European Society of Endocrinology

11–14 May 2024, Stockholm, Sweden

EDITORS

Abstracts were marked by the Abstract Marking Panel and selected by the Programme Organising Committee.

ECE 2024 Programme Organising Committee

Cynthia Andoniadou (UK) Congress Committee Chair
Darko Kastelan (Croatia) ECE 2024 Clinical Co-Chair
Suzanne Dickson (Sweden) ECE 2024 Basic Science Co-Chair
Charlotte Höybye (Sweden) ECE 2024 Local Organising Committee Chair
Aleksandra Buha Djordjevic (Serbia)
Pia Burman (Sweden)
Waljit Dhillo (UK)
Helena Filipsson Nyström (Sweden)
Manuel Gahete (Spain)
Neil Gittoes (UK)
Peter Igaz (Hungary)
Tomaz Kocjan (Slovenia)
Tim Korevaar (Netherlands)
Dong-Jun Lim (S. Korea)
Sarantis Livadas (Greece)
Ana Luiza Maia (Brazil)
Juan Pedro Martinez Barbera (UK)
Robin Maskey (Nepal)
Nikolay Ninov (Germany)
Barbara Obermayer-Pietsch (Austria)
Agnieszka Piekiełko-Witkowska (Poland)
Stefan Pilz (Austria)
Ferruccio Santini (Italy)
Marianne Skovsager Andersen (Denmark)
Aleksandra Buha Djordjevic (Serbia)

Ex Officio Members

ESE President – Jérôme Bertherat (France)
ESE President-Elect – Wiebke Arlt (UK)
ESE Treasurer – Djuro Macut (Serbia)
EJE Editor-in-Chief – Wiebke Arlt (UK)
Endocrine Connections Editor-in-Chief 2021-2023 – Adrian Clark (UK)
ESPE Representative – Nils Krone (UK)
ECAS representative – Charlotte Höybye (Sweden)
EYES Representative – Walter Vena (Italy)
Endo-ERN Representative – Frederic Castinetti (France)
ESE Rare Disease Committee Chair – Sebastian Neggers (The Netherlands)
ESE Nurse Committee representative – Kirsten Davidse (The Netherlands)

ECE 2024 Local Organising Committee

Charlotte Höybye LOC Chair (Stockholm)
Michael Alvarsson (Stockholm)
Sophie Bensing (Stockholm)
Katarina Berinder (Stockholm)
Sigridur Björnsdottir (Stockholm)
Jan Calissendorff (Stockholm)
Olle Kõmpe (Stockholm)
Mikael Rydén (Stockholm)

Abstract Marking Panel

Adamski, Jerzy (Germany)
Aimaretti, Gianluca (Italy)
Alevizaki, Maria (Greece)
Alexandraki, Krystallenia (Greece)
Alonso-Magdalena, Paloma (Spain)
Ambroziak, Urszula (Poland)
Amrein, Karin (Austria)
Anastasilakis, Athanasios (Greece)
Andrew, Ruth (UK)
Appelman-Dijkstra, Natasha (Netherlands)
Arlt, Wiebke (UK)
Ayuk, John (UK)
Badenhoop, Klaus (Germany)
Badiu, Corin (Romania)
Bancos, Irina (USA)
Baranowska-Bik, Agnieszka (Poland)
Bargiota, Alexandra (Greece)
Barlier, Anne (France)
Basham, Katie (USA)
Bednarczuk, Tomasz (Poland)
Belaya, Zhanna (Russia)
Bertherat, Jérôme (France)
Bevan, Charlotte (UK)
Bidlingmaier, Martin (Germany)
Biermasz, Nienke (Netherlands)
Birkeland, Kåre Inge (Norway)
Boelen, Anita (Netherlands)
Boguslawska, Joanna (Poland)
Boguszewski, Cesar Luiz (Brazil)
Bolanowski, Marek (Poland)
Bollerslev, Jens (Norway)
Bonneville, Jean-François (France)
Bouillon, Roger (Belgium)
Boutzios, Georgios (Greece)
Brandi, Maria Luisa (Italy)
Broglio, Fabio (Italy)
Brue, Thierry (France)
Brunetti, Giacomina (Italy)
Buchanan, Charles (UK)
Buchfelder, Michael (Germany)
Buffet, Alexandre (France)
Buha, Aleksandra (Serbia)
Burman, Pia (Sweden)
Calissendorff, Jan (Sweden)
Campi, Irene
Cannavo, Salvatore (Italy)
Čáp, Jan (Czech Republic)
Capatina, Cristina (Romania)
Caputo, Marina (Italy)
Cariboni, Anna (Italy)
Carmeliet, Geert (Belgium)
Caron, Philippe (France)
Castinetti, Frederic (France)
Censi, Simona
Ceriello Antonio (Italy)
Chabre, Olivier (France)
Chanson, Philippe (France)
Charmandari, Evangelia (Greece)
Cherifi, Blandine Gatta (France)
Chowen, Julie (Spain)
Chrisoulidou, Alexandra (Greece)
Christ-Crain, Mirjam (Switzerland)
Christin-Maitre, Sophie (France)
Cohen-Solal, Martine (France)
Crona, Joakim (Sweden)
Dahlgren, Jovanna (Sweden)
Dahlqvist, Per (Sweden)
Daly, Adrian (Belgium)
Damdimopoulou, Pauliina (Sweden)
Daousi, Christina (UK)
de Herder, Wouter (Netherlands)
de Roux, Nicolas (France)
Delemer, Brigitte (France)
Derakhshan, Arash (Netherlands)
Dhillo, Waljit (UK)
Dieguez, Carlos (Spain)
Dischinger, Ulrich (Germany)
Donath, Marc (Switzerland)
Drouin, Jacques (Canada)
Duntas, Leonidas (Greece)
Dwyer, Andrew (USA)
Effraimidis, Grigoris (Denmark)
Elian, Viviana (Romania)
Elisei, Rossella (Italy)
Evang, Johan Arild (Norway)
Fahrleitner-Pammer, Astrid (Austria)
Falhammar, Henrik (Sweden)
Fallo, Francesco (Italy)
Fassnacht, Martin (Germany)
Favier, Judith (France)
Fekete, Csaba (Hungary)
Feldt-Rasmussen, Ulla (Denmark)
Ferone, Diego (Italy)
Ferraù, Francesco (Italy)
Fini, Jean-Baptiste (France)
Follin, Cecila (Sweden)
Fowkes, Robert (UK)
Franks, Steven (UK)
Frara, Stefano (Italy)
Fraser, William (UK)
Froidevaux, Marie-Stephanie (France)
Frystyk, Jan (Denmark)
Fugazzola, Laura (Italy)
Fuβ, Carmina Teresa (Germany)
Gabalec, Filip (Czech Republic)
Gaberšček, Simona (Slovenia)
Gahete, Manuel (Spain)
Gatto, Federico (France)
Gawel, Damian (Poland)
Gennari, Luigi (Italy)
Gheorghiu, Monica (Romania)
Gherlan, Iuliana (Romania)
Gibb, Fraser (UK)
Gibson, Douglas (UK)
Gilis-Januszewska, Aleksandra (Poland)
Gittoes, Neil (UK)
Glasberg, Simona (Israel)
Godlewska, Marlena (Poland)
Goulis, Dimitrios (Greece)
Granata, Riccarda (Italy)
Gravholt, Claus H. (Denmark)
Grineva, Elena (Russia)
Grossman, Ashley (UK)
Guasti, Leo (UK)
Gurnell, Mark (UK)
Haluzik, Martin (Czech Republic)
Václav Hána (Czech Republic)
Hannan, Fadil (UK)
Hansen, Troels Krarup (Denmark)
Heck, Ansgar (Norway)
Hodson, David UK
Hofland, Hans (Netherlands)
Hofland, Leo (Netherlands)
Howard, Sasha (UK)
Hoybye, Charlotte (Sweden)
Hubalewska-Dydejczyk, Alicja (Poland)
Huhtaniemi, Ilpo (UK)
Husebye, Eystein (Norway)
Ibąbez-Costa, Alejandro (Spain)
Igaz, Peter (Hungary)
Ilias, Ioannis (Greece)
Ilovayskaya, Irena (Russia)
Iotova, Violeta (Bulgaria)
Isenovic, Esma R (Serbia)
Isgaard, Jörgen (Sweden)
Jaatinen, Pia (Finland)
Jácome de Castro, João (Portugal)
Jessen, Niels (Denmark)
Jeová, Daniela (Slovakia)
Johannsson, Gudmundur (Sweden)
Jørgensenrgensen Anders, P (Norway)
Jørgensen, Jens Otto (Denmark)
Juhlin, Christofer (Sweden)
Kaiser, Ursula (USA)
Kalsbeek, Andries (Netherlands)
Kaltsas, Gregory (Greece)
Kanakis, George (Greece)
Kandaraki, Eleni (Greece)
Karlsson, Anders (Sweden)
Kastelan, Darko (Croatia)
Kaufman, Jean-Marc (Belgium)
Keil, Meg (USA)
Kelestimur, Fahrettin (Turkey)
Kelk, Eve (Estonia)
Kero, Jukka (Finland)
King, Aileen (UK)
Kocjan, Toma (Slovenia)
Köhrle, Josef (Germany)
Konrāde, Ilze (Latvia)
Korevaar, Tim (Netherlands)
Krajewska, Jolanta (Poland)
Krsek, Michal (Czech Republic)
Khnen, Peter (Germany)
Kurylowicz, Alina (Poland)
Kyle, Catriona (UK)
Lalli, Enzo (France)
Langdahl, Bente (Denmark)
Lapauw, Bruno (Belgium)
Laven, Joop (Netherlands)
Laviola, Luigi (Italy)
Lazurova, Ivica (Slovakia)
Le Tissier, Paul (UK)
Lefebvre, Hervé (France)
Léger, Juliane (France)
Links, Thera (Netherlands)
Livingstone, Dawn (UK)
Llahana, Sofia (UK)
Ludwig, Barbara (Germany)
Luger, Anton (Austria)
Luque, Raúl M (Spain)
Lyssenko, Valeriya (Sweden)
MacKenzie, Scott (UK)
Macut, Djuro (Serbia)
Maggi, Mario (Italy)
Maiter, Dominique (France)
Makras, Polyzois (Greece)
Mannelli, Massimo (Italy)
Mannucci, Edoardo (Italy)
Mantero, Franco (Italy)
Mantovani, Giovanna (ITALY)
Marazuela, Monica (Spain)
Marina, Ljiljana (Serbia)
Markou, Athina (Greece)
Martinez-Barbera, Juan Pedro (UK)
Marzullo, Paolo (Italy)
McCabe, Chris (UK)
Medici, Marco (Netherlands)
Meijer, Onno (Netherlands)
Metso, Saara (Finland)
Mian, Caterina (Italy)
Michalaki, Marina (Greece)
Miljic, Dragana (Serbia)
Minnetti, Marianna (Italy)
Mittag, Jens (Germany)
Møller, Niels (Denmark)
Morin-Papunen, Laure (Finland)
Mukherjee, Abir (UK)
Musat, Madalina (Romania)
Naciu, Anda Michaela (Italy)
Neggers, Sebastian (Netherlands)
Newell-Price, John (UK)
Newey, Paul (UK)
Nicolaides, Nicolas (Greece)
Niculescu, Dan (Romania)
Niedziela, Marek (Poland)
Niina, Matikainen (Finland)
Nogueiras, Ruben (Spain)
Olarescu, Cristina (Norway)
Oliveira, Pedro (Portugal)
Olsson, Daniel (Sweden)
Pagotto, Uberto (Italy)
Papanas, Nikolaos (Greece)
Papanastasiou, Labrini (Greece)
Pavel, Marianne (Germany)
Pearce, Simon (UK)
Peeters, Robin (Netherlands)
Pekic, Sandra (Serbia)
Pellegata, Natalia (Germany)
Perez-Rivas, Luis (Germany)
Persani, Luca (Italy)
Perseghin, Gianluca (Italy)
Piekiełko-Witkowska, Agnieszka (Poland)
Pilz, Stefan (Austria)
Poladian, Raffi (Lebanon)
Polyzos, Stergios (Greece)
Popławski, Piotr (Poland)
Popović, Vera (Serbia)
Poutanen, Matti (Finland)
Power, Deborah (Portugal)
Prevot, Vincent (France)
Prodam, Flavia (Italy)
Quarta, Carmelo (France)
Radian, Serban (Romania)
Ragnarsson, Oskar (Sweden)
Rahman, Nafis (Finland)
Rainey, William (USA)
Rajpert-De Meyts, Ewa (Denmark)
Ramhoj, Louise (Denmark)
Rapizzi, Elena (Italy)
Rauner, Martina (Germany)
Raverot, Gerald (France)
Reincke, Martin (Germany)
Rejnmark, Lars (Denmark)

Rizzoti, Karine (UK)
Robert, Opitz (Germany)
Robledo, Mercedes (Spain)
Roman, Gabriela (Romania)
Romijn, Hans (Netherlands)
Ronchi, Cristina (Italy)
Ross, Richard (UK)
Ruchala, Marek (Poland)
Rutten, Elisabeth (Belgium)
Sachs, Laurent (France)
Sancak, Seda (Turkey)
Santi, Daniele (Greece)
Schopohl, Jochen (Germany)
Schwarz, Peter (Denmark)
Shestakova, Ekaterina (Russia)
Shestakova, Marina (Russia)
Shimon, Ilan (Israel)
Skrha, Jan (Austria)
Soares, Paula (Portugal)
Söderlund, Sanni (Finland)
Sofie Bislev, Lise (Denmark)
Sourij, Harald (Austria)
Steenblock, Charlotte (Germany)
Stener-Victorin, Elisabet (Sweden)
Stimson, Roland (UK)
Storbeck, Karl (South Africa)
Strasburger, Christian (Germany)
Sykiotis, Gerasimos (Switzerland)
Tabarin, Antoine (France)
Tamagno, Gianluca (Ireland)
Tena-Sempere, Manuel (Spain)
Tentolouris, Nikolaos (Greece)
Terzolo, Massimo (Italy)
Theiler-Schwetz, Verena (Austria)
Theodoropoulou, Marily (Germany)
Tigas, Stelios (Greece)
Timmers, Henri (Netherlands)
Toledo, Rodrigo (Spain)
Tomlinson, Jeremy (UK)
Toppari, Jorma (Finland)
Tœth, Miklœs (Hungary)
Tsagarakis, Stylianos (Greece)
Tsourdi, Elena (Germany)
Tuomilehto, Jaakko (Finland)
Tzanela, Marinela (Greece)
Underbjerg, Line Mouritsen (Denmark)
van der Lely, Aart Jan (Netherlands)
van Hul, Wim (Belgium)
Vantyghem, Marie-Christine (France)
Vassiliadi, Dimitra (Greece)
Vila, Greisa (Austria)
Visser, Edward (Netherlands)
Visser, Jenny (Netherlands)
Wass, John (UK)
Widimsky, Jiri (Czech Republic)
Wiersinga, Wilmar (Netherlands)
Wilkinson, Ian (UK)
Winter, Elizabeth (Netherlands)
Xekouki, Paraskevi (Greece)
Yavropoulou, Maria (Greece)
Yedinak, Christine (USA)
Yildiz, Bulent (Turkey)
Zabuliene, Lina (Lithuania)
Zandee, Wouter (Netherlands)
Zatelli Maria, Chiara (Italy)
Zavattaro, Marco (Italy)
Zennaro, Maria-Chri stina (France)
Zilaitiene, Birute (Lithuania)
Zillikens, Carola (Netherlands)

The European Society of Endocrinology would like to thank its ECE 2024 sponsors and supporters:

Gold Sponsors
Ascendis Pharma

Silver Sponsors
Amgen Rare Disease
Amryt Pharma
Chiesi Global Rare Disease
HRA Pharma Rare Diseases

Bronze Sponsors
Camurus
Diurnal
Neurocrine Biosciences
Novo Nordisk
Pfizer
Recordati Rare Diseases
Uni-Pharma

Supporters
Amolyt Pharma
Crinetics Pharmaceuticals
Ipsen
Rhythm Pharmaceuticals
Serb Pharmaceuticals
Soleno Therapeutics

CONTENTS

26th European Congress of Endocrinology 2024

PRIZE LECTURES

The Geoffrey Harris Award Lecture AP1
The European Journal of Endocrinology Award Lecture AP2
Clinical Endocrinology Journal Foundation Award Lecture AP3
European Hormone Medal Award Lecture AP4
The Transatlantic Alliance Award Lecture AP5
Jens Sandahl Christiansen Awards JSC1–JSC2

PLENARY LECTURES

Hypoxia PL1
The clinical importance of high resolution, automated, ambulatory measurement of tissue steroids PL2
The Silent Decline: Unlocking the Enigma of Dropping Sperm Counts and Fertility Rates PL3
From molecular biology to precision medicine in endocrine tumors: Are we there yet? PL4
Machine Learning Based Data Analysis in Endocrinology PL5
Focus on the pancreas PL6

SYMPOSIA

Craniopharyngioma: Pathogenesis and novel targeted treatments SL1.1–SL1.3
Thyroid hormones and development S2.1–S2.3
Neural pathways controlling feeding behaviour: impact of circulating hormones S3.1–S3.3
Osteoporosis Conundrums S4.1–S4.3
Emerging aspects of menopause S5.1–S5.3
New applications of Steroid Hormones S6.1–S6.3
What's new in metabolic-associated fatty liver disease?.. . . . . S7.1–S7.3
Novel pathological aspects of adipose tissue S8.1–S8.3
Microscopic companions of the endocrine system S9.1–S9.3
Bone and muscle vitamin replacement S10.1–S10.3
Recent studies that changed my practice S11.1–S11.3
Senescence-mediated signalling in the pathogenesis of endocrine-related cancer: Pathogenesis and novel therapeutic opportunities S12.1–S12.3
From reproduction to male contraception S13.1–S13.3
Endocrine disruption – from bench to bedside S14.1–S14.3
Genetics and molecules in pituitary tumours S15.1–S15.3
The role of muscle in metabolic diseases S16.1–S16.3
Advances in the management of adrenocortical carcinoma S17.1–S17.3

JOINT SESSIONS

Joint Session 1: ESE and the European Society of Endocrine Surgeons JS1
Joint Session 2: ESE and European Society of Paediatric Endocrinology JS2.1–JS2.2
Joint Session 3: ESE and the Korean Endocrine Society – Mild autonomous cortisol secretion (MACS): new insights from European and Korean studies JS3.1–JS3.3
Joint Session 4: European Society of Endocrinology and the SBEM, FASEN, SMNE (Central/South America societies) JS4.1–JS4.3
Joint Session 5: European Society of Endocrinology and the Androgen Excess and PCOS Society JS5.1–JS5.3

EYES SYMPOSIUM EYES1

ECAS SYMPOSIUM ECAS1

NEW SCIENTIFIC APPROACHES

Insights into Endocrine Pathology: What Does the Endocrinologist Need to Know? . . . NSA1
Methylomics in aggressive pituitary tumours . . . NSA2
Artificial intelligence in Endocrinology . . . NSA3

DEBATE SESSIONS

Bone biomarkers – helpful for decisions in osteoporosis patients? . . . D1.1–D1.2
Pituitary tumours: Should Cavernous sinus invasion be removed . . . D2.1–D2.2
Active surveillance of thyroid cancer FOR or AGAINST . . . D3.1–D3.2

MEET THE EXPERT BASIC SCIENTIST SESSIONS

Human adrenal development . . . MTEBS1
Identifying new receptors in the regulation of fertility . . . MTEBS2
In vitro cellular reprogramming to model gonad development and its disorders . . . MTEBS3

MEET THE EXPERT SESSIONS

Osteoporosis in advanced chronic kidney disease . . . MTE1
Radiotherapy/radiosurgery for pituitary tumours; long term outcome and consequences . . . MTE2
Estogen & immune micro environment in tumour progression . . . MTE3
The HPA axis response to critical illness . . . MTE4
Paediatric concerns of endocrine disruptors . . . MTE5
Female infertility . . . MTE6
Management of Functional Pancreatic Neuroendocrine Neoplasms . . . MTE7
Primary Hyperparathyroidism 2024: What's new and Further Perspectives . . . MTE8
Update on the management of Graves Disease . . . MTE9
How to prevent weight regain? . . . MTE10
Management of malignant pheochromocytoma . . . MTE11

PRE-CONGRESS COURSE

Androgen Excess and PCOS Society (AEPCOS) Update Meeting . . . PCC1.1–PCC1.9
Growth Hormone Research Society (GRS) Congress (Day1) . . . PCC2.1–PCC2.6
Growth Hormone Research Society (GRS) Congress (Day2) . . . PCC3.1–PCC3.4
Thyroid Ultrasound Practical Course . . . PCC4.1–PCC4.6
European Academy of Andrology (EAA) pre-congress course . . . PCC5.1–PCC5.5

NURSE SESSIONS

Precision Medicine: Thyroid Disorder . . . N1.1–N1.3
Precision Medicine: Craniopharyngioma . . . N2.1–N2.3
How to Workshop . . . N3.1–N3.3
Endocrine Nurse Achievement Session . . . N4.1–N4.2

ORAL COMMUNICATIONS

Oral Communications 1: Reproductive and Developmental Endocrinology . . . OC1.1–OC1.6
Oral Communications 2: Calcium and Bone | Part I . . . OC2.1–OC2.6
Oral Communications 3: Adrenal and Cardiovascular Endocrinology | Part I . . . OC3.1–OC3.6
Oral Communications 4: Diabetes, Obesity, Metabolism and Nutrition | Part I . . . OC4.1–OC4.6
Oral Communications 5: Pituitary and Neuroendocrinology | Part I . . . OC5.1–OC5.6
Oral Communications 6: Environmental Endocrinology . . . OC6.1–OC6.6
Oral Communications 7: Endocrine-related Cancer . . . OC7.1–OC7.6
Oral Communications 8: Thyroid . . . OC8.1–OC8.6
Oral Communications 9: Pituitary and Neuroendocrinology | Part II . . . OC9.1–OC9.6
Oral Communications 10: Calcium and Bone | Part II . . . OC10.1–OC10.6
Oral Communications 11: Adrenal and Cardiovascular Endocrinology | Part II . . . OC11.1–OC11.6
Oral Communications 12: Diabetes, Obesity, Metabolism and Nutrition | Part II . . . OC12.1–OC12.6
Oral Communications 13: Late Breaking . . . OC13.1–OC13.6

RAPID COMMUNICATIONS

Rapid Communications 1: Reproductive and Developmental Endocrinology RC1.1–RC1.7
Rapid Communications 2: Calcium and Bone | Part I RC2.1–RC2.6
Rapid Communications 3: Adrenal and Cardiovascular Endocrinology | Part I RC3.1–RC3.7
Rapid Communications 4: Diabetes, Obesity, Metabolism and Nutrition | Part I RC4.1–RC4.5
Rapid Communications 5: Pituitary and Neuroendocrinology | Part I RC5.1–RC5.8
Rapid Communications 6: Thyroid | Part I RC6.1–RC6.5
Rapid Communications 7: Endocrine-related Cancer RC7.1–RC7.6
Rapid Communications 8: Thyroid | Part II RC8.1–RC8.5
Rapid Communications 9: Pituitary and Neuroendocrinology | Part II RC9.1–RC9.7
Rapid Communications 10: Calcium and Bone | Part II RC10.1–RC10.5
Rapid Communications 11: Adrenal and Cardiovascular Endocrinology | Part II RC11.1–RC11.7
Rapid Communications 12: Diabetes, Obesity, Metabolism and Nutrition | Part II RC12.1–RC12.5
Rapid Communications 13: Late Breaking RC13.1–RC13.6

POSTER PRESENTATIONS

Adrenal and Cardiovascular Endocrinology P1–P32, P208, P214–P244, P412–P442
Calcium and Bone P33–P44, P245–P256, P443–P454
Diabetes, Obesity, Metabolism and Nutrition P45–P87, P212, P257–P299, P455–P497
Endocrine-Related Cancer P88–P100, P209–P210, P213, P300–P311, P498–P509
Environmental Endocrinology P201–P206
Pituitary and Neuroendocrinology P101–110, P326, P112–P140, P312–P325, P111, P327–P351, P510–P549
Reproductive and Developmental Endocrinology P141–P154, P207, P211, P352–P366, P550–P563
Thyroid P155–P174, P367–P385, P564–P582
Late-Breaking P175–P200, P386–P411, P583–P607

EPOSTER PRESENTATIONS

Adrenal and Cardiovascular Endocrinology EP13, EP15, EP48, EP89–EP91, EP113–EP115, EP182, EP186, EP195, EP196, EP215, EP217, EP232–EP234, EP239, EP240, EP252, EP254, EP258, EP266, EP267, EP282, EP287, EP294, EP296, EP297–EP300, EP304, EP311, EP315, EP325–EP329, EP372, EP375,EP376, EP385, EP387, EP389–EP394, EP405–EP408, EP410, EP412–EP420, EP540, EP541, EP560, EP582, EP593, EP599, EP629–EP633, EP703, EP705, EP707, EP708, EP717, EP720, EP721, EP723, EP726, EP727–EP745, EP746, EP755, EP759, EP760, EP768, EP877, EP905, EP915–EP920, EP923, EP929, EP930, EP974, EP978–EP980, EP1014, EP1019, EP1056–EP1059, EP1091–EP1095, EP1097–EP1103, EP1105, EP1164–EP1169, EP1192, EP1199, EP1214, EP1215, EP1223

The clinical importance of high resolution, automated, ambulatory measurement of tissue steroids
PL2

Stafford Lightman, University of Bristol, UK

Almost all hormonal systems are dynamic with hormones being secreted in various combinations of ultradian, circadian, monthly and even yearly patterns.These patterns have emerged as natural consequences of the multilevel regulation of the hormone axes themselves and in response to environmental conditions such as the light:dark cycle, food availability and temperature. The Hypothalamic-Pituitary-Adrenal (HPA) axis is critical for life and delivers a complex system of pulsed steroid release from the adrenal gland with an approximate hourly ultradian rhythm underlying a much better recognised circadian rhythm. Both of these rhythms have been shown to be critical for good health, and are an important aspect of the regulation of cognitive, appetitive,-metabolic, immunological and cardiovascular function. Since these oscillating levels of corticosteroids are so important for health, and so many disease processes from Cushings disease, hyperaldosteronism and Addisons disease to metabolic immunological and psychiatric disorders., are associated with HPA dysfunction, it is clearly important to be able to assess 24 hour hormone levels. As it is not feasible to take multiple blood samples from subjects going about their normal lives- including during normal sleep- we have designed a novel automated ambulatory sampling system that allows us to sample interstitial fluid hormone levels in normal ambulant subjects (www.u-rhythm.co.uk). Using our automated sampler the Horizon 2020 funded 'Ultradian' project between Bergen, The Karolinska, Athens and Bristol, has now published our first paper on 214 normal subjects to establish normal indices for the dynamic changes in the corticosteroidome across the day. I will be discussing the rich data set from these subjects and what it tells us about the heterogeneity of HPA activity between normal subjects, differences between blood and tissue for cortisol and cortisone levels,and the remarkable evidence for differences in aldosterone regulation between different subjects.The use of multiple sampling technology for the diagnosis and management of patients with adrenal disorders will be discussed by Dr Thomas Upton in his talk on Monday.

Amylin – an anorexigenic pancreas-brain signal
Christelle Le Foll

Amylin is a pancreatic gut hormone co-released with insulin in response to a meal. Amylin signaling has drawn a large amount of interest these past years due to its potential as an anti-obesity treatment. Amylin binds to an heterodimeric receptor (AMY1-3) composed of the calcitonin receptor (CTR) and the receptor activity modifying proteins (RAMP1-3). These receptors are located in multiples brain areas involved in the homeostatic and hedonic control of energy homeostasis. The distribution and the localization of these receptors subtype may be important in mediating amylin's specific effects. Amylin's main binding site is located in the area postrema where its activates noradrenergic neurons to produce its anorectic effect by decreasing meal size. The signal is then propagated to the nucleus of the solitary tract and lateral parabrachial nucleus (LPBN) and transmitted to forebrain areas such as central amygdala and bed nucleus of the stria terminalis. In the LPBN, amylin signaling mainly activates non-aversive non-CGRP (calcitonin-gene related peptide) neurons while the AMY agonist salmon calcitonin, which also binds the CTR alone, activates CGRP neurons leading to malaise and nausea. Amylin also act in the mediobasal hypothalamus where it sensitize leptin action. Cagrilintide is a long acting, dual amylin and calcitonin receptor agonist (DACRA) that induces weight loss in people living with obesity. The combination of cagrilintide and the long-acting glucagon-like peptide 1 receptor (GLP-1R) agonist, semaglutide (CagriSema) is currently in clinical development for treatment of obesity and type-2-diabetes. Our current work aim to identify the exact neuronal pathways and molecular identity of the neurons activated by these drugs.
Key learning points
- Amylin is a pancreatic peptide secreted in response to a meal; it controls eating and energy homeostasis.
- Amylin acts through a variety of receptor composed of the calcitonin receptor and the receptor activity modifying protein 1-3.
- Amylin primary sites of action are located in the area postrema and the arcuate nucleus of the hypothalamus.
- Amylin receptor agonist promote an aversive through NTS-LPBN neuronal pathway.
- The amylin receptor agonist, cagrilintide, acts in concert with semaglutide to decrease body weight at lower dose than each compound alone.

Symposium: 'Does sclerostin inhibition increase cardiovascular risk?'

Elena Tsourdi

In the ARCH study[1], romosozumab was compared with an active comparator, alendronate. Unexpectedly, an imbalance in adjudicated serious cardiovascular AEs was observed during the first year of the study, triggering numerous discussions among experts and giving rise to hypotheses regarding the mechanism leading to such a difference. However, it should be noted that an even lower cardiovascular risk in high-dose romosozumab treatment as compared to placebo was reported in a meta-analysis[2]. In addition, a recent systematic review and meta-analysis showed no increase in cardiovascular risk with regard to stroke, atrial fibrillation, heart failure, coronary artery disease, and cardiovascular death individually while, however, increasing the risk for the composite of four-point major adverse cardiovascular events[3]. Given that these results were not completely conclusive[3], a comparative trial between romosozumab and antiresorptive agents is needed to shed further light on this question. In conclusion, he difference in rates of cardiovascular events between romosozumab and alendronate seen in ARCH could be attributable to a possible cardioprotective effect of alendronate or could also represent a chance finding[4]. However, a recent genome-wide association study meta-analysis using Mendelian randomization in 33.961 European individuals provided genetic evidence to suggest that lower levels of sclerostin may increase the risk of hypertension, type 2 diabetes mellitus, myocardial infarction, and the extent of cardiovascular disease[5]. Thus, there is a need to develop strategies to mitigate potential AEs associated with romosozumab treatment on atherosclerosis and its related risk factors.

Highlights

- The role of wnt signalling in atherogenesis raises the possibility that the wnt inhibitor, sclerostin, provides a natural defence to this process, and that anti-sclerostin antibodies might increase the risk of atherosclerosis and associated conditions such as CVD.
- Randomised controlled trials of treatment with the anti-sclerostin antibody, romosozumab, have yielded conflicting evidence with respect to possible adverse effects of sclerostin inhibition on CVD risk.
- Three Mendelian randomisation (MR) studies have examined effects of sclerostin lowering on CVD outcomes. Concordant findings were seen in two studies, comprising an effect of sclerostin lowering on increased risk of MI and type II diabetes mellitus. One study also suggested that sclerostin lowering increases coronary artery calcification.

Triangulation of evidence from different sources provides some suggestion that sclerostin lowering increases MI risk, supporting the need for CVD risk assessment when considering treatment with romosozumab.

Novel forms of adrenal insufficiency

Christa E. Flück
Division of Pediatric Endocrinology, Diabetology and Metabolism, Department of Pediatrics, Bern University Hospital, University of Bern, Switzerland and Department of Biomedical Research, University of Bern, Switzerland. Christa.flueck@unibe.ch

Genetic variants causing adrenal insufficiency (AI) are either disrupting corticosteroid production exclusively leading to isolated AI or they are causing additional organ malfunctions as part of a syndromic form of AI. In **isolated AI**, genetic disorders may affect structure and function of the adrenal cortex or adrenal steroidogenesis specifically, but often also lead to overall disturbances of steroidogenesis affecting other steroid organs (mainly the gonads or the placenta). This can then result in a disorder of sex development (DSD, e.g. congenital adrenal hyperplasia (CAH)) as steroid hormone biosynthesis, regulation and metabolism rely on a common gene network. Nevertheless, cell- and tissue-specific expression and regulation of steroidogenic genes leads to organ-specific steroid production. Genetic variants in core genes of steroid hormone biosynthesis may therefore be recognized by characteristic clinical phenotypes and changes of steroid profiles. However, considerable overlap exists. Although **syndromic forms of AI** seem easier to recognize through their broader range of typically involved organ systems, this remains theory in many cases. Syndromes with primary AI can manifest similar, oligosymptomatic or atypical mainly because the typical spectrum may only develop over time or simply because the phenotype is only recognized when searched for. Molecular disease mechanisms causing genetic forms of primary AI are manifold and include disorders of steroidogenesis, adrenal dysgenesis (e.g. IMAGe, MIRAGE), familial glucocorticoid deficiency (e.g. *MC2R*/*MRAP*, OXPHOS system and ROS detoxification (*NNT*), metabolic (e.g. *SGPL1*) and autoimmune disorders (*AIRE*). Remarkably, only a few variants in genes critically involved in **adrenal development**, as revealed by basic research studies, have been identified in humans with dysgenetic, syndromic AI. It is highly likely that pathogenic variants of genes essential for adrenal development and beyond are embryonic lethal and thus go undetected. For instance, a homozygous mutation in *WNT4* has been found in three fetuses with SERKAL syndrome, characterized by female sex reversal and dysgenesis of kidneys, adrenals, and lungs. In a recent study, we reported a homozygous splice variant in the *LGR4* gene within a highly consanguineous family. Offspring with this variant either died in utero or at birth from adrenal salt-wasting crises. Only three affected children survived the neonatal period, and they required early steroid replacement therapy. These survivors manifested symptoms including adrenal insufficiency, hearing loss, nail anomalies, short stature, delayed puberty, and mental retardation. LGR4 is the R-spondin-dependent receptor that stimulates the WNT/β-catenin signaling in the adrenal cortex, playing a crucial role in adrenal cortex zona glomerulosa formation and function, thus aldosterone synthesis.
Key learning points
- Genetic forms of (primary) adrenal insufficiency may manifest isolated or as syndromic forms.
- Clinical characteristics may overlap that a genetic diagnosis is mostly necessary.
- Genotype-phenotype correlation is also variable.
- Genes and pathways involved in adrenal development are excellent candidates for explaining adrenal disorders, but seldom found in patients.
A variant in LGR4, an R-spondin stimulated receptor for activating WNT/β-catenin signaling, has been found in several members of a consanguineous family presenting with a novel syndromic form of isolated mineralocorticoid deficiency.

A macrophage-collagen fragment axis in the regulation of adipose tissue functionality

Milica Vujičić, Isabella Broderick, Pegah Salmantabar, Charlène Perian, Jonas Nilsson, Carina Sihlbom Wallem & Ingrid Wernstedt Asterholm
University of Gothenburg, Sweden

Efficient removal of fibrillar collagen is essential for adaptive expansion of subcutaneous adipose tissue (SAT); a process that protects against deleterious ectopic lipid deposition in the visceral compartment during weight gain. Fibrillar collagen degradation in adipose tissue is initiated by extracellular collagenases, and we recently found that SAT-resident M2-like macrophages remove the fragmented collagen via endocytosis and lysosomal degradation. Moreover, these macrophages' engagement in collagen endocytosis is diminished in obesity/insulin resistance associated with elevated levels of collagen fragments that exert fibroinflammatory changes in fibroblasts. Accordingly, we propose that collagen sequences that normally are hidden within the triple-helical structure of fibrillar collagen act as endogenous danger signals. Our new data within this area indicate that our findings translate to the clinic. We have also observed sex differences; female M2-like macrophages are more engaged in collagen endocytosis than those of males. In conclusion, our data delineate the importance of a macrophage-collagen fragment axis in physiological SAT expansion. Therapeutic targeting of this process may be a mean to improve adipose tissue function in obesity, which in turn may reduce the risk for metabolic disorders.

The HPA axis response to critical illness
MTE4

The HPA axis response to critical illness
Prof. dr. Greet Van den Berghe
(adapted from Langouche, Téblick, Gunst, Van den Berghe, Endocrine Reviews 2023.44.1096-1106)

Based on insights obtained during the last decade, the classical concept of an activated hypothalamus-pituitary-adrenocortical (HPA) axis in response to critical illness is in need of revision. After a brief central HPA axis activation, the vital maintenance of increased systemic cortisol availability and action in response to critical illness is predominantly driven by peripheral adaptations rather than by an ongoing centrally-activated several-fold increased production and secretion of cortisol. Besides the known reduction of cortisol binding proteins that increases free cortisol, these peripheral responses comprise suppressed cortisol metabolism in liver and kidney, prolonging cortisol half-life, and local alterations in expression of 11βHSD1, GRα and FKBP51 that appear to titrate increased GRα-action in vital organs and tissues while reducing GRα-action in neutrophils possibly preventing immune-suppressive side effects of increased systemic cortisol availability. Peripherally increased cortisol can exert negative feed-back inhibition at the pituitary level impairing processing of POMC into ACTH and reducing ACTH-driven cortisol secretion, while ongoing central activation explains increased circulating POMC. These alterations are likely adaptive and beneficial for the host in the short term. However, as a consequence, patients with prolonged critical illness who require intensive care for weeks or longer may develop a form of central adrenal insufficiency. The new insights challenge the validity of earlier concepts such as "relative", as opposed to "absolute", adrenal insufficiency and generalized systemic glucocorticoid resistance in the critically ill. They also question the scientific basis for broad implementation of stress dose hydrocortisone treatment of patients suffering from acute septic shock solely based on assumption of cortisol insufficiency.

Growth hormone, mini-mice, football, dirty shorts, and a new drug
John J Kopchick

The growth hormone receptor antagonist was discovered via expression of mutated GH genes in transgenic mice. Although we were attempting to generate potent GH analogs, our mouse studies indicated that the compound was 'inhibiting' GH action. We subsequently showed that it was a GH receptor antagonist, the first of its type. Many hurdles needed to be 'jumped' in the development of this compound into a drug including protection of intellectual property; funding for purification, preclinical, and clinical trials; and registration to and approval by the various regulatory agencies. Ultimately the compound was approved in the mid-2000s for the treatment of patients with acromegaly. The name of the drug is Somavert (Pegvisomant for injection). Pegvisomant treatment in a dose dependent manner results in normalization of IGF-1 levels in most patients and has been found to be safe and efficacious. Since the GH/IGF-1 axis has been implicated in the progression of several types of cancers, many have suggested the use of Pegvisomant as an anti-cancer therapeutic. In this talk, I will describe experiments in which the GHA was discovered, review results of Pegvisomant's preclinical and clinical trials, and provide data suggesting Pegvisomant's value in selected types of cancer.
Key Learning Points
- Unexpected experimental findings can, at times, be very promising.
- Trials and tribulations of translating laboratory finding to the patient.
- Serendipity played an important role in our drug development process.

Hypospadias is linked to genetic susceptibility to the environment through oncogenes and its incidence is geographically correlated to that of cancers worldwide

Nicolas Kalfa[1], Anne Bergougnoux[1], Pascal Philibert[2], Nadège Servant Fauconnet[1], Alice Faure[3], Jean Breaud[4], Laura Gaspari[1], Charles Sultan[1] & Francoise Paris[1]
[1]Hospital Center University De Montpellier, Montpellier, France; [2]University Hospital of Nimes, Nîmes, France; [3]Hospitals Academics De Marseille, Marseille, France; [4]Hospital Pasteur, Nice, France

Background
The etiology of hypospadias may be at the crossroad of genetics and environment. The study of these factors taken individually failed to find an unequivocal explanation in most cases. But the interactions between exposure to endocrine disruptors chemicals (EDC) and genetic background have not yet been studied. We thus aimed to find a genetic susceptibility to the environment in hypospadias.
Methods
Through a multicenter prospective comparative study, we gathered environmental and genetic data from patients with isolated hypospadias to determine at-risk polymorphisms when combined to exposure to EDC compared to a control group. 300 boys with hypospadias and 300 controls were included and evaluated by: 1-Questionnaire QLK4-1999-01422 to detect personal, environmental, professional exposures to pollutants. 2-Next-generation-sequencing of 336 genes implicated in genital and gonadal development and hypospadias. The interaction between genetics and environment was studied using logistic regression analysis.
Results
We identified 4 variants at risk for hypospadias when combined to exposure to EDC in the following genes: BRAF (rs3789806), AKR1C3 (rs10508293), AHR (rs2074113) and CITED2 (rs4076025). Surprisingly, beside their role in steroidogenesis and sensitivity to chemicals, these genes are also identified as oncogenes. The in-silico predictions of these variants are to modify the transcription factor binding sites for proteins encoded by other oncogenes and genital development genes. We thus hypothesized a connection between hypospadias and cancers. To further evaluate this association, we used data from the International Birth-Defect Surveillance Systems and from the International Agency for Research on Cancer (WHO). We found a geographical correlation, across 17 countries, between the incidence of hypospadias and the overall incidence of cancers ($r=0.81$). This correlation was particularly observable for urological tumors and leukemias, two cancers highly suspected to be linked to pollutants.
Conclusions
Hypospadias is at the crossroad of genetics and environment. Susceptibility to EDC may be associated with genetic variants on genes both implicated in fetal development and oncogenesis. Moreover, the incidence of hypospadias is geographically correlated to that of cancers worldwide. Hypospadias may thus not be a simple defect of the urethra but a witness of the global health population and of EDC impregnation.

