35 to 79 years, were examined. The control group consisted of 20 practically healthy individuals.
Results
Evaluating subjective manifestations, it was noted that the asthenovegetative syndrome was present in 45.2% ($n=56$) of patients who complained of general weakness and rapid fatigue, significantly affecting work capacity. Patients complained of a bitter taste in the oral cavity, changes in dietary behavior in response to changes in appetite, periodic nausea, and a feeling of bloating in the abdomen, which manifested as dyspeptic syndrome in 25.8% ($n=32$), the latter had a reliable connection with the asthenovegetative syndrome ($r=0.65$, $P<0.05$). During the objective examination, an increase in liver size was detected in 51.2% ($n=63$) of patients, while the feeling of heaviness in the right hypochondrium was felt by 28.5% ($n=35$) of patients ($r=0.62$; $P<0.05$). An increase in blood pressure was diagnosed in 25.2% ($n=31$) of patients, and arterial hypertension had a reliable dependence on the asthenovegetative syndrome ($r=0.64$; $P<0.05$), hepatomegaly ($r=0.57$; $P<0.05$), and the feeling of heaviness in the right hypochondrium ($r=0.92$; $P<0.05$). Additionally, high normal blood pressure was found in 16.35% ($n=20$) of patients, and in turn, indicators corresponding to the criteria for stage I hypertension were found in 8.94% ($n=11$) of those examined.
Conclusions
In patients with DILI during chemotherapy with normal and excess body weight, the presence of asthenovegetative and dyspeptic syndromes, a feeling of heaviness in the right hypochondrium, hepatomegaly, and increased blood pressure were detected, which should be taken into account when choosing treatment tactics.

EP1348

Mild hypercalcemia and osteoporosis in a patient with breast cancer: case report

Magdalena Matejkova Behanova[1], Petr Libansky[2], Kateřina Personová[3], Josef Vcelak[4], Kristyna Procykova[4] & Petr Vlcek[5]
[1]Motol University Hospital Prague, Department of Nuclear Medicine and Endocrinology, Prague, Czech Republic; [2]Motol University Hospital, 3rd Department of Surgery, Prague, Czech Republic; [3]Motol University Hospital, Department of Nuclear Medicine and Endocrinology,, Prague, Czech Republic; [4]Institute of Endocrinology, Czech Republic; [5]Fn Motol, Czech Republic

Introduction
The most common causes of hypercalcemia are primary hyperparathyroidism and malignancy. Malignancy-related hypercalcemia occurs in approximately

(Abstract EP1348)
Table 1.

	Sept2020	Jul2021	Jan2022	Aug2022	Feb2023	Aug2023	Feb2024
Ca	2.74	2.72	2.70	2.75	2.93	2.62	2.65
correctedCa	2.61	2.69	2.59	2.68	2.84	2.47	2.54
P	0.72	0.61	0.64	0.66	0.66	0.67	0.79
PTH	10.21	7.23	8.56	8.56	6.45		7.36
Vitamin D	52.2	69.7	57.6		62.7		67.9

20% - 30% of all cancer patients during their clinical course and mainly affects patients with solid tumors such as breast carcinoma.
Case Report
57 yrs old woman was referred for hypercalcemia and osteoporosis. Laboratory: calcium 2.8 mmol/l (normal range 2.15 - 2.55) calculated ionized calcium 1.41 mmol/l (normal 0.9 – 1.3), PTH 8.2 pmol/l (normal 1.3 - 7.6), normal renal function, no symptoms of hypercalcemia. Osteoporosis was diagnosed in routine screening by decreased density in lumbar spine (0, 700 g/cm^2, T score – 3.2), no compressive fractures. She was managed with ibandronate 150 mg monthly and we continued with differential diagnosis of hypercalcemia. We found hypercalciuria: urine calcium 16.7 mmol/24 hours, urine calcium/creatinine 1.4 (normal 0.25-0.55), CCCR (calcium creatinine clearance ratio) 0, 04. Vitamin D supplementation was added to ibandronate. The ongoing laboratory monitoring is in the table. During the follow-up the patients was diagnosed with breast cancer. PTH was only slightly elevated and malignancy could be a possible cause of hypercalcemia in this case. She underwent oncological treatment: surgery 11/2020, chemotherapy 1-5/2021, radiotherapy 5-7/2021 and anti-oestrogen therapy from 5/2021. The final diagnosis: 30 mm invasive (no special type) breast carcinoma with one micrometastasis in one sentinel lymph node, no distant metastasis. Remission of the breast cancer has been documented after the treatment. The hypercalcemia persisted until we noticed the normalization of calcium levels during the last two visits to our clinic.
Conclusion
This case represents mild hypercalcemia in patient with osteoporosis and breast cancer. The diagnosis of osteoporosis and hypercalcemia was prior of the cancer diagnosis. Hypercalcemia of malignancy should be considered in cases without known malignancy. The calcium level normalised during more than 2 years after completed oncological treatment and documented remission. Bisphoshonates were indicated for osteoporosis and also probably helped maintain calcium levels.