Mortality among women with POI, nationwide register based case-control study

Hilla Haapakoski[1], Heidi Silvén[1,2], Paula Pesonen[1], Susanna Savukoski[1,2] & Maarit Niinimäki[1,2]
[1]University of Oulu; [2]Department of Obstetrics and gynecology, University Hospital of Oulu, Obstetrics and Gynecology

Introduction/Purpose
Despite some evidence that women with premature ovarian insufficiency (POI, loss of ovarian activity <40 years of age) are at risk for diminished life expectancy, large scale population-based studies are still scarce. The evidence on whether hormone replacement therapy (HRT) use decreases the mortality risk among women with POI are lacking. The aim of our study was to explore mortality among women with spontaneous POI and their controls in a large national cohort and whether HRT use modifies the mortality risk among them.
Methods
All spontaneous POI cases diagnosed in Finland between 1988-2017 were identified by their reimbursement right for HRT, from Social Insurance Institution medicine reimbursement registry. We explored mortality among women with spontaneous POI, compared to age and municipality matched controls (four/each POI case, $n=22859$). Cox regression analysis was used to compare mortality hazard ratio (HR) between women with POI and their controls in different causes of death. Women with cancer or cardiovascular morbidity before the index day were excluded from the analysis. Women with POI were classified as HRT users if they had purchased systemic HRT for ≥ 6 months. The data on mortality, causes of death and death ages were collected from Cause of Death Registry.
Results
The mean follow-up time for all groups was 17.5 years (standard deviation 8.5). At the end of the follow-up, 9.8% of women with spontaneous POI and 2.9% of controls were deceased. Compared to control women, age-standardized all-cause mortality was increased among women with spontaneous POI, among those without HRT (HR 1.60 95% Confidence Interval, CI 1.07-2.37) and those with HRT (HR 2.27 95% CI 1.46-3.5). Cancer mortality was also increased among spontaneous POI cases without HRT use, (HR 4.04 95% CI 3.04-5.37) and with HRT (HR 1.78 95%CI 1.27-2.48), as well as cardiovascular mortality (HR 2.30 95% CI 1.34-3.97) and (2.53 95% CI 1.58-4.06), respectively.
Conclusions
Women with spontaneous POI are at increased risk for all-cause, cardiovascular and cancer mortality, and HRT use of ≥ 6 months did not eliminate the risk. Future studies should focus on whether longer use of HRT associates with diminished mortality risk among women with POI. Specific attention should be paid to health of women with spontaneous POI to decrease excess mortality.

Pregnancy loss in women with endocrine disorders – a nationwide registry-based cohort study of 366,548 Danish women

Pia Egerup[1], Sofie Bliddal[1,2], David Westergaard[1], Dorte Glintborg[3], Steen J. Bonnema[3], Ulla Feldt-Rasmussen[2], Mette Nyegaard[4,5], Laust Hvas Mortensen[6] & Henriette Svarre Nielsen[1]
[1]Copenhagen University Hospital Hvidovre, Department of Obstetrics and Gynecology, Hvidovre, Denmark; [2]Copenhagen University Hospital Rigshospitalet, Department of Endocrinology and Metabolism, Copenhagen, Denmark; [3]Odense University Hospital, Department of Endocrinology, Odense, Denmark; [4]Aalborg University, Department of Health Science and Technology, Aalborg, Denmark; [5]Statens Serum Institut, Department of Congenital Disorders, Copenhagen, Denmark; [6]Statistic Denmark, Copenhagen, Denmark

Background
Pregnancy loss affects approximately 25% of pregnancies, of which 40% have no detectable chromosome abnormalities and are suspected to be caused by maternal comorbidity. Pregnancy loss has been associated with specific endocrine disorders, e.g. autoimmune thyroid disease (AITD), polycystic ovarian syndrome (PCOS) or diabetes mellitus (DM). Because of the well-described overlap between these endocrine disorders, we hypothesized that pregnancy loss is associated with any endocrine disorder and that having more than one endocrine disorder constitutes a more severe phenotype with a higher risk of pregnancy loss.
Methods
Danish nationwide cohort based on the Danish Health Registries containing information on ICD-8/ICD-10-diagnoses, all redeemed medicine prescriptions, and pregnancy outcomes. We identified women born from 1977-1993 with ≥ 1 pregnancy. Cases had a diagnosis of a non-iatrogenic endocrine disorder and controls had none. Logistics regression models, with the number of pregnancy losses as the outcome, adjusted for birth year provided odds ratios for endocrine disorders. Results are given as odds ratio with 95% confidence interval.
Results
The cohort consisted of 366,548 women of which 54,394 (15%) had an endocrine disorder. There was a highly significant association between endocrine disorders and pregnancy loss increasing with the number of pregnancy losses; one loss 1.15 (1.12-1.17), two losses 1.31 (1.24-1.38) and three losses 1.81 (1.70-1.93), $P<0.001$. The risk of pregnancy loss was also increased by AITD (1.21, 1.17-1.25), PCOS (1.32, 1.26-1.38), DM1 (1.38, 1.25-1.53), and DM2 (1.22, 1.09-1.35) , respectively, and increased further with a higher number of pregnancy losses. When these disorders were included simultaneously in the model, the increased risk associated with each individual condition persisted, suggesting that each disorder contributes distinctly to the pregnancy loss risk. Lastly, compared to

individuals with no endocrine disorders, those with one disorder had a higher risk of pregnancy loss (1.23, 1.19-2.6). This risk was further amplified in individuals with two disorders (1.60, 1.44-1.78), indicating a progressive elevation in risk correlating with the number of comorbid endocrine conditions.
Conclusion
In this nationwide register-based cohort study, there was a highly significant association between endocrine disorders and pregnancy loss. This was especially the case with an increasing number of pregnancy losses, and in women having more than one endocrine disorder. The observed additive effects indicates that each endocrine condition independently elevates the risk of pregnancy loss. This underscores the critical need for personalized intervention strategies including monitoring of each endocrine disorder to reduce the cumulative risk of pregnancy loss.

Kisspeptin as a test of hypothalamic function in women presenting with oligo / amenorrhoea

Bijal Patel[1], Ali Abbara[1], Arthur Yeung[1], Maria Phylactou[1], Jovanna Tsoutsouki[1], Kanyada Koysombat[1], Megan Young[1], Sandhi Nyunt[1], Ambreen Qayum[1], Aaran Patel[1], Agata Zielinska[1], Yusra Omar[1], Pei Eng[1], Edouard G Mills[1], Simon Hanassab[1], Lisa Webber[1,2], Channa Jayasena[1], Tricia Tan[1], Richard Quinton[3], Sophie Clarke[4], Alexander Comninos[1] & Waljit Dhillo[1]
[1]Imperial College London, United Kingdom; [2]Singapore General Hospital, Obstetrics and Gynaecology, Singapore, Singapore; [3]Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom; [4]University College London Hospitals Nhs Foundation Trust, United Kingdom

Background
Polycystic Ovary Syndrome (PCOS) and Functional Hypothalamic Amenorrhoea (FHA) are the two commonest causes of menstrual disturbance in pre-menopausal women. In practice, differentiating these two common reproductive disorders can be challenging. A fundamental abnormality that underpins both conditions is altered gonadotrophin releasing hormone (GnRH) pulsatility, being increased in PCOS but reduced in FHA. Likewise, congenital (e.g. congenital hypogonadotropic hypogonadism; CHH) and functional causes of hypogonadotropic hypogonadism (e.g. FHA) both have decreased hypothalamic function and can exhibit similar hormonal profiles presenting a diagnostic dilemma. Kisspeptin is a potent stimulator of hypothalamic GnRH secretion, and thus could be a novel tool to interrogate hypothalamic function in women presenting with menstrual disturbance.
Methods
Healthy women ($n=33$), women with PCOS ($n=30$), FHA ($n=30$), or CHH ($n=8$) aged 18-35 yrs not currently taking hormonal treatments, underwent two study visits to assess the hypothalamic response to an intravenous bolus of kisspeptin-54 (9.6 nmol/kg), and the pituitary response to GnRH (100 mg). Serum luteinising hormone (LH) and follicle stimulating hormone (FSH) were measured every 15 mins for 8 hrs. The maximal rise in LH and FSH from baseline was compared between the groups using an unpaired t test or Mann Whitney U test according to the distribution of the data. Receiver Operator Characteristic (ROC) analysis was used to assess the discriminatory potential of the hormonal response to kisspeptin and GnRH.
Results
The mean (SD) of the maximal rise in LH (IU/l) after kisspeptin was 9.7 (11.4) in healthy women, 9.7 (8.3) in women with PCOS, 17.6 (10.8) in women with FHA, and 1.0 (1.1) in women with CHH. The mean (SD) of the maximal rise in FSH (IU/l) after kisspeptin was 4.2 (3.4) in healthy women, 2.8 (2.1) in women with PCOS, 9.2 (5.6) in women with FHA, and 0.7 (0.5) in women with CHH. The maximal rise in FSH after kisspeptin could differentiate women with lean PCOS (BMI <25 kg/m^2) from those with FHA (area under ROC 0.91, $P=0.0001$). The maximal rise in FSH after kisspeptin could differentiate women with FHA from women with CHH (auROC 1.00, $P<0.0001$), whereas the equivalent auROC for FSH rise after GnRH was 0.7 ($P=0.086$).
Conclusion
Kisspeptin offers a novel approach to assessing hypothalamic function in patients presenting with different reproductive disorders causing oligo/ amenorrhoea. Our data reveals for the first time that the hormonal response to kisspeptin has promising diagnostic potential to aid in the evaluation of women presenting with menstrual disturbance.

Gender affirming treatment and employment rate in 3,812 Danish transgender persons and 38,120 controls. A nationwide register-based cohort study

Dorte Glintborg[1,2], Jens-Jakob Møller[1,3], Katrine Rubin[3,4], Øjvind Lidegaard[5], Guy T'Sjoen[6], Mie-Louise Larsen[5], Malene Hilden[5] & Marianne Andersen[1,2]
[1]Odense University Hospital, Odense, Denmark; [2]University of Southern Denmark, Klinisk Institut, Odense, Denmark; [3]Odense University Hospital, OPEN, Odense, Denmark; [4]University of Southern Denmark, Research unit OPEN, department of clinical research,, Odense, Denmark; [5]Copenhagen University, Københavns, Denmark; [6]Ghent University Hospital, Gent, Belgium

Objective
Transgender persons often experience low socioeconomic status. Gender affirming treatment aims to improve gender dysphoria. We assessed employment rates in transgender persons compared to controls and demographic, health and treatment-related factors associated with unemployment in transgender persons.
Methods
National register-based cohort study in Danish transgender persons with diagnosis code of gender identity disorder during year 2000-2021. Five age-matched controls of the same sex at birth and five age-matched controls of the other sex at birth were included. The date of study inclusion was the first date of transgender diagnosis. Employment was the primary study outcome.
Results
The cohort included 3812 transgender persons with median age (interquartile range) 19 (15; 24) years for persons assigned female at birth (AFAB, $n=1993$) and 23 (19; 33) years for persons assigned male at birth (AMAB, $n=1819$) and 38,120 controls. Mean (standard deviation) follow up was 4.7 (4.6) years. The proportion of employment the year before study inclusion was 78.1% in transgender persons AFAB vs 91.6% female controls, and 56.2% vs 85.5% were employed after 5 years follow up. In transgender persons AMAB vs male controls, 69.1% vs 88.0% were employed the year before study inclusion and 50.4% vs 85.5% were employed after 5 years follow up. In transgender persons AFAB compared to control women, the OR (95% confidence interval) for unemployment was 2.99 (2.63; 3.40) before study inclusion and 4.14 (3.42; 5.00) in the fifth calendar year after index. In transgender persons AMAB compared to control men, corresponding ORs were 3.30 (2.93; 3.72) and 4.77 (4.04; 5.64). Use of gender affirming hormone in persons AFAB decreased probability of unemployment at all time points with OR after 5 years 0.62 (0.41; 0.93), $P=0.02$ (odds ratio (95% confidence interval). In persons AMAB, use of hormone treatment was not associated with changed employment rates, 5 years OR: 0.77 (0.55; 1.07), $P=0.11$.
Conclusion
Unemployment was more prevalent in transgender persons compared to controls. Masculinizing hormone treatment was associated with lower probability of unemployment.

Sertoli cell function and the dose of denosumab is critical for the response to RANKL inhibition in human testis cultures

Christine Hjorth Andreassen[1], Nadia Krarup Knudsen[1], John Erik Nielsen[2], Sam Kafai Yahyavi[1,2], Rune Holt[1], Anne Jørgensen[1] & Martin Blomberg Jensen[1]
[1]Copenhagen University Hospital-Herlev and Gentofte, Division of Translational Endocrinology, Department of Endocrinology and Internal Medicine, Herlev, Denmark; [2]Copenhagen University Hospital-Rigshospitalet, Department of Growth and Reproduction, Copenhagen OE, Denmark

Currently, no treatment options exist to improve semen quality for the majority of infertile men, but it is well known that the interaction between Sertoli- and germ cells is essential to ensure complete spermatogenesis. A recent study suggested that denosumab, an inhibitor of receptor activator of nuclear factor kappa-B ligand (RANKL) signaling, may decrease germ cell apoptosis in human *ex vivo* testis cultures and stimulate sperm production in some infertile men. Here, we propose that the level of osteoprotegerin (OPG) expression in Sertoli cells may be indicative of dysgenesis in human testis tissue cultured *ex vivo* and that the expression of the RANKL signaling system, in combination with the dose, is predictive for the testicular response to denosumab. Human testis from orchiectomies was cultured *ex vivo* for 48 hours (34°C, 5% CO$<$ce:sub$>$2$<$/ce:sub$>$) and treated with 1, 30, or 100 ng/ml denosumab or vehicle. Samples positive for D2-40, a marker of germ cell neoplasia *in situ* (the precursor cell for

testicular cancer), were excluded. Immunohistochemical staining for OPG was used to assess dysgenesis in Sertoli cells in each seminiferous tubule of testis cultures. Proliferation and apoptosis were assessed by quantification of poly(ADP-ribose) polymerase cleavage (cPARP) and Bromdeoxyuridin (BrdU) positive germ cells, respectively. Treatment with 100 ng/ml of denosumab increased germ cell proliferation and decreased apoptosis in testis cultures with low or moderate OPG expression in Sertoli cells, while lower doses of denosumab had no effect. In contrast, 100 ng/ml denosumab increased germ cell apoptosis in testis tissue with high OPG expression in Sertoli cells but did not affect germ cell proliferation. Lower doses of denosumab did not affect germ cell proliferation or apoptosis in testis tissue with high OPG expression. This study suggests that the effect of denosumab depends on the function of Sertoli cells, with high OPG expression being a marker of dysgenesis. In addition, the testicular effect of denosumab is determined by the dose, and future clinical trials in infertile men should aim for a dose resulting in an intratesticular concentration close to 100 ng/ml.

Encaleret (CLTX-305) sustained normalization of mineral homeostasis in patients with autosomal dominant hypocalcemia type 1 over 18 months in a phase 2 study [NCT04581629]

Rachel Gafni[1], Iris Hartley[1], Kelly Roszko[1], Karen Pozo[1], Edward Nemeth[2], Arun Mathew[3], Mary Scott Roberts[3], Scott Adler[3] & Michael Collins[1]
[1]National Institutes of Health, National Institute of Dental and Craniofacial Research, Bethesda, United States; [2]MetisMedica, Toronto, Canada; [3]Calcilytix Therapeutics Inc., San Francisco, United States

Autosomal dominant hypocalcemia type 1 (ADH1), caused by gain-of-function calcium-sensing receptor gene (*CASR*) variants, is characterized by low parathyroid hormone (PTH) levels, hypocalcemia, hypercalciuria, hyperphosphatemia and hypomagnesemia. Conventional therapy (calcium and active vitamin D) can exacerbate hypercalciuria, which may result in renal complications. Calcilytics that act as negative allosteric modulators of the calcium-sensing receptor (CaSR), like encaleret, decrease the sensitivity of hyperactive receptors to extracellular calcium and normalize biochemical abnormalities in ADH1 rodent models. This Phase 2b open-label study of the oral investigational calcilytic encaleret was comprised of 3 periods followed by a long-term extension (LTE). Conventional therapy was discontinued prior to encaleret initiation. Periods 1&2 included dose-finding and safety/tolerability evaluation. Period 3 (P3) optimized dosing and assessed safety and efficacy over 24 outpatient weeks; participants were then allowed to continue in the LTE. Thirteen adults with ADH1 were enrolled and encaleret was individually titrated to normalize albumin-corrected calcium (cCa) and minimize hypercalciuria. Encaleret was well-tolerated with no serious adverse events reported. There were no treatment discontinuations or withdrawals prior to the LTE; one participant withdrew during the LTE for family planning. The mean $\pm$ SD encaleret sulfate dose at the end of P3, Week 24 (P3W24) was 86 $\pm$ 70 mg BID, remaining stable at LTE Month 12 (LTEM12) ($n=12$) (75 $\pm$ 66 mg BID). Mean $\pm$ SD values taken 4-hours post-dose for P3W24 and LTEM12 compared to baseline (BL) are presented. PTH levels were low at BL (6.3 $\pm$ 7.8 pg/ml [nl 10-65]), normal at P3W24 (35.3 $\pm$ 10.2 [$P<0.01$]) and remained consistent through LTEM12 (36.9 $\pm$ 15.2 [$P<0.01$]). Similarly, the hypocalcemia seen at BL (cCa = 7.1 $\pm$ 0.4 mg/dl [nl 8.4-10.2]) was corrected at P3W24 (9.2 $\pm$ 0.5 [$P<0.01$]); eucalcemia was maintained through LTEM12 (9.2 $\pm$ 0.4 [$P<0.01$]). BL hypercalciuria (395 $\pm$ 216 mg/d [nl < 250-300]) decreased to 202 $\pm$ 83 ($P<0.05$) at P3W24 and normalization was sustained through LTEM12 (177 $\pm$ 94 [$P<0.05$]). BL blood phosphate (4.5 $\pm$ 1.1 mg/dl [nl 2.3-4.7]) decreased by P3W24 (3.4 $\pm$ 0.4 [$P<0.05$]) and was maintained at LTEM12 (3.4 $\pm$ 0.5 [$P<0.01$]). Blood magnesium increased (BL 1.7 $\pm$ 0.2 mg/dl [nl 1.6-2.6]); P3W24 2.0 $\pm$ 0.2 [$P<0.01$]; LTEM12 2.1 $\pm$ 0.2 [$P<0.01$]). Bone turnover markers increased from BL ($n=7$) (CT_X = 253 $\pm$ 111 pg/ml; P1NP = 34 $\pm$ 10 mg/l) by P3W24 ($n=13$) (CT_X = 744 $\pm$ 565; P1NP = 104 $\pm$ 87) [$P<0.01$] and remained elevated at LTEM12 (CT_X = 988 $\pm$ 652; P1NP = 83 $\pm$ 49 [$P<0.01$]). This study represents a molecularly targeted, precision medicine approach to the treatment of ADH1. The consistent and sustained results from over 18 months of outpatient encaleret treatment are clinically meaningful and support Phase 3 evaluation of the efficacy and safety of encaleret as the first potential treatment indicated for ADH1.

Hypoparathyroidism is an endocrine disease caused by insufficient levels of parathyroid hormone (PTH). Individuals with chronic hypoparathyroidism managed with conventional therapy (active vitamin D and calcium) are at increased risk for renal complications and declines in renal function. In clinical trials, palopegteriparatide treatment enabled independence from conventional therapy (no active vitamin D and $\leq$600 mg/day elemental calcium) and maintained serum biochemistries within normal ranges. This analysis examines the impact of palopegteriparatide treatment on renal function in adults with chronic hypoparathyroidism through week 104 of the PaTHway trial. PaTHway is a phase 3 trial with a randomized, double-blind, placebo-controlled 26-week period and ongoing 156-week open-label extension. Estimated glomerular filtration rate (eGFR) $\geq$30 ml/min/1.73 m^2 was required for eligibility. In this post hoc analysis, changes in renal function were assessed using eGFR. Safety assessments included 24-hour urine calcium excretion and treatment-emergent adverse events (TEAEs). At week 104, 93% (76/82) of participants remained in the trial. Of those, 82% had normal albumin-adjusted serum calcium levels (2.07-2.64 mmol/l), 97% were independent from conventional therapy, and none required active vitamin D. Mean (SD) serum phosphate (1.1(0.2) mmol/l) and albumin-adjusted calcium $\times$ phosphate product (2.5(0.4) $mmol^2/l^2$) levels were also within normal ranges. At week 104, mean (SD) eGFR was 77.8 (14.8) ml/min/1.73 m^2. Palopegteriparatide treatment resulted in a mean (SD) increase in eGFR of 8.9 (11.0) ml/min/1.73 m^2 ($P<.0001$) from baseline to week 52, which was sustained through week 104 with a mean (SD) change from baseline of 9.0 (10.3) ml/min/1.73 m^2 ($P<.0001$). By week 104, 61% and 44% of participants had an increase in eGFR of $\geq$5 ml/min/1.73 m^2 and $\geq$10 ml/min/1.73 m^2 respectively. Among participants with baseline eGFR < 60 ml/min/1.73 m^2 ($n=23$), palopegteriparatide treatment resulted in a mean (SD) increase in eGFR of 13.8 (10.0) ml/min/1.73 m^2 from baseline to week 104, and 78% and 57% had an increase in eGFR of $\geq$5 ml/min/1.73 m^2 and $\geq$10 ml/min/1.73m^2 respectively. Palopegteriparatide treatment normalized mean 24-hour urine calcium within 26 weeks and maintained levels below 6.2 mmol/day through week 104 (4.0(2.3) mmol/day). No cases of nephrolithiasis were reported with palopegteriparatide treatment. Most TEAEs were mild or moderate; no new safety signals were reported. This post hoc analysis of the phase 3 PaTHway trial through week 104 demonstrates the sustained renal safety of palopegteriparatide and suggests that PTH replacement therapy with palopegteriparatide and independence from conventional therapy may not only preserve but improve renal function in adults with chronic hypoparathyroidism.

A translational approach to investigate the mechanism whereby eneboparatide induces prolonged calcium normalization in patients with chronic hypoparathyroidism

Guillaume Ravel[1], Rakesh Datta[2], Stephane Milano[1], Michel Ovize[1], Soraya Allas[1], Myriam Aouadi[1] & Michael Culler[2]

[1]Amolyt Pharma, Écully, France; [2]Amolyt Pharma, Cambridge, United States

Maintaining normal serum and urinary calcium in patients with chronic hypoparathyroidism (cHP) remains a therapeutic challenge. Parathyroid hormone (PTH) replacement therapy is not ideal due to its short half-life and transient activation of the PTH 1 receptor (PTH1R). Eneboparatide is a hybrid analog of PTH and PTH-related peptide specifically designed to induce prolonged activation of the PTH1R. Despite a short half-life, eneboparatide is able to normalize serum and urinary calcium levels over a full 24 hours in cHP patients. To gain deeper insight into the mechanism whereby eneboparatide provides sustained calcium normalization, we analyzed tissue distribution and retention of eneboparatide in comparison to natural PTH(1-34) following subcutaneous injection in rats. Quantitative whole-body autoradiography in rats treated with radiolabeled eneboparatide and PTH(1-34) revealed similar rapid elimination from the circulation and accumulation of both compounds in tissues expressing PTH1R, with highest levels observed in renal cortex. However, 6 hours postdose, 38.6% of eneboparatide remained in renal cortex, while only 3.7% of PTH(1-34) was detectable. These results demonstrated a preferential retention of eneboparatide in the renal cortex, where the PTH1R regulates calcium reabsorption. We next assessed whether the eneboparatide tissue retention observed *in vivo* was due to prolonged binding to the PTH1R. Ligand binding to the PTH1R leads to conformational changes of the receptor from G protein-dependent (RG) to G protein-independent (R^0). Using a specific PTH1R binding assay, we confirmed high affinity of eneboparatide for the R^0 conformation compared to PTH(1-34) (1.5 nM vs 30.9 nM, respectively). We next investigated whether the strong affinity of eneboparatide for the R^0 conformation translated into prolonged receptor activation. To mimic the rapid elimination from the circulation *in vivo*, we treated HEK293 cells overexpressing the human PTH1R with both ligands for 15 min and, after washing, continued incubation with media alone. As expected, activation of the PTH1R by both PTH(1-34) and eneboparatide led to a rapid and similar increase in cAMP. After removal of PTH(1-34), cAMP production returned to baseline in less than 1 hour. However, following removal of eneboparatide, cAMP production decreased gradually, and residual signal remained strikingly constant and detectable through the last time point measured, 16 hours. Our translational approach demonstrates the potential therapeutic advantage of eneboparatide over PTH(1-34) due to its ability to be retained in renal cortex, to induce a prolonged activation of the PTH1R and to maintain normal serum and urinary calcium over 24 hours in cHP patients.

Increased urinary excretion of calcium and nephrolithiasis: Real-life data from the epi-hypo cohort of hypoparathyroidism patients

Bertocchio Jean-Philippe[1], Nidercorn Christelle[2], Peter Kamenicky[3], Vantyghem Marie Christine[4], Maruani Gerard[5], Lionel Groussin[6], Michel Ovize[7], Agnès Linglart[3] & Pascal Houillier[5]
[1]APHP-Hopital Pitié Slapétrière, Service Thyroïde-Tumeurs endocrines, Paris, France; [2]Hypoparathyroidisme France, Annecy-le-Vieux, France; [3]APHP-Hopital du Kremlin Bicetre, Service Endocrinologie et Maladies de la Reproduction, Le Kremlin-Bicêtre, France; [4]CHU de Lille, Lille, France; [5]APHP Hopital Européen Georges Pompidou, Service de Physiologie Rénale, Paris, France; [6]APHP Hopital Cochin, Service d'Endocrinologie Adulte, Paris, France; [7]Amolyt Pharma, Clinical Development, Ecully, France

Introduction
In chronic hypoparathyroidism (cHP), hypercalciuria is frequent, the mechanism of which remains unclear. The repetition of episodes of urinary tract obstruction by lithiasis can play a key role in the progressive deterioration of renal function. Taking advantage of the prospective cohort Epi-Hypo, we examined the relationship between nephrolithiasis and hypercalciuria.
Methods
The Epi-Hypo cohort started in 2016 in France and is still actively recruiting. Inclusion criteria include i) chronic (i.e. $\geq$6 months) cHP, ii) patient followed in France, and iii) patient agreement to participate. Exclusion criteria include i) transient cHP and ii) pseudo-hypoparathyroidism. Both pediatric and adult participants are recruited by physicians. Data are collected online through a secure digital platform for: demographics, circumstances of diagnosis, and follow-up (clinical events such as nephrolithiasis, as well as biology including calciuria) and entered in the database by physicians.
Results
The database was frozen on March 1st, 2023. At that time, urinary excretion of calcium was available for 776 patients; 74% were female and the median [IQR] age at diagnosis was 43 [31;56] years. Neck surgery accounted for 73% of cases. Hypercalciuria (defined as urinary calcium excretion $>$7.5 mmol/d in men and $>$ 6.25 mmol/d in women) was present in 258 (33%) of study patients. The proportion of patients with nephrolithiasis was significantly higher in patients with than in patients without hypercalciuria (26 vs 17%, $P=0.023$). Age, gender, or cause of hypoparathyroidism did not differ between patients with or without nephrolithiasis. The percentage of patients with hypercalciuria treated by oral calcium or active vitamin D was significantly higher than that of patients without hypercalciuria (72% vs 52%; 78% vs 65%, respectively; $P<0.05$ for both). Alternatively, hypercalciuric patients received significantly less often 25(OH) vitamin D (28% vs 35%; $P=0.024$).
Discussion/Conclusion
These data indicate that nephrolithiasis is more prevalent in cHP patients with hypercalciuria. The follow-up of this population may allow to assess a causal relationship between hypercalciuria and nephrolithiasis. It further suggests that normalization of urinary calcium excretion is a key therapeutic objective in patients with cHP hypoparathyroidism. Its impact on renal function remains to be investigated.

DOI: 10.1530/endoabs.99.OC2.4

OC2.5

Remaining secretion of parathyroid hormone is associated with calcium excretion in chronic hypoparathyroidism

Bertocchio Jean-Philippe[1], Nidercorn Christelle[2], Peter Kamenicky[3], Vantyghem Marie Christine[4], Maruani Gerard[5], Lionel Groussin[6], Michel Ovize[7], Agnès Linglart[3] & Pascal Houillier[5]
[1]APHP-Hopital Pitié Slapétrière, Paris, France; [2]Hypoparathyroidisme France, Annecy-le-Vieux, France; [3]APHP-Hopital du Kremlin Bicetre, Le Kremlin-Bicêtre, France; [4]CHU de Lille, Lille, France; [5]APHP Hopital Européen Georges Pompidou, Paris, France; [6]APHP Hopital Cochin, Paris, France; [7]Amolyt Pharma, Ecully, France

Introduction
In Chronic hypoparathyroidism (cHP), secretion of parathyroid hormone (PTH) is insufficient to maintain blood calcium concentration (PCa) steady. More than 70% of cases result from neck surgery and therefore in insufficient secretion of PTH as in mutations of genes involved in PTH synthesis, while mutations of the calcium-sensing receptor (CaSR) and its signaling pathway may result in a remaining secretion of PTH. cHP can exert nephrocalcinosis and/or nephrolithiasis in which calciuria (CaU) may play a key role. If the relationship between PCa and CaU has been studied, very few is known about the determinants of CaU during cHP. Taking advantage of the prospective cohort Epi-Hypo, we designed a study to analyze the determinants of CaU during cHP.
Methods
Epi-Hypo started in 2016 in France and is still actively recruiting. Inclusion criteria are i) chronic (i.e. $\geq$6 months) hypoPT, ii) followed in France, and iii) agreement to participate. Exclusion criteria are i) transient hypoPT and ii) pseudo-hypoparathyroidism. Both pediatric and adult participants are recruited. Data collected online through a secure digital platform refer to: demographics, circumstances of diagnosis, and follow-up including biology (PCa, CaU, and PTH as its ratio (PTHr) to the upper level of the normal laboratory range).
Results
The database was frozen on March 1st, 2023. At that time, 1,249 patients were included: 893 (71%) were female with median[IQR] age at diagnosis 43[31;56] years. In 937 (73%) patients, the cause was surgery. Nephrolithiasis and/or nephrocalcinosis was diagnosed in 198 (15%) patients over a mean$\pm$SD period of 12$\pm$10 years of follow-up. We gathered a subpopulation of 768 patients in whom both PCa and CaU (collected in 24-h urine collection) were available at least once. Mean$\pm$SD PCa and CaU values were 2.08$\pm$0.28 mM and 5.5$\pm$4.2 mmol/day, respectively, 33% patients exhibiting hypercalciuria. A positive correlation between PCa and CaU ($r^2=0.29$, $P<0.001$) and a negative correlation between blood PTH level and CaU ($r^2=-0.30$, $P<0.001$) were identified. Neither age, gender, or etiology of hypoparathyroidism were significantly different among patients with or without a remaining secretion of PTHr (ie PTHr $\geq$0.10).
Discussion/Conclusion
Controlling CaU during cHP is a challenging task. For the first time in a large cohort of patients, we report that a remaining secretion of PTH is linked to a lower CaU. Further studies are required to decipher whether this secretion is stable over time and whether it has to be taken into account when treating patients suffering from cHP.

DOI: 10.1530/endoabs.99.OC2.5

OC2.6

CALIBRATE: A phase 3, randomized, open-label study evaluating the efficacy and safety of encaleret (CLTX-305) compared to standard of care in participants with autosomal dominant hypocalcemia type 1 [NCT05680818]

Lars Rejnmark[1], Michael Mannstadt[2], Maria Luisa Brandi[3], Keiichi Ozono[4], Peter Tebben[5], Arun Mathew[6], Mary Scott Roberts[6], Scott Adler[6] & Rachel Gafni[7]
[1]Aarhus University Hospital, Institute of Clinical Medicine, Aarhus, Denmark; [2]Massachusetts General Hospital and Harvard Medical School, Endocrine Unit, Boston, United States; [3]University of Florence, Florence, Italy; [4]Osaka University, Osaka, Japan; [5]Mayo Clinic, Division of Endocrinology, Rochester, United States; [6]Calcilytix Therapeutics, Inc., San Francisco, United States; [7]National Institutes of Health, National Institute of Dental and Craniofacial Research, Bethesda, United States

Autosomal dominant hypocalcemia type 1 (ADH1), caused by pathogenic gain-of-function calcium-sensing receptor gene (*CASR*) variants, is characterized by low parathyroid hormone (PTH) levels, hypocalcemia, hypercalciuria, hyperphosphatemia and hypomagnesemia. Current standard-of-care (SoC) (calcium and active vitamin D) can exacerbate hypercalciuria, which may result in renal complications. Encaleret is an investigational oral calcilytic, functioning as a negative allosteric modulator of the calcium-sensing receptor, that is being studied as a potential treatment for ADH1. A Phase 2b study [NCT04581629] in 13 adults with ADH1 showed that encaleret led to sustained normalization in mean blood levels of intact PTH, albumin-corrected calcium (cCa), phosphorus, magnesium and 24-hr urine calcium (UCa) excretion over 24 weeks compared with baseline. Encaleret was well-tolerated with no serious adverse events reported. CALIBRATE is a global Phase 3 study designed to evaluate the efficacy and safety of encaleret compared to SoC in approximately 60 participants ($\geq$18-years-old in Europe; $\geq$16-years in other sites) with ADH1. After a screening evaluation, eligible participants will undergo SoC optimization followed by a 4-week SoC maintenance period (Period 1 [P1]). Participants will then be randomized 2:1 (encaleret:SoC) into a 20-week dose titration period (Period 2). Doses of encaleret or SoC will be titrated to achieve target cCa concentrations while minimizing UCa excretion. Participants will then enter a 4-week maintenance period (Period 3 [P3]) where doses of encaleret or SoC are intended to be fixed. The primary efficacy endpoint is a composite endpoint: a) cCa within 8.3-10.7 mg/dl (2.1-2.7 mmol/l) AND b) 24-hr UCa within reference range (men: $<$300 mg/day [7.5 mmol/day]; women: $<$250 mg/day [6.25 mmol/day]). Participants who meet both criteria will be considered responders. The primary analysis will be a within-patient comparison of the proportion of responders in the encaleret group at the completion of P3 vs P1 (SoC). Key secondary endpoints include between-treatment arm comparisons (encaleret vs SoC at P3) as well as the evaluation of mineral homeostasis parameters, renal health, bone health, and patient-reported outcomes. Following completion of P3, eligible participants will have the option to enter a long-term extension (LTE) period with all participants having access to encaleret. CALIBRATE is actively recruiting study participants and has sites (active and planned) in 12 countries: USA, Canada, Brazil, Netherlands, Denmark, France, Italy, Czech Republic, Taiwan, Australia, United Kingdom, and Japan.

Long-term incidence of acute cardiovascular events in transgender people – a large cohort study with national registry data

Lieve van Zijverden[1], Abel Thijs[2], Jeske van Diemen[2], Annemieke Staphorsius[1], Martin den Heijer[1] & Chantal Wiepjes[1]
[1]Amsterdam University Medical Centre, Department of Endocrinology, Centre of Expertise on Gender Dysphoria, Amsterdam, Netherlands; [2]Amsterdam University Medical Centre, Department of Internal Medicine, Amsterdam, Netherlands

Background
Transgender people often use gender-affirming hormone therapy to obtain physical characteristics that comply with their experienced gender. Transgender women use estradiol, usually with anti-androgens. Transgender men use testosterone. It has been reported that gender-affirming hormone therapy is associated with increased risk of acute cardiovascular events, however, this data constitutes largely of low quality evidence. We aimed to investigate the long-term incidence of acute cardiovascular events (CVEs) in our large cohort of transgender people compared with incidence in cisgender men and women.

Methods
This retrospective cohort study includes all people who visited the gender identity clinic of the Amsterdam University Medical Centre in the Netherlands between 1972 and 2018. All people were linked to a nationwide data registry (Statistics Netherlands) to obtain data on medical diagnoses, which were registered from 2012 until 2021. The outcomes were myocardial infarction, stroke, thrombosis and overall acute CVE incidence. Exclusion criteria were not using hormones and death before 2012. Standardized incidence ratios (SIRs) for each outcome were calculated using general population incidence rates stratified by age, sex and calendar year.
Results
2983 transgender women (follow-up: 49440 person-years) and 2143 transgender men (follow-up: 25346 person-years) were included. Median age at hormone therapy initiation was 29 (IQR 22-40) and 21 (IQR 18-28) years, respectively. Transgender women experienced 142 acute CVEs, which was higher compared with cisgender women (SIR 1.5, 95%CI 1.3-1.8), but not cisgender men (SIR 1.1, 95%CI 0.9-1.3). Myocardial infarction incidence was higher compared with cisgender women (SIR 1.8, 95%CI 1.2-2.5), and lower compared with cisgender men (SIR 0.7, 95%CI 0.5-0.9). Thrombosis incidence was elevated compared with both cisgender groups (women: SIR 1.9 [95%CI 1.4-2.4], men: SIR 1.8 [95%CI 1.4-2.4]). Stroke SIR was 1.2 (95%CI 0.9-1.5) compared with cisgender women and 0.9 (95%CI 0.7-1.2) compared with cisgender men. Transgender men experienced 62 CVEs, which was higher compared with cisgender women (SIR 1.9, 95%CI 1.5-2.4) and men (SIR 1.5, 95%CI 1.1-1.9). Myocardial infarction SIRs were also higher than in cisgender women (4.8, 95%CI 3.1-6.9) and men (1.7, 95%CI 1.1-2.4). This was not the case for stroke SIRs (cisgender women: 1.5 [95%CI 0.9-2.1], men: 1.2 [95%CI 0.8-1.8]) and thrombosis SIRs (cisgender women: 1.2 [95%CI 0.7-1.9], men: 1.5 [95%CI 0.9-2.4]).
Conclusion
Transgender women have a higher overall CVE risk than cisgender women, particularly in thrombosis and myocardial infarction. For transgender men overall CVE risk is higher than in both cisgender groups, mostly affected by increased myocardial infarction risk.

Copeptin and asymptomatic arterial disorder in patients with type 2 diabetes, a cross-sectional study

Lee Ti Davidson[1], Jan Engvall[2], Simona Chisalita[3], Carl Johan Östgren[4] & Fredrik Nyström[2]
[1]Linköping University, Department of Emergency Medicine and Department of Biomedical and Clinical Sciences, Linköping, Sweden; [2]Linköping University, Division of Diagnostics and Specialist Medicine, Department of Health, Medicine and Caring Sciences, Linköping, Sweden; [3]Linköping University, Department of Endocrinology and Department of Health, Medicine and Caring Sciences, Linköping University, Linköping, Sweden; [4]Linköping University, Division of Prevention, Rehabilitation and Community Medicine, Department of Health, Medicine and Caring Sciences, Linköping, Sweden

Background
Individuals with diabetes are at higher risk for developing arterial disorders. The toe-brachial index (TBI) is associated with peripheral vascular disease, and aortic pulse-wave velocity (aPWV) is currently the gold standard for assessing arterial stiffness. High concentrations of plasma arginine vasopressin (AVP) preferentially stimulate V1a receptors, which affect the vascular bed and may contribute to cardiovascular (CV) complications. Copeptin, a more stable peptide of AVP, is co-secreted from the pituitary gland in equimolar amounts to AVP upon hemodynamic, osmotic, and other stress-related stimuli. Elevated levels of copeptin are potentially linked to vascular dysfunction.
Objective
To analyze the association of copeptin to TBI and aPWV as a marker of arterial disorder in patients with type 2 diabetes mellitus (T2D).
Methods
A cross-sectional analysis was conducted on 681 patients from the epidemiological study CARDIPP (Cardiovascular Risk Factors in Patients with Diabetes – a Prospective Study in Primary Care; ClinicalTrials.gov identifier NCT01049737) with data on copeptin, TBI, and aPWV. The relationship between the conventional cardiovascular risk factors and copeptin with TBI and aPWV were examined, respectively. Pearson correlation analysis and linear regression analyses were used.
Results
Copeptin correlated to TBI (r=-0.086, P=0.027) and aPWV (r=0.143, $P<$0,001). Copeptin was also negatively associated with TBI (β=-0.093, P=0.027) and aPWV (β=0.121, P=0.004) independently of age, sex, diabetes

duration, BMI, smoking, previous cardiovascular diseases, HbA1c, HDL cholesterol, and estimated glomerular filtration rate.
Conclusion
Copeptin is independently associated with TBI and aPWV. Copeptin may play an important role in the development of arterial disorders. Measuring copeptin levels may be a simpler method and more efficient way to identify individuals at risk for arterial disorders compared to current methods such as TBI and aPWV.

Inflammation-based scores in patients with pheochromocytoma

Chiara Parazzoli[1], Alessandro Prete[2,3,4,5], Vittoria Favero[1,6], Carmen Aresta[7], Valentina Pucino[8,9], John Ayuk[4], Miriam Asia[4], Yasir S Elhassan[2,3,4], Iacopo Chiodini[1,6] & Cristina L Ronchi[3,4,9]
[1]University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan, Italy; [2]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [3]Birmingham Health Partners, Centre for Endocrinology, Diabetes and Metabolism, Birmingham, United Kingdom; [4]Queen Elizabeth Hospital Birmingham, Department of Endocrinology, Birmingham, United Kingdom; [5]University of Birmingham and University Hospitals Birmingham NHS Foundation Trust, National Institute for Health Research Birmingham Biomedical Research Centre, Birmingham, United Kingdom; [6]Ospedale Niguarda Cà Granda, Unit of Endocrinology, Milan, Italy; [7]IRCCS, Istituto Auxologico Italiano, Department of Endocrine and Metabolic Diseases, Milan, Italy; [8]University of Oxford, Kennedy Institute of Rheumatology, Birmingham, United Kingdom; [9]University of Birmingham, Institute of Inflammation and Ageing, Birmingham, United Kingdom

Background
Pheochromocytoma is associated with systemic inflammation, but the underlying mechanisms are unclear. Hypothesising a putative effect of catecholamines on immune cells, we investigated the relationship between plasma metanephrine levels and haematological parameters – as surrogates for systemic inflammation – in patients with pheochromocytoma. Moreover, we aimed to assess the influence of preoperative α-blockade treatment on the inflammation-based scores.
Design and Methods
We included a retrospective cohort of 68 patients with pheochromocytoma who underwent adrenalectomy (mean age 53 years, 64.7% female) and two control groups matched for age, sex and body mass index: 68 patients with non-functioning adrenocortical tumours (NFAT) and 53 with essential hypertension. The full blood count and various inflammation-based scores [neutrophil/lymphocyte ratio (NLR), platelet/lymphocyte ratio (PLR), lymphocyte/monocyte ratio (LMR), Systemic Inflammation Index (SII), Prognostic-Nutrition Index (PNI)] were assessed in all patients at diagnosis and compared between the three groups. In addition, in a subgroup of pheochromocytomas, these parameters were compared before and after preoperative α-blockade treatment ($n=29$, median time 110 days, IQR 78.5-261.5) and before and after adrenalectomy ($n=26$, median time 15.6 months, IQR 5.7-42.3).
Results
A higher inflammatory state, as reflected by both full blood count and inflammation-based scores, was observed in patients with pheochromocytoma compared to NFAT and essential hypertension, whilst no differences were found between the two control groups. Notably, plasma metanephrine levels showed a positive correlation with NLR ($r=0.4631$), PLR ($r=0.3174$), SII ($r=0.3709$), and a negative correlation with LMR ($r=0.4368$) and PNI ($r=0.3741$), even after adjustment for age, sex, ethnicity, BMI, and tumor size, except for PLR. After adrenalectomy, we observed a significant increase in lymphocyte count ($P=0.01$) with corresponding changes in the relative inflammation-based scores. Specifically, a decrease in NLR ($P=0.001$), PLR ($P=0.003$), SII ($P=0.004$) and a concomitant increase in LMR ($P=0.0002$) were detected postoperatively. Similarly, α-blockade treatment led to a reduction in NLR ($P=0.007$) and SII ($P=0.03$).
Conclusions
The preoperative systemic inflammatory state observed in patients with pheochromocytoma, reflected by high NLR, PLR and SII, as well as low LMR and PNI, and ameliorated by adrenalectomy and α-blockade, is probably related to an excessive amount of secreted catecholamines. The impact of circulating catecholamines on the systemic inflammatory response may play a role in the cardio-metabolic comorbidities in patients with pheochromocytoma and may optimise treatment approaches.

HHEX is required for maintaining circulating glucocorticoid levels through expression of steroid transporter ABCB1 and regulation of lipid droplet homeostasis in the adrenal cortex

Typhanie Dumontet[1], Katie Basham[2], Micah Foster[1], Kyle Heard[1], Christopher Lapensee[1], Christina Bothou[3], Felix Beuschlein[3], William Rainey[1], Adina F. Turcu[1], Antonio Lerario[1] & Gary Hammer[1]
[1]University of Michigan, Ann Arbor, United States; [2]Huntsman Cancer Institute, Salt Lake City, United States; [3]University Hospital of Zürich, Zürich, Switzerland

The adrenal cortex synthesizes glucocorticoids that are essential for metabolic homeostasis and modulation of immune responsiveness. Glucocorticoid-producing cells, located in the zona fasciculata (zF), constitute the critical effector of the HPA axis that serves to mediate the mammalian stress response. Dysregulation of glucocorticoid function results in significant morbidity with complete deficiency being incompatible with life. While the zF is composed of heterogenous cell populations exhibiting proliferative, remodeling, and differentiation capabilities, the mechanisms and physiological importance of such diversity remain unexplored. To define the functional significance of the cellular diversity of the zF, we first performed single-cell RNAseq of the steroidogenic lineage in the adult mouse adrenal. We identified the homeodomain protein, HHEX, as the top enriched transcription factor in zF cells. To determine its role in adrenal homeostasis, we generated adrenal-specific Hhex knockout mouse models. Importantly, *HHEX KO* mice exhibited a profound glucocorticoid deficiency at baseline. We then performed bulk RNAseq and identified *Abcb1b* as the top gene dysregulated in *HHEX KO* of both sexes. ABCB1 (also P-glycoprotein, multidrug resistance protein 1) is a steroid efflux pump that is enriched in an inner-most zF cluster of cells and centrifugally expands during chronic stress. In humans, ABCB1 polymorphisms are associated with altered HPA axis regulation suggesting a critical role in chronic stress adaptation. Using CUT&Tag technology to profile *in vivo* genomic binding, we provide evidence that HHEX directly occupies *Abcb1b* regulatory regions. By combining RNAscope for *in situ* localization, and chronic ACTH treatment, we observed that *HHEX KO* fail to increase *Abcb1b* expression. Taken together these results suggest a critical role for HHEX in *Abcb1b* expression and chronic stress adaptation in both sexes. We then proceeded to determine adrenocortical cholesterol content (steroid precursor), and a profound decrease was evident specifically in the inner zF of *KO* males. Temporal analyses of HHEX expression revealed an 8-fold higher level in males at puberty compared to female counterparts, and genomic binding studies confirmed AR binding to HHEX promoter region *in vivo*. These observations suggest a sexually dimorphic role of HHEX in lipid (cholesterol ester) homeostasis. To explore the possibility that the dimorphism was mediated in part by androgens, we gonadectomized males and observed a complete rescue of the lipid loss in *HHEX KO* adrenals. Taken together, our results provide evidence that HHEX orchestrates the function and identity of the zF to promote chronic stress adaptation and protect lipid droplet integrity in males.

Hip fractures in patients with primary aldosteronism – A Swedish nationwide study

Eleftheria Gkaniatsa[1,2], Tatiana Zverkova Sandström[3], Annika Rosengren[4,5], Penelope Trimpou[1,2], Andreas Muth[6], Gudmundur Johannsson[1,2] & Oskar Ragnarsson[1,2,7]
[1]Institute of Medicine, Sahlgrenska Academy, Department of Internal Medicine & Clinical Nutrition, Gothenburg, Sweden; [2]Sahlgrenska University Hospital, Department of Endocrinology, Gothenburg, Sweden; [3]Sahlgrenska Academy, University of Gothenburg, Health Metrics Unit, Gothenburg, Sweden; [4]Institute of Medicine, Sahlgrenska Academy, Department of Molecular and Clinical Medicine, Gothenburg, Sweden; [5]Sahlgrenska University Hospital, Department of Medicine, Geriatrics and Emergency Medicine, Gothenburg, Sweden; [6]Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Department of Surgery, Sweden; [7]Wallenberg Centre for Molecular and Translational Medicine, University of Gothenburg

Objectives
Clinical studies indicate that primary aldosteronism (PA) is associated with dysregulated bone homeostasis. The aim of this study was to evaluate the incidence of hip fractures in patients with PA.
Methods
We studied a nationwide cohort of 2419 patients with PA (1997-2019) and 24 187 age and sex matched controls from the general population. Hip fractures were

identified by ICD codes in the Swedish National Patient Register. We estimated hazard ratios (HRs) for incident hip fractures, adjusted for socioeconomic factors, diabetes, cardiovascular disease (CVD), osteoporosis, hyperparathyroidism, and prior fractures. Pairwise subgroup comparisons were performed by age (18-56 and $\geq$56 years), sex, CVD at baseline, and treatment for PA.
Results
During a mean follow up of 8 ± 5 years, 64 (2.6%) patients had a hip fracture after being diagnosed with PA, compared to 401 (1.7%) controls. After adjustments, PA was associated with increased risk of hip fracture compared to controls (HR 1.55 [1.18-2.03]). HRs were increased in women (HR 1.76 [95% CI 1.24-2.52]), patients aged >56 years (HR 1.62 [95% CI 1.21-2.17]), and patients with CVD at diagnosis (HR 2.15 [95% CI 1.37-3.37]). PA patients treated with adrenalectomy did not have higher risk than controls (HR 0.84 [95% CI 0.35-2.0]), while patients treated with mineralocorticoid receptor antagonists (MRA) retained a greater risk (HR 1.84 [95% CI 1.20-2.83]).
Conclusions
PA is associated with increased hip fracture risk, especially in women, patients diagnosed after the age of 56 years and patients with established CVD at diagnosis. Also, patients treated with MRA seem to have an increased risk of hip fractures, while adrenalectomy may be protective.

DOI: 10.1530/endoabs.99.OC3.5

OC3.6

Multiple dosing of immediate-release hydrocortisone is associated with a greater risk of hypothalamic-pituitary-adrenal axis suppression when compared to low-dose prednisolone when weaning in steroid-induced adrenal insufficiency

Simon Mifsud[1], Emma Louise Mifsud[1], John Newell-Price[1,2], Richard Ross[1] & Miguel Debono[1,2]
[1]The University of Sheffield, United Kingdom; [2]Sheffield Teaching Hospitals NHS Foundation Trust, United Kingdom

Background
Long-term glucocorticoids can result in iatrogenic Cushing's syndrome with adrenal suppression. Most patients reactivate their hypothalamic-pituitary-adrenal axis once they're weaned off glucocorticoids. During glucocorticoid withdrawal, many clinicians switch patients to hydrocortisone to benefit from its short half-life[1]. However, in some patients, hypothalamic-pituitary-adrenal axis recovery is delayed despite the above. It is unclear whether this could be related to persistent ongoing hydrocortisone overexposure. To investigate, we measured waking salivary cortisone (WSC), ACTH levels, blood pressure (BP), and body mass index (BMI) in patients on physiological doses of prednisolone and hydrocortisone with and without adrenal suppression after being weaned off high-dose glucocorticoids.
Method
A total of 99 patients on low-dose oral glucocorticoids (prednisolone $\leq$5 mg/day, or immediate-release hydrocortisone $\leq$25 mg/day) were assessed in a cross-sectional study. All patients were on glucocorticoids for more than 12 months. Patients with WSC levels >17 nmol/l were considered adrenal-sufficient, whereas those with levels <7 nmol/l, were adrenal-insufficient (AI). Patients with levels >7 nmol/l and <17 nmol/l had an ACTH-stimulation test, with a 30-minute post-Synacthen cortisol level >430 nmol/l confirming adrenal sufficiency. ACTH, BP, and BMI were measured on the day WSC was done.
Results
58.6% ($n=58$) of this cohort had AI. 22% ($n=13$) of the AI cohort had a suppressed ACTH (<5 ng/l). In contrast, no adrenal-sufficient patients had a suppressed ACTH(<5 ng/l) ($P=0.0006$). Systolic BP ($P=0.226$), diastolic BP ($P=0.968$), and BMI ($P=0.133$) did not differ significantly between patients with AI and adrenal sufficiency. 48.3% ($n=28$) of patients with AI and 31.7%($n=13$) with adrenal sufficiency were on hydrocortisone whilst the remaining were on prednisolone($P=0.146$). Patients on hydrocortisone with AI had a significantly lower WSC than patients on prednisolone (median WSC:3.68 nmol/l [IQR:0.74-4.43] vs median WSC:6.94 nmol/l [IQR:1.40-8.34], respectively; $P=0.0164$) and 84.6%($n=11$) of AI patients with a suppressed ACTH(<5 ng/l), were on hydrocortisone thrice daily($P=0.0046$).
Conclusion
Our study suggests that overall adrenal suppression in patients on physiological glucocorticoid doses is unlikely to be related to continuing steroid overexposure as only 22% of the AI cohort had a suppressed ACTH(<5 ng/l) and steroid biomarkers were not raised. Conversely, patients on multiple immediate-release hydrocortisone doses were more likely to have adrenal suppression, as evidenced by a fully suppressed ACTH (<5 ng/l) and a lower WSC level when compared to patients on prednisolone, indicating a greater risk of overexposure which could delay adrenal recovery.

Glucose-loaded dopamine transporter is associated with mood altering effect of sweet foods and control over eating sweets

Kyoungjune Pak[1], Jihyun Kim[1], Keunyoung Kim[1], Seongho Seo[2] & Myung Jun Lee[1]
[1]Pusan National University Hospital; [2]Pai Chai University

Introduction
Craving for sweet taste is innate, and spans all ages in humans. The hedonic response to sweet taste predicts the future weight gain in humans. In this study, we investigated the association of sweet taste questionnaires (STQ) with dopamine transporter and brain glucose uptake.
Methods
Thirty-five healthy, nonobese male subjects were enrolled in this study. Each subject visited the institution three times, on separate days, for three brain PET scans (two^{18} F-FP-CIT PET scans and one^{18} F-FDG PET scan). Dynamic^{18} F-FP-CIT PET scans were acquired 10 mins after injection of either glucose (300 mg/kg) or placebo. Static ^{18} F-FDG PET scans were acquired 60 mins after injection of^{18} F-FDG. For^{18} F-FP-CIT PET, dopamine transporter (DAT) availability, expressed in terms of binding potential (BP_{ND}), were measured by analyzing time-activity curve via the simplified reference tissue method. For^{18} F-FDG PET, the mean uptake of each striatal region-of-interest was scaled to the mean of global cortical uptake of each individual, and defined as standardized uptake value ratio (SUVR). Also, subjects were assessed with 12-item self-reporting Sweet Taste Questionnaire (STQ) with 2 factors; STQ 1: sensitivity to the mood altering effect of sweets, and STQ 2: impaired control over eating sweet foods. The effects of STQ on striatal $BP_{ND}$and SUVR were investigated using Bayesian hierarchical modelling. We created models separately with STQ 1, and STQ 2 as predictors, with striatal BP_{ND} and SUVR as a dependent variable, adjusting for age.
Results
Thirty-five subjects (age 24.4 ± 2.7 years, BMI 23.8 ± 3.4 kg/m^2) underwent two^{18} F-FP-CIT brain PET scans, and twenty-four underwent additional^{18} F-FDG brain PET scans. STQ 1 (sensitivity to the mood altering effect of sweets) ranged from 7 to 28 with the mean of 14.9 ± 5.9. STQ 2 (impaired control over eating sweet foods) ranged from 5 to 19 with the mean of 9.1 ± 4.3. Glucose-loaded DAT availability was negatively associated with STQ 1 (sensitivity to the mood altering effect of sweets), and positively with STQ 2 (impaired control over eating sweet foods). However, the effects of STQ 1 and STQ 2 on placebo-loaded DAT availability and brain glucose uptake markedly overlapped with zero.
Conclusion
Glucose-loaded dopamine transporter is associated with mood altering effect of sweet foods and control over eating sweets. The change of dopamine transporter after glucose loading may be the key role for the craving for the sweet foods.

Glucose at gestational diabetes diagnosis predicts neonatal hypoglycaemia, large-for-gestational age and post-partum abnormal maternal glucose homeostasis

Catarina Cidade-Rodrigues[1], Bruna Silva[1], Catarina Chaves[1], Vania Benido Silva[1], Ana Saavedra[1], Alexandra Araujo[1], Claudia Machado[1], Catarina Pereira[1], Vania Gomes[1], Odete Figueiredo[2], Anabela Melo[2], Anabela Ferreira[2], Mariana Martinho[3], Ana Morgado[2], Margarida Almeida[1], M Ceu Almeida[4] & Filipe Cunha[1]
[1]Centro Hospitalar do Tâmega e Sousa, Endocrinology, Guilhufe, Portugal; [2]Centro Hospitalar do Tâmega e Sousa, Gynecology and Obstetrics, Guilhufe, Portugal; [3]Centro Hospitalar Vila Nova de Gaia / Espinho-Unit 1, Endocrinology, Vila Nova de Gaia, Portugal; [4]Centro Hospitalar e Universitário de Coimbra, Gynecology and Obstetrics, Coimbra, Portugal

Introduction
Hyperglycaemia has been associated with worse maternal and foetal outcomes as well as higher risk for future type 2 diabetes (T2D).

Objectives
We study the association between glucose above diagnostic threshold (GADT) at gestational diabetes (GD) diagnosis and risk of perinatal complications and maternal glucose abnormalities at post-partum.
Materials and Methods
Retrospective study based on the national register of GD. Included women with live-born singleton pregnancies followed between 2012 and 2017. Excluded women without data on variables of interest. GADT defined as higher difference between measured glucose and diagnostic threshold at first trimester fasting glucose or 24-28th week OGTT. Primary endpoint: hypertensive disorders of pregnancy (HDP) – preeclampsia or gestational hypertension; preterm labour (PTL), caesarean section (CS), hypoglycaemia, large-for-gestational-age (LGA), and abnormal maternal glucose homeostasis (AMGH) at 4-12 weeks postpartum. Multivariate logistic regression models were built to test the association between GADT and the primary outcomes: adjustments for age, body mass index (BMI), family history of T2D, previous GD or macrosomia, insulin therapy, HbA1c, chronic hypertension, maternal excess weight gain during pregnancy, and time of GD diagnosis plus variables known to be associated with the primary outcome.
Results
We studied 6927 women with a median age of 34 (30-37) years and BMI of 25.8 (22.8-30.4) kg/m^2. Median GADT was 5 (2-11) mg/dl. HDP was found in 336 (4.9%) of women, PTL in 406 (5.9%), CS in 2704 (39.0%), neonatal hypoglycaemia in 262 (3.8%), LGA in 728 (10.5%), and AMGH in 486 (7.0%) – T2D in 56 (0.8%). In the univariate analysis, GADT, per 5 mg/dl increase, was associated with HDP, CS, neonatal hypoglycaemia, LGA, and AMGH, but not PTL with an OR (95% CI) of 1.07 (1.00-1.14), $P=0.04$; 1.06 (1.03-1.09), $P<0.001$; 1.08 (1.01-1.16), $P=0.03$; 1.08 (1.03-1.13, $P<0.001$); 1.32 (1.27-1.38), $P<0.001$, and 1.03 (0.97-1.09), $P=0.33$. After multivariate adjustments, GADT, per 5 mg/dl, remained associated with neonatal hypoglycaemia [1.09 (1.01-1.18), $P=0.03$], LGA [1.06 (1.00-1.11), $P=0.03$], and AMGH [1.31 (1.25-1.38), $P<0.001$] but not with HDP [1.04 (0.97-1.11), $P=0.30$] and CS [1.00 (1.00-1.01), $P=0.21$].
Conclusions
GADT is associated with worse neonatal outcomes and with AMGH but not with obstetric outcomes. Per 5 mg/dl increase of GADT, there is a 9% higher risk of neonatal hypoglycaemia, 6% higher risk of LGA newborns and 31% higher risk of AGMH at postpartum reclassification.

Nitrate-mediated dilation is impaired in people with type 1 diabetes and co-existent metabolic dysfunction-associated steatotic liver disease

Jonathan Mertens[1,2], Tibor Stoop[2], Sven Francque[1,2], Christophe De Block[1,2] & Hilde Heuten[2]
[1]University of Antwerp-Faculty of Medicine, Antwerpen, Belgium; [2]Antwerp University Hospital, Edegem, Belgium

Introduction
The risk of cardiovascular disease (CVD) is increased in type 1 diabetes (T1D). Metabolic dysfunction-associated steatotic liver disease (MASLD) is linked to CVD, but evidence hereof is limited in people with T1D. Endothelial dysfunction is currently considered a key early event in the atherosclerotic process, but is never determined in people with T1D and co-existent MASLD.
Methods
We measured flow-mediated dilation (FMD) and nitrate-mediated dilation (NMD) in non-smoking adults without prior CVD with T1D. MASLD was diagnosed using ultrasound and presence of minimally one cardiometabolic risk factor. FMD was evaluated by longitudinal ultrasonographic imaging of the right brachial artery at rest and during reactive hyperaemia after inflating and deflating a forearm blood pressure cuff distal to the ultrasound probe (200 mmHg or $\geq$50 mm Hg above peak systolic blood pressure for 5 minutes) using high-resolution B-mode ultrasound. Wall-tracking software and continuous ECG registration were used to measure the end-diastolic diameter, coincident with the R-wave. Following FMD, NMD was evaluated by administering 25 µg of nitro-glycerine.
Results
Ninety-two adults were included, of whom 23 had MASLD. Diabetes duration was 30$\pm$14 years, median HbA1c was 7.0% (IQR 6.6-7.6). People with MASLD had a higher BMI compared to those without (31.6 [29.0-34.0] (MASLD) vs 23.9 [22.5-26.7]kg/m^2 (no MASLD), $P<0.001$). There were no differences in age, diabetes duration, blood pressure, presence of arterial hypertension, kidney function, or low-density lipoprotein cholesterol between groups. Cohort FMD was 5.47$\pm$2.89%, while NMD measured 19.7$\pm$7.1%. There was no significant difference in FMD between groups (5.58$\pm$3.12 (MASLD) vs 5.43$\pm$2.83% (non MASLD), $P=0.836$), but NMD was lower in those with MASLD (16.8$\pm$5.0 (MASLD) vs 20.8$\pm$7.5% (non MASLD), $P=0.009$).
Conclusion
Endothelial-independent vasodilation (NMD) is compromised in people with T1D and co-existent MASLD. However we could not notice a difference in endothelial-dependent dilation (FMD) between groups.

Sphinganine increases GLP-1 secretion and causes weight loss in mice

Mark Smits[1], Anna Drzazga[1], Katrine Galsgaard[1], Jarkko Lackman[1], Victor Gerdes[2,3], Arnold van de Laar[3], Sjoerd Bruin[3], Mette Rosenkilde[1] & Jens J. Holst[1]
[1]University of Copenhagen, Department of Biomedical Sciences, København, Denmark; [2]Amsterdam UMC, locatie AMC, Amsterdam, Netherlands; [3]Spaarne Gasthuis, Hoofddorp, Netherlands

Recent years have demonstrated increasing focus on augmenting secretion of glucagon-like peptide (GLP)-1 from intestinal L cells, to improve the treatment and/or prevention of obesity and type 2 diabetes. However, finding strong stimuli and identifying novel compounds has proven difficult. To discover new GLP-1 secretagogues, we gave 49 individuals (76% female, BMI 28.3$\pm$4.8 kg/m^2) a high-fat liquid mixed meal (250 mL Nutridrink, Nutricia®). Plasma samples, taken before and repeatedly after the meal, were analysed for total GLP-1 (using radioimmunoassay) and subjected to untargeted metabolomics (LC-MS/MS, Metabolon). Using machine learning statistical techniques, we identified that among over 900 metabolites, the meal-induced increase in sphinganine was the strongest predictor of a strong GLP-1 response. In those subjects with high GLP-1 secretion, the increase in sphinganine was significantly higher ($P=0.027$). When murine GLUTag cells were exposed to sphinganine for 2 h, a dose-dependent increase in GLP-1 was seen (10 µM=28% [95%-CI 8–48]; 100 µM=[55% [37–73]). Moreover, sphinganine increased intracellular calcium mobilization (10 µM=3.9% [1.1–6.7]), as assessed using Fluo-4. This effect was reduced by concomitant exposure to 2-APB (IP-3 blocker, reduction 46%) and nifedipine (calcium-channel blocker, reduction 59%), suggesting a Gq-mediated pathway. Antagonists of GPR40, GPR55, GPR119 and S1PR1 reduced the effects of sphinganine by 30-59%. Next, we studied isolated intestinal and, separately, colon perfusion models in Wistar rats. In male rats, luminal perfusion with 100 µM sphinganine increased intestinal GLP-1 secretion (26% [1–52]) and tended to increase colonic GLP-1 secretion (18% [0-37]). Vascular administration did not affect GLP-1 secretion. In female rats, there were no significant effects. Single-dose sphinganine (20 mg/kg) given via oral gavage to male and female C57Bl6/JRj mice did not increase GLP-1 levels (measured with ELISA) compared to saline. Finally, male C57Bl6/JRj were fed a high-fat diet with or without sphinganine (dose of 0.05% w/w). After 21 days, sphinganine-fed mice had gained less weight compared to control diet (7% vs 13%, $P=0.045$). Sphinganine had no effect on food intake. No significant differences were seen during an insulin tolerance test and oral glucose tolerance test (OGTT), and sphinganine did not increase GLP-1 levels during the OGTT. In conclusion, sphinganine increases GLP-1 secretion *in vitro* and in perfusion studies in male rats. In mice, the effect of sphinganine on GLP-1 secretion is not evident, yet it reduces weight gain during high-fat feeding. As such, further studies for metabolic benefits of sphingolipids are warranted.

Characteristics of presentation and management of people admitted with severe hypoglycaemia highlight the need for targeted educational interventions to mitigate occurrences-Pilot data from DEKODE Hypoglycaemia study

Sam Sherratt-Mayhew[1], Aashritha Buchipudi[1], Aditya Bal[1], Alexandra Lubina Solomon[2], Amanda Ling Jie Yee[1], Kalyaani Persad[1], Mariam Idrissi[1], Pratik Choudhary[3], Punith Kempegowda[4] & Team Dekode[4]
[1]University of Birmingham Medical School, United Kingdom; [2]Dudley Group NHS Foundation Trust, United Kingdom; [3]University of Leicester, United Kingdom; [4]Institute of Applied Health Research, United Kingdom

Background
Severe hypoglycemia, marked by blood glucose levels below 3 mmol/l (level 2) or necessitating third-party assistance (level 3), poses a significant risk leading to unplanned hospital admissions in individuals with diabetes. However, there is a paucity of information on admitted patients' characteristics, management, and outcomes.

Objective
To explore the characteristics of the population, precipitating factors and outcomes of people admitted with either level 2 or 3 hypoglycemia.
Methods
This retrospective study was conducted from October 2023 to January 2024 across five hospitals in the UK. All adults aged > 18 years admitted to hospitals with either level 2 or level 3 hypoglycaemia from November 2022 to October 2023 were included in the study. Various data on sociodemographics, precipitating factors, management and outcomes were collected. Data was analysed on SPSS 29.0.
Results
We identified 222 episodes of severe hypoglycemia, with 160 occurrences in individuals with type 2 diabetes and 62 in those with type 1 diabetes. Among these episodes, 158 were classified as level 2 (110 in type 2 and 48 in type 1), while 64 were categorised as level 3 (50 in type 2 and 14 in type 1). 22.5% of individuals with type 2 diabetes had received insulin treatment before admission. The median (interquartile) age was 44.5 (40.0-64.3) and 80.0 (70.0-83.0) years for people with type 1 and type 2 diabetes, respectively. Their Charlson comorbidity index was 4 (2-6) and 7 (6-8) respectively. The primary precipitating factor for hypoglycemia was a missed meal, accounting for 58.8% of type 2 and 45.2% of type 1 diabetes cases. Furthermore, 17.7% of people with type 1 diabetes and 12.5% with type 2 diabetes received glucagon either at home, in an ambulance, or upon admission. However, only 2.7% (6/222) of individuals (6.5% (4/62) with type 1 diabetes and 1.3% (2/160) with type 2 diabetes) were prescribed glucagon upon discharge. Insulin dose reduction emerged as the most common therapeutic adjustment on discharge, with 111 cases overall (31 in type 1 and 80 in type 2). Additionally, 11.3% of type 1 and 2.5% of type 2 diabetes cases commenced continuous glucose monitoring (CGM) upon discharge for timely alerts and prevention of further hypoglycemic events.
Conclusion
Individuals requiring hospitalisation for severe hypoglycemia were typically elderly and frail, often due to missed meals. Despite glucagon needs during episodes, prescriptions upon discharge were infrequent. These findings underscore the need for targeted educational interventions to mitigate such occurrences.

GSDME Deficiency Sensitizes Mice to Diet-Induced Obesity by suppressing Lipolysis

Yuanyuan Wei[1,2], Yue Wu[2], Zuyi Yuan[2], Jian'an Wang[1] & De Ling Yin[1]
[1]Second Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, Department of Cardiology, Hangzhou, China; [2]The First Affiliated Hospital of Xi'an Jiaotong University, Department of Cardiology, Xi'An, China

Background
Obesity, as a worldwide healthcare problem, has been attracting more and more attention. Chronic low-grade inflammation is regarded as an inducer of adipocyte cell death. Pyroptosis,a kind of inflammatory cell death,is involved in various inflammatory diseases.Gasdermin E(GSDME) is a mediator of pyroptosis via the cleavage of caspase-3. However, whether GSDME is involved in the regulation of adipose tissue function remains unknown. In the present study, we aim to investigate the role of GSDME in the development of obesity.
Methods and results
To investigate the role of adipose GSDME, we generate GSDME knockout ($GSDME^{-/-}$) mice. As compared with control mice, GSDME-/- mice show obesity when induced with a high-fat diet(HFD), along with hepatic steatosis, insulin resistance, glucose intolerance, and hypercholesterolemia. The effect of GSDME ablation on basic metabolic activity was also evaluated. Under the HFD condition, $GSDME^{-/-}$ mice showed significantly increased respiratory exchange rate (RER) and reduced oxygen consumption as compared with the controls. Gene array assay of control and GSDME-deficient adipose tissue revealed that lipolysis-associated genes including ATGL were significantly decreased with GSDME ablation in adipose tissues. Furthermore,the epiWAT from HFD-fed control and $GSDME^{-/-}$ mice was isolated and treated with isoproterenol (ISO). ISO-stimulated glycerol and FFA release were decreased in $GSDME^{-/-}$ explants.In vivo,the serum FFA and glycerol levels were measured after stimulated lipolysis by CL316243. Serum FFA as well as glycerol levels were significantly lower in $GSDME^{-/-}$ than control mice 15 min after CL316243 stimulation.
Conclusions
This study reveals that GSDME functions as a positive regulator of lipolysis by the ATGL expression regulation. Deletion of GSDME promoted HFD-induced obesity, impaired adipose function and deteriorated glucose intolerance and insulin resistance. GSDME may be a potential therapeutic target for ameliorating obesity and obesity related metabolic disorders.

Effects of Glucagon-like Peptide-1 Receptor Agonists on Copeptin in healthy volunteers and patients with primary polydipsia-A secondary analysis of the randomized, double-blind, placebo-controlled, crossover GOLD & GATE trials

Svenja Leibnitz[1,2], Mirjam Christ-Crain[1] & Bettina Winzeler[1]
[1]University Hospital Basel, Endocrinology, Diabetes and Metabolism, Basel, Switzerland; [2]University Hospital Basel, Clinical Research, Basel, Switzerland

Background/Introduction
Today, GLP-1 receptor agonists have great clinical importance in the treatment of type 2 diabetes and obesity. Beside their known mechanisms to lower blood sugar and enhance satiety signals, GLP-1 also seems to play a significant role in sodium and water balance. This can be supported by the finding of GLP-1 receptor expression in various locations of the kidney, the enteric system and key brain structures. Recent findings investigating long-term effects of treatment with GLP-1 receptor agonists showed a significant reduction of fluid intake and 24-h-urine volume compared to placebo. There were no changes in serum sodium, urinary sodium excretion or in hormones of the RAAS system as a possible physiological explanation. To our knowledge data are inconclusive regarding physiological mechanisms that could explain these observations. Furthermore, no direct effect of GLP-1 on Vasopressin has been observed to date. The aim of this secondary analysis was to investigate changes of Copeptin levels in euvolemic participants treated with dulaglutide vs placebo. We hypothesize that dulaglutide effects a stimulation in Vasopressin due to reduced water intake, lowered blood pressure and nausea which are known side effects of GLP-1 receptor agonists.
Methods
A secondary analysis of randomized, double-blind, placebo-controlled, cross-over-trials in 20 healthy participants (GATE trial) and 34 patients with primary polydipsia (GOLD trial) was performed at the University Hospital of Basel between 2016 and 2019. In both studies participants received either Dulaglutide (Trulicity®) 1.5 mg or placebo, in random order, subcutaneously once weekly over a three-week treatment phase and attended an 8-hour evaluation visit during the last treatment week. After a wash-out period of at least three weeks, patients received the complementary intervention.
Results
All 54 participants of the two cross-over trials were included. Median age was 27 (IQR 24 to 37) years and 63% were female. Median plasma sodium concentration, plasma osmolality and GFR were all in the mid-normal range. To estimate the treatment effect of Dulaglutide, we derived the absolute within-subject differences of Copeptin between Dulaglutide and placebo and used the wilcoxon rank test for statistical analysis. After a three-week treatment phase, Dulaglutide showed a significant suppression of Copeptin in both trials ($P = 0.04$) compared to placebo [GOLD: treatment effect: -0.67 pmol/l vs GATE: treatment effect: -1 pmol/l].
Conclusion
This analysis provides further insights into the direct effects of GLP-1 on Vasopressin and reveals physiological mechanisms that could explain the role of GLP-1 in sodium and water balance.

(HURS), Córdoba, Spain; [5]Hospital Universitario Virgen del Rocío (HUVR), Department of Endocrinology and Nutrition, Institute of Biomedicine of Sevilla (IBiS), Sevilla, Spain; [6]Service of Endocrinology & Nutrition, HURS, Córdoba, Spain

Pituitary tumours (PTs) constitute approximately 15% of all brain tumours, affecting up to 5% of the general population. The majority of PTs are hormonally active tumours (approximately 70%), resulting in significant comorbidities associated with hormone release. Furthermore, clinically non-functioning PTs (NFPTs, around 30%) exhibit mass effect-related comorbidities due to delayed diagnosis, despite lacking a link to hormone excess. Recent studies indicate that aberrant alternative splicing is a prevalent characteristic observed in various endocrine and tumour pathologies, including PTs. In this context, other machineries involved in mRNA metabolism, such as RNA-Exosome and Nonsense-Mediated-Decay (NMD), have also been associated with several endocrine-related cancers. Therefore, our objective was to characterize the presence of components belonging to the RNA-Exosome and NMD machineries, and to determine their putative pathophysiological role in PTs. Specifically, we evaluated the expression levels of 28 and 24 genes involved in RNA-Exosome and NMD machineries, respectively, using 73 NFPTs, 50 somatotropinomas and 10 normal-pituitaries (as control-tissues) and a microfluidic-array based on qPCR-technology. The main results were consistently validated across various human external cohorts. Additionally, diverse functional and molecular approaches were performed in GH3 cell-line and primary patient-derived tumour cells using available pharmacological inhibitors of the RNA-Exosome (isoginkgetin) and NMD (NMDi) machineries, and specific candidate-genes siRNAs. Bioinformatic analysis revealed a heterogeneous dysregulation in both cellular machineries in PTs, highlighting the overexpression of EXOSC5 and CBP80 (from RNA-Exosome and NMD, respectively), as the most discriminating factors between tumour and non-tumour samples. Moreover, expression levels of these two genes were associated with different aggressiveness parameters, suggesting a potential oncogenic role in both GHomas and NFPTs. Additionally, *in vitro* silencing of CBP80 and EXOSC5 expression through specific siRNAs reduced several endocrine and tumour parameters (i.e., proliferation, colony-formation, secretion) in GH3 cells, as well as NFPT and GHoma primary patient-derived cells. We also observed a modulation of several molecular markers related to the cell-cycle and other key pro-oncogenic features in response to CBP80 and/or EXOSC5 silencing. Finally, pharmacological inhibition of the NMD but not of the RNA-Exosome resulted in a significant dose-response alteration of several functional parameters, including a reduction in the proliferation rate and other aggressiveness features. Altogether, we provide solid evidence indicating a drastic alteration of mRNA metabolism machineries (such as RNA-Exosome and NMD) in PTs, wherein CBP80 and EXOSC5 could represent novel diagnostic/prognostic biomarkers and therapeutic targets in GHomas and NFPTs.

Transcriptomics analysis confirms WHO classification of PitNETs and reveals distinct patterns related to invasiveness

Jelena Jotanovic[1,2], Abdellah Tebani[3,4], Neda Hekmati[1], Åsa Sivertsson[3], Cecilia Lindskog[1], Mathias Uhlèn[3], Olafur Gudjonsson[5], Erika Tsatsaris[6], Britt Eden Engstrom[6], Johan Wikström[7], Fredrik Pontén[1] & Olivera Casar-Borota[1,2]
[1]Uppsala University, Department of Immunology, Genetics and Pathology, Rudbeck Laboratory, Uppsala, Sweden; [2]Uppsala University Hospital, Department of Clinical Pathology, Uppsala, Sweden; [3]KTH Royal Institute of Technology, Science for Life Laboratory, Department of Protein Science, Stockholm, Sweden; [4]Normandie University, Department of Metabolic Biochemistry, UNIROUEN, INSERM U1245, CHU Rouen, Rouen, France; [5]Uppsala University, Department of Neuroscience, Uppsala, Sweden; [6]Uppsala University, Department of Medical Sciences, Endocrinology and Mineral Metabolism, Uppsala, Sweden; [7]Uppsala University, Department of Surgical Sciences, Neuroradiology, Uppsala, Sweden

Pituitary neuroendocrine tumors (PitNETs) are typically benign tumors presenting with symptoms related to hormone hypersecretion and/or intracranial mass. Current classification of PitNETs is based on the immunohistochemical expression of adenohypophysial hormones and three main pituitary-specific transcriptions factors PIT1, TPIT and SF1. PitNETs usually remain intrasellar, however, 20-40% of tumors show invasiveness into cavernous sinus and 6–8% infiltrate into the bones, affecting the prognosis. There is an unmet need to detect reliable biomarkers that can predict the parasellar and bone invasiveness of PitNETs as well as the factors related to tumor vascularization. We validated the current PitNETs classification by exploring gene expression patterns in a well-characterized cohort of 51 PitNETs of different histological and clinical types. The gene expression signatures were compared with clinical and immunohistochemically based classification. Next, we extended the cohort to acquire a higher fraction of invasive tumors. Applying the same transcriptomics analysis in this expanded cohort of 77 patients we studied the gene expression differences between invasive and non-invasive tumors regarding parasellar and bone-invasiveness. Moreover, we explored the genes that correlated to the contrast enhancement quotient, a radiological proxy of tumor vascularization. Our results revealed three main transcriptomics clusters of PitNETs, supporting the current immunohistochemical PitNETs classification. A few "null cell adenomas" clustered as either gonadotroph or corticotroph tumors, further questioning this controversial entity. Our results did not demonstrate clear clustering regarding the invasiveness. However, differentially expressed genes related to parasellar growth were genes with previously established role in tumor invasiveness, and the differentially expressed genes regarding bone invasiveness were those involved in anti-tumoral immune response and NF-κB pathway. Several genes involved in tumor biology and vascularization correlated significantly with the contrast enhancement quotient. In conclusion, we demonstrated that the current WHO classification of PitNETs based on the immunohistochemical expression of PIT1, TPIT and SF1 is in concordance with the three PitNETs subtypes with distinct gene expression patterns. The transcriptomic analysis also revealed differences in the molecular landscape between invasive and non-invasive PitNETs. However, a clear clustering was not demonstrated, which may, at least partly, be explained by the strong influence of the genes that drive the cell lineage differentiation in our diverse cohort of PitNETs. The contrast enhancement quotient appears as a novel potential radiological parameter of tumor vascularization. Several detected tumor-driving genes and genes related to the invasiveness and vascularization of PitNETs are potential therapeutic targets and prognostic biomarkers, thus warranting further research.

Mast cells, a new actor in gonadotroph tumors

Mirela Diana Ilie[1], Maxime Lepetit[2], Marie Chanal[1], Alexandre Vasiljevic[1], Emmanuel Jouanneau[1], Olivier Gandrillon[2], Franck Picard[2], Gérald Raverot[1] & Philippe Bertolino[1]
[1]Inserm U1052, CNRS UMR5286, Cancer Research Center of Lyon, Lyon 1 University, Lyon, France; [2]École Normale Supérieure de Lyon, Lyon, France

Background
While gonadotroph tumors are lacking both medical treatment options and prognostic markers, the tumor microenvironment represents a promising tool. The aim of this study was to 1) identify new tumor microenvironment actors in gonadotroph tumors, 2) gain insight into the tumorigenesis mechanisms driven by these tumor microenvironment cells, and 3) identify new tumor microenvironment-related prognostic markers, as well as new therapeutic targets.
Methods
Single-cell transcriptomics of six gonadotroph tumors, spatial transcriptomics of three gonadotroph tumors, followed by immunohistological validation on 49 gonadotroph tumors.
Results
24,471 cells from the six tumors passed the quality control. Clustering analysis revealed expected tumor and tumor microenvironment cell types, as well as mast cells as a new population in pituitary tumors. Regarding mast cells' phenotype, 132/133 mast cells expressed tryptase, of which three co-expressed chymase; no mast cell expressed only chymase. Immunohistochemistry for tryptase, followed by analysis of whole slides, confirmed mast cells were present in all 49 gonadotroph tumors (0.01-4.33%). Next, we investigated the ligand-receptor networks. Using CellPhoneDB, bilateral crosstalk was identified between mast and endothelial cells. The top ranked secreted ligand from mast cells signaling towards endothelial cells was VEGFA, suggesting mast cells have a pro-angiogenic role in gonadotroph tumors. In line with this hypothesis, there was a very strong and positive correlation between the percentages of endothelial cells and of mast cells in the 6 tumors (rho = 0.94, $P = 0.01$). In addition, analysis of spatial transcriptomics data showed mast cells were usually found in the vicinity of endothelial cells, which we confirmed with double immunofluorescence staining (tryptase/CD34). Furthermore, mast cells expressed more frequently *VEGFA* than *TNF*, suggesting a pro-tumorigenic role for mast cells in gonadotroph tumors. Indeed, mast cells were associated with a bad prognosis in the clinical cohort, notably tumors that progressed/relapsed more rapidly after surgery had more abundant mast cells ($P = 0.002$). Moreover, for a same patient, recurrent tumors had more mast cells than the initial tumor ($P = 0.007$). Finally, Nichenet analysis identified KITLG (acting via KIT) as one of the probable up-

regulators of *VEGFA* expression in mast cells. Interestingly, the top ranked interaction identified between endothelial and mast cells was also KITLG-KIT.
Conclusion
We identified mast cells as a new population in gonadotroph tumors. In these tumors, mast cells appear to have pro-angiogenic and pro-tumorigenic roles. Moreover, mast cells were associated with a bad prognosis in the clinical cohort, suggesting that KIT targeting might be beneficial for the treatment of gonadotroph tumors.

Background
Papillary craniopharyngiomas (PCPs) are driven by V600E BRAF mutations in 95% of cases. Recently, combined anti-BRAF/MEK targeted therapy (TT) has emerged as a potential treatment in aggressive PCPs. However, standardized data on large cohorts are still lacking. Our study aimed to assess the real-life efficacy and safety of TT in patients with PCPs.
Methods
This was a retrospective national multicenter study involving patients with V600E BRAF-mutated PCPs treated with anti-BRAF/MEK TT in France up to July 2023. Volumetric magnetic resonance imaging analysis, clinical and hormonal assessments were performed before TT, after 3 months, and at the last available follow-up during treatment. Radiological response was classified as either complete (lesion disappearance), subtotal (volume reduction $>80\%$), partial (volume decrease 30-80%), stable disease (volume decrease $<30\%$ or increase $<20\%$), or progressive disease (volume increase $>20\%$).
Results
Sixteen patients (8 females, mean age 50.5 ± 15.75 years) were included. Patients received either neoadjuvant therapy (NEO) for non-resectable tumors ($n=6$), adjuvant therapy (ADJ) post-surgery ($n=8$), or palliative therapy (PAL) after multimodal treatment ($n=2$).Before TT, symptoms included headache (5 patients), endocrine dysfunction (14), visual impairment (9), weight gain (3), and cognitive dysfunction (2). Mean tumor volume was 7429 ± 2483 mm^3. After 3 months of TT, mean volume reduction was $82.2\pm16.9\%$, $52.9\pm21.9\%$, and $60.8\pm17.3\%$ [43.5-78.1] in the NEO, ADJ, and PAL groups, respectively. At the last follow-up (mean 7.6 ± 5.3 months), 12 patients (6 NEO, 4 ADJ, 2 PAL) showed subtotal response, 3 ADJ patients exhibited partial response, and one ADJ patient maintained stable disease. Mean volume reduction was $88.9\pm4.4\%$, $73.3\pm23.4\%$, and $91.8\pm4.3\%$ in the NEO, ADJ, and PAL groups, respectively.Clinically, TT resolved headaches in all patients and visual impairment in 6. Two patients had improved neurological symptoms, one presented weight loss, and two recovered endocrine function. Five patients stopped treatment due to adverse events. Two developed hepatic cytolysis, leading to temporary TT discontinuation and later reintroduction. One patient permanently discontinued TT due to peripheral oedema, another due to febrile pneumopathy, and the remaining one due to vomiting, skin rash, urinary tract infections, and hyperthermia.
Conclusions
Targeted therapy in PCP patients can induce impressive tumor volume reduction and clinical improvement within a few months from treatment initiation. Adverse events warrant careful monitoring. Further research is needed to establish standardized protocols, but present results advocate for reframing usual strategies.