Association of parkinson's disease in a patient with graves' disease

Faizan Sandhu[1] & Muhammad Tahir Chohan[2]
[1]University Hospital of North Durham, General internal medicine, Durham, United Kingdom; [2]University Hospital of North Durham, Diabetes and Endocrinology, Durham, United Kingdom

Introduction
Parkinson's disease is considered as a second most common neurodegenerative disorder but rarely associated with the Graves' disease.
Case report
A 44-year-old female diagnosed as Graves' disease having classical features of hyperthyroidism i.e. tremors of hands, palpitations, weight loss despite of good appetite and biochemical evidence of thyroid function tests (TFTs) i.e. raised free T4, low TSH and positive antibodies. She was given carbimazole for twelve months and then stopped with a warning of disease relapse. She remained symptomatic and treatment free for about one and a half year, then reported back with similar presentation and investigations were in favour of hyperthyroidism. She was offered a radioactive iodine treatment but given a risk to her child, she opted for a medical treatment. After having carbimazole for the next two years, she had a radioactive iodine treatment which resulted in the hypothyroidism, therefore, started on levothyroxine. Her levothyroxine was titrated and despite of her tremors, the rest of her symptoms subsided. Hence, she was given a trial of propranolol. She presented back to the clinic with tiredness and tremors. The TFTs showed TSH 19.14, fT4 23.3 (slightly above then normal). It showed that either there is an issue with the intermittent compliance or it could be there is interference antibodies. It was decided to repeat her TFTs using different assay.
Management
There were no changes made with regards to her medications. In the meantime, she was referred to the movement disorder team and found to have tremors which, at that time, were more obvious in the left arm along with a degree of some stiffness and bradykinesia. Therefore, DaT scan, copper and autoimmune studies were arranged. The results of her DaT scan consistent with idiopathic Parkinson's disease. She was then reviewed by the Neurologist and started on anti-Parkinson's medications and she noticed a significant symptomatic improvement.
Conclusion/learning points
Parkinson's disease is a rare condition in young age group but, it should be considered in patients having non-resolving tremors, who had radioactive treatment for Graves' disease and biochemically hypothyroid.

EP1351

Graves' orbitopathy: Ocular manifestations and management

Imen Zone[1], Aida Jallouli[2], Faten Haj Kacem Akid[3], Nabila Rekik[3] & Trigui Amira[2]
[1]Habib Bourguiba Hospital., Department of ophtalmology; [2]Habib Bourguiba Hospital., Department of Ophtalmology, Tunisia; [3]Hedi Chaker Hospital, Department of Endocrinology, Tunisia