Background
Due to the rarity and the slow progress of the disease, there is a considerable diagnostic delay in acromegaly, contributing to increased morbidity and mortality. Voice analysis may decrease this delay as patients with acromegaly often develop a dark voice and unclear speech due to macroglossia, enlarged lips and edema in the pharynx and larynx. Modern technology offers higher speed and power of voice analysis and increased the interest in voice as a biomarker to identify several diseases. The aim of this study was to develop an algorithm identifying patients with acromegaly using a wide range of acoustic parameters and machine learning.
Method
Voice recordings from patients with acromegaly and from matched controls were collected using a mobile phone with a sound recording application (Voice Record Pro) at all University hospitals in Sweden. The recordings included a sustained "aaaaa". Anthropometric and clinical data and self-reported voice handicap index (VHI) were assessed. The voice analysis of the sustained "aaaaa" included 3274 parameters, used for training of three different models (Support Vector Machines, Random forests and k-Nearest Neighbor) to classify the speaker as "acromegaly" or "control". The models were combined into a model ensemble, a machine learning approach to combine models in the prediction process to increase the accuracy of classification. The model was trained with 75% of available data and its performance was assessed using the remaining 25% of the data set.
Results
We included 151 (39% women) Swedish patients with acromegaly, 77% in biochemical remission, 10% biochemically active despite treatment and 13% recently diagnosed and treatment naive. For comparison 139 matched controls (41% women) were included. The model ensemble could identify patients with acromegaly with a sensitivity of 71% and a specificity of 77% (diagnostic accuracy 74%, ROC AUC 84%) based on voice classification of the sustained "aaaaa". Self-reported voice problems (VHI) were significantly higher in patients with acromegaly compared to controls (median VHI 6 vs 2, $P<0.01$). The proportion of individuals with VHI >20, representing a clinically significant voice impairment was higher in the acromegaly group than the control group (22.5% vs 3.6%).
Conclusions
Modern voice analysis can identify patients with acromegaly from short voice recordings with a reasonable accuracy. Patients with acromegaly have an

increased prevalence of self-reported speech and voice disturbances even after biochemical control of acromegaly.

Higher PFOS exposure associated with higher SHBG in third trimester. The odense child cohort

Richard Christian Jensen[1,2], Dorte Glintborg[1], Flemming Nielsen[2], Henriette Boye[3], Anne Schmedes[4], Tina Jensen[2,3] & Marianne Andersen[1]
[1]Odense University Hospital, Department of Medical Endocrinology, Odense C, Denmark; [2]University of Southern Denmark, Clinical Pharmacology, Pharmacy and Environmental Medicine, Odense C, Denmark; [3]Odense University Hospital, Odense Child Cohort, Odense C, Denmark; [4]Lillebaelt Hospital, Department of Biochemistry and Immunology, Vejle, Denmark

Background
Perfluoroalkyl substances (PFAS) are endocrine disrupting chemicals, with elimination half-lives ranging from four to eight years. Experimental studies indicate that PFAS may disrupt androgenic and estrogenic pathways, potentially affecting fetal development. During 1st trimester, concentrations of sex hormone-binding globulin (SHBG) increase due to higher estrogen levels from the placenta. The increment of SHBG concentration results in a compensatory increase in total testosterone (TT) in women at 1st and 2nd trimester, but levels of free testosterone (Free-T) remain within the range of non-pregnant women. Circulating Free-T increases significantly in women during 3rd trimester. To our knowledge, no previous study has investigated associations between PFAS exposure and concentrations of both SHBG and androgens in pregnant women.
Objective
To investigate associations between maternal PFAS concentrations and levels of SHBG and androgens in pregnancy.
Methods
In Odense Child Cohort (OCC), a single-center study, pregnancy serum concentrations of five PFAS: perfluorohexane sulfonic acid (PFHxS), perfluorooctane sulfonic acid (PFOS), perfluorooctanoic acid (PFOA), perfluorononanoic acid (PFNA), and perfluorodecanoic acid (PFDA) were measured in 1,609 eligible women at median gestational week (GW) 12 (25th, 75th percentile: 10, 15). Among these, concentrations of SHBG, calculated Free-T, and TT were assessed in 1,048 pregnant women at median GW 29 (25th, 75th percentile: 28, 30). Multivariate linear regression models were performed to estimate associations between PFAS concentrations and levels of SHBG and androgens.
Results
Included women had a mean age of 30.2 ($\pm$4.5 SD) years and median pre-pregnancy BMI of 23.5 (5th, 95th percentiles: 19.2, 32.6) kg/m^2 and 57.8% were nulliparous. A doubling in PFOS concentration was associated with an increment in SHBG concentration by 2.29% (95% CI: 0.04%, 4.59%) in adjusted analyses. PFOS exposure in the third tertile, as compared to the first tertile, significantly increased SHBG concentrations by 4.60% (95% CI: 0.46%, 8.26%). A significant dose-response relationship was observed across exposure tertiles for PFOS in the association with SHBG. A non-significant inverse association was found between PFAS and Free-T. No significant association was demonstrated between PFAS and TT.
Conclusion and perspectives
Our data suggested that PFOS exposure was associated with higher SHBG concentrations in pregnant women. This increase in SHBG may indirectly be through a PFOS-mediated aromatase induction. Possibly, the increase in SHBG without a compensatory TT increment may result in the non-significant decrease in Free-T. The findings underscore the necessity of the follow-up of children in terms of assessing putative long-term associations with PFAS during childhood.

Thyroid Cancer and Endocrine Disruptive Chemicals: A Case-Control Study on Persistent Organic Pollutants (POPs)

Marina Lugaresi[1], Catherine Pirard[2,3], Claudia Moneta[1], Patrice Dufour[2,3], Erika Carbone[4], Alessandro Manzo[1,4], Carla Colombo[4,5], Laura Fugazzola[4,5], Corinne Charlier[2,3] & Valentina Cirello[4,5]
[1]University of Milan, Department of Biotechnology and Translational Medicine, Milan, Italy; [2]University Hospital of Liege (CHU Liège), Department of Clinical, Forensic and Environmental Toxicology, Liège, Belgium; [3]University of Liege (ULiège), Center for Interdisciplinary Research on Medicines (C.I.R.M.), Liège, Belgium; [4]Istituto Auxologico Italiano IRCCS, Department of Endocrine and Metabolic Diseases, Milan, Italy; [5]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy

Objectives
Recent evidence suggest that environmental pollution may be involved in the worldwide increase of thyroid cancer (TC) incidence occurred over the last few decades. Indeed, some environmental pollutants, namely endocrine disruptive chemicals (EDCs), have been linked to endocrine system disruption, including thyroid dysfunction, and increased risk of TC. Several EDCs are known to be Persistent Organic Pollutants (POPs) due to their long half-life in the environment, such as Per-Fluoroalkyl Substances (PFAS), poly-chlorinated biphenyls (PCBs), and the pesticide dichlorodiphenyltrichloroethane (4,4'-DDT, and its metabolite 4,4'-DDE). Threatening ecosystems and human health, POPs have raised global concern, but to date few studies explored their association with TC and none considered the possible correlation with TC clinical and molecular features. The present case-control study aimed to evaluate the possible association between serum PFAS, PCBs and 4,4'-DDE concentrations, TC, and its clinical and molecular characteristics.
Materials and methods
We recruited 224 participants, of which 112 patients with a diagnosis of TC in the last five years and 112 sex and age-matched controls with no known history of thyroid diseases, primitive gonadic diseases, or other malignancies. Blood samples were taken from all participants and serum concentrations of some PFAS and PCBs, and 4,4'-DDE were measured using liquid chromatography or gas chromatography coupled to mass spectrometry. *BRAF* V600E mutation was assessed by standard methods. Logistic regression models were used to evaluate the association between TC, its clinical and molecular features, and POPs serums levels.
Results
The detection of perfluorodecanoic acid (PFDA) was positively correlated to TC (OR = 2.03), while a negative association was found with perfluorohexanesulfonic acid (PFHxS) levels (OR = 0.63). Worthy, perfluorononanoic acid (PFNA) was positively associated with the presence of thyroiditis, while PFHxS and perfluorooctane sulfonic acid (PFOS) with higher levels of pre-surgical TSH. PFHxS, PFOS, PFNA and PFDA were associated with less aggressive TC, while two poly-chlorinated biphenyls (PCB-105 and PCB-118) with larger and more aggressive tumours. Lastly, the presence of *BRAF* V600E mutation resulted associated with PCB-153, PCB-138 and PCB-180.
Conclusions
Our case-control study evaluate the impact of some POPs on TC, and it is the first to investigate their association with clinical and molecular features of the tumour. Beside the already known association between TC and PFDA, we found interesting correlations between some POPs and tumour aggressiveness, and between *BRAF* V600E mutation and PCBs. On the other hand, an inverse association was found with PFHxS, already reported in TC, but the underlying biochemical mechanisms are still unclear.

NRF2 genetic polymorphisms modify the longitudinal association of serum polychlorinated biphenyls with glucose homeostasis damage: A gene-environment interaction analysis among Chinese general adults

Qiyou Tan[1], Min Zhou[1], Linling Yu[1], Bin Wang[1], Mengyi Wang[1] & Weihong Chen[1]
[1]Huazhong University of Science and Technology, School of Public Health, Wuhan, China

Background
As persistant organic pollutants, polychlorinated biphenyls (PCBs) are widespread in environment worldwide. Serum PCBs and nuclear factor erythroid 2-related factor 2 (NRF2) are associated with glucose homeostasis damage in the general population. However, there is a lack of epidemiological evidence on the interaction between serum PCBs and *NRF2* gene in relation to glucose homeostasis damage.
Objectives
We aimed to explore the interaction effects of PCB exposure and *NRF2* genetic polymorphisms on glucose homeostasis through a longitudinal epidemiological study.
Methods
A total of 1705 participants with 6 years follow-up from the Wuhan-Zhuhai prospective cohort was included. Repeated fasting plasma glucose (FPG) and

insulin (FPI), and serum PCBs were measured for each participant. The genotypes were determined using the Infinium OmniZhongHua-8 BeadChip and 39 single nucleotide polymorphisms within the *NRF2* gene were included. Generalized linear models were used to analyze the relationships of serum PCBs and *NRF2* genetic polymorphisms with glucose homeostasis indices over 6 years.

Results

NRF2 genetic polymorphisms (rs1806649, rs62173695, rs34468415, rs117045674, rs141429955, and rs117263449) were significantly associated with changes in glucose homeostasis indices over 6 years. Furthermore, we observed significant interactions between *NRF2* genetic polymorphisms and PCBs on changes in glucose homeostasis indices over 6 years (P interaction <0.05), especially rs117263449 and rs141429955. Each 1-unit increase in ln-transformed PCB-118 was associated with a 0.472 increment of FPG over 6 years among rs117263449 TT/TC genotype; and a 1.898 mmol/l, 47.894 mU/l, and 20.571 increment of FPG, FPI, and homeostasis model assessment of insulin resistance (HOMA-IR) over 6 years among rs141429955 AG genotype, respectively. Each 1-unit increase in ln-transformed PCB-52 and PCB-101 was associated with a 5.862 and 15.325 mU/l increment of FPI, and a 2.634 and 6.518 increment of HOMA-IR among rs117263449 TT/TC genotype, respectively. Each 1-unit increase in ln-transformed PCB-52 and PCB-101 was associated with a 27.386 and 60.361 mU/l increment of FPI, and a 11.849 and 25.636 increment of HOMA-IR among rs141429955 AG genotype, respectively.

Conclusions

The *NRF2* gene might modify the longitudinal relationships between PCB exposure and glucose homeostasis damage among Chinese general adults. Our results suggested that redox-related *NRF2* gene should be more considered to prevent glucose homeostasis damage, especially among individuals with high PCB exposure. More mechanistic studies are warranted.

1,25-Dihydroxyvitamin D3 reduces adipogenesis and mitigates the bisphenol-A-induced pro-adipogenic effect in mouse 3T3-L1 cell line and human adipose-derived mesenchymal stem cells through miR-27-3p regulation

Donatella Provvisiero[1], Mariarosaria Negri[2], Feliciana Amatrudo[2], Roberta Patalano[1], Tatiana Montò[1], Gabriella Pugliese[1], Giulia de Alteriis[1], Chiara Graziadio[1], Annamaria Colao[1], Rosario Pivonello[1], Silvia Savastano[1] & Claudia Pivonello[3]

[1]Federico II University of Naples, Department of Clinical Medicine and Surgery, Naples, Italy; [2]Università Telematica Pegaso, Dipartimento di Scienze Umanistiche, Naples, Italy; [3]Federico II University of Naples, Department of Public Health, Naples, Italy

Endocrine-disrupting chemicals, including bisphenol A (BPA) may promote obesity. The role of 1,25-Dihydroxyvitamin D3 (VitD) in counteracting adipogenesis is still a matter of question. Thus, the current study aims to investigate whether and how VitD exposure during adipogenesis could prevent the BPA pro-adipogenic effect in adipocyte models: the mouse pre-adipocytes 3T3-L1 and the human adipose-derived mesenchymal stem cells (hAMSC). 3T3-L1 and hAMSC were treated with VitD (10^{-7} M) and BPA (10^{-8} M and 10^{-9} M), alone or in combination, throughout the differentiation in mature white adipocytes. Lipid droplet accumulation was assessed by RedOilO staining, mRNA and protein expression of key adipogenic markers were investigated by RT-qPCR and WB, respectively. miRNAs involved in the regulation of adipogenic transcription factors were evaluated by RT-qPCR and miRNA inhibitors were used to modulate miRNAs expression. RedOilO staining quantification evidenced a significant VitD anti-adipogenic outcome (~54%, $P=0.0022$) and a significant BPA pro-adipogenic outcome (~29%, $P=0.047$ BPA10^{-8} M and ~42%, $P=0.047$ BPA10^{-9} M) compared to 3T3-L1 control cells, and a significant VitD anti-adipogenic outcome (~27%, $P<0.0001$) and a significant BPA pro-adipogenic outcome (~8%, $P=0.0007$ BPA10^{-9} M) compared to hAMSC control cells. In both cell models VitD counterbalanced BPA pro-adipogenic effect by reducing lipid accumulation, with a maximum effect of ~76%, $P=0.0022$ (BPA10^{-9} M vs VitD+BPA10^{-9} M) and 34.9%, $P=0.0022$ (control vs VitD+BPA10^{-9} M)) compared with untreated 3T3-L1 cells and ~12%, $P=0.0003$ (BPA10^{-9} M vs VitD+BPA10^{-9} M) in hAMSC. In both 3T3-L1 and hAMSC, BPA significantly induced while VitD significantly inhibited mRNA and protein expression of the main adipogenic markers such as PPARγ, C/EBPα, leptin, adiponectin, and LPL. MiR-27a-3p and miR-27b-3p are known regulators of PPARγ. RedOilO staining revealed that miR-27a-3p and miR-27b-3p blocking prevents the anti-adipogenic effect of VitD in both cell models: in 3T3-L1 VitD significantly reduced lipid accumulation compared to untreated cells (58.5%, $P=0.0002$) whereas miR-27a-3p and miR-27b-3p inhibitors reverted the VitD anti-adipogenic effect (+35.8%, $P=0.013$ and +87.0%, $P<0.0001$ compared to VitD, respectively) and in hAMSC VitD significantly reduced lipid accumulation compared to untreated cells (32.9%, $P<0.0001$) whereas miR-27a-3p and miR-27b-3p inhibitors reverted the VitD anti-adipogenic effect (30.1%, $P<0.0001$ and 30.4%, $P<0.0001$ compared to VitD, respectively). In 3T3-L1 and hAMSC, VitD treatment reduced PPARγ, C/EBPα, adiponectin and leptin protein expression. This effect was reverted when miR-27a-3p and miR-27b-3p were blocked by inhibitors. These results suggest that VitD induces an anti-adipogenic effect and prevents BPA pro-adipogenic effect through the activation of miR-27a-3p and miR-27b-3p effectors in mature white adipocytes derived from 3T3-L1 and hAMSC.

Assessing the interaction of styrene/ethylbenzene exposure with genetic susceptibility in type 2 diabetes mellitus: insights from a cohort study

Linling Yu[1,†], Qiyou Tan[1], Yongfang Zhang[1], Bin Wang[1] & Weihong Chen[1]

[1]School of Public Health, Tongji Medical College, Huazhong University of Science and Technology, Department of Occupational and Environmental Health, Wuhan

Background

Styrene and ethylbenzene (S/EB), the monomers found in polystyrene (PS) and polyethylene (PE), are known to continuously leach into the environment and food products. The prevalent use of hand sanitizers containing S/EB during the COVID-19 pandemic has heightened concerns about the health implications of S/EB exposure. Notably, the impact of S/EB exposure on the risk of type 2 diabetes mellitus (T2DM) and its interaction with genetic factors in the general population is not well understood. Additionally, the role of oxidative stress in the S/EB-T2DM link warrants further investigation to clarify the biological mechanisms involved.

Methods

In this prospective cohort study of 2219 Chinese adults followed for 6 years, we evaluated the association between S/EB exposure and T2DM incidence. We constructed a Genetic Risk Score (GRS) based on 205 T2DM-related SNPs to assess cumulative genetic effects and examined the interaction between S/EB exposure and GRS using both multiplicative and additive models. We also measured oxidative stress markers (8-hydroxy-2'-deoxyguanosine, 8-iso-prostaglandin F2α, and protein carbonyl) and developed an Oxidative Stress Score (OSS) to explore the potential mediating role of oxidative stress in the S/EB-T2DM association.

Results

A dose-dependent positive correlation was observed between S/EB exposure and T2DM incidence. High levels of S/EB exposure (RR = 1.930, 95% CI: 1.157-3.309) and GRS (RR = 1.943, 95% CI: 1.110-3.462) were significantly associated with an increased risk of T2DM. Notably, a substantial additive interaction between S/EB exposure and GRS was identified, with a relative excess risk due to interaction of 0.178 (95% CI: 0.065-0.292). Individuals with high S/EB and GRS levels had a markedly elevated risk of T2DM (RR = 2.602, 95% CI: 1.238-6.140) compared to those with low levels of both. Oxidative stress was found to partially mediate the relationship between S/EB exposure and T2DM, contributing to 5.98% of the association.

Discussion

This study provides the first clear evidence that S/EB exposure significantly increases the risk of T2DM, with this risk further exacerbated by genetic susceptibility. The role of oxidative stress in this association suggests potential pathways for intervention. These findings could lead to novel strategies for managing S/EB pollution and personalized approaches for T2DM prevention, emphasizing the importance of addressing both environmental and genetic factors in disease risk management.

Polyclinic, Bologna, Italy, Bologna, Italy; [2]Endocrinology and Diabetes Care and Prevention Unit, IRCCS Sant'Orsola-Malpighi Polyclinic, Bologna, Italy; [3]Radiology Unit, Department of Specialized, Diagnostic and Experimental Medicine (DIMES), Alma Mater Studiorum University of Bologna, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, Bologna, Italy

Background
Active smoking has been associated with alterations of the hypothalamic-pituitary-adrenal axis. A role in the pathogenesis of adrenal tumors has also been proposed previously. No data investigating the relationship between smoking and hormonal secretion of adrenal tumors are yet available.
Aim
To investigate the association between smoking habit with morphology and hormonal pattern of adrenal tumors.
Methods
We retrospectively evaluated 1346 patients with adrenal adenomas, hyperplasia, or adrenocortical carcinoma (ACC). We enrolled 1024 patients (wome $n=646$) fulfilling the inclusion criteria (adrenocortical tumors with data on hormonal secretion and smoking status): non-functioning tumors (NF, $n=572$), mild autonomous cortisol secretion (MACS, $n=310$), ACTH-independent Cushing Syndrome (CS, $n=33$), ACC ($n=34$), primary aldosteronism (PA, $n=75$). We analyzed the prevalence of active, former, and non-smokers among groups and the association with cortisol levels by regression analysis.
Results
Prevalence of active smokers was significantly different among groups (overall $P<0.001$): 28.1% ($n=161$) in NS, 39.4% ($n=122$) in MACS, 60.6% ($n=20$) in CS, 35.3% ($n=12$) in ACC, and 22.7% ($n=17$) in PA. Paired test revealed significant differences between NF vs MACS and CS, with no differences between MACS vs CS. Prevalence of former smokers was not significantly different among groups. The significant differences in active smokers among groups was confirmed in males ($P=0.002$) and females ($P<0.001$). Prevalence of smokers was significantly higher in female MACS (43.6%, $n=85/195$) and CS (53.8%, $n=14/26$) vs NF (28.5%, $n=102/358$), whereas it was not significantly different in MACS vs CS. In males, the proportion of smoker was higher in CS (85.7%, $n=6/7$) vs NF (27.6%, $n=59/214$) and MACS (32.2%, $n=37/115$), with no significant differences in MACS vs NF. Prevalence of former smokers was not significantly different in either sex. Logistic regression analysis revealed a significant association between cortisol after 1 mg-dexamethasone suppression test (DST) with active smoking (odds ratio [OR] = 1.03 each 10 nmol/l increase, 95% confidence interval [CI] = 1.01-1.04, $P=0.001$). This significant association was confirmed when sex (P for sex not significant) and age (P for age = 0.001, OR = 0.98, 95%CI = 0.97-0.99) where added to the model. When adrenal tumor morphology was analyzed, the prevalence of active smokers was significantly higher in patients with adrenal hyperplasia and MACS, when compared to NF adenomas and hyperplasia and adenomas with MACS.
Conclusion
The prevalence of active smokers is significantly higher in cortisol-producing lesions vs NF tumors, with some differences according to sex. Increasing post-DST cortisol is significantly associated with active smoking, independently of sex and age.

CRISPR/Cas9-mediated glucocorticoid receptor knockout effectively enhances antitumor efficacy of ROR1 specific CAR-T cells in advanced adrenocortical carcinoma

Marc Philipp Schauer[1,2], Justus Weber[2], Laura-Sophie Landwehr[1], Peter Spieler[2], Barbara Altieri[1], Tanja Maier[3], Matthias Kroiss[1,3,4], Stefan Kircher[5], Max Kurlbaum[1], Liz Tony[2], Silviu Sbiera[1], Martin Fassnacht[1,4] & Michael Hudecek[2]
[1]University Hospital Würzburg, Department of Internal Medicine I, Division of Endocrinology & Diabetes, Germany; [2]University Hospital Würzburg, Department of Internal Medicine II, Chair for Cellular Immunotherapy, Germany; [3]LMU Hospital Munich, Department of Internal Medicine IV, Division of Endocrinology & Diabetes, Germany; [4]Comprehensive Cancer Center Mainfranken, University of Würzburg, Germany; [5]University Hospital Würzburg, Institute of Pathology, Germany

Background
Adrenocortical carcinoma (ACC) is a rare and aggressive endocrine malignancy with poor prognosis and very limited treatment options in advanced disease. The only curative approach is complete surgical resection. Additionally, 60% of patients show endogenous glucocorticoid (GC) excess with clinical apparent hypercortisolism and low to no immune cell infiltration. To date, no therapeutically relevant surface markers are known for ACC, which is why it has not been considered for cell therapeutic interventions like CAR-T cell therapy.
Methods
In this study, we identified the receptor tyrosine kinase-like orphan receptor-1 (ROR1) as new promising target antigen for CAR-T cell therapy in a representative cohort of 197 ACC patientś samples using RNA-sequencing, qRT-PCR ($n=62$) and IHC ($n=135$). We further evaluated ROR1 expression in five human ACC cell lines using qRT-PCR, qFACS, super high resolution single molecule microscopy (dSTORM) and RNAscope single cell analysis. Lastly, we assessed immunotherapeutic performance of different next-generation ROR1 CAR-T cell modifications in different preclinical models of ACC.
Results
We demonstrate ROR1 to be highly upregulated in in 92.7% of human ACC specimen ($n=197$) as compared to healthy tissue and as clinically relevant prognostic marker for GC excess and disease progression in ACC. All five ACC cell lines were expressing ROR1 in different levels. ROR1 CAR-T cells were generated and functionally tested using preclinical models of ACC. Considering the GC-enriched inhibitory tumor microenvironment, we recapitulated these modalities using steroidogenic ACC cell lines, exogenous supplementation of dexamethasone, 3D cell culture and a novel difficult-to-treat steroidogenic ACC xenograft mouse model. We observed a considerable decrease in antitumor efficacy elicited by ROR1 CAR-T cells in vitro and in vivo. Pharmaceutical inhibition of GC effector functions induced significant mitigation of CAR-T cell potency and antitumor killing due to a corticosteroid inhibitor-related down-regulation of ROR1 on ACC tumor cells. This effect could be attributed to the inhibition of activated hGR/Stat3 tethered proximal transcription factor signaling. To maintain immunotherapeutic efficacy, we therefore desensitized ROR1 CAR-T cells by CRISPR/Cas9-mediated genome editing of the GC receptor (hGR) locus enabling (^{hGRKO} ROR1 CAR-T cells to completely eradicate all ACC xenografts while persisting in vivo, keeping periodic tumor regressions stable and inducing complete and sustained remission in 30% of all mice without toxicity.
Conclusions
Our results demonstrate ROR1 as promising target antigen for CAR-T cell therapy in ACC, while hGRKOROR1-CAR-T cells have been superior to a combined therapy using pharmaceutical blockade of GC effector functions in preclinical models of ACC.

Background
There is no universally accepted first-line (1L) therapy for higher grade, well-differentiated gastroenteropancreatic neuroendocrine tumors (GEP-NETs). The Phase 3 NETTER-2 study (NCT03972488) evaluated [^{177} Lu]Lu-DOTA-TATE

(hereafter ^{177} Lu-DOTATATE) as 1L treatment in patients with grade (G)2 and G3 advanced GEP-NETs. This is the first trial to assess 1L radioligand therapy (RLT) in any solid tumor.

Methods

Eligible patients were newly diagnosed with somatostatin receptor-positive high G2 or G3 (Ki-67 $\geq$10% and $\leq$55%) advanced GEP-NETs within the last 6 months prior to enrollment. Patients were randomized (2:1) to receive 4 cycles of ^{177} Lu-DOTATATE (4 $\times$ 7.4 GBq) plus 30 mg octreotide long-acting release (LAR) at 8-weekly intervals during ^{177} Lu-DOTATATE treatment then every 4 weeks (^{177} Lu-DOTATATE arm), or 60 mg octreotide LAR every 4 weeks (control arm), stratified by grade (G2 vs G3) and tumor origin (pancreas vs other). The primary endpoint was progression-free survival (PFS), centrally assessed using RECIST 1.1. Objective response rate (ORR) was a key secondary endpoint.

Results

Overall, 226 patients were randomized to ^{177} Lu-DOTATATE (n=151) or control (n=75). Most tumors originated in the pancreas (54.4%) or small intestine (29.2%); G3 tumors were reported in 35.0% of patients. Median cumulative dose of ^{177} Lu-DOTATATE was 29.2 GBq, with 87.8% of patients receiving all 4 doses. Median PFS (95% confidence interval [CI]) was significantly prolonged by ~14.3 months from 8.5 months (7.7, 13.8) in the control arm to 22.8 months (19.4, not estimable) in the ^{177} Lu-DOTATATE arm; stratified hazard ratio 0.276 (95% CI: 0.182, 0.418; $P<0.0001$). The ORR was significantly higher in the ^{177} Lu-DOTATATE arm (43.0%) vs the control arm (9.3%); stratified odds ratio 7.81 (95% CI: 3.32, 18.4; $P<0.0001$). PFS and ORR results were consistent across all pre-specified demographic and prognostic subgroups. Among adverse events of special interest to RLT, G3/4 leukopenia, anemia and thrombocytopenia occurred in $\leq$3 patients each in the ^{177} Lu-DOTATATE arm. One case of myelodysplastic syndrome was reported (^{177} Lu-DOTATATE arm).

Conclusion

^{177} Lu-DOTATATE significantly prolonged PFS and demonstrated a clinically meaningful ORR, vs high-dose octreotide LAR, in patients with newly diagnosed advanced G2 and G3 GEP-NETs. Safety was in line with the established profile of ^{177} Lu-DOTATATE. This is the first randomized study to demonstrate efficacy of RLT as first-line treatment in any solid tumor and will change clinical practice.

How close we are to optimise the assessment of SSTR status in NEN with a radiolabelled SSTR antagonist-final results of the TECANT clinical trial: Novel 99mTc-labelled somatostatin antagonists in the diagnostic algorithm of neuroendocrine neoplasms

[1]Jagiellonian University Medical College, Department of Endocrinology, Kraków, Poland; [2]University Medical Centre Ljubljana, Department of Nuclear Medicine, Ljubljana, Slovenia; [3]Medical University Innsbruck, Department of Nuclear Medicine,, Innsbruck, Austria; [4]National Centre For Nuclear Research Radioisotope Centre POLATOM, National Centre For Nuclear Research Radioisotope Centre POLATOM, Otwock, Poland; [5]University of Ljubljana, Faculty of Mathematics and Physics, Ljubljana, Slovenia; [6]SP ZOZ Szpital Uniwersytecki w Krakowie, Kraków, Poland; [7]Universitätsspital Basel, Basel, Switzerland

Introduction/Aim

Within the past two decades, the imaging and treatment of patients with neuroendocrine neoplasms (NEN) has been redefined by the successful introduction of radiolabelled somatostatin receptor (SSTR)-agonists targeting SSTR-subtype2 ($SSTR_2$) overexpressed in NEN cells. Reliable assessment of the SSTR status of the primary focus/metastasis in different NEN locations is a cornerstone of NEN management and enables a personalised/precise therapeutic approach. Recently, novel molecular probes based on antagonists have been shown to recognise more binding sites compared to commonly used agonists, which should lead to improved diagnostic/treatment outcomes for NEN patients, especially at lower SSTR expression. The aim of the multicenter phase 0/1 TECANT study was to develop a ^{99m} Tc-labelled $SSTR_2$-antagonist, a new sensitive diagnostic tool for a reliable SSTR status assessment on tumour cells and to initiate a clinical feasibility study.

Material/Methods

Within the preclinical study, two radiolabelled $SSTR_2$-antagonists: N4-LM-3(TECANT1) and N4-p-Cl-BASS(TECANT2), were tested in cell lines and animal studies assessing receptor affinity, internalisation status, toxicity, biodistribution and SSTR targeting properties. [^{99m} Tc]Tc-TECANT1 showed better targeting properties/lower toxicity, and was ultimately selected for clinical trial. Ten patients with advanced NEN and SSTR-positivity confirmed by routinely performed [^{68} Ga]Ga-DOTA-TATE/TOC-PET/CT were enrolled in clinical study (EudraCT no:2019-003379-20). Safety, tolerability, human pharmacokinetics, dosimetry, and NEN targeting properties of the TECANT1 were assessed. Clinical and imaging data collected at each clinical center were stored in a centralized secured database to standardize image analysis and integrate statistical tools.

Results

[^{99m} Tc]Tc-TECANT1 SPECT/CT was performed in all patients and no radiopharmaceutical-related side effects were observed. Tumour uptake was visible as early as 5 minutes after administration and retained 24 hours p.i. In all patients, rapid distribution with predominant renal excretion with a typical pattern for SSTR-analogues was observed. An excellent visualization of NEN lesions was obtained; in most cases with tumour-to-background ratio(TBR) superior to ^{68} Ga-SSTR-agonists, with the highest values of TBR at 4 hours p.i.

Conclusions

Images obtained with [^{99m} Tc]Tc-TECANT1 appear to be of great clinical importance and may be a step toward a more reliable assessment of SSTR status. Detailed quantitative analysis will be reported to support the initial highly comparable diagnostic performance to [^{68} Ga] Ga-DOTA-TATE PET/CT. Using a ^{99m} Tc-labeled SSTR antagonist may provide a widely available method for SPECT imaging, which should lead to further improvements in personalised NEN management.

This research is a part of the project "Novel ^{99m} Tc-labelled somatostatin receptor antagonists in the diagnostic algorithm of neuroendocrine neoplasms-a feasibility study" (TECANT), funded by ERA PerMed (ERAPERMED2018-125).

Background

Bulk genomic studies have identified distinct molecular classes of adrenocortical tumors (ACT). Transcriptome profiles separate benign ACT ("C2" cluster) from carcinomas (ACC) and identify two groups of ACC, "C1A" ("steroid" and "proliferation" signatures) and "C1B" ("immune" signature), of poor and better prognosis respectively. However, these signatures were characterized at the tissue level ("bulk") and our knowledge of the cell composition of ACT is limited.

Aim

This study aims at providing a single-nucleus atlas of human normal adrenal cortex and ACT.

Methods

We performed single-nucleus RNA-sequencing (10$\times$) of ~170,000 cells from normal adrenal (n=4), benign ACT (n=14) and ACC (n=20). Cell Ranger and

Seurat pipelines were used for deciphering the cellular heterogeneity of steroid and microenvironment cells. Steroid and microenvironment signatures were then scored (ssGSEA and CIBERSORTx) in "bulk" transcriptomes of 201 ACC patients (ENSAT 2014 ($n=33$), TCGA 2016 ($n=79$) and ENSAT 2022 ($n=89$)), to define tumor ecotypes (consensus clustering) and to test their association with outcome.

Results

In steroid tumor cells, 8 variable expression programs were identified, including 4 related to steroidogenesis, mirroring normal adrenal functional zonation, and 4 related to oncogenic processes. Microenvironment of steroid cells was scarce, mainly composed of fibroblasts (4.7% of total cells), endothelial cells (5.1%), macrophages (9.9%) and T cells (1.2%). ACC microenvironment was characterized by cancer-associated signatures, including cancer-associated fibroblasts (CAF, expressing *PDGFRB* and *FN1*), tumor-associated endothelial cells (expressing *ANGPT2* and *VWF*) and tumor-associated macrophages (expressing *CD163* and *F13A1*). Compared to "C1A", "C1B" ACC were enriched in inflammatory "M1-like" macrophages. Deconvolution in ACC bulk transcriptomes identified 3 tumor ecotypes associated with outcome. A first ecotype combined cancer-associated fibroblasts and tumor-associated endothelial cells, with hypoxia and mitosis signatures in steroid cells. A second ecotype combined exhausted T cells, with zona fasciculata steroid signature. These ecotypes were associated with "C1A" and poor survival (log-rank $P<10^{-6}$ and $<10^{-9}$ respectively). Conversely, a third ecotype combined inflammatory macrophages, with zona reticularis steroid signature, and was associated with "C1B" and better outcome (log-rank $P<10^{-7}$).

Conclusion

Single-cell steroid and microenvironment signatures combine into tumor ecotypes associated with outcome, participating in the understanding of ACC heterogeneity and the C1A/C1B partition that we previously reported.

Characterization and targeting of serpins alteration in chronic liver disease and hepatocellular carcinoma

Natalia Hermán- Sánchez[1,2,3,4], María Serrano-Jiménez[1,2,3,4], Victor Amado[1,5,6], Manuel Rodriguez-Peralvarez[1,5,6], Raul M Luque[1,2,3,4], Juan L. López-Cánovas[1,2,3,4] & Manuel D. Gahete[1,2,3,4]

[1]Maimónides Institute of Biomedical Research of Córdoba (IMIBIC), Córdoba, Spain; [2]University of Córdoba, Department of Cell Biology, Physiology and Immunology, Córdoba, Spain; [3]Reina Sofía University Hospital (HURS), Córdoba, Spain; [4]CIBER Pathophysiology of Obesity and Nutrition (CIBERobn), Córdoba, Spain; [5]Reina Sofía University Hospital, Department of Hepatology and Liver Transplantation, Córdoba, Spain; [6]CIBER Hepatic and Digestive Diseases (CIBERehd), Córdoba, Spain

Hepatocellular carcinoma (HCC) is an aggressive tumour frequently associated to an underlying chronic liver disease. In this sense, metabolic dysfunction-associated steatotic liver disease (MASLD) is considered as a growing cause of HCC development. Considering the need of novel therapeutic approaches, and the promising data about targeting the tumour microenvironment in cancer, we performed quantitative proteomics on HCC samples to characterize the components and regulators of the extracellular matrix (the matrisome). The cytosolic and nuclear proteomes of hepatic tissues of HCC patients [$n=42$; HCC vs non-tumour adjacent tissue (NTAT)] were determined using SWATH-MS. The abundance of matrisome proteins was evaluated in the proteomic HCC cohort, two retrospective HCC mRNA cohorts ($n=151$), and different *in silico* cohorts (8 HCC, 10 MASLD and cirrhosis; mRNA and protein). Functional assays (proliferation, migration, colony/tumorspheres formation) were performed in 2 HCC cell lines (Hep3B, SNU-387) after silencing/overexpressing *SERPINF2*. Finally, *in silico* scRNAseq cohorts of MASLD and non-MASLD-derived HCC were analysed. Through quantitative proteomics we identified 34 (cytosol) and 61 (nucleus) differentially expressed matrisome proteins (HCC vs NTAT). A broad dysregulation of the serpins family of protease inhibitors was corroborated in most MASLD, cirrhosis and HCC *in silico* cohorts, confirming their dysregulation in advanced stages of chronic liver disease and in HCC, wherein they were associated with aggressiveness and altered metabolic status. SERPINF2 was consistently dysregulated in most cohorts and associated to metabolic alterations (BMI, leptin/adiponectin ratio) and aggressiveness (survival, microinvasion). *SERPINF2* silencing in HCC cell lines reduced all the functional parameters evaluated, while SERPINF2 overexpression had the opposite effect. Interestingly, the supernatant of SERPINF2-overexpressing cell lines did not affect proliferation, suggesting different roles of intracellular and extracellular SERPINF2. Finally, the analysis of HCC single-cell-RNAseq *in silico* cohorts revealed a decreased expression of *SERPINF2* in tumour-associated endothelial cells and an increased expression in tumour cells. The comparison of cell populations with high or low *SERPINF2* expression also pointed to an alteration of cell-to-cell signalling including angiogenic (i.e. VEGF) and immune-associated (i.e. MIF) factors, consistently with the associations observed in *in silico* RNAseq and with the positive correlation between *SERPINF2* expression and the infiltration score in HCC patients. Taken together, we propose a potential role of serpins in the clinical management of chronic liver disease. Specially, SERPINF2 could represent a relevant tool for targeting HCC tumour cells and their microenvironment.

Whole-exome sequencing of atypical parathyroid tumors identifies novel genes and mutations in common with benign and malignant parathyroid tumors

Elena Pardi, Marcello Poma[2], Liborio Torregrossa[2], Laura Pierotti, Simona Borsari, Simone Della Valentina, Claudio Marcocci & Filomena Cetani[3]

[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]University of Pisa, Department of Surgical, Medical, Molecular Pathology and Critical Area,, Pisa, Italy; [3]Pisa University Hospital, Unit of Endocrinology 2, Pisa, Italy

Atypical parathyroid tumors (APT) represent parathyroid neoplasms characterized by an uncertain malignant potential due to the presence of histological features typical of parathyroid carcinomas (PC), without infiltration of surrounding tissues. The diagnosis of APT can be very challenging. Surgery is often curative but patients with APT may experience recurrence. Although the molecular landscape of benign parathyroid adenoma (PA) and PC has been explored, only few cases of APT have been included in low-throughput genomic analyses. We performed the first study investigating the whole exome sequencing (WES) of APT cases to characterize molecular signatures and deregulated pathways. Tumor specimens having a histopathological diagnosis of APT were collected from 16 Italian patients treated surgically for sporadic PHPT. DNA from tumors and matched peripheral blood were analyzed by WES on an Illumina HiSeq3000 instrument. A total of 192 somatic nonsynonymous variants were found. The median number of protein-altering mutations in APT was 9, lower than previously found in PC and higher than PA. No genes altered in more than 2 samples were observed. The most frequently mutated genes were *BCOR*, *CLMN*, *EZH1*, *JAM2*, *KRTAP13-3*, *MUC16*, *MUC19*, *OR1S1*. Seventeen mutated genes are reported in the Cancer Gene Census (*ATM*, *BCOR*, *CDC73*, *DNM2*, *EZH2*, *GPC3*, *MED12*, *MEN1*, *MTOR*, *PIK3CA*, *PIK3CB*, *RANBP2*, *RNF213*, *UBR5*, *ZNF521*, *FAT3*, *MUC16*). The gene network created with STRING had significantly more interactions than expected by chance ($P=0.001$). The most consistent hub genes were *ATM*, *COL4A5*, *EZH2*, *MED12*, *MEN1*, *MTOR*, *PI3*, *PIK3CA*, *PIK3CB* and *UBR5*. The PI3K/AKT/mTOR and Wnt signaling as well as the extracellular matrix organization were the main deregulated pathways. Interestingly, the study revealed variants in genes (*MEN1*, *CDC73*, *EZH2*, *PIK3CA*, *MTOR*) previously reported as established or putative/candidate driver genes in PA and/or PC. Only the APT sample *CDC73* mutation-positive was significantly enriched in APOBEC mutations. In conclusion, we provide evidence that APT might represent an intermediate entity between PA and PC even from a genomic point of view. It should be clarified if the rare occurrence of somatic *CDC73* mutations in APT is associated with higher risk of recurrence, although all patients of our series were cured after >6 years of average follow-up. This study also pinpointed the role of key epigenetic modifier genes (*BCOR*, *KDM2A*, *CHD4*, *MBD4*, *EZH2*) involved in chromatin remodeling, DNA and histone methylation. These mechanisms take on a role of growing interest in cancer development and offer promise for the development of novel epigenome-targeted therapies.

Autonomous AI-based diagnostic system for predicting malignancy in thyroid nodules

Saturnino Domínguez Cárdenas[1,2]
[1]Hospital Santa Fe, General Surgery, Panama, Panama; [2]Hospital Panamericano, General Surgery, Panama Oeste, Panama

Introduction
The present study investigates the efficacy of an autonomous diagnostic system that employs artificial intelligence (AI) for the prediction of malignancy in thyroid nodules. The study focuses on evaluating the performance of this AI-based system in detecting malignant thyroid nodules, with the aim of improving diagnostic accuracy and patient outcomes. AI, with its ability to analyze large amounts of complex data and identify patterns that may be difficult for humans to detect, can potentially improve the accuracy and speed of thyroid carcinoma diagnosis.
Materials and methods
A retrospective single-center study was carried out, where 1104 patients who required surgical management of thyroid nodules were included. We collected a new clinical dataset of 1104 clinical health records with their respective nodule histopathology; after that, we trained ten machine learning models on this dataset and estimated their prediction performance by cross-validation. The data is optimized, and each artificial intelligence algorithm is evaluated independently and through cross-validation to obtain the lowest possible error, the highest accuracy, and the highest precision with the shortest response time. Also, we conducted a variable importance analysis to examine the relevance of nodule characteristics on the model performance.
Results
In this study, 1104 subjects were enrolled, and 925 (83.78%) were women. The mean age was 47.7 years (24-82 y); the histopathology analysis diagnosed 753 (68.21%) nodules with malignancy. The accuracy of the recurrent neural network model after hyperparameter turning was as high as 99.06%, and the F1-Score was 0.971, whereas its sensitivity and specificity varied significantly in detecting malignancy with different algorithms. The sensitivity-specificity to detect any malignant nodule for the three most accurate algorithms was: Recurrent neural network (RNN) 95.06%-99.19%, Support Vector Machine (SVM) 88.17%-94.33%, and Random Forest (RF) 78.86%-93.28%. Also, our analysis of variable importance helps us identify three key variables in diagnosing malignant thyroid nodules. The variables that have been recognized are the existence of calcification, the cyst's composition, and the nodule's size. Each of these factors is a powerful indicator of malignancy in nodules and aligns with the findings of clinical research and prior modeling studies.
Conclusion
After conducting cross-validation, we've successfully created an AI model that accurately detects the potential risk of thyroid carcinoma. Nonetheless, since the models were trained based on a small dataset, more patient data would be required, and external validation through prospective studies is necessary.

Antigen-specific peptide immunotherapy attenuates the pathogenic response in a murine model of Graves' disease

Yi-Li Cho, Clara Wenhart, Silvia Göbel, Andreas Reimann, Zhongmin Li & Götz Münch
advanceCOR, Munich, Germany

Background
Graves' disease (GD) is an autoimmune disease caused by autoantibody targeting the thyrotropin receptor (TSHR) in the thyroid gland, resulting in hyperthyroidism with an annual incidence of 15 to 80/100,000 people worldwide. Current mainstream treatments for GD include aggressive treatment with radioiodine and thyroidectomy or unspecific immune-modulating therapy with glucocorticoids, antithyroid medications or anti-CD20 antibodies like Rituximab. Therefore, our current focus is on the application of an antigen-specific immune modulation, namely peptide therapy using altered peptide ligands, which potentially reduce inflammatory responses via induction of immune tolerance in GD patients.
Methods
A mouse model that mimics symptoms of human GD was established by monthly immunization of adenovirus that produces TSHR A subunit protein (Ad-TSHR) and Ad-GFP adenovirus as control for 35 weeks. Herein, the therapeutic peptide P19 which was selected from potential antigens via *in silico* and *in vitro* evaluation was applied monthly in the diseased mice starting from 11 weeks after the first Ad-TSHR immunization to investigate its therapeutic effect. The study was achieved by conduction of typical clinical examinations including macro- and microscopic observation of affected organs i.e. thyroid, eye and heart, along with determination of thyroxine (T4) and anti-TSHR autoantibody level.
Results
Macroscopic examination revealed clearly enlarged thyroid glands in mice that had received nine immunizations of Ad-TSHR compared to the native and Ad-GFP mouse groups. On the contrary, diseased mice receiving P19 treatment had a significant decrease in thyroid size ($P>0.05$). Moreover, scalloped colloid and collapsed follicles were prominent in the Ad-TSHR mouse group under microscopic investigation, yet the histological presentation was markedly improved in the P19-treated group. Further analysis showed a remarkable reduction on T4 after two administrations of P19 ($P>0.05$) and the reduction was well maintained by means of P19 till the end of experiment. It indicated a significant amelioration of hyperthyroidism through application with P19. Autoantibody against TSHR as an essential clinical parameter was also tested and the result showed a concurrent decline of T4 and anti-TSHR autoantibody in a well correlated fashion with P19 treatment ($P>0.05$). Subsequently, the P19 application also represented a mild improvement on both orbital fibrosis and heart function in the diseased mice.
Conclusion
The therapeutic peptide P19 we identified revealed an anticipated benefit in the mouse model of Graves' disease with relevant clinical improvement. Thus, the results encourage further insightful exploration of this therapeutic application as a potential treatment for Graves' disease.

Magnetic resonance imaging characteristics of Graves orbitopathy with elevated IgG4 serum concentration

Michał Olejarz[1], Marika Martelus[2], Ewelina Szczepanek-Parulska[1], Elżbieta Wrotkowska[1], Katarzyna Katulska[2] & Marek Ruchala[1]
[1]Poznan University of Medical Sciences, Department of Endocrinology, Metabolism and Internal Medicine, Poznan, Poland; [2]Poznan University of Medical Sciences, Department of General Radiology and Neuroradiology, Poznan, Poland

Background
Graves disease with elevated Immunoglobulin G4 serum concentration is a novel subtype of Graves disease (GD), which seems to be particularly associated with Graves orbitopathy (GO). It occurs in 17.6% of patients with GO and 5.4% of patients with GD without GO. In this study, we compare multiple magnetic resonance imaging (MRI) features of GO with elevated IgG4 serum concentration (IgG4-GO) with the classic GO subtype without IgG4 elevation. No such research has been performed to date.
Methods
We recruited 39 patients with GO. An unenhanced MRI of the orbits was performed on a 3T scanner. T1 weighted (T1WI) and short tau inversion recovery (STIR) sequences were obtained. The dimensions of orbital structures, extraocular muscles (EOM), and the presence of fatty infiltration were assessed on T1WI. The signal intensity (SI) was evaluated on the STIR sequence. Two assessors evaluated all images. IgG4 serum values were measured. Patients with IgG4 values >135 mg/dl were placed in the IgG4-GO group.
Results
There were 11 patients with elevated and 27 with normal IgG4 serum concentration. Patients with IgG4-GO had a larger diameter of the lateral rectus (5.25 [4.73; 5.88] vs 3.98 [3.49; 4.45], $P=0.004$), medial rectus (7.85 [5.68; 8.58] vs 5.08 [4.15; 5.45], $P=0.027$), and superior rectus muscle (5.75 [4.4; 6.78] vs 4.03 [3.14; 5.05], $P=0.022$). There was no significant difference in the diameter of the inferior rectus, inferior oblique, and superior oblique muscle. Patients with IgG4-GO had higher mean EOM to white matter SI ratio (SIR) (2.24 ± 0.39 vs 1.79 ± 0.32, $P>0.001$) and higher maximal EOM to white matter (3.03 [2.72; 3.34] vs 2.43 [2.24; 2.69], $P>0.001$). There was a lower prevalence of EOM fatty infiltration in IgG4-GO patients (9.09% vs 57.14%, $P=0.011$). The IgG4-GO group had a larger diameter of the lacrimal gland in the long axis (19.5 ± 3.1 vs 17.03 ± 3.44, $P=0.046$) but not short axis (6.25 [5.43; 7.15] vs 5.35 [4.6; 6.4] mm, $P=0.089$). IgG4-GO patients had a greater horizontal Barret's Index (51.88 [41.98; 57.55] vs 41.93 [37.04; 47.84]%, $P=0.048$) but not vertical Barret's index. No patient in the IgG4-GO group and only one in the normal IgG4 group had infraorbital nerve enlargement. All patients but one in the normal IgG4 group presented tendon sparing.
Conclusions
Graves orbitopathy with elevated serum IgG4 concentration is characterized by larger diameters of several EOMs, higher EOM mean and maximal signal intensity ratio on STIR, larger lacrimal gland size, and a lower prevalence of EOM fatty infiltration.

The significance of 3-nitrotyrosine quantification in angioinvasive papillary thyroid carcinoma

Angelika Buczyńska[1], Maria Kościuszko[2], Aleksandra Wiatr[1], Agnieszka Adamska[2], Katarzyna Siewko[2], Janusz Dzieciol[3], Anna Popławska-Kita[2] & Adam Krętowski[2]
[1]Medical University of Bialystok, Clinical Reserch Centre, Bialystok, Poland; [2]Medical University of Bialystok, Department of Endocrinology, Diabetology and Internal Medicine, Bialystok, Poland; [3]Medical University of Bialystok, Department of Human Anatomy, Bialystok, Poland

Angioinvasion in papillary thyroid cancer (PTC) is a crucial determinant of patient prognosis. 3-Nitrotyrosine (3-NT) is a byproduct resulting from the interaction between nitric oxide and tyrosine, serving as a discernible marker indicative of oxidative stress. Within the context of PTC, oxidative stress plays a pivotal role in carcinogenic processes, particularly concerning angioinvasion. Patients with elevated levels of oxidative stress are correlated with an unfavorable clinical prognosis. Oxidative stress is intricately linked to the modulation of molecular pathways governing tumor progression, influencing the invasive potential of PTC. Hence, the quantitative assessment of 3-NT holds promise as a prognostic indicator for angioinvasion, providing valuable insights for the clinical management of PTC patients. This study aims to elucidate the potential of 3-NT quantification as a discerning marker of oxidative stress for stratifying patients at risk of angioinvasion in PTC. For the purpose of this study, 80 patients diagnosed with PTC participated in the study, with 55 exhibiting angioinvasion and 25 without. 3-NT levels were assessed using the enzyme-linked immunosorbent assay (ELISA). Robust statistical analyses, incorporating logistic regression, assessed the correlation between 3-NT levels and angioinvasion. Receiver Operating Characteristic (ROC) curves were meticulously constructed, unveiling Area Under the Curve (AUC) values. Significant differences in 3-NT levels were observed between patients with PTC with and without angioinvasion. Elevated concentrations of 3-NT were identified in the angioinvasion group, indicating a potential association between the angioinvasion process and elevated oxidative stress ($P<0.001$). The validation of these findings, particularly through logistic regression analysis with an odds ratio of 1.16 ($P=0.0006$), and ROC curves with an AUC of 0.963 ($P<0.0001$), carries substantial clinical implications. The quantification of 3-NT levels emerges as a promising tool for identifying a high-risk cohort of patients with angioinvasion in PTC. This approach facilitates personalized therapeutic strategies, potentially improving prognoses for individuals affected by PTC.

Introduction
Autoimmune thyroid diseases (AITD) such as Graves' disease (GD) or Hashimoto's thyroiditis (HT) are autoimmune, organ-specific diseases probably related to a complex and multifactorial interplay of specific susceptibility genes and environmental exposures. T lymphocytes and their secretory cytokines play indispensable roles in disrupting tolerance. However, their roles are often complex and full of interactions among distinct components of the thyroid ecosystem. Novel technologies such as spatial transcriptomics (ST), allow us to explore the molecular architecture and the heterogeneity and landscape of the different cell-states within tissues.
Methodology
We profiled 8 human thyroid samples (3 HT, 3 GD and 2 controls) samples by ST using the Visium Spatial Gene Expression platform (10× Genomics). We spatially localized and histologically annotated thyroid folicular cells (TFCs), connective tissue and vessel areas to be independently studied. Furthermore, we defined and mapped into the space disease-associated subpopulations of cells. These markers have been validated using public single cell data and by protein in situ detection with immunofluorescence (IF) and/or immunohistochemistry (IHC).
Results
We revealed damaged antigen-presenting TFCs located close to the immune infiltration that contributed to the autoperpetuation of the immune response in AITD. Interestingly, we reported the participation of different fibroblasts subpopulations in HT and GD patients. Specifically, GD-associated ADIRF+ myofibroblasts surrounding TFCs and inflammation-associated fibroblasts (IAFs) within the connective tissue of HT patients. Furthermore, the presence of fenestrated PLVAP+ vessels in AITD, especially in GD, was highlighted.
Conclusions
Our data provides the molecular and cellular heterogeneity of AITD microenvironment and points toward the importance of different novel markers associated to cell subpopulations in the stroma and thyroid epithelium that could be essential to understand the pathogenesis of AITD.

Filamin A is required for RET expression and signaling in medullary thyroid carcinoma (MTC) cells

Giusy Marra[1], Rosa Catalano, Emma Nozza[1,2], Gianluca Lopez[3,4], Andrea Contarino[1], Alessia Dolci[5], Elisabetta Iofrida[6], Giovanna Mantovani[1,5] & Erika Peverelli[1,5]
[1]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy, Milan, Italy; [2]PhD Programme in Experimental Medicine, University of Milan, Milan, Italy, Milan, Italy; [3]Department of Biomedical, Surgical and Dental Sciences, University of Milan, Italy, Milan, Italy; [4]Division of Pathology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, Milan, Italy; [5]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, milan, Italy; [6]Otolaryngology and Head and Neck Surgery Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, milan, Italy

Medullary thyroid carcinoma (MTC) is a rare neuroendocrine tumor originating from parafollicular thyroid C cells that produce calcitonin, accounting for 5%-10% of thyroid cancers. In all inherited cases of MTC, and in about 40% of sporadic cases, activating mutations of the receptor tyrosine kinase proto-oncogene RET are found. Signaling pathways involved in cell proliferation, survival and motility are triggered by constitutively active RET, but the mechanisms underlying malignant transformation of C cells have been only partially elucidated. Neck surgery is the mainstay of treatment. New modalities of target treatments, including cabozantinib and vandetanib, two tyrosine kinase inhibitors, and selpercatinib and pralsetanib, two selective ret inhibitors have shown to be promising in advanced and recurrent disease. However, patients with unresectable MTC are difficult to treat and the prognosis remains unfavorable. The cytoskeletal protein filamin A (FLNA) is involved in the regulation of different signaling pathways mediated by various tyrosine kinase receptors, but there are no data on the role of FLNA in the RET-mediated pathway. Aim of this study was to test the role of FLNA in regulating RET expression, RET and ERK1/2 phosphorylation and cell proliferation, in human TT cell line, harboring the RET mutation C634W, and primary cultures cells deriving from surgically removed MTC. Our data showed that genetic silencing of FLNA in TT cell line significantly reduced RET expression (-18.54 (30.79)% vs control cells, P value<0.01) and its phosphorylation (-35.9 (37.4)% vs control cells, P value<0.01); moreover, it inhibited ERK1/2 phosphorylation (-40.73 (33.33)% vs control cells, P value<0.01) in accordance with cell proliferation reduction (-33 (21.08)% vs control cells, P value<0.01). Furthermore, we found a decrease in calcitonin secretion (-19.78 (17.57)% vs control cells, P value<0.05) in FLNA silenced cells. In primary cultured cells derived from MTC ($n=4$ RET wild type and $n=1$ C634S RET), FLNA knockdown reduced cell proliferation, regardless of RET mutational status. In conclusion, these data demonstrated that FLNA is required for RET expression and signaling and promotes cell growth in MTC cells, suggesting FLNA may represent as a novel possible target for effective treatment of MTC.

Differential gene expression in dopamine agonist sensitive and resistant human prolactinomas

Etienne Delgrange, Jacqueline Trouillas[2] & Anne Wierinckx[3]
[1]Université catholique de Louvain, CHU UCL Namur, Yvoir, Belgium; [2]Faculté de Médecine Lyon-Est, Lyon, France; [3]Institut Universitaire de Technologie, Université Lyon 1, Lyon, France

Dopamine agonists (DAs) are usually used as first line treatment in prolactinomas. Some tumors do not normalize prolactin levels under treatment and demonstrate a more aggressive course. The mechanisms underlying this chemoresistance are poorly understood. Previous gene expression studies have focused on candidate genes such as the DA receptor 2 (DRD2) or the nerve growth factor (NGF), but transcriptome analyses comparing tumors resistant and responsive to DA are still lacking. We compared gene expression, by microarray, in lactotroph pituitary tumors from male patients either resistant to DA ($n=5$) or demonstrating postoperative normalization of serum prolactin levels under conventional doses of DA ($n=11$). A fold change (FC) of at least 1.3 with a p value <0.05 was considered significant. The expression of the top 30 deregulated genes either with the highest FC or the most significant p values was correlated to proliferation markers and tumor grade. Among candidate genes, DRD2 was in the top list of genes with the most significant differential expression ($P=0.001$; FC -1.3), confirming its low expression in DA resistant tumors. Moreover, we identified molecules interacting with DRD2 or implicated in its pathway: a down regulation of GPR37, a G protein-coupled receptor (GPCR), interacting with DRD2; and, using Gene Set Enrichment Analysis and Ingenuity pathway analysis, a significant loss of expression of DA uptake and of DA signaling cascade. We observed also an under expression of a cell adhesion molecule, close homolog of L1 (CHL1), coding for a protein interfering with the trafficking of the DRD2 and an overexpression of fibronectin type III domain-containing protein 1 (FNDC1), which is known to modulate the PI3K/Akt signaling pathway. Overlapping in the top 30 lists for both p value and FC, was centrosomal protein 55 (CEP55), considered as an oncogene, which was overexpressed in case of DA resistance (FC +2.5; $P=0.005$) and correlated positively with mitoses ($r=0.63$; $P=0.01$) and tumor grade ($r=0.69$; $P=0.01$). Interestingly, the only pathways and functions significantly activated in resistant vs DA sensitive tumors are the pathways known to induce drug resistance of cancer cells. Our findings precise the deregulation of the DRD2 pathway in resistant lactotroph tumors and show that other GPCR possibly interacting with DRD2 could be implicated. They shed light on putative new players, such as an adhesion molecule (CHL1) and an oncogene (CEP55), in the DA chemoresistance.

Successful breastfeeding in a parturient with panhypopituitarism: A case report and literature review with implications for endocrine practice

Yael Derdikman Ofir[1], Anne Eglash[2], Kerstin Moberg[3] & Irit Hochberg[4]
[1]Rambam Health Care Campus, Department of Anesthesiology, Haifa, Israel; [2]University of Wisconsin School of Medicine and Public Health, Department of Family and Community Medicine, Madison, Wisconsin, United States; [3]Swedish University Agriculture, Department of Animal Health and Welfare, Skara, Sweden; [4]Rambam Health Care Campus, Institute of Endocrinology, Diabetes and Metabolism, Haifa, Israel

Panhypopituitarism is a complex endocrine condition often thought to preclude breastfeeding due to its inherent hormonal deficiencies. Breastfeeding, however, is an important health behavior that reduces maternal morbidity and mortality. Breastfeeding reverses cardiometabolic risk factors acquired during pregnancy by reducing visceral fat and cholesterol, lowering risks of type 2 diabetes, cardiovascular and neurovascular comorbidity, and breast and ovarian cancer. We report on the management and outcome of a 34-year-old parturient with panhypopituitarism secondary to craniopharyngioma treatment who desired to breastfeed. The patient, with endocrine and lactation specialist support, prepared prenatally for lactation. Post-delivery, she used intranasal oxytocin to stimulate milk ejection and was treated with galactagogues. Despite her prolactin levels remaining below typical lactogenic ranges and the need for formula supplementation, she established a partial breastfeeding routine. Key to this success was the use of a supplemental nursing system, combined with regular milk expression and multidisciplinary support. We also reviewed published cases of women with hypopituitarism or panhypopituitarism who gave birth, where there was mention of attempted breastfeeding with successful or unsuccessful results. Our literature review, encompassing 33 articles and detailing 85 live births, found that a minority of these women succeeded in breastfeeding, with 96% of unsuccessful cases lacking documentation of lactation support. Our analysis also suggests a correlation between low prolactin levels or inadequate prolactin response to TRH-stimulation testing with the absence of spontaneous lactation post-delivery. These findings suggest that recombinant prolactin may be of benefit in the management of lactation in women with panhypopituitarism. Following these results, our case challenges the assumption that achieving successful breastfeeding is unfeasible in women with panhypopituitarism. The innovative application of intranasal oxytocin with a lactation plan of care that involves multispecialty involvement demonstrates a novel approach to managing such cases. This report emphasizes the importance of reassessing the lactation potential in women with endocrine disorders and encourages proactive, multidisciplinary support in their care.

Loss of heterozygosity predicts treatment-refractory behavior in pituitary neuroendocrine tumors

Andrew Lin[1], Vasilisa Rudneva[1], Allison Richards[1], Yanming Zhang[2], Marc Rosenblum[1], Mark Donoghue[1], Viviane Tabar[1] & Eliza Geer[1]
[1]Memorial Sloan Kettering Cancer Center New York, New York, United States; [2]Memorial Sloan Kettering Cancer Center New York, Department of Pathology and Laboratory Medicine, New York, United States

Background
Pituitary neuroendocrine tumors (PitNETs) exhibiting treatment-refractory behavior are the rare subset that progress after radiation and are characterized by unrelenting growth and metastatic dissemination.
Methods
To identify biomarkers of treatment-refractory behavior, two groups of patients with PitNETs were consented to matched tumor-normal whole exome and targeted next-generation DNA sequencing on a clinical protocol: a prospective group ($n=66$) that was enrolled prior to surgery and a retrospective group ($n=26$) comprised of aggressive PitNETs.
Results
Across the cohort, treatment-refractory behavior, defined by progression following standard treatments including radiation, was associated with a higher mutational burden, $P=1.3\times10^{-10}$. Common genetic alterations in the treatment-refractory corticotroph PitNETs include mutations in *TP53*, *ATRX*, *DAXX*, and potentially targetable mutations in *TSC2* and mismatch repair genes (*MSH2*, *MSH6*, and *MLH1* with corresponding loss of protein expression on mismatch repair immunohistochemistry); only *TP53* was recurrently mutated in treatment-refractory lactotroph tumors. Treatment-refractory behavior was associated with increased fraction of loss of heterozygosity (LOH), $P=8.5\times10^{-9}$, and a higher fraction of LOH was associated with *TP53* mutations, $P=3.3\times10^{-8}$. Within the corticotroph lineage, treatment-refractoriness correlated with a characteristic pattern of recurrent chromosomal LOH, $P=1.7\times10^{-4}$. A machine learning approach confirmed that LOH is the most predictive variable tested for treatment-refractory behavior, outperforming the most common gene-level alteration. A fraction of LOH-based classifier identified treatment-refractory behavior with an accuracy of 0.88 (95% CI:0.70-0.96), sensitivity of 0.83, and specficity of 0.90.
Conclusion
Treatment-refractory PitNETs are genomically distinct from their benign counterparts; LOH predicts treatment-refractory behavior with high sensitivity and specificity.

Kisspeptin administration does not alter anxiety or circulating cortisol levels in humans

Edouard G Mills[1,2], Layla Thurston, Lisa Yang, Sofiya Suladze[1], Tia Hunjan[1], Maria Phylactou[1,2], Bijal Patel[1], Sophie A. Clarke[1,2], Amar J. Shah[1], Chioma Izzi-Engbeaya[1,2], Jovanna Tsoutsouki[1], Paul Bech[1], Natalie Ertl[1,3], Lysia Demetriou[1,3], Matthew B. Wall[1,3], David Goldmeier[4], Ali Abbara[1,2], Alexander N. Comninos[1,2] & Waljit S. Dhillo[1,2]
[1]Imperial College London, Section of Endocrinology and Investigative Medicine, London, United Kingdom; [2]Imperial College Healthcare NHS Trust, Department of Endocrinology, London, United Kingdom; [3]Invicro London, London, United Kingdom; [4]Imperial College Healthcare NHS Trust, Jane Wadsworth Sexual Function Clinic, London, United Kingdom

Background
The neuropeptide kisspeptin is a key endogenous activator of the reproductive system. Due to its crucial role in modulating reproductive and behavioural processes, there has been accelerating interest in targeting kisspeptin-pathways to treat reproductive and psychosexual disorders. However, contradictory pre-clinical data from animal models suggests that kisspeptin can have an anxiolytic, anxiogenic or have no effects on anxiety. Given the rapid development of kisspeptin-based therapeutics, it is imperative to elucidate kisspeptin's effects on anxiety in humans. Herein, we report the largest study investigating the effects of kisspeptin on psychometric measures of anxiety and circulating cortisol levels.
Methods
Ninety-three eugonadal participants ($n=29$ healthy men, $n=32$ men with low sexual desire, $n=32$ women with low sexual desire) completed a double-blind, randomised, placebo-controlled, crossover study. Participants attended twice: once for intravenous infusion of kisspeptin-54 (1 nmol/kg/h) over 75 mins and for rate-matched placebo. Blood was sampled at 15 min intervals from -30 to 75 mins to measure circulating kisspeptin, LH, testosterone and cortisol [in men] and oestradiol [in women]. The validated 'State-Trait Anxiety Inventory (STAI) Y2-Trait' was completed prior to infusions to exclude abnormal anxiety traits, with all scores within normal limits. Subsequently, participants completed the 'STAI Y1-State' before and at the end of the infusions to assess for any dynamic effects on anxiety.
Results
Ninety-three participants (mean age $\pm$ SD 30.9 $\pm$ 8.7 yrs, BMI 24.0 $\pm$ 3.7 kg/m^2) completed the study. Baseline state anxiety and circulating cortisol levels were equivalent at the beginning of the kisspeptin and placebo visits. Intravenous kisspeptin potently increased serum LH to levels previously described using this administration protocol, confirming that the dose was biologically active ($P>0.001$). Importantly, state anxiety was unaltered by kisspeptin, compared to placebo (mean difference in 'STAI Y1-State' scores during the infusions: kisspeptin -0.03 $\pm$ 8.11, placebo 0.77 $\pm$ 8.08, $P=0.43$). Furthermore, kisspeptin had no effect on circulating cortisol compared to placebo during the 75 min study period ($P=0.92$). As expected, kisspeptin had no significant effects on downstream sex-steroid levels during the 75 min study period, thereby removing these as possible confounders.
Discussion
This is the largest study demonstrating that a biologically active dose of kisspeptin to healthy participants and patients with psychosexual disorders does not affect psychometric measures of anxiety and associated circulating cortisol levels. Given that animal studies have yielded inconsistent results, this provides key clinical data and reassurance that kisspeptin administration in humans does not induce anxiety and so informs safety for the rapid development of kisspeptin-based therapeutics for reproductive and psychosexual disorders.

Defining the role of androgen signalling in GABA neurons in the development of PCOS-like traits

Christopher Coyle[1], Melanie Prescott[2], Kyoko Potapov[1] & Rebecca Campbell[2]
[1]University of Edinburgh, Centre for Discovery of Brain Sciences, Edinburgh, United Kingdom; [2]University of Otago, Centre for Neuroendocrinology and Department of Physiology, Dunedin, New Zealand

Androgen excess is a hallmark feature of polycystic ovary syndrome (PCOS), the most common form of anovulatory infertility. Clinical and preclinical evidence links developmental exposure to hyperandrogenism with programming the reproductive traits of PCOS. While the critical androgen targets remain to be determined, GABAergic neurons in the brain are postulated to be involved. GABA levels are elevated in the cerebrospinal fluid of PCOS patients, and both GABA transmission and innervation to gonadotrophin relseasing hormone (GnRH) neurons are elevated in prenatally androgenised models of PCOS. Here, we tested the hypothesis that androgen signalling in GABAergic neurons is critical in PCOS pathogenesis in a well-characterised, hyperandrogenic mouse model of PCOS. To generate mice with GABA neuron-specific knockout of androgen receptors (referred to as GABARKO), vesicular GABA transporter (VGAT)-ires-Cre (VGAT-Cre$^{\pm}$) mice were crossed with androgen receptor flox (AR$^{fl/fl}$) mice. Experimental animals were produced by crossing heterozygous VGAT-Cre$^{\pm}$; AR$^{fl/wt}$ females with homozygous AR$^{fl/Y}$ males. To generate experimental animals with fluorescent GnRH neurons, VGAT-Cre$^{\pm}$;AR$^{fl/wt}$ females were bred with AR$^{fl/Y}$;GnRH-GFP$^{+/+}$ males. VGAT-Cre$^{-/-}$; AR$^{fl/fl}$ females were used as controls (referred to as wildtype). Prenatally androgenized (PNA) PCOS-like mice and vehicle controls (VEH) were generated by injecting pregnant dams s.c. with 100 µl of either dihydrotestosterone (250 µg) dissolved in sesame oil or an oil vehicle alone on gestational days 16, 17 and 18. Female offspring were phenotyped for PCOS-like reproductive features and fixed brain sections were subsequently assessed for elevated GABAergic input to GnRH neurons using immunofluorescence and confocal microscopy. GABARKO did not impact the timing of pubertal onset, estrous cyclicity or ovarian morphology in VEH mice. As expected, wildtype PNA mice exhibited delayed pubertal onset and complete acyclicity compared to VEH mice. The majority of GABARKO PNA mice remained acyclic and ovarian morphology was unaffected across groups. However, while PNA predictably increased the density of putative GABAergic synapses to gonadotropin-releasing hormone (GnRH) neurons in adult WT mice, this PNA-induced plasticity in GABAergic innervation to the GnRH neurons was absent in GABARKO mice. Together, these findings suggest that while direct androgen signalling in GABA neurons is largely not required for the development of the reproductive PCOS-like traits in androgenised models of PCOS, developmental programming of GnRH neuron innervation is dependent upon androgen signalling in GABA neurons.

DOI: 10.1530/endoabs.99.OC9.5

OC9.6

Antiproliferative role of the vasopressin V2 receptor antagonist tolvaptan in a murine xenograft model of small cell lung cancer

Giada Marroncini, Laura Naldi, Simone Polvani, Francesca Pasella, Chiara Cirillo, Benedetta Fibbi & Alessandro Peri
[1]University of Florence, Experimental and Clinical Biomedical Sciences "Mario Serio", Florence, Italy

Vaptans are nonpeptide vasopressin receptors antagonists, developed for the treatment of euvolemic or hypervolemic hyponatremia. Among them, tolvaptan, a selective V_2receptors antagonist, approved for the treatment of hyponatremia secondary to the syndrome of inappropriate antidiuresis, was also approved for the treatment of polycystic kidney disease. Here, tolvaptan is able to reduce the growth of renal cysts and the rate of estimated glomerular filtration decrease. This unpredicted antiproliferative effect has been related to its inhibitory effect on the intracellular cAMP/PKA pathway in kidney epithelial cells. Noteworthy, there is *in vitro* evidence showing that tolvaptan reduces cell proliferation and invasion, and triggers apoptosis in different human cancer cell lines. To study this effect *in vivo*, a xenograft model of small cell lung cancer in Fox1$^{nu/nu}$ nude mice ($n=10$) was developed through subcutaneous inoculation of H69 cells transfected with a plasmid containing the luciferase gene. When masses of about 100 mm^3 were formed, mice were divided into two groups, a control group and a treatment group, which received tolvaptan at 0.15% daily. During the 60-day experimental period (T0-T60), tumor volume was assessed at different time points, both by using a digital caliper and by the IVIS Lumina system, which exploits the bioluminescence emitted by transfected cells. Through these observations, the size of the lesions appeared significantly greater in the control group compared with the treatment group at T60 (4271 $\pm$ 1915 mm^3 and 2307 $\pm$ 463 mm^3,respectively, $P\leq0.05$). Interestingly, there was a trend toward a longer survival in the treatment group compared to the control group (59 + 1 vs 50.4 + 4.7 days, mean + SE, respectively). The expression of PCNA, a proliferative marker, and of caspase 3, a marker of apoptosis, were evaluated on explanted tumors. The level of expression of PCNA was significantly lower in the masses of tolvaptan-treated mice compared to control ones, whereas caspase 3 was more abundantly expressed in the treatment group. In conclusion, these findings confirm also *in vivo* an effective role of tolvaptan in counteracting tumor progression. Overall, these results suggest a possible dual role of this drug in cancer patients with hyponatremia, which is a frequent finding in this condition and is most often related to the syndrome of inappropriate antidiuresis.

Time to severe chronic kidney disease and nephrolithiasis in hypoparathyroidism: results from a large longitudinal retrospective study

Anna Piazza, Nicolò Bisceglia, Matteo Malagrinò, Paola Altieri, Andrea Repaci, Uberto Pagotto & Guido Zavatta
Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Italy

Introduction
Hypoparathyroidism (Hypo) is associated with a higher risk of chronic kidney disease (CKD) and renal stones, although the time to onset of these complications in the disease's natural history has never been explored. Calcium-Phosphate product (CaxP) has been shown to be a risk factor for moderate renal disease in Hypo in a limited number of cross-sectional or case-control studies.
Objective
To determine the time of onset of incident severe CKD and nephrolithiasis and their biochemical predictors in a cohort of Hypo patients treated with conventional therapy.
Design
Longitudinal retrospective study with review of paper and electronic medical records over 40 years.
Setting
Single academic medical center.
Patients
203 patients with chronic hypoparathyroidism who were regularly followed between 1980 and 2023 in an outpatient setting.
Main outcome measures
Demographic and biochemistries, time to first incident GFR <30 ml/min and time to first incident nephrolithiasis diagnosed clinically or radiologically.
Results
Mean age at last follow-up was 61 years [range, 20-93], with most patients having post-surgical Hypo (94.1%), predominantly women (79.3%), with a median disease duration of 11 years (range 0-50 years). The time-weighted average (TWA) of serum calcium was 8.4 ± 0.8 mg/dl, TWA serum phosphate was 4.4 ± 0.8 and the TWA CaxP was 38.2 [range, 23-47] mg^2/dl^2, while TWA urinary calcium was normal at 126 mg/day [range, 118-233]. Twenty-five (12.3%) patients experienced a GFR decline to less than 30 ml/min. In a Kaplan-Meier analysis, mean time from diagnosis to first GFR <30 ml/min was 38.6 years [33.9-43.3]95%CI. A shorter time to CKD was associated with greater CaxP (HR 45, $P=0.043$) and longer duration of Hypo (HR 16.9, $P>0.001$) in a Cox-regression model ($P>0.001$) independent of hypertension, TWA calcitriol dosage and TWA calcium supplements doses. Thirty-two (15.8%) patients experienced asymptomatic incident kidney stones. Mean time to first incident nephrolithiasis was estimated to be 36.6 years [31.7-41.7] 95%CI in a Kaplan-Meier analysis. In a Cox-regression model ($P>0.001$) adjusted for TWA urinary calcium, TWA calcitriol dosage, sex and TWA calcium supplements doses, a higher CaxP (HR 1.76, $P=0.048$) and longer duration of Hypo (HR 4.26, $P>0.001$) were the only significant predictors of early kidney stones.
Conclusions
In a predominantly post-surgical cohort of Hypo, a higher CaxP product accelerates the onset of severe CKD and nephrolithiasis despite averagely well biochemical control. A lower CaxP target than 55 mg^2/dl^2 might be considered to delay future renal disease in chronic hypoparathyroidism.

The effect of gender affirming hormone therapy on calcium-phosphate homeostasis in transgender persons

Raya Geels[1,2], Renate de Jongh, Daan van Velzen[1,2], Mariska Vlot[3], Chantal Wiepjes[1,2], Guy T' Sjoen[4], Marc Vervloet[5], Annemieke C Heijboer[6] & Martin den Heijer[1,2]
[1]Amsterdam UMC, Department of Endocrinology, Amsterdam, Netherlands; [2]Amsterdam UMC, Center of Expertise on Gender Dysphoria, Amsterdam, Netherlands; [3]St. Jansdal Hospital, Department of Endocrinology, Harderwijk, Netherlands; [4]Ghent University Hopsital, Center for Sexology and Gender, Ghent, Belgium; [5]Amsterdam UMC, Department of Nephrology, Amsterdam, Netherlands; [6]Amsterdam UMC, Department of Clinical Chemistry Endocrinology, Amsterdam, Netherlands

Objective
The aim of the current study is to examine the effects of gender affirming hormone therapy in transgender persons on calcium and phosphate concentrations and their regulatory hormones.
Design
A prospective cohort study
Methods
This study investigated changes in calcium and phosphate concentrations and their regulatory hormones in trans women and trans men during the first year of hormone therapy. Trans women received estradiol and anti-androgens, while trans men received testosterone. Calcium, phosphate, PTH, FGF23 and 1,25diOHD were measured at baseline and after 1 year of hormone therapy. Calcium concentrations were corrected for serum albumin. Correlations between change in gonadal hormones and change in calcium- and phosphate and related hormone concentrations were studied.
Results
In 40 trans women [median age 29.1 years, 95% CI 25.7 to 45.4] calcium decreased with 1.7% [95% CI -2.8 to -0.6] and phosphate increased with 6.1% [95% CI 0.9 to 11.3]. PTH decreased with 8.9% [95% CI -17.2 to -0.6], whereas FGF23 and 1,25diOHD did not change in trans woman. In 40 trans man [median age 25.5 years, 95% CI 24.1 to 29.1] calcium increased with 1.2% [95% CI 0.1 to 2.3] and phosphate decreased with 9.7% [95% CI -14.9 to -4.5]. PTH decreased with 10.5% [95% CI -19.5 to -1.5] and FGF23 increased with 31.8% [95% CI 18.2-45.3], while 1,25diOHD concentrations did not change in trans man. In a pooled analysis, 1 SD change in testosterone concentrations [32.7 nmol/l] was related to an increase in calcium of 0.02 mmol/l [95% CI 0.01 to 0.04], a decrease in phosphate concentration of 0.06 mmol/l [95% CI -0.09 to -0.03] an increase of FGF23 concentrations of 18 U/ml [95% CI 6 to 31]. Changes in estradiol or LH concentrations were not related to any of the outcomes.
Conclusions
1 year of hormone therapy resulted in a decrease in phosphate concentrations in trans men and an increase in trans women. For calcium only a subtle change was observed in an opposite manner as phosphate changes. The increase in testosterone levels correlated with the decrease in phosphate concentrations. Increased phosphate excretion through FGF23 secretion or increased bone formation, may mediate the effects of testosterone.

Calcium to magnesium ratio can be a new marker for predicting nephrolithiasis in patients with primary hyperparathyroidism

Ekin Yiğit Köroğlu[1], Abbas Ali Tam[2], Sevgül Fakı[1], Belma Tural Balsak[1], Fatma Ayça Edis Özdemir[3], Didem Özdemir[2], Oya Topaloğlu[2], Reyhan Ersoy[2] & Bekir Çakır[2]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara; [2]Ankara Yıldırım Beyazıt University Faculty Of Medicine, Endocrinology and Metabolism, Ankara; [3]Ankara Bilkent City Hospital, Radiology, Ankara

Purpose
In previous studies, magnesium (Mg) was found to be lower in cases with more severe primary hyperparathyroidism (PHPT) and higher calcium (Ca) levels. This study evaluated the relationship between serum Mg and serum Ca and phosphorus (P) levels in PHPT and their utility in discriminating osteoporosis and nephrolithiasis.
Methods
Patients who were followed up with PHPT between March 2019 and March 2023 were analyzed retrospectively. Biochemical data, renal ultrasonography results, dual-energy x-ray absorptiometry reports, and technetium 99m sestamibi parathyroid scintigraphy reports were obtained. MgxP, Mg/P, Ca/P, and corrected Ca (cCa)/P values were calculated. The relationships between biochemical parameters and clinical outcomes were evaluated statistically.
Results
A total of 543 patients were included in the study. For Ca/Mg, a cut-off value of 5.47 had a sensitivity of 74% and a specificity of 73% for the presence of nephrolithiasis. The cut-off value for cCa/Mg that can be used to predict nephrolithiasis was 5.24, with a sensitivity of 73.3% and a specificity of 73%. No statistically significant correlation existed between the Mg/P, MgxP, cCa/Mg, Ca/Mg values, and DEXA results.
Conclusion
Ca/Mg and cCa/Mg ratios especially seem more valuable in discriminating nephrolithiasis than the currently used 24-hour urine Ca measurement. Unlike urinary Ca measurements, they are cheaper, more practical, and more accessible.

Morning urinary Calcium/Creatinine Ratio as screening tool for hypercalciuria in patients with hypoparathyroidism

Christina Berr[1], Carmina Teresa Fuss[2], Karen Gronemeyer[2], Christian Pfob[3], Thomas Pusl[1] & Stefanie Hahner[2]
[1]Augsburg, Department of Endocrinology, I. Medical Clinic, University Hospital Augsburg, Augsburg, Germany; [2]Würzburg, Endocrinology and Diabetes Unit, Department of Medicine I, University Hospital Würzburg, Würzburg, Germany; [3]Augsburg, Nuclear Medicine, Faculty of Medicine, University of Augsburg, Augsburg, Germany

Background
Hypercalciuria is a relevant complication in patients with treated hypoparathyroidism. Hypercalciuria is usually estimated by 24 h urinary calcium excretion (24 hUCa). In contrast, in pediatric endocrinology the calcium-creatinine-ratio (CaCrR) is more often used due to feasibility. This study aims to compare these two approaches in adult patients with hypoparathyroidism.
Methods
In 181 systematically evaluated patients with primary hypoparathyroidism (93% postoperative, 73% female), the 24 hUCa was compared with the CaCrR of a fasting morning spot urine. All patients were evaluated at two University hospitals.
Results
60% of patients met the sex-specific targets of 24 hUCa ($<$6.23 mmol/d for female, $<$7.51 mmol/d for men). CaCrR of spot urine correlated significantly with 24 hUCa ($n=181$, $r=0.583$, $P<0.001$). Although there were no significant differences between sexes in serum Calcium and 24 hUCa, females showed significant higher CaCrRs than men (0.41 vs 0.28; $P=0.02$) due to lower creatinine levels ($P=0.001$). In an ROC-analysis of the CaCrR the cutoff of 0.31 mmol/mmol correctly identified hypercalciuria in men with a sensitivity of 83.3% and a specificity of 86.7% (AUROC 0.88). By contrast, in females the optimal cutoff of 0.31 mmol/mmol only discriminated hypercalciuria from normocalciuria with a sensitivity of 83.3% and a specificity of 64.6% (AUROC 0.82). The negative predictive value for males was 86%. For females it was 64% (cutoff 0.3 mmol/mmol) or 85% (cutoff 0.45 mmol/mmol), respectively.
Conclusion
There are sex-specific differences in CaCrRs between female and male patients with hypoparathyroidism. Only in male patients a cutoff of 0.31 mmol/mmol discriminated well between normocalciuria and hypercalciuria. Highlight: To our knowledge, this is the largest cohort of patients with hypoparathyroidism in which urinary calcium excretion has been systematically investigated under standardized conditions.

The utility of contrast-enhanced ultrasound (CEUS) in the preoperative localization of parathyroid gland adenomas

Agnieszka Żyłka[1], Katarzyna Dobruch-Sobczak[2], Elwira Bakuła-Zalewska[3], Hanna Piotrzkowska-Wróblewska[4], Piotr Góralski[1], Jacek Gałczyński[1] & Marek Dedecjus[1]
[1]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Endocrine Oncology and Nuclear Medicine, Warsaw, Poland; [2]Maria Sklodowska-Curie National Research Institute of Oncology, Radiology Department II, Warsaw, Poland; [3]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Pathology, Warsaw, Poland; [4]Institute of Fundamental Technological Research, Polish Academy of Sciences, Department of Ultrasound, Warsaw, Poland

Objectives
Preoperative detection of parathyroid gland adenomas in patients diagnosed with primary hyperparathyroidism (pHPT) represents a diagnostic challenge. The aim of the study was to assess the utility of contrast-enhanced ultrasound (CEUS) as the diagnostic tool for preoperative localization of parathyroid gland adenomas in conjuction with a conventional ultrasonography.
Methods
Between the years 2021 and 2022, 33 adult patients (30 women and 3 men, aged 37-79) diagnosed with pHPT, underwent high-resolution ultrasound (US) and CEUS of parathyroid gland adenomas preoperatively. During CEUS examination 1.5 ml of SonoVue contrast was administered intravenously. All patients were qualified to surgical treatment according to laboratory and imaging findings in a combination with clinical symptoms and underwent parathyroidectomy with histopathologic confirmation of parathyroid adenomas. Analysis of the B-mode features involved size, echogenicity, calcifications, cystic components and vascularity patterns assessed in color Doppler and superb microvascular imaging. Secondly contrast distribution in CEUS examination was evaluated in real-time and retrospectively. Qualitative contrast patterns assessed in CEUS involved: homo- or heterogenous enhancement; hyper- or hypoenhancement; distribution of contrast in wash-in phase (centripetal, centrifugal or combined) and in wash-out phase (centrally, peripherally or combined).
Results
Histopathologic results included 33 parathyroid adenomas (involved two cases of atypic adenomas) in 30 women and 3 men, the medium size 11.6 mm ($\pm$6.9) and volume 2.1 mm^3 ($\pm$2.3). In conventional US examination the majority of lesions were assessed as hypoechoic ($n=36$; 100%) with dominant inhomogenous echostructure ($n=18$; 54.5%), mixed vascularity ($n=22$; 66.6%) and polar vessel observed in 14 lesions (42.4%). Dominated qualitative features assessed in CEUS involved homogenous ($n=22$; 66.6%) and hyperenhancement ($n=25$; 75.7%), with centripetal distribution of contrast in wash-in phase ($n=24$; 72.7%) and dominant centrally wash-out of the contrast ($n=19$; 57.5%).
Conclusions
The study indicates that CEUS examinations in conjuction with the high-resolution ultrasonography facilitated the detection of parathyroid adenomas. The use of CEUS qualitative features is advised to improve the localization of suspected parathyroid lesions preoperatively. Further studies should be performed to introduce CEUS patterns in the diagnostic algorithm of primary hyperparathyroidism.