Introduction
Graves' orbitopathy is an inflammatory autoimmune disorder. It is the most common extrathyroidal manifestation of Graves' disease and it is the leading cause of proptosis in adults. We report 3 cases of Graves' orbitopathy in order to detail ocular manifestations and protocol management in this disease.
Observation 1
A 63-year-old woman was referred for left conjunctival redness. The best-corrected visual acuity was 10/10 in the right eye and 6/10 in the left eye. Examination showed von Graves' sign, bilateral proptosis, and eyelid retraction. Slit lamp examination revealed left conjunctival hyperemia and superficial punctuate keratitis. Elevated levels of thyroid hormones and the presence of anti-TSH receptor antibodies confirm the diagnosis of moderate Graves' orbitopathy.
Observation 2
A 52-year-old woman presented with orbital pain with eye movement. Ophthalmological examination revealed bilateral proptosis mainly affecting the left eye, restriction of eye movements, left relative afferent pupillary defect and high left intra-ocular pressure. Brain MRI showed bilateral orbital involvement extraocular muscle enlargement and left optic nerve sheath infiltration. The diagnosis of severe Graves' orbitopathy with dysthroid optic neuropathy was established. The patient received 500 mg intravenous methylprednisolone /week for 6 weeks with a good response.
Observation 3
A 16-year-old woman with a history of Grave's disease since 2 months was referred for bilateral eyelid swelling. Ophthalmological examination revealed best-corrected visual acuity of 8/10, ophthalmoplegia, bilateral conjunctival hyperemia with swelling of caruncle. The patient was treated with corticosteroids 60 mg/day with complete restoration of the eye motility.
Discussion
The most common clinical signs of Graves' orbitopathy are proptosis, upper eyelid retraction, oculomotor disorders, and ocular inflammatory signs such as conjunctival hyperemia, and caruncle swelling. Optic neuropathy and corneal ulceration are the most vision-threatening complications. Clinical examination allows assessing the activity and severity of the disease on the basis of predefined scores. Computerized tomographic and magnetic resonance imaging are both useful in establishing the diagnosis and in evaluating the severity of orbital damage. The management of moderate and severe Graves'orbitopathy is based on local treatment and intravenous glucocorticosteroids. Immunosuppression therapy is administered in cases of resistance to corticosteroids.

Researching of the relationship between the numberof t regulatory cells and serum arachidonic acid level in autoimmune thyroiditis patients

Eylem Cagiltay[1], Cengiz Bukrek[2], Kırkık Duygu[3] & Fatih Hacımustafaoğlu[4]
[1]Memorial Hospital, Endocrinology and Metabolic Diseases, Istanbul, Turkey; [2]Sultan 2. Abdulhamid Han Training and Research Hospital, Endocrinology and Metabolic Diseases, Istanbul, Turkey; [3]Health Sciences University, Biology, Istanbul, Turkey; [4]Health Sciences University, Biochemistry Department, Istanbul, Turkey

Objective
Autoimmune Thyroid Disease (AITD) is a common disease, accounting for 1-4% of the overall episode. Regulatory T Cells are a substructure of CD4 + T cells that have received great attention for their role in maintaining tolerance by suppressing the growth response and preventing autoimmune diseases. Arachidonic Acid is found in cell membrane phospholipids and is the lipid mediator affected by the inactivation of bacteria. We aimed to determine the change in Regulatory T Cell and Arachidonic Acid levels in Autoimmune Thyroiditis patients compared to healthy controls.
Materials and Methods
The scope of the study was conducted at S.B.Ü. between 01.04.2023 and 01.04.2024. Patients and healthy volunteers who applied to the Internal Medicine and Endocrinology Polyclinics of Sultan Abdülhamid Han Training and Research Hospital were recruited. A total of 42 people, 12 men and 30 women, aged between 21 and 76, participated in the study. 13 of them are in the healthy control group, 14 in the Hashimoto Thyroiditis group and 15 in the Graves' Disease group. Peripheral blood samples were taken and Human Arachidonic Acid and Human T-Cell Immune Regulator 1 Elisa Kits were tested in these samples and measured at the level.
Results
There was no significant difference in serum Treg levels between Hashimoto's Thyroiditis, Graves' patients and the control group ($P=0.884$, $P=0.765$, $P=0.663$, respectively). Arachidonic Acid levels were found to be higher in Hashimoto Thyroiditis and Graves patients than in the control group, but were not found to be statistically significant ($P=0.081$, $P=0.369$, $P=0.844$, respectively). Anti-TPO, Anti-Thyroglobin and TRAB were examined separately in the Healthy, Hashimoto's Thyroiditis and Graves' Disease groups for comparison purposes between individuals with high and normal arachidonic acid levels, and no significant results were found.
Conclusion
In this study, in Autoimmune Thyroiditis Patients; It was observed that there was no statistically significant difference in the amount of T Regulatory Cells and Arachidonic Acid in serum. More studies are needed to clarify the contradictory results in the literature regarding the amount and function of Arachidonic Acid and Treg Cells, and to develop genetic data that predict AITD and diagnostic tests that can measure the functions of Treg Cells.