Efficacy of a computerized therapeutic decision-making algorithm in a Fracture Liaison Service targeting hip fracture patients

Rachel Chava Rosenblum, Arthur Kogan, Dana Herzberg, Maysara Najjar, Oded Hershkovich, Orit Twito & Raphael Lotan
Wolfson Medical Center, Holon, Israel

Background
Osteoporotic fracture risk is doubled in patients with recent fracture; however, post-fracture treatment rates remain dismal. Fracture Liaison Services (FLS) aim to close the secondary prevention 'gap' and reduce fracture risk. This study evaluates the efficacy of a computer algorithm-supported, Nurse Practitioner-managed FLS developed in Wolfson Medical Center (WMC).
Methods
A computerized decision-making algorithm was developed using zoledronic acid as the default medication, and recommending endocrinology consultation for patients younger than 65 years, with estimated glomerular filtration rate (eGFR) $<$35 or prior osteoporosis therapy. The algorithm is performed by a Nurse Practitioner. Patients with vitamin D deficiency/insufficiency are given a loading dose. This retrospective study assesses utility of the algorithm in hip fracture patients hospitalized in WMC between 01/04/2023-31/10/2023.
Results
Two-hundred and eight hip fractures were identified. The cohort was predominantly female (137/208,65.9%); mean age was 79.9$\pm$9.6 years. Nurse practitioner evaluation was performed in 200/208 patients (96.2%). The algorithm provided a treatment recommendation in 140/200 (70.0%), while 60/200 (30.0%) required endocrinology consultation due to prior therapy)31/60,51.7%), low eGFR (20/60,33.3%), and/or age below 65 years (12/60,20.0%). Patients requiring endocrinology consultation were more likely to be female. Vitamin D deficiency/insufficiency was present in 161/202 (79.7%), and loading dose given in 89/99 (89.9%) deficiency and 44/62 (71.0%) insufficiency cases.
Discussion
This streamlined algorithm-based, FLS model was practical and functional; the algorithm provided therapeutic recommendations in 70% of cases without need for physician intervention. Simplified FLS interventions requiring minimal healthcare worker loads are feasible and hold promise for resource-poor healthcare settings.

Germline DNA methylation analysis reveals distinct alterations in a large cohort of patients with germline SDHB pathogenic variant

Reut Halperin[1,2,3], Roi Horwitz[4], Amna Jabarin & Amit Tirosh[1,2,3]
[1]Sheba, Endocrinology, diabetes and metabolism, Ramat Gan, Israel; [2]Sheba, ENTIRE Endocrine Neoplasia Translational Research Center, Ramat Gan, Israel; [3]Tel Aviv University, Medicine, Tel Aviv-Yafo, Israel; [4]Technion-Israel Institute of Technology, Medicine, Haifa, Israel

Patients with germline pathogenic variant (PV) in the *SDHB* gene (Paraganglioma syndrome type 4, PPGL4) have a high-risk of developing paragangliomas and pheochromocytomas. PPGL4 has increased risk for aggressive and metastatic abdominal-thoracic paragangliomas compared with other paraganglioma syndromes.
Aims
To assess possible germline DNA epigenetic alterations in patients harboring the *SDHB* PV.

Materials and Methods
Patients with PPGL4 were characterized clinically in our clinic and genetically via germline DNA sequencing for the familial variant (*SDHB* c.640C>T p.Q214Ter, $n=144$) and whole genome methylation analysis compared 19 patients vs 129 controls. The control group consisted of four *SDHB* PV-negative family members and 125 samples retrieved from a public database (GSE224359). Analysis was performed on Rstudio, using the ChAMP suite for normalization, imputation, differentially methylated probes (DMP), and regions (DMR) analyses. Pathway analysis and visualization were executed using the clusterprofiler and enrichplot packages. Promoter regions were defined by the transcription start site (TSS1500).
Results
The cohort includes three kindreds, presenting independently with an index patient: Index patient in <ce:bold>kindred A</ce:bold>, a 12-year-old boy, with thoracic paraspinal and testicular paragangliomas. Index patient in <ce:bold>kindred B</ce:bold>, a 26-year-old woman with abdominal paraganglioma, metastatic to the lungs and spine. Index patient in <ce:bold>kindred C</ce:bold>, a 41-year-old man with a locally aggressive abdominal paraganglioma, metastatic to the skull and spine. A total of 114 (44.2% females) patients underwent genetic evaluation (45/50, 16/28, and 25/36 in kindreds A, B and C, respectively). Of those, 50 (58.1%) harbored the familial *SDHB* PV (68.9%, 56.2%, and 40.0%, respectively). Twenty-six patients underwent at least partial clinical evaluation: eight had paraganglioma (4/8 had metastatic disease), three had pheochromocytoma, and two patients had neck masses that are currently being evaluated. Based on germline DNA promoter methylation data, *SDHB* PV carriers clustered separately from controls, including the *SDHB* PV non-carriers from the same kindred. No separation was demonstrated between patients that developed vs not developed PPGL at the time of the data collection. CpGs annotated to multiple genes were found differentially methylated between the groups. Of special interest are *MGMT* (encoding methyl guanine O-methyl transferase), and *ARID1B* (encoding AT-rich interactive domain-containing protein 1B) in the *SDHB* PV positive group.
Conclusions
We report one of the largest cohorts of PPGL4, showing typical low penetrance and aggressive phenotype. Genomic analysis shows distinct germline DNA methylation in *SDHB* PV-positive compared with the control group. Future studies may reveal an association between specific epigenetic alterations and penetrance/phenotypic patterns.

Characterization of the interplay between the neuroendocrine stress axes and metabolic diseases

Diana Cozma[1,2], Panagiota Siatra[1,2], Ioannis Oikonomakos[1,2], Ulrike Friedrich[1,2,3], Stefan Bornstein[1,2,4], Cynthia Andoniadou[1,2,4] & Charlotte Steenblock[1,2]
[1]University Hospital Carl Gustav Carus Dresden, Medizinische Klinik 3, Dresden, Germany; [2]Technical University of Dresden Medical School, Dresden, Germany; [3]DRESDEN-concept Genome Center, Dresden, Germany; [4]King's College London Guy's Campus, United Kingdom

Metabolic syndrome is characterized by the hyperactivation of the hypothalamic-pituitary-adrenal (HPA) axis, leading to increased steroidogenesis and altered cortisol secretion. The molecular signaling mechanisms underlying HPA axis alterations in metabolic diseases remain poorly understood. In this study, our objective is to investigate how changes in signaling molecules within both plasma and adipose tissue contribute to the regulation of adrenal steroidogenesis in metabolic diseases and to elucidate the modified response of adrenocortical cells. Using a mouse model of obesity induced by a high-fat diet, we aim to pinpoint the onset of changes in steroid hormone response, correlating these changes with the metabolic status of the mice. We observed increased leptin and insulin concentrations in the mouse plasma as early as 8 weeks of high-fat diet feeding. Further, our findings revealed increased expression of *Lep* (leptin), and decreased expression of *Adipoq* (adiponectin) in the adipose tissue surrounding the adrenal upon 16 weeks of high-fat diet. These changes coincided with a rise in adrenal gland weight and elevated levels of steroid hormones, suggesting that increased steroidogenesis could directly be caused by interactions between adipokines and adrenocortical cells. To explore the direct impact on adrenocortical cells, we treated primary adrenocortical cell-derived spheroids with insulin and adiponectin. We observed that insulin induced an increase in diameter, indicating enhanced cell expansion and steroidogenesis, while adiponectin decreased the spheroid diameter, indicating an inhibitory effect on steroidogenesis. Bulk RNA sequencing of these *in vitro* primary spheroid cultures with and without insulin stimulation revealed differential expression of steroidogenic genes. Gene Set Enrichment Analysis indicated upregulation of gene sets associated with steroid biosynthesis among the top 5, suggesting a direct induction of adrenal steroidogenesis by insulin. Hyperinsulinemia together with a decreased expression of *Adipoq* in the peri-adrenal adipose tissue could be a cause of increased steroidogenesis observed in metabolic diseases *in vivo*. Our results underscore the crucial role of insulin and adipose tissue in regulating adrenal gland function in metabolic diseases contributing to a comprehensive understanding of HPA axis activity in these conditions.

Background
Current parameters of conventional radiology have several limitations in defining the nature of adrenal masses. Radiomics, or texture analysis, has shown high diagnostic performance in recent pilot studies, although confirmatory studies are needed. Moreover, the effect of combination of radiomics with hormonal secretion on diagnostic performance is poorly explored.
Aim
To evaluate the accuracy of radiomics in predicting adrenal masses nature in a large cohort of patients.
Methods
In 7 European Centres, we retrospectively analyzed 794 adrenal masses from 2006 to 2023: 472 lipid-rich adenomas (LRA), 178 benign indeterminate adrenal masses (BIAM, with histological confirmation or radiologic stability at 6-12 months), 33 adrenocortical carcinomas (ACC), 45 pheochromocytomas, 48 adrenal metastases, and 18 adrenal cysts (confirmed by nuclear magnetic resonance or histology). Adrenal masses were also divided by hormonal secretion: 354 non secreting, 261 with mild autonomous cortisol secretion, 42 with Cushing's syndrome, 45 pheochromocytomas and 94 with unknown secretion. ACC, pheochromocytomas and adrenal metastases were grouped together and labeled as malignant. Texture analysis was performed on unenhanced computerized tomography scan with LifeX software (version 7.2.0, ©LITO, France). We employed Deep Learning (DL) with 10-fold validation with hormonal secretion as factor and radiomic features as covariates.
Results
DL algorithms with radiomic parameters predicted the presence of malignant masses with average area under the receiver operating characteristic curve (AUROCC)=0.974, F1-score=0.801, sensitivity=92.7%, specificity=92.8%. Diagnostic accuracy was also high for subtyping adrenal masses: LRA with average AUROCC=0.979, F1-score=0.944, sensitivity=91.3%, specificity=96.8%, BIAM with average AUROCC=0.936, F1-score=0.746, sensitivity=93.1%, specificity=

83.8%, ACC with average AUROCC = 0.973, F1-score = 0.405, sensitivity = 100%, specificity = 88%, pheochromocytoma with average AUROCC = 0.908, F1-score = 0.341, sensitivity = 93.3%, specificity = 78.6%, adrenal metastasis with average AUROCC = 0.902, F1-score = 0.367, sensitivity = 97.9%, specificity = 78.3%, and adrenal cysts with average AUROCC = 0.899, F1-score = 0.123, sensitivity = 100%, specificity = 67.1%. When hormonal secretion was added as a factor, the prediction of malignant adrenal masses by DL algorithms was even higher, with average AUROCC = 0.999, F1-score 0.988, sensitivity 98.4%, specificity 99.9%. DL with radiomics and hormonal secretion predicted LRA with average AUROCC = 0.983, F1-score = 0.953, sensitivity = 92.7%, specificity = 97.3%, BIAM with average AUROCC = 0.968, F1-score = 0.816, sensitivity = 96.3%, specificity = 89.1%, ACC with average AUROCC = 0.933, F1-score = 0.318, sensitivity = 96.4%, specificity = 83.9%, pheochromocytoma with average AUROCC = 0.941, F1-score = 0.542, sensitivity = 100%, specificity = 89.2%, adrenal metastasis with average AUROCC = 0.951, F1-score = 0.599, sensitivity = 97.9%, specificity = 91.2%, and adrenal cysts with average AUROCC = 0.848, F1-score = 0.1, sensitivity = 100%, specificity = 63.4%.

Conclusion

Radiomic-based DL algorithm showed a high accuracy in predicting the presence of malignant adrenal masses and a heterogenous performance in predicting specific subtypes. The performance of the model was increased by adding the hormonal secretion to the models.

Background

Primary aldosteronism (PA) is the most prevalent cause of secondary hypertension. Its two main clinical forms are unilateral adenoma (APA) and bilateral hyperplasia (BAH), which require markedly different medical treatments, so differentiating between the two is of utmost clinical importance. The current gold standard method for this is adrenal vein sampling (AVS), the application of which is hindered by limited availability and high skill requirements.

Aim

Our goal was to identify circulating microRNAs – or their combinations – which enable differentiation between the two most prevalent aetiologies of PA from a peripheral blood sample.

Methods

MicroRNA specific sequencing was performed on an Illumina platform, using EDTA coagulated blood samples taken during AVS, from 18 patients (10 uni-, and 8 bilateral). First, plasma samples from both adrenal veins were evaluated. Bioinformatical analysis applying the DeSeq2 algorithm was used to evaluate the differences in expression; and a neural network model, tasked to identify the most fit individual and groups of microRNAs for differentiation was used. The microRNAs comprising the five best performing models were then validated using reverse transcription real-time PCR, on 90 samples, including right and left AVS and peripheral plasma samples from 30 patients (15 uni-, and 15 bilateral). The qPCR results were then re-analysed using the same neural network. Finally, the model was validated on an independent peripheral plasma sample group from 84 patients (42 uni-, and 42 bilateral).

Results

Based on the qPCR results, miRNA abundance shows a non-significant decrease on the periphery compared to the adrenal vein samples. 10 neural network models comprised of 4 to 10 microRNAs were able to differentiate BAH and APA using peripheral plasma samples with an accuracy above 85%, with the best model consisting of 6 miRNAs having a specificity of 87.91%, a sensitivity of 86.3%, and an AUC value of 87.1%. The inclusion of clinical parameters into the models, such as imaging results, aldosterone, renin and potassium plasma levels and BMI did not meaningfully alter the performance of the model.

Conclusion

Circulating microRNA-based differentiation between uni-, and bilateral PA could prove to be a reliable diagnostic method. Should the diagnosis of BAH be established, medical treatment may begin immediately, with no further tests required to establish localization. This could prove highly beneficial for decreasing the health and financial costs of patients and providers alike.

Introduction

Primary Bilateral Macronodular Adrenal Hyperplasia (PBMAH) is a rare disease responsible for variable levels of cortisol excess. Constitutional pathogenic variants of the tumor suppressor gene *ARMC5* are its most frequent molecular cause (20% of index cases). Recently, *KDM1A* has been identified as the causing gene for PBMAH associated with food-dependent Cushing's syndrome (FDCS), consecutive to the illegitimate expression of the GIP receptor (GIPR) in adrenocortical nodules. *KDM1A* has also been associated with multiple myeloma. This work aimed to assess the prevalence of *KDM1A* mutations in a large series of PBMAH index cases.

Methods

The constitutional genotyping of *KDM1A* and *ARMC5* genes has been performed by targeted NGS in 301 PBMAH index cases (67% female) from 8 centers (Cochin, Bicêtre, Lille, Lyon, Bordeaux, Sao Paulo, NIH, Munich), presenting with bilateral adrenal nodules and evidence for autonomous cortisol secretion (plasma cortisol after 1 mg dexamethasone suppression test >50 nmol/l and/or elevated 24 h urinary cortisol and/or high midnight plasma cortisol and/or suppressed plasma ACTH).

Results

Among the 301 index cases, 10 (3.3%) had a *KDM1A* and 60 (19.9%) an *ARMC5* pathogenic or likely pathogenic constitutional variant. *KDM1A* patients are all women with FDCS. Their median 24 h cortisoluria was 3.0N (0.7-6.6) vs 1.23N in *ARMC5* patients (0.2-10.7) and 0.66N in wild-type patients (0.1-10.1), $P<0.001$. Morning plasma cortisol was significantly lower: 192 nmol/l (86-672) vs 407 (111-1166) vs 428 (170-859), respectively, $P<0.001$; and their midnight cortisol significantly higher: 487 nmol/l (275-634) vs 262 (64-1178) vs 173 (39-867), respectively, $P<0.001$. A morning/midnight cortisol ratio <0.7 holds a sensitivity of 100% and a specificity of 99% for detecting of FDCS in PBMAH. Of the ten *KDM1A* patients, one had a monoclonal gammopathy of unknown significance (MGUS) and one had a familial history of multiple myeloma.

Conclusion

Constitutional *KDM1A* pathogenic variants are rare, occurring in less than 5% of PBMAH index cases, mutually exclusive with *ARMC5* variants, and always associated with FDCS. Conversely, all patients with FDCS were diagnosed with a germline *KDM1A* pathogenic variant. *KDM1A* genotyping should be considered in every patients with PBMAH and a morning/midnight cortisol ratio <0.7 and in all first-degree relatives of known *KDM1A* pathogenic/likely pathogenic variant carriers. Considering the association with myeloma, we

suggest a regular screening by serum protein electrophoresis in pathogenic/likely pathogenic variant carriers. Moreover, gender may play a role in the adrenal effect of *KDM1A* inactivation, since all *KDM1A* patients identified in this series were female.

FKBP5 methylation in adrenal insufficiency: New insights into assessing the quality of glucocorticoid replacement

Irina Chifu[1], Anna-Lena Richter[1], Juliane Lippert[1], Mario Detomas[1], Carolin Scheuermann[1], Sabine Herterich[2], Janik Freytag[1], Barbara Altieri[1] & Stefanie Hahner[1]
[1]University Hospital of Würzburg, Endocrinology and Diabetes, Würzburg; [2]University Hospital of Würzburg, Clinical Chemistry and Laboratory Medicine, Würzburg

Introduction
Methylation of FKBP5, a glucocorticoid(GC)-receptor co-chaperone, negatively correlates with cortisol levels in both healthy and hypercortisolaemic individuals, and may serve as an indicator of GC exposure. We explored whether GC replacement correlates with FKBP5 methylation levels in patients with adrenal insufficiency (AI), aiming to assess the adequacy of substitution therapy.
Methods
In 122 patients with chronic primary ($n=73$) and secondary ($n=49$) AI on hydrocortisone replacement, we analyzed FKBP5 gene methylation at 54 CpG sites in introns, promoters, and proximal enhancers using bisulfite pyrosequencing. Results were correlated with GC replacement, salivary cortisol, 24-hour urinary cortisol, FKBP5 polymorphisms, physician-guided therapy adjustments, and a predefined clinical score for assessment of GC exposure. Methylation levels were further compared between AI patients, patients with cortisol-producing adenomas (CPA, $n=64$) and patients with non-functioning adrenal adenomas (NFA, $n=46$).
Results
Significant negative correlations were found between FKBP5 methylation levels in various regions and GC dose, clinical GC-replacement score, salivary/urinary cortisol levels, persisting after adjusting for sex and FKBP5 polymorphisms. Patients advised to increase their GC dose showed higher methylation levels than those recommended to reduce or maintain their dose. AI patients exhibited similar or lower methylation levels compared to those with CPA and NFA.
Conclusion
Findings suggest a dose-dependent impact of GC replacement on FKBP5 methylation. The alignment between methylation and clinical evaluation encourages further investigations with regard to an additional benefit in the assessment of replacement therapy. The unexpected observation of partially lower methylation in patients with AI compared to CPA and NFA raises the hypothesis that cortisol peaks in AI patients under conventional treatment have a relevant impact on FKBP5-methylation.

Loss of murine Gpr45 leads to significant obesity due to hyperphagia and hypoactivity

Iqra Mumal, Soo Min, Diana Lee, Jacob Trenish, Dwaine Pryce, Daniel Gomez, Erqian Na, Parnian Bigdelou, Judith Altarejos, Mark Sleeman & Jason Mastaitis
Regeneron Pharmaceuticals, Inc., Tarrytown, United States

Monogenic obesity in humans is caused by loss-of-function mutations in several genes, all of which reside in the CNS, and many of which are involved in either leptin signaling or the downstream melanocortin pathway. Ablation of the CNS-specific orphan GPCR Gpr45 in mice is associated with significant monogenic obesity. However, to date, there are no associations between the loss of GPR45 and obesity in human genetics. To that end, we made our own line of Gpr45-/- mice and found, similar to published findings, that Gpr45-/- mice are obese, with significantly increased adiposity. In addition, these mice are hypoactive and have reduced energy expenditure compared to their wildtype counterparts. Interestingly, we also found there were phenotypic differences between the male and female knockout mice, which has not been previously shown. Specifically, we found male Gpr45-/- mice preferentially store fat in their livers, while the female knockouts have large subcutaneous and visceral adipose depots. Accordingly, the male knockouts have significantly increased serum levels of enzymes indicative of liver damage and are significantly more hyperglycemic and insulin-resistant compared to the females. Contrary to prior findings, we discovered that all Gpr45-/- mice exhibit hyperphagia, suggesting both a food intake and metabolic role in their obesity phenotype. Gpr45-/- mice have levels of leptin consistent with their adiposity, suggesting it is not leptin deficiency driving the obesity. Accordingly, administration of setmelanotide, which acts as a melanocortin 4 receptor agonist was effective at reducing food intake in Gpr45-/- mice indicating intact melanocortin signaling downstream of leptin. These results reveal that in mice, Gpr45 is a critical regulator of appetite and metabolism as well as a modulator of lipid storage in peripheral tissues.

Intestinimonas butyriciproducens as a new preventive therapy for type 2 diabetes: a proof of concept randomized controlled trial

Valentina Antoniotti[1], Marina Caputo[2,3], Edoardo Luigi Maria Mollero[2], Alessandro Antonioli[3], Sabrina Tlni[3], Marcello Manfredi[4,5], Elisa Bona[6], Marco Pane[7], Angela Amoruso[7], Annachiara De Prisco[7], Sahin Gul[8], Nam Bui[8], Jos Seegers[8], Willem M De Vos[9], Gianluca Aimaretti[2] & Flavia Prodam[2,3]
[1]University of Piemonte Orientale, SCDU of Pediatrics, Department of Health Sciences, Novara, Italy; [2]University of Piemonte Orientale, SCDU of Endocrinology, Department of Translational Medicine, Novara, Italy; [3]University of Piemonte Orientale, Department of Health Sciences, Novara, Italy; [4]University of Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [5]University of Piemonte Orientale, Center for Translational Research on Allergic and Autoimmune Diseases (CAAD), Novara, Italy; [6]University of Piemonte Orientale, Department of Sciences and Technological Innovation, Novara, Italy; [7]Probiotical Research Srl, Research & Development, Novara, Italy; [8]Caelus Health, Amsterdam, Netherlands; [9]Wageningen University, Wageningen, Netherlands

Background
The incidence of type 2 Diabetes Mellitus (T2D) is increasing worldwide. Prevention is possible by changing lifestyle but it's not effective alone in real life, due to poor compliance over time. New strategies are necessary, mostly for high-risk individuals. Therapeutic microbiology is a further proposed target, and butyrate-producing bacteria can improve metabolic parameters in obese patients. Our study aims to evaluate the effect of *Intestinimonas butyriciproducens* as a preventive therapy for T2D in prediabetes thanks to its effects in decreasing Advanced Glycation End Products (AGEs), converting sugars and proteins in butyrate, and increasing insulin sensitivity.
Methods
The trial is a double-blind, randomized, placebo-controlled (phase 1) and open-label pilot study with two different doses (phase 2) of 26 weeks. *I. butyriciproducens* (10^5 CFU/day) or placebo were given for 12 weeks, then subjects in placebo will start the treatment (10^5 CFU/day), and the other group will increase the dose (10^8 CFU/day) for 14 weeks. Overweight or obese patients with impaired fasting glucose (IFG) or impaired glucose tolerance (IGT) were included. Patients were assessed for clinical, biochemical, and microbiota parameters at the time of recruitment (V1), after phase 1 (V7) and phase 2 (V10), during which the eating and lifestyle habits were also evaluated. No dietary advice was given.
Results
Nineteen have completed the study. Treated patients during the first phase had a significant improvement in glucose-insulin metabolism demonstrated through the HOMA Disposition Index ($P=0.0075$). Lipid profile also ameliorates in patients treated at a low dose and then at a high dose, particularly decreasing triglycerides (phase 1: $P=0.0212$; phase 2: $P=0.0261$). The weight and BMI of patients were stable throughout the period of study. Data from Flash glucose Monitoring (FGM) show a more stable glucose, mainly at the end of the study. Serum AGE concentrations showed a trend towards a decrease in treated patients, whereas IL-10 slowly increased without changes in IL-6 and IL-17. Lastly, 10 out of 19 patients after 26 weeks of treatment had a remission in IFG or IGT (52.6%).
Conclusions
Intestinimonas butyriciproducens seems to improve insulin sensitivity and triglycerides in treated patients. *Intestinimonas butyriciproducens* could be a new strategy in the work-up of T2D prevention.

Growth hormone promotes in-vivo hepatic triglyceride export in humans

Clemens Baumgartner[1,2], Matthaeus Metz[1], Lorenz Pfleger[1], Anna Tosin[1], Marianna Beghini[1], Hannes Beiglboeck[1], Paul Fellinger[1], Franziska Schnait[1], Greisa Vila[1], Anton Luger[1], Alexandra Kautzky-Willer[1], Angelika Freudenthaler[1], Sabina Baumgartner-Parzer[1], Herbert Stangl[3], Martin Krssak[1,4], Thomas Scherer[1], Michael Krebs[1] & Peter Wolf[1]
[1]Medical University of Vienna, Department of Endocrinology and Metabolism, Wien, Austria; [2]Medical University of Vienna, Clinical Department of Nephrology and Dialysis, Wien, Austria; [3]Medical University of Vienna, Institute of Medical Chemistry, Center for Pathobiochemistry and Genetics, Wien, Austria; [4]Medical University of Vienna, High-Field MR Centre, Department of Biomedical Imaging and Image-Guided Therapy, Wien, Austria

Overview
Non-alcoholic fatty liver disease (NAFLD) is defined as a chronic increase in intrahepatic lipids (IHL). A surplus of IHL can be compensated through increased lipid export via very-low density lipoprotein (VLDL) particles. Growth hormone (GH) is known to reduce visceral and ectopic fat. However, the main pathways responsible for the in-vivo decrease of IHL under the influence of GH are yet to be determined.
Methods
We assessed hepatic lipid metabolism of 10 healthy, male volunteers (26 ± 5 years; BMI $=23\pm3$ kg/m^2) before and after one week of daily subcutaneous treatment with either 2 mg Genotropin® or the GH-antagonist Somavert® (20 mg/day, loading dose of 40 mg at the first day) in a single blinded, crossover balanced study design. After a washout period of ≥6 weeks (116 ± 67 days), the study protocol was repeated with the respective other drug. Experiments comprised IHL measurement withH-magnetic resonance spectroscopy, fasting blood analysis and the quantification of VLDL1-triglyceride (VLDL-TG) secretion via an intralipid infusion protocol.
Results
After GH treatment, IHL slightly increased in 8 of 10 cases, but drastically decreased in two participants with IHL $>10\%$ at baseline (11.2 and 12%, respectively). With respect to other participants ($n=8$), the increase in IHL reached statistical significance ($0.9\pm0.5\%$ vs 1.6 ± 0.9, $P=0.005$). Secretion of VLDL1-TG was available for nine subjects and showed an overall increase of 26.1% (590.5 ± 282.3 mg/h vs 738.8 ± 424.9 mg/h, $P=0.035$). After Somavert®, IHL also tended to increase in all ten participants compared to baseline (no significance), whereby no trends were observed regarding VLDL1-TG secretion. Marked and divergent changes in serum concentrations of IGF-1, insulin, and c-peptide during both conditions indicated a sufficient impact of individual treatment.
Conclusion
Our findings demonstrate a GH mediated increase in hepatic VLDL1-TG secretion. The promoted efflux of hepatic lipids may in the long term even be responsible for an overall decrease in IHL. We further report increases in IHL after both short-term GH excess and suppression. However, a slight increase in IHL due to GH-mediated lipolysis in white adipose tissue appears reasonable. We conclude that promoted VLDL1-TG secretion in response to short term GH therapy may be beneficial for hepatic lipid turnover and might lay the foundation of novel therapeutic strategies against NAFLD.

Characteristics and outcomes of DKA in people taking SGLT2 inhibitors: DEKODE study

Nitish Mathur[1], Angelica Sharma[2], Nevil Philip[3], Lakshmi Rengarajan[3,4], Lucy Bomphrey[5], Anu Abraham[3], Sanjay Saraf[6], Ketan Dhatariya[2,7], Punith Kempegowda[3,4] & Dekode Working Group[4]
[1]The Royal Wolverhampton NHS Trust, Diabetes and Endocrinology, Wolverhampton, United Kingdom; [2]Norfolk and Norwich University Hospitals NHS Foundation Trust, Norwich, United Kingdom; [3]The University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom; [4]Institute of Applied Health Research, Clinical Trials Unit College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom; [5]Walsall Manor Hospital, Walsall, United Kingdom; [6]Good Hope Hospital, Birmingham, United Kingdom; [7]University of East Anglia, Norwich, United Kingdom

Background
Although SGLT2 inhibitors (SGLT2-i) have revolutionised the management of diabetes, they are associated with an increased risk of developing diabetic ketoacidosis (DKA). However, there remains a paucity of evidence about the risk factors, management, and outcomes of DKA episodes associated with SGLT2-i therapy. Improved understanding of these factors in order to optimise education, minimise risk, and improve outcomes of DKA episodes in individuals receiving SGLT2-i therapy is important.
Objective
To study the characteristics, causes and complications associated with the management of DKA in patients who were on SGLT2-i therapy vs those who were not.
Methods
We retrospectively analysed all DKA episodes across six hospitals participating in the DEKODE (Digital Evaluation of Ketosis and Other Diabetes-related Emergencies) initiative between January 2020-December 2022. Parameters including demographics, DKA precipitants, laboratory values, duration of DKA (hours), length of hospital stay (days), and mortality were collated and compared among individuals who developed a DKA episode on SGLT2-i vs those who did not. Statistical analyses were performed using SPSS 29.0.
Results
Of 1398 DKA episodes, 6% ($n=84$) developed DKA whilst on SGLT2-i therapy. Of these, 19% ($n=16/84$) were directly attributable to SGLT2-i therapy. SGLT2-i users were older (58 years vs 41 years, $P<.001$) and more commonly of Afro-Caribbean ethnicity (15.5% vs 6.2%). At presentation, SGLT2-i users had a lower pH (7.17 vs 7.20, $P=.024$), bicarbonate (10.7 vs 12.0 mmol/l, $P=.039$), glucose (18.4 vs 27.6 mmol/l, $P<.001$) and ketone (5.5 vs 6.0 mmol/l, $P=.018$) concentrations. COVID infections (13.1% vs 3.9%, $P=.00007$) accounted for a greater proportion of DKA episodes amongst SGLT2-i users. SGLT2-i users developed more episodes of hypokalaemia during DKA management (46.4% vs 33.9%, $P=.024$). However, the development of hyperglycaemia and hyperkalaemia during DKA management were comparable in patients with or without SGLT2-i therapy. DKA episodes whilst on SGLT2-i therapy had a longer duration (19.6 hrs vs 14.9 hrs, $P=.001$), prolonged hospital admission (5.4 days vs 3.4 days, $P<.001$) and higher mortality (7.1% vs 2.7%, $P=.048$).
Conclusion
DKA episodes in individuals receiving SGLT2-i therapy presented with lower glucose and ketone concentrations but more severe acidosis. These episodes were associated with more adverse outcomes compared to DKA in individuals not treated with SGLT2-i therapy.

OC12.5

The effects of semaglutide vs testosterone replacement therapy on functional hypogonadism and sperm quality in men with type 2 diabetes mellitus and obesity

Nadan Gregoric[1], Jaka Sikonja[1], Andrej Janez[1] & Mojca Jensterle[1,2]
[1]University Medical Centre Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]University of Ljubljana, Faculty of Medicine, Ljubljana, Slovenia

Objective
Diabetes and obesity cause functional hypogonadism (FH) and impair sperm quality. Testosterone replacement therapy (TRT) improves the signs and symptoms of FH but it further deteriorates sperm quality by inhibiting the endogenous gonadal axis. The effect of glucagon-like peptide-1 receptor agonists (GLP-1-RAs) on FH is suggested to be beneficial due to weight loss. However, the effect of GLP-1 RAs on sperm quality in patients with type 2 diabetes mellitus and obesity has not been sufficiently investigated.
Aim
We compared the effects of semaglutide and TRT on parameters of FH and semen quality in men with type 2 diabetes mellitus and obesity.
Design
We designed a randomized open-label trial that included 26 men with type 2 diabetes (aged 50 [46 to 60] years, BMI 35.9 [32.8 to 38.7] kg/m^2) and FH, characterized as the presence of at least 2 symptoms consistent with hypogonadism, two values of total testosterone below 11 nmol/l measured at least four weeks apart and exclusion of other causes of hypogonadism. Participants were randomized to semaglutide 1 mg/week or intramuscular testosterone undecanoate 1000 mg for a period of 24 weeks by following the standard titration protocols.
Methods
We measured anthropometric parameters and parameters of FH. Participants completed questionnaires of the International Index of Erectile Function-15 (IIEF-15) and the Aging Symptoms in Men (AMS). Seminal fluid analysis included measurements of ejaculate volume, sperm count, concentration, morphology and total number of motile sperm. All assessments were performed at baseline and after 24 weeks of treatment.
Results
Both groups experienced a significant increase in total testosterone and an improvement in AMS score, whereas IIEF-15 score was significantly improved

only in the TRT group. Seminal fluid volume, total mobile sperm cell concentration, and sperm normal morphology did not significantly change compared to baseline and did not differ between the groups at the end of the study. However, there was a significant difference between the groups in sperm cell concentration (semaglutide 16.7 [-2.6 to 70.5]% vs TRT -60.6 [-80.2 to -13.2]%; $P=0.039$). Significant weight loss (baseline 115 [102 to 120] kg vs 24-week 99 [96 to 118] kg; $P=0.004$) and visceral adipose tissue reduction as assessed by dual x-ray absorptiometry were achieved in semaglutide group ($P>0.05$ for between-treatment effect).
Conclusion
Semaglutide was superior to TRT in improving body composition and comparably increased testosterone along with improved AMS score. As opposed to TRT, semaglutide maintained sperm quality.

Efficacy and safety of postbiotic supplementation for type 2 diabetes patients: Randomized clinical Ttrial (DELI Diab study)

Maryana Savytska[1], Olena Baka[2], Elina Manzhalii[3], Dmytro Kyriienko[3,4], Tetyana Falalyeyeva[5,6], Liubov Sichel[7] & Nazarii Kobyliak[6,8]
[1]Danylo Halytsky Lviv National Medical University, Lviv, Ukraine; [2]Center for Innovative Medical Technologies of the National Academy of Sciences of Ukraine, Kyiv, Ukraine; [3]Bogomolets National Medical University, Kyiv, Ukraine; [4]Kyiv City Clinical Endocrinology Center, Kyiv, Ukraine; [5]Taras Shevchenko National University of Kyiv, Kyiv, Ukraine; [6]Medical Laboratory CSD, Scientific, Kyiv, Ukraine; [7]Stellar Biotics, United States; [8]Bogomolets National Medical University, Endocrinology, Kyiv, Ukraine

Background
Probiotics have beneficial effect on obesity/type 2 diabetes (T2D) related disorders in both animal models and clinical trials, at the same time, some scientific papers question the effectiveness and the safety of probiotics. In turn, postbiotics are preparations of inanimate microorganisms and / or their components, which are directly identified with the safety of their use and the health benefits of the host.
Aim
To conduct placebo-controlled randomize clinical trial (RCT) to assess the short-term efficacy and safety of postbiotics as an adjunction to the standard anti-diabetic therapy on glycemic control parameters, insulin resistance, β-cells functional activity and anthropometric parameters in T2D patients.
Method
A total of 55 patients met the criteria for inclusion. The study includes 3 periods. Screening period of up to 1 week to assess the eligibility to inclusion/exclusion criteria. Treatment and follow-up periods for 3 months each. The participants receive a twice daily oral dose of postbiotics « Del-Immune V® Extra» (cell lysate and DNA fragments of the probiotic strain *L. rhamnosus DV*-NRRLB-68023) at the assigned dose of 100 mg or placebo in capsules. The primary main outcomes were the change of HbA1c and fasting plasma glucose (FPG). Secondary outcomes were the changes in HOMA-IR, insulin sensitivity (%S) and β-cells functional activity (%B) as assessed by HOMA-2 model and anthropomorphic variables. Trial registration: NCT05770076.
Results
Supplementation with postbiotic for 3 month was associated with significant reduction of HbA1c (7.88 ± 1.07 to 7.25 ± 0.92%; $P=0.001$) and FPG (7.99 ± 3.89 to 6.67 ± 2.01 mmol/l; $P=0.030$) mainly due to improvement of β-cells functional activity (%B-78.77 ± 41.26 to 91.17 ± 38.99; $P=0.011$). Also in postbiotic group insignificant improvement of insulin sensitivity was found (%S-60.69 ± 26.09 to 64.45 ± 28.04; $P=0.235$). In placebo group significant worsening of glycemic conrol in intra-group analysis was observed: HbA1C and FPG decreased on 6.85% ($P=0.05$) and 1.6% ($P=0.696$) respectively as compared to baseline value. In both groups we observed the reduction of anthropometric parameters. However, only in postbiotic group it was significant. After intervention discontinuation, at follow up visit worsening of endpoints was found as compared to end of treatment visit However, parameters did not achieve the baseline level.
Conclusion
To our knowledge its first RCT which demonstrate that postbiotic supplementation can improve glycemic-related parameters and β-cells functional activity in patients with T2D. Modulation of the gut microbiota represents a new treatment for T2D/obesity and should be tested in larger studies.

[1]The Institute of Cancer Research, London, United Kingdom; [2]The Royal Marsden NHS Foundation Trust, Sutton, United Kingdom; [3]Fred Hutchinson Cancer Center, Seattle, United States; [4]Beth Israel Deaconess Medical Center, Boston, United States; [5]Australian Prostate Cancer Research Centre-Queensland, Queensland University of Technology, Brisbane, Australia; [6]University of Washington, Seattle, United States

Background
Treatment resistance in prostate cancer can be the result of multiple different tumour cell adaptations generating castration-resistant prostate cancer (CRPC). Despite advancements in treatment, CRPC remains a highly lethal disease. Some CRPCs become AR independent with loss of AR expression and lineage plasticity, urgently requiring novel therapeutic strategies. BCL2 can be upregulated in some CRPCs and may be a therapeutic target for this disease subset.
Objective
To characterise BCL2 expression in late stage CRPC, determine its association with AR expression, uncover its mechanisms of regulation, elucidate their clinical significance, and evaluate BCL2 as a therapeutic target and/or biomarker with clinical utility.
Methods
AR and BCL2 protein expression were determined by immunohistochemistry (IHC) in two separate CRPC cohorts. IHC data were correlated with clinical outcomes. IHC for neuroendocrine markers was performed in a subset of tumours. Whole genome bisulfite sequencing (WGBS), RNA sequencing, and chromatin immunoprecipitation (ChIP) data from multiple independent CRPC cohorts were analysed. Finally, PC cell lines and patient-derived xenograft (PDX) models were characterised and treated with BH3-mimetics *in vitro*.
Results
AR protein loss emerged with castration resistance and was detected in 4.8% of metastatic CRPC (mCRPC), associating with shorter overall survival (OS). BCL2 expression was primarily detected in AR-negative mCRPC, and associated with shorter OS, and with resistance to AR-signalling inhibitors (ARSIs) but not docetaxel. High BCL2 expression associated with lineage plasticity features and neuroendocrine marker positivity. BCL2 expression was regulated by DNA methylation and increased by Snail and the neuronal transcription factor ASCL1. BCL2 inhibition has anti-tumour activity in some, but not all, BCL2-positive PC models. Simultaneously targeting other antiapoptotic proteins, including BCLXL and MCL1, resulted in rapid apoptotic cell death.
Conclusions
BCL2 expression is enriched in AR-negative mCRPC with features of lineage plasticity, and associated with worse clinical outcomes, with BCL2-positive mCRPC appearing more sensitive to docetaxel than ARSI. BCL2 expression is regulated by DNA methylation and driven by Snail and ASCL1. BCL2 inhibition has anti-tumour activity in some, but not all, BCL2-positive PC models identifying the need for combination strategies that selectively target tumour cell apoptosis to enhance response to therapy.

Assessment of mitochondrial peptide humanin in women with polycystic ovary syndrome: Serum and skeletal muscle profile

Irem Sonmezoglu Kutuk[1], Senay Akı[2], Ali Haydar Demirel[3], Sezcan Mumusoglu[4], Turkmen Turan Ciftci[5] & Bulent Yildiz[6]
[1]Department of Internal Medicine, Hacettepe University School of Medicine, Ankara, Turkey; [2]Division of Exercise and Sport Physiology, Faculty of Sport Sciences, Hacettepe University, Ankara, Turkey; [3]Faculty of Sport Sciences, Near East University, Lefkosa, Cyprus; [4]Department of Obstetrics and Gynecology, Hacettepe University School of Medicine,

Ankara, Turkey; [5]Department of Radiology, Hacettepe University School of Medicine, Ankara, Turkey; [6]Division of Endocrinology and Metabolism, Hacettepe University School of Medicine, Ankara, Turkey

Background and Aim
Humanin is a mitochondria-derived peptide (MDP) secreted in response to oxidative stress and linked to diverse cellular processes including inflammation and insulin resistance. Humanin has been shown to be downregulated in polycystic ovaries and exogenous humanin supplementation has attenuated insulin resistance and ovarian morphological abnormalities in a PCOS rat model. The aim of this study was to investigate the role of humanin in the pathophysiology of PCOS by comparing serum and skeletal muscle tissue profile of humanin in women with PCOS and healthy women.
Subjects and Methods
Forty women with PCOS [(mean ± SD) age:21.8 ± 2.3 years, BMI:25.0 ± 4.8 kg/m^2] and 40 age- and BMI-matched healthy controls were included. Anthropometric, hormonal, biochemical measurements and body composition analyses were carried out in all participants. Vastus lateralis muscle biopsies were analyzed for humanin expression on 6 PCOS and 6 age- and BMI-matched healthy controls within the study group.
Results
Women with PCOS showed significantly increased waist circumference, total testosterone, FAI, LDL, triglycerides, 120 min insulin during 75 gr OGTT compared to controls. Serum humanin levels were significantly lower in the PCOS group than those in controls [Median (IQR):474.9 (313.0 – 633.5) pg/ml vs 672.3 (481.7-764.6) pg/ml $P<0.001$)]. Humanin showed negative correlations with total testosterone, 120 min insulin during OGTT, total cholesterol, LDL, non-HDL cholesterol and triglycerides [(r=-0.275, P=0.013), (r=-0.266, P=0.017), (r=-0.306, P=0.006), (r=-0.292, P=0.009), (r=-0.241, P=0.032), (r=-0.261, P=0.02)]. Western blot analysis showed no significant difference in skeletal muscle humanin levels between PCOS and control groups (P=0.71).
Conclusion
Serum humanin levels are decreased in PCOS suggesting mitochondrial dysfunction that is associated with androgen excess, insulin resistance and dyslipidemia. Reduction of circulating humanin is not linked to an alteration of this MDP in the skeletal muscle which constitutes the majority of the mitochondrial reserve in the body. A better understanding of potential roles of humanin and other MDPs in the pathophysiology of PCOS may enable development of new treatment options for mitochondrial dysfunction in the future.

Circulating CircRNAs for early diagnosis and prediction of gdm and their impact on trophoblast cell function

Shuo Ma & Guoqiu Wu
Zhongda Hospital, Medical School of Southeast University, Center of Clinical Laboratory Medicine, Nanjing, China

Background
Gestational diabetes mellitus (GDM) is one of the most common complications during pregnancy, with a globally increasing incidence that significantly affects maternal and infant health. Currently, there is a lack of effective early diagnostic markers for GDM. Therefore, it is necessary to identify diagnostic biomarkers for early screening of GDM during pregnancy. Circular RNA (CircRNA) has been found to be a structurally unique non-coding RNA, more stable than linear RNA, and can be encapsulated in exosomes, playing a role in the pathogenesis of various diseases, making it a promising candidate biomarker for various diseases.
Methods
We compared the expression profiles of circRNAs in the serum samples of three GDM patients and three matched controls using high-throughput sequencing technology. The specificity of circRNAs was validated using Sanger sequencing and agarose gel electrophoresis. The stability of circRNAs was assessed through RNase R and actinomycin D experiments. The relative expression levels of circRNAs in serum samples were measured using RT-qPCR. A logistic regression model was constructed for early prediction of GDM using circRNAs. The overall performance of circRNAs and the constructed model for early prediction and diagnosis of GDM was evaluated using ROC curves. The correlation between circRNAs and OGTT levels was assessed using Pearson correlation analysis. The effects of circRNAs on proliferation, migration, invasion, apoptosis, and cell cycle of human trophoblast cells were investigated using CCK-8 assays, EdU staining, Transwell assays, and flow cytometry.
Results
Hsa_circ_0031560 and hsa_circ_0000793 were highly expressed in the serum of GDM patients, and their expression levels were also high in the early stages of GDM development. Both circRNAs were positively correlated with OGTT expression. Hsa_circ_0031560 and hsa_circ_0000793 effectively diagnosed GDM in different cohorts. Furthermore, the model constructed using these two circRNAs effectively differentiated between GDM and non-GDM groups, with an AUC value of 0.852 in the overall cohort. In subsequent in vitro functional experiments, knockdown of hsa_circ_0031560 and hsa_circ_0000793 promoted proliferation, migration, and invasion of human trophoblast cells (HTR-8), increased the proportion of cells in the S phase, and suppressed cell apoptosis. Finally, knockdown of hsa_circ_0031560 and hsa_circ_0000793 was found to inhibit IL-8 expression.
Conclusion
Our study revealed high expression of hsa_circ_0031560 and hsa_circ_0000793 in the serum of GDM patients and their impact on trophoblast cells, suggesting their potential as candidate biomarkers for early diagnosis of GDM.

Protective effect of growth hormone-releasing hormone (GHRH) and its agonistic analog MR-409 in Alzheimer's disease

Francesca Pedrolli[1], Giulia Morello[2], Iacopo Gesmundo[1], Renzhi Cai[3,4], Wei Sha[4], Andrew V. Schally[3,4,5], Ezio Ghigo[1], Elena Tamagno[2], Michela Guglielmotto[2] & Riccarda Granata[1]
[1]Division of Endocrinology, Diabetes and Metabolism, Department of Medical Sciences, University of Turin, Turin, Italy; [2]Department of Neuroscience and Neuroscience Institute Cavalieri Ottolenghi Foundation (NICO), University of Turin, Turin, Italy; [3]Endocrine, Polypeptide, and Cancer Institute, Veterans Affairs Medical Center, Miami, FL, United States; [4]South Florida VA Foundation for Research and Education, Veterans Affairs Medical Center, Miami, FL, United States; [5]Department of Medicine, Divisions of Medical/Oncology and Endocrinology, and Department of Pathology, Miller School of Medicine, University of Miami, Miami, FL, United States

Alzheimer's disease (AD) is a neurodegenerative disorder characterized by the formation of amyloid-β (Aβ) plaques and Tau neurofibrillary tangles, leading to neuronal loss, inflammation, reduced neurogenesis, and cognitive impairment. Currently, there is no effective cure for AD, highlighting the urgent need for novel therapeutic strategies. Growth hormone-releasing hormone (GHRH), besides promoting the release of pituitary growth hormone (GH), exerts many peripheral functions, such as the stimulation of cell survival and proliferation. Notably, both GHRH and its agonistic analog MR-409 exert antinflammatory, cardioprotective, and neuroprotective effects, and protect against skeletal muscle atrophy. However, the role of GHRH in AD remains to be elucidated. Thus, in the present study we explored the neuroprotective functions of GHRH *in vitro*, in rat hippocampal neural stem cells (NSCs) and human neuroblastoma SH-SY5Y cell line, and *in vivo*, in transgenic 5xFAD mouse model of AD. *In vitro*, GHRH(1-44)NH_2increased cell survival and proliferation, and reduced apoptosis in NSCs and SH-SY5Y cells, under both growth factor deprivation and exposure to amyoid-β 1-42 ($A\beta_{1-42}$) peptide. The underlying mechanisms included stimulation of $G\beta_{\alpha s\beta}$/cAMP/PKA/CREB pathway, as well as ERK1/2 and PI3K/Akt, and inactivation of GSK-3β. Furthermore, GHRH showed neurogenic effects by promoting the differentiation of NSCs into neurons and astrocytes, and SH-SY5Y cells into neurons. Importantly, GHRH counteracted the $A\beta_{1-42}$-induced phosphorylation of Tau and activation of GSK-3β while suppressing the expression of inflammatory cytokines and phosphorylation of NF-κB. *In vivo*, 3-month-old male mice were assigned to the following groups: wild type (WT)-vehicle (VH) (n=7); WT-MR-409 (n=7); 5xFAD-VH (n=10); 5xFAD-MR-409 (n=10). Mice were subcutaneously treated daily with 0.8 mg/kg MR-409 or VH for 3 months. Compared with untreated, 5xFAD-MR-409 mice showed increased body weight. Importantly, we observed that treatment with MR-409 strongly reduced brain amyloid-β deposits and astrogliosis, as well as mRNA expression of inflammatory cytokines and phosphorylation of NF-κB in brain tissues of 5xFAD mice. Moreover, MR-409 reduced neuron loss, evaluated by neuronal marker NeuN, and increased brain-derived neurotrophic factor (BDNF) expression in brain lysates of 5xFAD mice. MR-409 also reduced the phosphorylation of Tau protein and inhibited the activation of GSK-3β in brain tissues of AD mice. Finally, AD mice treated with MR-409 showed attenuated expression of the atrophy-related markers atrogin and MurF1 in the skeletal muscle. Overall, these results, combined with our previous *in vitro* findings, suggest a protective role for MR-409 in AD.

Use of thiazide diuretics in hypoparathyroidism: indication and effects

Marie Helene Schernthaner-Reiter, Claudius Looser, Anna Nagel, Alexandra Kautzky-Willer, Anton Luger & Greisa Vila
Medical University of Vienna, Clinical Division of Endocrinology and Metabolism, Department of Internal Medicine III, Vienna, Austria

Introduction
Hypoparathyroidism can occur post-surgically after thyroid or parathyroid surgery or in autoimmune or genetic diseases. Over several decades, the management of hypoparathyroidism included only supplementation with calcium, vitamin D3 (cholecaliferol), as well as active 1,25-dihydroxyvitamin D (calcitriol). In cases with severe hypoparathyroidism, this treatment can be limited by hypercalciuria, and these patients often need substitution with recombinant parathyroid hormone. In daily clinical practice, thiazide diuretics may also be administered to reduce calciuria, however few data are available on the effects of thiazide use in hypoparathyroidism.
Methods
In this observational study, we retrospectively analyzed patients with hypoparathyroidism in routine medical treatment at our endocrine outpatient clinic. Clinical and biochemical parameters were collected at the time of first presentation, before the initiation of thiazide treatment, and at the time of last check-up.
Results
Our cohort includes 103 patients (m/f $n=21/82$) with hypoparathyroidism who were observed for a median of 2.1 ($\pm$ 6.6) years. 81 of those patients had prior thyroid or parathyroid surgery (26 due to thyroid nodules, 14 due to thyroid cancer, 17 due to Graves' disease, 4 due to primary hyperparathyroidism and 2 due to primary hyperparathyroidism and thyroid nodules), while hypoparathyroidism was not surgery-related in 19 patients.A therapy with thiazide diuretics (hydrochlorothiazide with a median dose of 12.5 mg $\pm$ 12.5 mg) was established in 40 of those patients. During treatment with thiazides, while parathyroid hormone measurements significantly decreased (7.9 to 4.8 pg/ml, $P=0.011$), albumin-adjusted serum calcium (2.0 and 2.1 mmol/l, respectively), estimated glomerular filtration rate (81.6 and 77.5 ml/min/1.73 m^2), magnesium (0.79 and 0.78 mmol/l) and blood pressure levels (135/85 and 134/84 mmHg) remained stable. Calciuria significantly decreased (9.5 to 6.2 mmol/24 h, $P=0.018$) and calcium and calcitriol dosages were non-significantly reduced.
Conclusion
Out data show that thiazide diuretics significantly lower calciuria in patients with hypoparathyroidism, but they do not impact serum calcium, magnesium, eGFR or blood pressure levels.

Growth hormone-releasing hormone (GHRH) promotes transdifferentiation of myoblasts and white adipocytes into brown/beige adipocytes

Alessia Bertoldo, Giuseppina Granato, Iacopo Gesmundo, Ezio Ghigo & Riccarda Granata
Division of Endocrinology, Diabetes and Metabolism, Department of Medical Sciences, University of Turin, Turin, Italy

Brown adipocytes dissipate energy through the production of heat, acting as a defense against cold and obesity, and secrete batokines, that positively regulate metabolic functions. Thus, identifying brown-promoting molecules is crucial for developing novel therapeutic strategies against obesity and metabolic disorders. Of note, differentiation into myoblasts and later myocytes of myogenic factor 5 (Myf5) positive progenitors, the same from which brown adipocytes originate, is controlled by several transcription factors, such as Myf5, myogenic differentiation 1 (MyoD1), myogenin (MyoG) and myogenic regulatory factor 4 (MRF4). Moreover, different compounds can induce myoblasts to transdifferentiate into non-muscle cells, including brown adipocytes. Similarly, in response to different stimuli, white preadipocytes transdifferentiate into beige adipocytes, morphologically and functionally similar to brown adipocytes. Growth hormone-releasing hormone (GHRH), a hypothalamic neuropeptide that regulates synthesis and secretion of pituitary growth hormone (GH), exerts peripheral effects through binding to GHRH receptor (GHRH-R), expressed in many extrapituitary tissues, including adipocytes and skeletal muscle cells. Although studies have shown that GHRH counteracts skeletal muscle atrophy and ameliorates dyslipidaemia, its role in browning remains unknown. Thus, we evaluated the role of GHRH in transdifferentiation of murine C2C12 myoblasts and 3T3-L1 preadipocytes into brown/beige adipocytes. C2C12 myoblasts were treated with brown adipogenic differentiation medium for 7 days, in either absence or presence of GHRH (0.1 and 0.5 μM). Instead, 3T3-L1 preadipocytes were first differentiated into white adipocytes for 10 days (in whitening medium), then transdifferentiated for 72 h into beige adipocytes (in browning medium), in either absence or presence of GHRH (0.5 and 1 μM). In C2C12 myoblasts, GHRH (0.5 μM) suppressed the mRNA expression of myogenic markers *MyoD1*, *MyoG*, *Myf5* and *MRF4*, whilst increasing brown/beige genes *UCP1*, *PGC-1α*, *PRMD16*, *DIO2*, *CIDEA*, *Tmem26* and *CD137*. These results were confirmed by a decrease in protein levels of MyoG and increase in UCP1, PGC-1α and PRMD16. Similarly, in 3T3-L1 preadipocytes, GHRH (1 μM) increased mRNA and protein levels of brown/beige markers. Furthermore, in both cell types, Oil Red O staining showed that GHRH enhanced the number of small lipid droplets, characteristics of brown/beige adipocytes. Overall, these preliminary findings suggest that GHRH promotes transdifferentiation of both myoblasts and preadipocytes into beige/brown adipocytes, suggesting a potential therapeutic role in obesity and metabolic diseases.

Comparative study of the legal framework for the medical care of people with differences of sex developmental (DSD) across the world

Nicolas Kalfa[1], Beth Drzewiecki[2], Luis Braga[3], Marco Castagnetti[4], Jacques Birraux[5], Magdalena Fossum[6], Alexander Springer[7], Anka Nieuwhof-Leppink[8], PJ Lopez[9], Abraham Cherian[10], Piet Hoebeke[11], Clementine Vialla[12], Francoise Paris[1] & François Vialla[12]
[1]Hospital Center University De Montpellier, Montpellier, France; [2]Mass-General Hospital for Children, Boston, United States; [3]McMaster University, Hamilton, Canada; [4]Bambino Gesù Children's Hospital, Roma, Italy; [5]Hôpitaux Universitaires de Genève (HUG), Genève, Switzerland; [6]Karolinska Institute, Sweden; [7]Medical University of Vienna, Wien, Austria; [8]UMC Utrecht, Utrecht, Netherlands; [9]Universidad De Chile Facultad De Medicina Division Sur, San Miguel, Chile; [10]Great Ormond Street Hospital for Children, United Kingdom, [11]Ghent University Hospital, Gent, Belgium; [12]Faculty of Law and Political Science, Montpellier, France

Purpose
Some countries have introduced legislation to regulate medical practices regarding DSD. We performed an international comparative law study to better understand how to integrate our medical decisions into these regulations.
Material and Methods
With an international medical law research unit 1- we extracted legislative texts, decrees, ministerial recommendations from different countries 2- we sent a questionnaire to surgeons caring for DSD-children to understand the medical decision-making procedures.
Results
Data from 19 countries and 8 US states were analyzed. Legislation was enacted in only 6 countries and ministerial orders or case-law were issued in 4. Legislation is still in preparation in 11 countries while 6 have none. Laws range from a ban on surgery (Malta, Iceland) to the establishment of a multidisciplinary decision-making circuit in case of medical necessity. The decision is made at the local level (14 cases: Belgium, Italy, UK…), at the national level (8 cases: Nordic countries, France…) or after a court decision (Germany, Australia). Most countries recognize the person's consent as essential and the parents' decision cannot replace it (24/27). Age of consent varies from 5 to 18 years but most texts don't stipulate clear limits or defer to the child's maturity. Risks of sanctions for practitioners are most often unspecified, of a professional medical board nature ($n=8$) or rarely criminal ($n=2$). Posterior hypospadias are included in this process in 74% of cases, either systematically or when associated with micropenis or undescended testis (Switzerland, Australia, France).
Conclusions
Rarely has a medical activity been subject to such legislative framework while medical data and long- term studies remain sparse. This raises the question of how far we should genetically explore minor genital variations and if the patients with minor phenotypes but with genetic variants are included in this legal frame. This situation illustrates the special position pediatric urologists occupy at the interface of society, law and scientific knowledge and profoundly changes the way we practice, think and make therapeutic decisions.

Endometrial transcriptome alterations following short-term liraglutide treatment in infertile women with polycystic ovary syndrome and obesity

Mojca Jensterle[1], Vesna Salamun[2], Eda Vrtacnik Bokal[2], Luca Lovrecic[2], Ales Maver[2], Borut Peterlin[2], Rok Herman[1] & Andrej Janez[1]
[1]University Medical Centre Ljubljana, Slovenia, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]University Medical Centre Ljubljana, Slovenia, Division of Obstetrics and Gynecology, Department of Human Reproduction, Ljubljana, Slovenia

Objective
Obesity and polycystic ovary syndrome (PCOS) affect endomertial receptivity and may cause implantation failure, defective placentation, and pregnancy loss. Glucagon-like peptide-1 (GLP-1) receptor agonist (RA) improved the endometrial function in animal models, presumably by anti-inflammatory action and reduction of endometrial fibrosis. The impact of GLP-1RA on human endometrioum has not yet been investigated.
Aim
We compared endometrial transcriptome of women with obesity and PCOS pre-treated with liraglutide and endometrial transcriptome of treatment-naive BMI and age-matched controls.
Design
Cross-sectional study.
Methods
Endometrial biopsies were collected during the window of implantation from 20 infertile women with PCOS and BMI ≥ 30 kg/m^2 before in-vitro fertilization (IVF) procedure. The endometrium transcriptome of ten women who had been pretreated with low-dose liraglutide 1.2 mg QD for 12-weeks and achieved at least 5% weight loss from baseline were compared with 10 BMI and age matched PCOS controls who were treatment naïve and had a stable weight over the previous 12 weeks. Next-generation sequencing was conducted using the Illumina HiSeq 2000 platform to analyze RNA samples. The resulting data were processed through Ingenuity® Pathway Analysis to discern key canonical pathways and predict activations or inhibitions. Additionally, gene networks were constructed based on established published associations to further interpret the findings.
Results
Endometrial biopsy analysis demonstrated distinct gene expression profiles between both groups. A total of 1036 genes displayed differential expression with statistical significance (P-value <0.05); 478 genes were upregulated, and 558 genes downregulated in the treatment group, including ones already demonstrated to be associated with liraglutide treatment (*PCSK2*, *ACTN3*, *NOS2*). Functional analysis identified that the most important canonical pathways that differed between the comparison groups included GLP-1 receptor activation, modulation of inflammation and oxidative stress response, alterations in glucose homeostasis and energy consumption, with *YWHAG* being a notable central gene in the associated network. The results indicate a possible involvement of the AKT pathway in the liraglutide's mode of action.
Conclusions
Short-term low-dose liraglutide treatment prior to IVF was associated with changes in the endometrial transcriptome that could potentially be important for improving endometrial receptivity and fertility in infertile women with obesity and PCOS.

Clinical and genetic characterization of a large cohort of patients with premature ovarian failure

Silvia Federici[1,2], Dario Messetti[1], Raffaella Rossetti[2], Silvia Moleri[2], Luca Persani[1,2] & Marco Bonomi[1,2]
[1]University of Milan, Dept. of Medical Biotechnology and Translational Medicine; [2]IRCCS Istituto Auxologico, Dept. of Endocrine and Metabolic Diseases

Primary ovarian insufficiency (POI) affects 1% of women before age 40 years, and in 70-90% of cases is defined as idiopathic. Although numerous POI-associated genes have been identified in recent years, the prevalence and pathogenicity of individual rare gene variants is still difficult to establish. The aim of our study was to retrospectively analyze the correlation between genotype and phenotype in patients with idiopathic POI, providing a more detailed characterization of POI-associated gene variants. 83 patients were enrolled, clinical data at diagnosis were collected and genetic analysis was performed with NGS technique to search for rare variants (RVs) in 9 candidate genes (*BMP15*, *FIGLA*, *FOXL2*, *GDF9*, *NOBOX*, *NR5A1*, *FSHR*, *SYCE1*, *STAG3*). We also classified the RVs we found according with ACMG criteria. Thus, RVs "of uncertain significance," "probably pathogenic," and "pathogenic" were defined as "potentially pathogenic variants" (PPRVs). Family history of POI was present in 27.5% of patients with secondary amenorrhea (SA) and 6.7% of patients with primary amenorrhea (PA). Patients with PA presented phenotypic abnormalities associated with ovarian failure in 25% percent of cases, while those with of SA in 8.7% of cases. However, none of these differences were found to be statistically significant. Genetic analysis showed the presence of several RVs and PPRVs in the 9 genes analyzed, with STAG3 being the gene with the highest enrichment in rare variants in our sample. In patients with PA we observed a greater enrichment, statistically significant, in RVs (respectively 43.5% in PA vs in 13.7% SA) and PPRVs, as well as in biallelic and oligogenic RVs (respectively 8.7% and 13% in PA vs 0% and 2% in SA). In addition, we found the presence of family history in 40% of PPRV carrier patients (vs 20% in PPRV-negative cases). Finally, no difference in prevalence of associated phenotypes was found in patients carrying RVs or not. Our analysis showed that higher enrichment in RVs, especially those with likely pathogenetic impact, correlates with greater clinical severity. In

particular, the presence of oligogenicity and homozygosity/ compound heterozygosity appears to correlate with PA. In contrast, the more blunted clinical forms, presenting with SA, seem to associate less frequently with RVs in candidate genes, while showing even more prevalent family history: genetic background may consist of a combination of polymorphic variants or rare variants in genes not classically associated with POI, combined with the effect of stochastic and environmental factors.

The role of rare human PROK2/R2 mutations in the reproductive and metabolic health of the general population: A recall-by-genotype study

Maria Stamou[1], Crystal Chiu[1], Shreya V. Jadhav[1], Kathryn B. Salnikov[1], Lacey Plummer[1], Stephanie B. Seminara[1] & Ravikumar Balasubramanian[1]
[1]Massachusetts General Hospital, Reproductive Endocrinology, Boston, United States

Mutations in the genes of *PROK2/R2* cause isolated hypogonadotropic hypogonadism (IHH) in humans, and defects in the PROK2/R2 pathway metabolic disturbances in mice. The role of naturally occuring mutations in the reproductive and metabolic health of the general population remains unknown. We hypothesized that individuals with naturally occurring rare *PROK/R2* variants will display dysregulation of their reproductive and metabolic fitness. We examined whole exome sequencing data of participants of the large dataset of the Massachusetts General Brigham Biobank (MGBB) (N = 53,408). Using a recall-by-genotype approach, we recruited and examined the reproductive and overall health of 25 individuals with rare *PROK2/R2* deleterious variants (cases) compared to 24 non-carrier controls. Evaluation of medical histories, physical exams, laboratory test results and dedicated questionnaires were used for assessment of the reproductive and overall health of the participants. A frequently sampled intravenous glucose tolerance test was performed in a subset of individuals to assess the β-cell function and insulin sensitivity of the participants. While no differences were observed in the overall health of individuals with *PROK2/R2* variants compared to health controls, *PROK2/R2*-positive male participants were at higher risk for being evaluated for infertility compared to healthy controls [41% of *PROK2/R2* positive participants were evaluated for infertility compared to 6% of non-carrier controls, OR 12.5 (1.19-130), *P* value 0.04]. In addition, they demonstrated a lower adult size testicular volume at exam compared to non-carrier controls [19 (2.7) mls vs 21 (2.9) mls, *P* value 0.02]. No differences in glucose regulation was noted between the two groups. In conclusion, impaired PROK2/R2 signaling may contribute to subtle deficits in reproductive fitness of male carriers in the general population. This study highlights the importance of recall by genotype studies in assessing the phenotypic expressivity, the full phenotypic spectrum, and the penetrance of disease associated human genetic variants.

Puberty is a key maturational process that culminates with the acquisition of reproductive capacity. This event demands significant energy resources to support the profound biological changes that occur during this period, including the activation of the reproductive axis. To this end, a plethora of signals operate for transmitting metabolic information to the reproductive axis in order to precisely regulate pubertal awakening depending on energy availability. Among others, ghrelin is an orexigenic hormone, primarily secreted by the stomach, exerting its effect via activation of the growth hormone secretagogue receptor (GHS-R1a), with crucial implications in the control of metabolism and puberty onset. In recent years, special attention has been also paid to the hepatic peptide LEAP-2, identified as a potential antagonist of ghrelin receptor, particularly in the context of energy homeostasis. However, the influence of LEAP-2 on pubertal maturation has not yet been explored. Therefore, the aim of this project was to unveil the contribution of LEAP-2 to the metabolic control of puberty. To this regard, we investigated the impact of LEAP-2 treatment during the pubertal transition in intact female Wistar rats under different metabolic conditions. In addition, we analyzed the effect of chronic administration of LEAP-2 to ovariectomized peripubertal rats replaced with physiological levels of estradiol (OVX + E2) to avoid the potential confounding effects of fluctuating sex steroid levels. Our results revealed that acute central administration of LEAP-2 increases luteinizing hormone (LH) release in a dose-dependent manner in peripubertal rats subjected to 24 h fasting, an experimental condition known to elevate circulating ghrelin levels. In the same line, chronic central administration of LEAP-2 to prepubertal female rats, either fed ad libitum (normonutrition) or subjected to 20% food restriction, induced a significant advance in puberty onset. This effect was defined by earlier vaginal opening, increased LH levels and accelerated ovarian maturation, regardless the nutritional status of the animals, being this effect more pronounced in undernourished animals. Similar effect on LH levels was detected in OVX + E2 animals treated with LEAP-2. Notably, central treatment with LEAP-2 in OVX + E2 rats led to an increase in Kiss1 mRNA levels, smggesting a potential implication of this neuropeptide in the actions of LEAP-2 on puberty onset under different metabolic conditions. Altogether, our data provide the first evidence about the important role of LEAP-2 in the metabolic control of pubertal maturation, potentially via Kiss1 neurons.

Introduction
Autoimmunity is an important etiological factor of premature ovarian insufficiency (POI, menopause <40 years). It has been estimated that 4-50 % of POI cases are of autoimmune origin. Only a few studies, with sample sizes of dozens to hundreds POI cases, have investigated the prevalence of autoimmune diseases in women with POI. We aimed to assess in an essentially larger data set the prevalence of severe autoimmune diseases treated in tertiary care prior to POI diagnosis compared to matched controls.
Materials and Methods
Women diagnosed with POI between the years 1988-2017 (n = 5,714) in Finland were identified from the reimbursement registry of the Social Insurance Institution by their right for hormone replacement therapy. Women with a history of cancer or bilateral oophorectomy (n = 1,742), were excluded leaving 3,972 women spontaneous POI cases into the study population. Four population controls matched by age and municipality of residence (n = 15,708) were searched for each POI case. Severe autoimmune disease diagnoses for years 1970-2017 were identified from the Hospital Discharge Registry. Odds ratios (ORs) with 95% confidence intervals (CIs) were calculated using binary logistic regression for having autoimmune diseases preceding the index date (the date when reimbursement for HRT was granted for the POI case in the case-control set) among POI cases compared to controls.
Results
In women with POI, 5.6% had a severe autoimmune disease before the index date. The prevalence of having any severe autoimmune disease prior to the index date was higher among women with POI (OR 2.6, 95% CI 2.2–3.0). Women with POI had an increased prevalence of several specific autoimmune diseases: polyglandular autoimmune diseases (OR 25.8, 95% CI 9.0-74.1), Addisońs

disease (OR 22.9, 95% CI 7.9-66.1), vasculitis (OR 10.2, 95% 4.3-24.5), systemic lupus erythematosus (OR 6.2 95% CI 4.2-20.3), rheumatoid arthritis (OR 2.3, 95% CI 1.7-3.2), sarcoidosis (OR 2.3, 95% CI 1.2-4.5), inflammatory bowel diseases (OR 2.2, 95% CI 1.5-3.3), and hyperthyroidism (OR 1.9, 95% CI 1.2-3.1). The prevalence of diabetes type 1 and ankylosing spondylitis did not differ between cases and controls.
Conclusion
Women with severe autoimmune diseases have a more than two-fold increased risk of developing POI, smggesting that immunological mechanisms play a pivotal role in POI. Future studies should focus on specific autoimmune mechanisms behind POI from a preventive perspective.

Characterisation of the daily rhythm of salivary androgens in healthy women and in women with polycystic ovary syndrome by liquid chromatography-tandem mass spectrometry

Laura Rotolo[1,2], Alessandra Gambineri[1,2], Valentina Bissi[1], Francesca Zauli[1,2], Greta Galante[1], Carolina Cecchetti[1,2], Paola Dionese[1,2], Elisabetta Belardinelli[1,2], Beatrice Solmi[1,2], Uberto Pagotto[1,2] & Flaminia Fanelli[1]
[1]Center for Applied Biomedical Research, Dept. Of Medical and Surgical Sciences, Alma Mater Studiorum - Bologna University, Bologna, Italy; [2]Endocrinology and Diabetes Prevention and Care Unit, IRCCS Azienda Ospedaliero-Universitaria, Bologna, Italy

Background
PCOS is characterised by increased production of ovarian and adrenal androgens. Obesity is closely connected to excess androgens and to the disruption of hormone circadian rhythmicity. To date, it is not clear whether hyperandrogenism in PCOS, complicated or not by obesity, is associated with androgen rhythm dysregulation.
Aim
To investigate androgen diurnal rhythmicity and overall daily androgen exposure by measuring testosterone(T), androstenedione(A4) and dehydroepiandrosterone(DHEA) in saliva of healthy women(HW) and women with PCOS fulfilling the three Rotterdam diagnostic criteria, according to their BMI status.
Methods
HW ($n=24$), aged 23-37 y, showed no PCO morphology (PCOm), menstrual irregularity or hyperandrogenism. PCOS ($n=18$) were 15-38 y old and showed oligo-amenorrhea, PCOm and either clinical or biochemical hyperandrogenism. Both groups were subdivided into normal weight (NW:BMI <25kg/m^2; HW:$n=20$, PCOS:$n=5$) and overweight/obese (OW/OB:BMI ≥ 25kg/m^2; HW:$n=4$, PCOS:$n=13$). All were in early follicular phase, had standardised meals at 8, 13 and 20am, and self-collected saliva hourly from 7 until 23am. Salivary T, A4 and DHEA were measured by a validated LC-MS/MS method.
Results
All women presented elevated androgen levels upon awakening, decreasing until bedtime (all $P<0.001$). Compared to HW, PCOS displayed higher T and A4 levels at each time point, and higher DHEA at 9, 11 and 16 am (all $P<0.050$). Throughout the day, minor androgen peaks were detected at 14 (A4,DHEA), 18 (DHEA) and 23 (T,A4,DHEA) am in HW, and at 11 (T,A4,DHEA), 17 (T,A4,DHEA) and 23 (T) am in PCOS. The AUC for daily T and A4 profiles was significantly greater in PCOS vs HW, irrespectively of BMI, whereas DHEA AUC was higher in OW/OB PCOS compared to NW PCOS and to both NW and OW/OB HW (all $P<0.050$). Multiple regression, including androgen AUC as the dependent variable and age, BMI and PCOS status as covariates, showed an independent impact of PCOS on T and A4 (both $P<0.001$) and of BMI on DHEA ($P=0.031$).
Conclusions
Our study provides novel insights into circadian androgen regulation in healthy and PCOS women, enabled by a highly sensitive and specific LC-MS/MS technology. While overall diurnal androgen rhythmicity was preserved, PCOS exhibited a time-specific dysregulation of small androgen surges. Excess T and A4 were detectable in saliva throughout the day in PCOS, whereas DHEA excess was only noticeable in the mid-morning and afternoon. While increased T and A4 secretion characterised PCOS condition regardless of BMI, excess DHEA specifically typified the obese PCOS phenotype, smggesting a specific adrenal contribution to PCOS-related dysmetabolic sequelae.

Genetics of congenital hypoparathyroidism and pseudohypoparathyroidism: results of a multigenic screening in an Italian cohort of affected patients

Francesca Marini[1], Francesca Giusti[2], Filomena Cetani[3], Giovanna Mantovani[4,5], Paolo Garagnani[6] & Maria Luisa Brandi[1,2]
[1]Fondazione FIRMO Onlus, Firenze, Italy; [2]Donatello Bone Clinic, Villa Donatello Hospital, Sesto Fiorentino, Italy; [3]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [4]University of Milan, Department of Clinical Sciences and Community Health, Milano, Italy; [5]Fondazione IRCCS Cà Granada Ospedale Maggiore Policlinico, Endocrinology Unit, Milano, Italy; [6]University of Bologna, Department of Medical and Surgical Sciences (DIMEC), Bologna, Italy

Introduction
Hypoparathyroidism (HPT), pseudohypoparathyroidism (PHP), and end-organ parathyroid hormone (PTH)-resistance are rare metabolic disorders characterized by low serum calcium and increased serum phosphorus due to a PTH-deficient or resistant state. Various genes/loci have been identified as responsible for the development of congenital/familial forms of HPT, PHP and related diseases.
Patients and Methods
A total of 39 patients with a clinical diagnostic suspicion of congenital forms of HPT ($n=30$) or PHP ($n=9$), previously resulted negative to monogenic genetic screening with PCR-based Sanger sequencing ($n=13$) or not yet being genetically analyzed ($n=26$), were collected by 4 major endocrinology centers in Italy. They were all analyzed by Next Generation Sequencing (NGS) using a customized multigenic panel containing 24 human genes whose mutations have been associated with the development of congenital forms of HPT and PHP. Obtained sequences were mapped on the HG38 human reference genome; genetic variants were annotated and analyzed using human gene variant databases and variant allele frequency projects. Variants were classified as "common" or "rare" with a frequency over or less than 1% in the general population, respectively, and then as benign (B), likely benign (LB), variants of uncertain clinical significance (VUS), likely pathogenic (LP), or pathogenic (P), according to the Standards and Guidelines for the Interpretation of Human Sequence Variants of the American College of Medical Genetics and Genomics (ACMG).
Results
Twenty-two patients (56.4%) were found not bearing any rare genetic variant, while in 4 patients (10.3%) we identified 4 different rare variants classified as benign. Thirteen patients (33.3%) were found to be carriers of at least one rare variant classified as VUS, LP, or P, out of them 8 (20.5%) had a single VUS, 3 (7.7%) had one VUS and one LP variant, one (2.6%) had a single LP variant, and one (2.6%) had a P variant. A total of 14 different VUS, LP and P variants were identified, all being heterozygous, 3 in *AIRE* gene (2 VUS, 1 P), 2 in *GCM2* gene (1 VUS, 1 LP), and one in *ACADM* (VUS), *CaSR* (LP), *CDH7* (VUS), *FAM111A* (VUS), *GATA3* (LP), *GNAS* (VUS), *PTH1R* (VUS), *TBCE* (VUS) and *TBX1* (VUS) genes.
Conclusions
Multigenic panel screening by NGS allowed the identification of rare VUS, LP, or P variants in patients previously resulted negative to monogenic Sanger's sequencing (6/13; 46.2%). Segregation analysis is needed to assess the real clinical significance of identified variants.

Irisin levels are correlated with age and behavioural performance in Post-surgical HypoPT condition

Federica Saponaro[1], Grazia Chiellini[1], Beatrice Polini[1], Caterina Ricardi[1], Patrizia Pignataro[2], Roberta Zerlotin[3], Angela Oranger[3], Silvia Colucci[2], Manuela Di Carlo[3], Graziana Colaianni[3], Alessandro Saba[1] & Maria Grano[3]
[1]Biochemistry Unit, Department of Surgical, Medical and Molecular Pathology and Critical Care, University of Pisa, Pisa, Italy; [2]Department of Translational Biomedicine and Neuroscience, University of Bari, Bari, Italy; [3]Department of Precision and Regenerative Medicine and Ionian Area, University of Bari, Bari, Italy

Introduction
Hypoparathyroidism (HypoPT) is a rare endocrine disease and Post-surgical HypoPT (PS-HypoPT) is the most common cause, caused by accidental parathyroid injury. From a neuropsychological standpoint, patients with PS-HypoPT present cognitive and neuropsychological symptoms. Irisin is a myokine secreted by contracting muscle, which mediates beneficial effects on several targets, including brain. The aim of this study was to evaluate irisin in the context of PS-HypoPT condition.

Methods
a surgical rat model of PS-HypoPT was obtained, treated with gluconate-calcium to maintain normocalcemia. A cohort of 40 animals was included, divided in 4 subgroups: $n=10$ PS-HypoPT rats (PTx) 11 weeks of age, $n=10$ PTx rats 28 weeks of age, $n=10$ controls shamed-operated (Crl) 11 weeks of age and $n=10$ Crl 28 weeks of age. All animals underwent serum calcium and irisin measurement and behavioural testing Morris Water Maze (MWM).
Results
Both PTx ($n=20$) and Crl rats ($n=20$) showed a normal growth and comparable serum calcium levels. In the whole animal cohort, serum irisin levels were statistically significantly lower in younger animals compared to elderly (16.5 ± 3.3 vs 13.0 ± 3.5, $P=0.014$), regardless the belonging group (PTx or Crl). In the ANOVA analysis including the 4 groups, we observed that PTx old animals (28 weeks of age) showed the lowest levels of irisin ($P=0.04$) and the rate of irisin decrease between 11 and 28 weeks of age was significantly higher in PTx animals, compared with Crl ($P=0.03$). We also observed that in MWM test, animals with lower levels of irisin (<14 mg/dl as median cut-off), showed a worse performance at the test, measured as parameters in the probe day (last day): number of entries in the zone of the platform ($P=0.04$), time spent in the zone of platform ($P=0.03$), total distance ($P=0.02$), resting time in the zone of platform ($P=0.02$). Moreover, PTx animals with lower levels of irisin, showed a higher Escape Latency Time compared to the other groups ($P=0.01$).
Conclusions
Irisin is a myokine, with potential protective effects on CNS. We observed that irisin is decreased with age and it is reduced in the animal model of PS-HypoPT. Moreover, irisin levels are correlated with the worse performance at behavioural testing evaluating locomotory capacity and memory in the PS-HypoPT group of animals. This mechanism could explain the known neuropsychological and cognitive symptoms of patients with PS-HypoPT. Further studies are ongoing to understand the role of irisin and its downstream effectors on CNS in PS-HypoPT.

Metformin prevents glucocorticoid-induced bone resorption in healthy subjects

Stéphanie Pfammatter[1], Zanetti Lisa[1], Susanne Thierry[1], Christian Meier[1] & Eleonora Seelig[1,2]
[1]Universitätsspital Basel, Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]Cantonal Hospital Baselland, University Clinic of Medicine, Liestal, Switzerland

Background
Glucocorticoids are crucial for treating various medical conditions due to their beneficial immunosuppressive effects. However, glucocorticoids also carry a high risk for osteoporosis. Notably, within just a few months of glucocorticoid therapy, bone density can be significantly reduced, and up to 5% of patients undergoing such treatment may experience fractures. There is promising evidence from preclinical studies and observations in patients with type 2 diabetes that metformin may prevent glucocorticoid-induced osteoporosis. We aim to investigate whether metformin prevents glucocorticoid-induced osteoporosis as assessed by biochemical markers of bone turnover in healthy subjects.
Methods
In a randomized, placebo-controlled, cross-over trial, we compared metformin to placebo during high-dose glucocorticoid treatment in 18 lean, healthy males. All participants received prednisone 30 mg/d for two 7-day periods separated by a 28-day washout period. During one period, participants additionally had metformin; during the other, they received a placebo. In an exploratory analysis, we assessed changes in bone turnover markers before and after glucocorticoid treatment in both study phases.
Results
18 male subjects (mean age 27, standard deviation [SD] ±5.2 years, BMI 22.9 ± 1.8 kg/m^2) were enrolled in the study. During glucocorticoid treatment, serum C-terminal telopeptide (CTX) increased with placebo but remained stable with metformin (placebo: 0.2 ± 0.2 ng/ml; metformin 0.06 ± 0.2 ng/ml, $P=0.03$). Serum procollagen I Intact N-terminal (PINP) decreased with both treatments (placebo: -20.6 ± 11.8 ng/ml; metformin -22.3 ± 16.7 ng/ml, $P=0.7$). Serum osteocalcin decreased with both treatments (placebo -10.8 ± 6.9 mg/l; metformin -12.1 ± 9.4 mg/l, $P=0.3$).
Conclusion
Our study demonstrated that metformin has a protective effect during GC-therapy with diminished bone resorption, while no effect on bone formation can be observed. These findings indicate that metformin may have a promising role in mitigating some of the detrimental effects of glucocorticoids on bone health.

Primary hyperparathyroidism (PHPT) is rare in the pediatric population, with an estimated incidence of 0.5–5 cases per 100,000 person-years in children. Data regarding the clinical phenotype, the surgical outcomes are scarce. The objective of our study was to retrospectively analyze the phenotype of apparently sporadic PHPT in patients ≤21 years in major endocrinology reference centers in Italy. None of the patients had known familial syndromes. A total of 41 patients were included, 14 males and 27 females with a median age at diagnosis of 18 years (IR 16-20). Twenty-nine percent of diagnoses ($n=12$) were made incidentally through laboratory evaluation performed for other reasons while 71% ($n=29$) had PHPT-related symptoms. The most common symptom was nephrolithiasis in 58.6% of the symptomatic cohort ($n=17$), followed by bone pain (11.1%) and acute pancreatitis (6.9%). Median total serum calcium concentration was 11.7 mg/dl (IR 11.1-12.5), ionized calcium was 1.58 mmol/l (IR 1.43-1.71) and PTH levels, evaluated as fold increase of the upper limit of reference range, were 2.96. Fifty-nine percent (19/32 with available 24-hour urinary calcium) had hypercalciuria with a median value of 342 mg (IR 258-498). Fifty-three percent (15/28 with available dual-energy x-ray absorptiometry) had low bone mineral density (mean lumbar Z-score -2.8; femoral neck -2.6; total femur -2.9; 1/3 distal radius -3.7 DS). Genetic analysis of genes that have been associated with the development of genetic PHPT was performed in 34 patients. Eleven patients (33.3%) carried a heterozygous germline variant: 7 in *CDC73* gene, 1 in *MEN1* gene, 1 in *AP2S1* gene, 1 in *GCM2* gene, 1 in CASR of uncertain significance. The latter two variants were classified of uncertain significance. Thirty-one (75%) patients underwent surgery, 15 of them had bilateral cervical exploration. Histology was consistent with the diagnosis of chief cell adenoma in 27 (87%) patients, atypical adenoma in 2 (6.5%) and carcinoma in 2 (6.5%). The post-surgical follow-up (median 5 years) was available in 23 patients. The cure rate following primary surgery was 95.7%. Persistence of PHPT was evident in one patient. No recurrence was evident. Our findings smggest that PHPT in children and adolescence is frequently sporadic, although a substantial proportion of patients (approximately one-third) have a genetic predisposition. Therefore, an appropriate familial screen should be performed clinically and if relevant, tested genetically. Most cases are seemingly due to isolated adenomas.

Genetic testing for syndromic conditions in patients referred with primary hyperparathyroidism: a retrospective observational analysis

Kyi Pyar Than Yu[1], Andrew Gregory[1], Mustafa Abdulkareem[1], Biju Jose[1] & Lakshminarayanan Varadhan[1]
[1]University Hospital of North Midlands, Diabetes and Endocrinology, Stoke-on-Trent, United Kingdom

Background and Aim
Primary hyperparathyroidism (PHPT) is a common endocrine disorder. A small proportion of these patients may have syndromic conditions such as multiple endocrine neoplasia (MEN) or familial hypocalciuric hypercalcemia (FHH). The UK national guidelines recommend genetic testing for familial hyperparathyroidism in individuals under 50 or any age with specific criteria such as family history, multi glandular disease, hyperplasia, or parathyroid carcinoma. Genetic testing for familial hypocalciuric hypercalcemia (FHH) is recommended in patients with hypercalcemia with hypocalciuria (urinary calcium creatinine clearance ratio $<$ 0.02). The aim of our study was to assess the uptake and utility of genetic testing and its diagnostic yield in patients referred to endocrine clinic with possible primary hyperparathyroidism.
Methods
A retrospective analysis of the genetic tests performed in patients with primary hyperparathyroidism over 7 years was done. Along with routine testing with PTH, bone profile and vitamin D, all patients underwent screening for FHH with urinary calcium/creatinine ratio and/or 24 h urine calcium excretion. Data on additional hormonal tests (fasting gut hormone profiles, pituitary profile, catecholamine level), and imaging to evaluate pathological glands (Ultrasound (US) and MIBI scan) was collected.
Results
A total of 33 patients underwent genetic testing for PHPT, and results were available for 26. 70% ($n=23$) were females. The mean age at diagnosis was 44 years (range 16-66). Additional hormonal testing was conducted for 25 patients. Ultrasound of parathyroid glands was performed in 30 patients, with 21 positive results. Additionally, 28 patients underwent Nuclear Medicine Parathyroid MIBI scans with 12 positive results. Various indications and numbers tested were: a) 14 patients due to age $<$50 years old. b) 8 for failed localization on imaging modalities. c) 4 for low urine calcium creatinine ratio. d) 2 for recurrence of primary hyperparathyroidism. e) 2 for parathyroid hyperplasia on post-operative histology. f) 2 for associated hormone problems (one each with elevated gastrin and chromogranin A). 1 for coexistent pituitary adenoma. Genetic tests confirmed CASR gene mutation in 2 patients confirming FHH. None of the patients had MEN-1 or MEN-2 gene mutations.
Conclusion
Our data indicates that, despite a high index of suspicion for MEN and FHH based on risk factors and clinical presentation, the actual prevalence is low in this highly selected cohort, with sporadic occurrence being the most common presentation.

DOI: 10.1530/endoabs.99.RC2.5

Role of FGF23 in patients with transfusion-dependent β-thalassemia and hypercalciuria

Alberto Gobbo[1], Fatima Chamekh[2], Camilla Alice Cattaneo[1], Martina Verrienti[1], Stefano Pizzicotti[3], Filomena Longo[4], Maria Chiara Zatelli[1] & Maria Rosaria Ambrosio[1]
[1]University of Ferrara, Section of Endocrinology and Internal Medicine, Department of Medical Sciences, Ferrara, Italy; [2]University of Ferrara, Ferrara, Italy; [3]University Hospital of Ferrara, Laboratorio Unico Provinciale, Ferrara, Italy; [4]University Hospital of Ferrara, Regional HUB Centre for Thalassaemia and Haemoglobinopathies, Department of Medicine, Ferrara, Italy

Introduction
Patients with transfusion-dependent β-thalassemia (TDT) frequently exhibit elevated urinary calcium excretion, contributing to kidney stone formation and osteoporosis. The underlying mechanism of hypercalciuria in β-thalassemia remains elusive, with FGF23 playing a potential role. FGF23, a bone-derived hormone, primarily acts on the kidneys by inhibiting phosphate reabsorption in the proximal tubules while enhancing calcium uptake in the distal tubules. Few studies have evaluated FGF23 levels in β-thalassemic patients as compared to the general population with contradictory results.
Objective
This study aims to investigate FGF23 levels in patients with TDT and hypercalciuria vs those without.
Methods
Our study included 126 patients referring to the Regional HUB Centre for Thalassaemia and Haemoglobinopathies in Ferrara in 2023. The parameters we assessed are shown in the Table. Hypercalciuria was defined as a 24-hour urinary calcium level $\geq$4 mg/kg/day. The intact FGF23 polypeptide was quantified using the chemiluminescence immunoassay "LIAISON® FGF 23 test".
Results

	Normocalciuric	Hypercalciuric
$N=126$	39 (31%)	87 (69%)
Sex (F/M)	27/12	44/43
	Median [IQR]	**Median [IQR]**
Age (years)	51 [45; 56]	49 [44; 53]
BMI (kg/m^2) *	23.8 [21.4; 26.7]	21.9 [20.2; 24.8]
FGF23 (pg/ml) **	42.6 [30.1; 58.7]	32.5 [23.8; 42.7]
Urinay creatinine (g/day) *	0.9 [0.8; 1.1]	1.1 [0.8; 1.4]
Urinary phosphate (g/day) ***	0.55 [0.3; 0.7]	0.8 [0.6; 1]
Urinary proteins (mg/day)	131 [101; 207]	176 [114; 242]
Calcium (mg/dl)	9.3 [9; 9.7]	9.5 [9.3; 9.8]
Phosphate (mg/dl)	3.6 [3.2; 3.9]	3.5 [3.3; 3.9]
Vitamin D (ng/ml) *	34.9 [27.2; 37.5]	28.8 [19.4; 34.6]
PTH (pg/ml)	28 [21.5; 41.5]	25 [19; 33.8]
Magnesium (mg/dl)	2.2 [2; 2.4]	2.1 [2; 2.3]
Ferritin (ng/ml)	548 [334; 889]	447 [298; 676]
Iron (ug/dl)	223.5 [195.8; 272.3]	241 [215.5; 270]
eGFR (ml/min)	91.6 [75; 109]	90.8 [77.1; 116.7]
Creatinine (mg/dl)	0.74 [0.59; 0.89]	0.73 [0.61; 0.9]

Mann-Whitney test was applied. $P<0.05$*; $P<0.01$**; $P<0.001$***

Conclusions
Hypercalciuric patients exhibited lower FGF23 levels combined with higher urinary creatinine and phosphate levels as compared to normocalciuric patients. This smggests a potential role of FGF23 in the development of hypercalciuria, but additional mechanisms (i.e., renal impairment due to iron overload or chelation therapy) may contribute to the increased phosphate and calcium renal losses in these patients. Further studies are warranted to better explore this issue.

[1]The University of Sheffield, United Kingdom; [2]National Institutes of Health, Bethesda, United States; [3]MRC Laboratory of Medical Sciences, United Kingdom; [4]Louis Pradel Hospital, Bron, France; [5]Karolinska Institute, Sweden; [6]University of Birmingham, United Kingdom; [7]Cardiff University, United Kingdom; [8]Klinikum der Universität München, München, Germany; [9]Charlottenburg, Berlin, Germany, [10]University Hospitals Pitié Salpêtrière - Charles Foix, Paris, France, [11]Diurnal, United Kingdom

Background
Management of CAH involves replacing cortisol deficiency and reducing raised adrenal androgens, however the supraphysiological glucocorticoid doses often required to treat hyperandrogenism are associated with poor long-term health outcomes. Modified-release hydrocortisone (MRHC) capsules, Efmody, replicate cortisol diurnal rhythm and improve control of CAH compared to standard glucocorticoid therapy. Here we report changes in glucocorticoid daily dose and 9am 17-hydroxyprogesterone (17-OHP) and androstenedione (A4) in MRHC-treated patients after 48 months in the MRHC single-arm extension study.
Methods
Participants completing MRHC Ph2 and Ph3 studies were eligible to enter a single-arm, open-label extension study. Visits occurred at baseline, weeks 4, 12, 24 and 6-monthly thereafter. MRHC doses were adjusted on the basis of an adrenal insufficiency checklist, and measurement of A4 and 17-OHP at 9am and 1pm, targeting 17-OHP to $<$36 nmol/l and A4 into the reference range. Participants that completed 48 months in the extension study were reviewed. Participants were considered responders when 9am 17OHP $\leq$36 nmol/l or A4 $\leq$7nmol/l and hydrocortisone (HC) dose $\leq$25 mg/day.
Results
Data were available for 91 participants at baseline and 71 participants (61 with hormone blood results) at 48 months. The median daily HC dose (Inter-Quartile Range [IQR]) at baseline and 48 months were 30 mg (IQR 20–35) and 20 mg (IQR 15–25), respectively (nominal $P<0.0001$). Geomean (95% CI) 17-OHP

was 15.84 (10.32–24.31) and 11.34 (7.048–18.23) nmol/l at baseline and 48 months, respectively. Geomean A4 (95% CI) was 2.242 (1.669–3.012) and 2.092 (1.604–2.727) nmol/l at baseline and 48 months, respectively. Quadrant analysis showed the following:

		Dose	
		≤25 mg/day	>25 mg/day
Baseline	>36 nmol/l 17-OHP	14/91 (15%)	21/91 (23%)
	≤36nmol/l 17-OHP	29/91 (32%)	27/91 (30%)
48 months	>36 nmol/l 17-OHP	15/61 (24%)	3/61 (5%)
	≤36 nmol/l 17-OHP	31/61 (51%)	12/61 (20%)

Responder status 51% vs 32% at baseline, $P=0.0274$ by Fisher's exact test.

		Dose	
		≤25 mg/day	>25 mg/day
Baseline	>7 nmol/l A4	6/91 (7%)	14/91 (15%)
	≤7nmol/l A4	37/91 (41%)	34/91 (37%)
48 months	>7n mol/l A4	5/61 (8%)	1/61 (1%)
	≤7nmol/l A4	41/61 (67%)	14/61 (23%)

Responder status 67% vs 41% at baseline, $P=0.0016$ by Fisher's exact test.

Conclusions

After 48 months of MRHC treatment the median daily HC dose was reduced from a median of 30mg to 20mg and the number of patients achieving responder status based on 9am 17-OHP or A4 while receiving HC ≤25 mg/day increased.

Adrenal tumours are frequently detected by conventional cross-sectional imaging, which, however, has limited specificity in identifying the most prevalent tumour type, benign, non-functional adrenocortical adenomas (ACA) not requiring surgery. We assessed the diagnostic accuracy of adrenal molecular imaging with [^{18}F]Fluorodeoxyglucose-positron emission tomography (FDG-PET) and [^{123I}]Iodometomidate-single photon emission tomography (IMTO-SPECT). We performed a prospective, multicentre study in adult patients (≥30 years) with indeterminate adrenal masses (diameter >3 cm and unenhanced computed tomography [CT] tumour attenuation ≥10 Hounsfield units [HU]). We assessed the diagnostic performance of combined FDG/IMTO imaging in detecting ACA, using a reference standard of histopathology. Low FDG uptake (=FDG-negative) with high IMTO uptake (=IMTO-positive) was considered indicative of ACA. We also assessed the utility of FDG and unenhanced CT tumour attenuation in detecting malignancy. Between July 2015 and December 2020, 85 patients were enrolled and 77 included in the final analysis; 53 harboured benign and 24 malignant adrenal masses. Combined FDG/IMTO-imaging identified ACA with high specificity (95·7% [95%CI 85·2-99·5%]; positive predictive value 87·5% [95%CI 61·7-98·5%]; positive likelihood ratio 11·1 [95%CI 3·2-122·2%]). However, sensitivity was low (48·3% [95%CI 29·4-67·5%]) due to moderate or high FDG uptake in 14 of 30 ACAs. Malignant masses were identified with high sensitivity but low specificity both by unenhanced CT (cut-off HU ≥20 sensitivity 100% [95%CI 85·8-100%], specificity 26·4% [95%CI 15·3-40·3%]) and FDG (sensitivity 95·8% [95%CI 78·9-99·9%], specificity 62·3% [95%CI 47·9-75·2%]). Combined FDG/IMTO-imaging identifies ACA with high specificity in this cohort with indeterminate masses. However, the presence of a sub-cohort of FDG-positive ACA decreases sensitivity.

Quantifying variability in ambulatory 24-hour tissue hormones for personalised management of hormonal replacement in patients with adrenal insufficiency

Ileana R. Botusan[1,2], Katarina Berinder[1,2], Paal Methlie[3,4], Thomas Upton[5], Eder Zavala[6], Georgina Russell[5], Katerina Simunkova[3], Dimitra Vassiliadi[7], Isabella Marinelli[6], Marianne Aardal Grytaas[3,4], Stylianos Tsagarakis[7], Stafford Lightman[5], Eystein Sverre Husebye[3,4], Olle Kämpe[1,2], Marianne Øksnes[3,4] & Sophie Bensing[1,2]

[1]Karolinska Institutet, Stockholm, Sweden; [2]Karolinska University Hospital, Stockholm, Sweden; [3]University of Bergen, Bergen, Norway; [4]Haukeland University Hospital, Bergen, Norway; [5]University of Bristol, Bristol, United Kingdom; [6]University of Birmingham, Birmingham, United Kingdom; [7]Evangelismos Hospital, Athens, Greece

Background

Recently, we have shown that ambulatory 24-hour dynamic steroid profiling using the newly developed U-RHYTHM system is possible and presented the circadian and ultradian rhythmicity of adrenal hormones in a healthy cohort. With U-RHYTHM, multiple hormones can be sampled simultaneously, and the free active hormones can be measured in local tissue where the effect is exerted. Thus the hormone fingerprint resulting from replacement therapy in individual patients can be visualized and compared to the normative references throughout the day.

Aim

To assess 24-hour profiles of free cortisol and metabolites in patients with Addisońs disease (AD) on different glucocorticoid replacement therapies (GRT) and compare the results with healthy volunteers (HV).

Material and Methods

The study was performed within the frame of a multi-center EU-funded H2020 ULTRADIAN study. HV group, enrolled 214 subjects, aged 18 to 68 years and with BMI 16 to 29.9 kg/m^2. Patients group enrolled 41 subjects with established AD within the same age span. All were 21 hydroxylase autoantibody positive. Median duration of AD was 6.5 years (IQR: 3.25-19.75). Median BMI was 25.2 kg/m^2. (IQR: 22.75-27). The enrollment was independent of their GRT regimes: 27 hydrocortisone, 9 cortisone-acetate, 4 modified release hydrocortisone and 1 pump. Their regular medication was not changed. Twenty-minute microdialysis fractions were collected ambulatory from subcutaneous tissue over 24 h using the portable fraction collector, U-RHYTHM. Steroid hormones were analyzed by ultrasensitive liquid chromatography tandem mass spectroscopy (LC-MS/MS). Dynamic biomarkers: area under the curve, concentration peak post -dose and time to peak were used to define hormone pattern differences, and to assess the "time in range" for patients compared with the profiles of HV.

Results

The U-RHYTHM ambulatory system was well tolerated, not disturbing the normal daily activities or sleep and 24-hour dynamic steroid profiling revealed marked interindividual variations partially depending on GRT and dosing-regime. Continuous overnight steroid profiling in patients was possible in ambulatory, without disturbing sleep. Tissue cortisol exposure expressed as a percentage of total (cortisol + cortisone) showed higher levels in patients AD compared with HV, throughout the day (8 am to 2 am) with levels even higher than in HV with high BMI (>25 kg/m^2). The exception was during night when, cortisol was very low in patients with AD.

Conclusion

Ambulatory 24-hour microdialysis sampling may provide a tool for precision medicine in AD, creating the opportunity for individual dose adjustment particularly in patients who are not well on current GRT.

Background

Current glucocorticoid replacement regimens for patients with primary adrenal insufficiency (PAI) mean patients wake with either low or undetectable cortisol levels[1], associated with fatigue and a reduced quality of life (QoL)[2]. Plenadren® (Takeda, UK) is a once-daily modified-release formulation of hydrocortisone that replaces daytime cortisol levels whereas Chronocort® (modified-release hydrocortisone hard capsules, Diurnal, UK) when taken twice-daily, has been shown to replicate the normal overnight rise in serum cortisol concentration and provide physiological levels throughout the day. We have undertaken a double-blind, double-dummy, two-way cross-over, randomised, phase II study of efficacy, safety and tolerability of modified-release hydrocortisones: Chronocort® Versus Plenadren®.

Aim

To test the hypothesis that Chronocort® provides more physiological waking cortisol levels than Plenadren®.

Methodology

The study was conducted across 8 sites in the UK and Germany. Male and female patients, aged $\geq$18 with confirmed PAI (defined as morning pre-dose cortisol $<$ 50 nmol/l) on stable therapy over the preceding three months and not currently treated with Chronocort®/Plenadren®. Participants with congenital adrenal hyperplasia (CAH), secondary or tertiary AI were excluded. Each participant was randomised on a 1:1 basis to either; treatment sequence I (Chronocort® first) or treatment sequence II (Plenadren® first) taking a 25 mg total daily dose for 4 weeks; either Plenadren® 25 mg in the morning or Chronocort® 10 mg in the morning and 15 mg at night with the associated dummy preparation followed immediately by the other treatment. The pre-dose morning serum cortisol level was assayed at baseline and after each treatment period. A physiological morning cortisol level was defined as a pre-dose level of $>$140 nmol/l. Secondary measures included: morning fatigue measured using the Multidimensional Assessment of Fatigue (MAF) questionnaire and the PROMIS® 7b questionnaire; QoL was assessed using the EuroQol 5-level Standardised Health Questionnaire (EQ-5D-5L™); Health-related Quality of Life in Addison's disease (AddiQoL) questionnaire and the 36-Item Short Form Health Survey (SF-36®) questionnaire.

Results

Of 49 evaluable participants with PAI, 45 achieved a physiological morning cortisol after four weeks of Chronocort® compared with 2 after four weeks of Plenadren® ($P<0.0001$). The mean (standard deviation) waking cortisol was 422.85 (203.50) vs 36.98 (113.87), respectively.Conclusion: Chronocort® provides more physiological waking cortisol levels than Plenadren®. Further analysis will test the hypothesis that waking with physiological cortisol levels improves fatigue and QoL in patients with PAI.

Background

Confirmation of primary aldosteronism (PA) with the saline infusion test (SIT) requires accurate measurements of plasma aldosterone, best achieved by mass spectrometry. Performance of the test and appropriate cut-offs remain inadequately defined.Design and methods: This prospective multicenter cohort study involved 451 patients with suspected PA who underwent a seated SIT. Among these, there were 90 and 76 in whom PA was respectively confirmed and excluded based on outcome assessment. Thirty-one patients who were not adrenalectomized underwent a repeat SIT at outcome assessment. Diagnostic performance and optimal cut-offs were determined from receiver operating characteristic (ROC) curves.

Results

Analysis of ROC curves indicated higher ($P=0.020$) areas under curves for the SIT than the aldosterone:renin ratio (0.968 vs 0.905). A cut-off of 141 pmol/l for the post-SIT aldosterone provided 100% sensitivity at a sub-optimal specificity of 87% for disease confirmation. A cut-off of 219 pmol/l provided improved specificity of 95%, though at a sensitivity of 87%. Among the 31 patients in whom the SIT was repeated, there were five (16%) in whom post-SIT aldosterone concentrations fell discordantly on both sides of the 141-219 pmol/l concentration range.

Conclusions

The SIT with mass spectrometric measurements of aldosterone provides superior performance over the ARR for diagnosis of PA, but is suboptimal as confirmatory test. Inaccuracy and discordance of the SIT indicate need for care in application and interpretation of the test. A cut-off for aldosterone above 219 pmol/l limits the false-positive rate to 5%, which may be suitable to select patients for adrenal venous sampling.

Background

DNA mismatch repair (MMR) maintains genomic integrity and stability. Inactivation of the MMR genes *MLH1*, *PMS2*, *MSH2*, and *MSH6* by somatic or germline variants or gene methylation causes MMR deficiency (dMMR) leading to microsatellite instability (MSI) and high tumour mutational burden. In many tumour entities, patients with dMMR/MSI respond well to immune checkpoint inhibitor (ICI) therapy. The clinical relevance of dMMR and MSI in adrenocortical carcinoma (ACC) remains uncertain.

Objective
To systematically investigate MMR gene variants and methylation, MMR protein expression, and MSI in patients with ACC and to test for their association with clinical variables including response to ICI.
Methods
Immunohistochemistry of MLH1, PMS2, MSH2, and MSH6 was performed in 109 ACC tissues with available germline and somatic MMR gene variants by whole-genome ($n=14$), exome ($n=7$) or targeted-panel sequencing ($n=88$). Pathogenic/likely pathogenic *MMR* variants were confirmed by Sanger-sequencing. Methylation status was evaluated by multiplex ligation-dependent probe amplification in patients with dMMR tumours. Microsatellite analysis of dinucleotide and mononucleotide microsatellite loci *NR21*, *NR27*, *BAT40*, and *KCNJ5* were analysed by plex PCR in 99 patients. Clinicopathological data were analysed retrospectively.
Results
Immunohistochemistry showed dMMR in 15/109 cases (13.8%) with prevalence of MSH6-loss either alone ($n=3$) or associated with MSH2-loss ($n=4$), MLH1/PMS2-loss ($n=1$), or as tetra-loss ($n=1$). Hormone secretion ($P=0.31$), ENSAT stage ($P=0.53$), Ki67% ($P=0.12$), S-GRAS score ($P=0.23$), history of other malignancy ($P=0.19$), progression-free (HR=1.21, 95%CI=0.63-2.31, $P=0.57$) and disease-specific survival (HR=1.26, 95%CI=0.58-2.71, $P=0.56$) did not differ between patients with and without dMMR. Weiss score was significantly higher in dMMR tumours ($P=0.008$). Ten patients with dMMR tumours had pathogenic/likely pathogenic germline ($n=4$) or somatic ($n=5$) *MMR* variants or *MLH1* hypermethylation ($n=1$), but plex PCR showed MSI only in 3 cases. Among patients without dMMR, few cases had germline ($n=1$) or somatic ($n=1$) *MMR* variants or MSI ($n=1$). 4/5 patients with dMMR and/or *MMR* variants who received ICI did not respond. A single patient with germline *MSH6* variant, tumoural dMMR, but lack of MSI, was stable on immunotherapy for 12 months.
Conclusion
This is the first large systematic multiparameter study of dMMR/MSI in ACC. Loss of MMR protein expression is rare in ACC. MSI is infrequent even in patients with dMMR at immunohistochemistry. Germline variants in MMR genes (Lynch syndrome) are found in 4.5% of ACC and not always associated with dMMR/MSI. Different from other cancers, dMMR in ACC is not associated with histopathological and clinical characteristics or prognosis, including response to immunotherapy.

Factors that influence pheochromocytoma penetrance in MEN2A Syndrome

Sofia-Maria Lider-Burciulescu [1,2], Monica Livia Gheorghiu[1,3], Andrei Muresan[3], Stanescu Laura-Semonia[1,3], Anda Dumitrașcu[3] & Corin Badiu[1,3]
[1]Carol Davila University of Medicine and Pharmacy, București, Romania; [2]"Ana Aslan" National Institute of Geriatrics and Gerontology, Endocrinology, Bucharest, Romania; [3]C.I. Parhon National Institute of Endocrinology, București, Romania

Introduction
It is known that phaeochromocytoma penetrance in MEN2A syndrome steadily increases with age. In general, MEN2A related pheochromocytomas (PHEOs) have a benign evolution; however, some of them have an aggressive behaviour despite the same genetic background as the benign forms.
Aim
To evaluate potential factors that may influence PHEO penetrance and tumor dimensions (age at diagnosis, MTC aggressiveness or genetic status).
Material and Methods
Patients with PHEOs in MEN2A syndrome were retrospectively retrieved from the database of a Tertiary Reference Centre from Romania. Genetic status, age at diagnosis, tumor dimensions, localisation, and the presence of other syndromic components were collected.
Results
Twenty-two patients from fifteen families were included in this study. Fourteen patients (63.6%) were women and 8 (36.4%) were men. Mean age for diagnosis was 36.6±2.8 years. Mean tumour diameter was 46.4±3.5 mm. Eighteen patients (12 families) had a pathogenic variant of exon 11 [p.Cys634Trp (55.5%), p.Cys634Arg/Tyr (22.2%/16.6%); p.Asp631Tyr (5.5%)] while 4 (3 families) of them had a pathogenic variant (PV) of exon 10 [p.Cys618Arg (75%), and p.Cys618Tyr (25%)]. Mean age in families with exon 11 was lower (35.6±2.9 years) than in exon 10 (41±9.2 years). Mean tumor diameter was non-significantly higher in exon 11 PV than in exon 10 (48±4 vs 38±5.8). In 3 patients PHEO was the first manifestation of the syndrome all with PV of exon 11, while in 4 CMT was the first manifestation of the disease. In other 15 patients CMT and PHEO were simultaneously diagnosed. Patients with exon 10 had a more aggressive form of CMT than those with exon 11. Regarding PHEO localisation, 31.8% ($n=7$) were right sided, 27.3% ($n=6$) were left sided, and 40.9% ($n=9$) presented bilateral PHEOs, four synchronous and five metachronous. Patients with bilateral disease tended to have a familial lateralisation pattern. Regarding tumor natural evolution, maximal tumor diameter did not correlate to age of diagnosis in any of the families.
Conclusion
Exon 11 mutation is the most frequently reported in MEN2A related PHEOs. p.Cys634Trp is the most pathogenic variant of exon 11, while in exon 10 was p.Cys618Arg. Patients with mutation in exon 11 tended to develop PHEOs in younger age than those with mutation in exon 10, and to have more rapidly evolving tumors. MTC was more aggressive in patients with exon 10 mutations. PHEOs in MEN2A tended to have a familial lateralisation pattern.

Baseline hormonal profiling and post-surgical outcomes in patients with obesity undergoing bariatric surgery: Results from the novara experience

Edoardo Luigi Maria Mollero[1], Chiara Mele[1], Maria Teresa Samà[1], Flavia Prodam[1,2], Marina Caputo[1,2], Martina Romanisio[1], Edda Cava[2], Sergio Riso[3], Gianluca Aimaretti[1] & Paolo Marzullo[1]
[1]SCDU Endocrinologia, University of Eastern Piedmont, Department of Translational Medicine, Novara, Italy; [2]University of Eastern Piedmont, Department of Health Sciences, Novara, Italy; [3]Dietetica e Nutrizione Clinica, AOU Maggiore della Carità, Novara, Italy

Purpose
Obesity is a chronic disease with a high risk of cardiovascular and metabolic comorbidities, hence a decrease > 5-10% of the initial body weight (BW) is essential to achieve improvement of cardiometabolic dysfunction. Bariatric surgery currently represents a valid therapeutic option in this clinical setting, especially in patients unresponsive to a dietary-nutritional approach. Obesity instigates adaptive hormone changes, yet the role of baseline hormone setting on postsurgical outcomes in terms of excess weight loss (%EWL) and post-nadir weight regain (%PNWR) remains unclear and warrants investigation.
Methods
Out of 202 patients with morbid obesity candidate to bariatric surgery enrolled between January 2017- December 2022, 79 patients (M/F: 16/63; age: 47.3±1.2 years; BMI: 44.2±0.5 kg/m^2) eventually admitted to sleeve gastrectomy ($n=72$) or gastric bypass ($n=7$) after multidisciplinary assessment were retrospectively analyzed for clinical, and biochemical data at baseline and after 6, 12 and 24 months since surgery. Baseline hormone assessment included TSH, 24 h urinary free cortisol (UFC) IGF-I and prolactin levels.
Results
As expected, bariatric surgery caused a progressive reduction in BW, with nadir BW being reached after 12 months (ΔBMI -29±0.9%; %EWL, 70.3±2.9%) and 77% of patients achieving a %EWL ≥50%, regardless of the surgical technique. Surgical treatment resulted in remission of hypertension and type 2 diabetes mellitus in 62.5% and 64% of patients, respectively. Patients who did not go into complete remission achieved an improvement in disease that required a reduction in therapy. The glycolipid profile of the patients showed statistically significant differences at 12 months following surgery. At baseline, no abnormalities in hormone levels were observed. The influence of hormone setting on patients' response in terms of %EWL ≥ 50% and %PNWR was null. Likewise, we failed to record associations between UFC, IGF-I or prolactin levels and post-surgical changes in BW or waist, although TSH was associated with 6-mo changes in BW ($r=$−0.74, $P<0.05$) after controlling for age and gender. Alternatively, there were correlations between %EWL and baseline BMI (r−0.39, $P<0.001$), %PNWR (r0.22, $P=0.05$), and age (r−0.20, $P=0.03$). The inverse correlation between baseline BMI and %EWL was confirmed by stepwise multivariate regression analysis (β=−0.45, $P=0.002$).
Conclusion
Bariatric surgery is an effective tool in inducing weight loss in adults with obesity and its effectiveness relates inversely to initial BMI. Baseline hormones play no role on postsurgical outcomes except for TSH, which potentially hints at the influence of the thyrostat on individual responsiveness to this weight-reducing approach.

Dysregulation of RNA-Exosome machinery in MASLD-HCC progression

Víctor J. Fernández-Ramírez[1,2,3,4], Samanta Lozano de la Haba[1,2,3,4], María Isabel Pozo-Relaño[1,2,3,4], Rafael J. Nieto-Santiago [1,2,3,4], Natalia Hermán-Sánchez[1,2,3,4], Prudencio Sáez-Martínez[1,2,3,4], Manuel Rodriguez-Peralvarez[1,4,5], Raúl M. Luque[1,2,3,4], Juan Luis López-Cánovas[1,2,3,4] & Manuel D. Gahete[1,2,3,4]
[1]Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [2]University of Cordoba, Department of Cell Biology, Physiology and Immunology, Cordoba, Spain; [3]Reina Sofía University Hospital, Cordoba, Spain; [4]Reina Sofía University Hospital, Department of Hepatology and Liver Transplantation, Cordoba, Spain; [5]CIBER Hepatic and Digestive Diseases (CIBERehd), Cordoba, Spain

Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common cause of chronic liver disease and is the leading cause of liver-related morbidity and mortality. MASLD is rapidly becoming a major aetiology for the development of hepatocellular carcinoma (HCC), the most common liver cancer. As the incidence of MASLD continues to rise, it is crucial to understand the molecular alterations that lead to HCC. Previous studies have revealed a significant alteration of the mechanisms controlling RNA processing and metabolism in MASLD-related HCC. However, the implication of the RNA-Exosome machinery, which is crucial for RNA processing, degradation, and quality control, is still to be fully defined. This work aims to elucidate the alteration of the RNA–Exosome components in MASLD and MASLD-related HCC, and its correlation with clinical parameters, in order to identify early biomarkers and new therapeutic opportunities. Therefore, we analyzed in silico the mRNA and/or protein expression levels of RNA-Exosome components in MASLD, MASLD-related HCC, Metabolic Dysfunction Associated Steatohepatitis (MASH), HCC and control (healthy and/or non-tumor) samples from fourteen cohorts: two retrospectives ($n=94$ and $n=62$ respectively) and twelve in silico (Zhou, GSE63067, Roessler 2, Mas, GSE135251, Wurmbach, TGCA, GSE147304, GSE167523 GSE185051, Arendt and Pinyol). Different bioinformatics approaches were performed, using software such as R, MetaboAnalyst, Gene Set Enrichment Analysis (GSEA) and Single-sample GSEA (ssGSEA). The results revealed a heterogeneous pattern of dysregulation in gene/protein expression of most of the RNA-Exosome components, with percentages of altered elements ranging from 7,7% (retrospective cohort) to 76,7% (Zhou cohort). The most consistently altered elements in MASLD cohorts were EXOSC10, ZFC3H1, PABPN1, EXOSC8, EXOSC4 and EXOSC9; standing out PABPN1, EXOSC4 and ZFC3H1, as they were also the most dysregulated genes in HCC patients. Expression of these components was associated with the enrichment in oncogenic traits (e.g., DNA repair pathway and expression of MYC targets), smggesting important clinical implications. In conclusion, analysis of gene expression dysregulation patterns in RNA-Exosome elements reveal a strong dysregulation in MASLD and MASLD-related HCC samples, which were associated with clinical parameters and with the dysregulation of oncogenic pathways.

RC4.3

Irrespective of diet composition, cycles of low-calorie intake imprint a unique hepatic signature throughout the secretome to influence organismal energy balance

Juan Luis López-Cánovas[1], Beatriz Naranjo-Martinez[1] & Alberto DIaz-Ruiz[1,2]
[1]IMDEA Food Institute/Instituto IMDEA Alimentación, Madrid, Spain; [2]CIBER Pathophysiology of Obesity and Nutrition (CIBERobn)

Identifying effective strategies and underneath molecular signatures is crucial to combat certain metabolic diseases with increasing incidence such as obesity and MASLD (metabolic dysfunction-associated steatotic liver disease). The hepatic secretome plays a crucial role at controlling global energy metabolism and inflammation in MASLD. However, the interplay between diet composition and the eating architecture on the dynamic response of secretome as a tool to improve disease outcomes remains unknown. Under these conditions, we aim to elucidate the influence of the hepatic secretome on the energetic homeostasis as a potential therapeutic mechanism in metabolic diseases. To this end, male C57BL/6 mice (1 year old) were subjected to 5 months of 4:10 feeding cycles [4 days of very low-calorie intake (VLCI) followed by 10 days of ad libitum feeding] under Standard (SD) and high-fat diet (HFD) feeding regime. Liver RNAseq was performed, and the modulation of secretome genes was studied by associating their expression with physiological data, mouse parameters, and biological energy homeostasis. VLCI effectively reduces body weight and fat mass, improving physical performance and glucose regulation. Hepatic RNAseq identified a total of 1607 secretome genes. A Heatmap and PCA analysis significantly distinguished the secretome profile between VLCI and ad libitum (AL) mice, under SD and HFD feeding regime. Subsequently, a Volcano Plot analysis between VLCI and AL mice, identified a molecular signature of 269 and 135 differentially expressed secretome genes [$FC>1.2$, $P<0.05$] induced by VLCI under Standard and high-fat diets, respectively, of which, a VLCI-specific signature of 46 genes were over-expressed and down-expressed identically in both SD and HFD. Moreover, a Gene Ontology analysis revealed specific metabolic pathways (cholesterol metabolism, regulation of kinase activity, etc.) related with VLCI intervention, independently of diet composition (SD or HFD). Finally, the VLCI-imprinted signature correlated with energy balance signals in the liver and plasma, including insulin, mTOR pathway, or beta-hydroxybutyrate. In summary, this study not only upholds the effectiveness of fasting-based strategies to enhance physiological health but also identifies a strong and dynamic modulation of the secretome, identifying VLCI-specific signature independent of diet composition. Therefore, our data smggest that secretome modulation could have a therapeutic impact on metabolic diseases involving energy balance dysregulation.

The beta-2-adrenoreceptor agonist fenoterol increases resting enery expenditure without activation of brown adipose tissue in humans

Laila Füchtbauer[1], Jaël Senn[1], Carole Baumann[1], Anninja Isenrich[1], Laura Ehlen[2], Marceline Fuh[2], Jörg Heeren[2] & Matthias Betz[1]
[1]University Hospital Basel and University of Basel, Department of Endocrinology, Diabetes and Metabolism, Basel; [2]University Medical Center Hamburg-Eppendorf, Center for Experimental Medicine, Department of Biochemistry and Molecular Cell Biology, Hamburg, Germany

Brown adipose tissue (BAT) may directly dissipate energy into heat and is associated with a metabolically favorable phenotype. Cold exposure activates BAT via the sympathetic nervous system and its transmitter norepinephrine. In rodents, the activation is facilitated by the β3-adrenoreceptor (β3-AR). In humans treatment with the β3-AR agonist mirabegon leads to a rather weak activation of BAT as compared to a cold stimulus. In vitro studies in cell lines from human BAT and have pointed towards the β2-AR as a possible activator. We studied the effect of an infusion with the potent and selective β2-AR agonist fenoterol on human resting energy expenditure (REE) and BAT activity compared to a mild cold stimulus in normal weight volunteers. REE was measured continously with indirect calorimetry, skin and core temperature were recorded, and BAT activity was quantified in the supraclavicular BAT depot by 18F-FDG-PET/CT after each intervention. Blood was sampled for metabolic analysis. Resting EE at baseline was similar before the two interventions. Cold exposure resulted in a mean increase in EE of 195 kcal/24 h ($P=0.044$ vs baseline) and fenoterol infusion increased EE by 358 kcal/24 h ($P<0.0001$). The mean standardized uptake value (SUVmean) of supraclavicular BAT was 3,06 (IQR 2,19;3,64) g/ml after cold exposure but only 1,66 g/ml [1,63;1,70] after fenoterol infusion. Correspondingly, the active BAT volume was 90 (26;190) ml vs 3 (1;16) ml, respectively. Analysis of the lipidome revealed higher levels of mono- and poly-unsaturated fatty acids after both interventions, which was stronger after fenoterol than after cold exposure ($P<0.0001$). In contrast, in all other lipid categories, fenoterol failed to replicate the pattern, which a cold stimulus induces in the lipidome. The main side effect of fenoterol was a feeling of warmth and a mild tachycardia. In conclusion fenoterol increased REE more than cold exposure but did not activate human BAT. This indicates that the human β2-AR does not play an important role in BAT activation which is underscored by differential lipid profiles after both interventions. However, β2-AR mediated increases in REE might be an attractive therapeutic target to treat obesity.

Precision medicine in type 2 diabetes mellitus: Unraveling the role of TCF7L2, CTRB1/2, and GLP-1R genetic variants in response to treatment with glucagon-like peptide-1 receptor agonists

Artemis Kyriakidou[1], Angeliki Kyriazou[1], Theocharis Koufakis[2], Yiannis Vasilopoulos[3], Iakovos Avramidis[4], Stefanos Baltagiannis[5], Dimitrios Goulis[6], Pantelis Zebekakis[1] & Kalliopi Kotsa[1]
[1]AHEPA University Hospital, Division of Endocrinology and Metabolism - Diabetes Center, 1st Department of Internal Medicine, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Hippokration General Hospital, 2nd Propedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece; [3]University of Patras, Department of Biology, Section of Genetics, Cell Biology and Development, Patras, Greece; [4]G. Papanikolaou General Hospital, Diabetes Center, Department of Internal Medicine, Thessaloniki, Greece; [5]General Hospital of Kastoria, Diabetes Outpatient Clinic, Kastoria, Greece; [6]Medical School, Aristotle University of Thessaloniki, Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynecology, Thessaloniki, Greece

Background and Aims
Our objective was to assess the association between genetic polymorphisms in *TCF7L2*, *CTRB1/2* and *GLP-1R* genes and inter-individual variability in response to treatment with glucagon-like peptide-1 receptor agonists (GLP-1 RAs) in terms of glycemic control and weight loss among Greek individuals with type 2 diabetes mellitus (T2DM) and to identify potential predictors of response to GLP-1 RA therapy.
Materials and Methods
Patients ($n=191$) treated with either liraglutide, exenatide, or lixisenatide for at least 6 months were enrolled in the study. Genotyping of *TCF7L2* rs7903146 (C>T), *CTRB1/2* rs7202877 (T>G) and *GLP-1R* rs367543060 (C>T) variants was conducted, using real-time PCR, while clinical and laboratory assessments were performed at baseline, 3- and 6-months post-treatment. Glycemic responders were defined as patients meeting one of the following criteria: i) HbA_{1c} <7% at 3 or 6 months after GLP-1 RA initiation, ii) reduction of baseline HbA_{1c} by ≥1% after 3 or 6 months of therapy, and iii) maintenance of HbA_{1c}<7% that a patient had before switching to GLP-1 RA, after 3 or 6 months of treatment. Weight loss responders were defined as individuals who achieved weight reduction ≥3% from their baseline weight after 3 or 6 months of GLP-1 RA administration.
Results
The minor allele frequencies for *TCF7L2* rs7903146, *CTRB1/2* rs7202877 and *GLP-1R* rs367543060 genetic polymorphisms were 79.1, 15.7 and 0%, respectively. 136 (71%) individuals were classified as glycemic responders and 125 (65%) as weight loss responders. Carriers of at least one rs7903146 "T" allele and rs7202877 "G" allele demonstrated a comparable glycemic control and weight loss response to GLP-1 RAs with the respective homozygous wild-type genotypes [odds ratio (OR): 1.08, 95% confidence interval (CI): 0.5, 2.31, $P=0.85$ and OR: 1.35, 95% CI: 0.66, 2.76, $P=0.42$; OR: 1.4, 95% CI: 0.56, 3.47, $P=0.47$ and OR: 1.28, 95% CI: 0.55, 2.98, $P=0.57$, respectively). Weight and BMI decreased in both glycemic responders ($P<0.0001$) and non-responders ($P<0.0001$) after 6 months of treatment. Weight loss responders and non-responders exhibited a significant reduction in fasting glucose ($P=0.003$ and $P=0.0004$, respectively) and HbA_{1c} at 6 months ($P<0.0001$). Female sex (OR: 0.5, 95%, CI: 0.26, 0.94, $P=0.03$) and lower baseline weight (OR: 0.97, 95%, CI: 0.95, 0.99, $P=0.024$) were associated with improved glycemic and weight loss response to GLP-1 RA administration, respectively.
Conclusion
Our findings do not indicate a role of the studied variants in predicting response to treatment with GLP-1 RAs in Greek patients with T2DM.

Clinical use of 18F-fluoro-ethyl-tyrosine PET co-registered with MRI for diagnostic dilemmas in prolactinoma

Victoria van Trigt[1], Leontine Bakker[1], Ling Lu[2], Iris Pelsma[1], Marco Verstegen[3], Wouter van Furth[3], Lenka Pereira Arias-Bouda[2] & Nienke Biermasz[1]
[1]Leiden University Medical Center, Department of Medicine, Division of Endocrinology, Leiden, Netherlands; [2]Leiden University Medical Center, Department of Radiology, Section of Nuclear Medicine, Leiden, Netherlands; [3]Leiden University Medical Center, Department of Neurosurgery, Leiden, Netherlands

Purpose
To assess the utility of (^{18}F)fluoroethyl-L-tyrosine PET co-registered with magnetic resonance imaging (FET-PET/MRI^{CR}) in patients with difficult-to-localize prolactinoma to inform clinical decision making and treatment planning.
Methods
Retrospective cohort study of 17 consecutive patients with difficult-to-localize prolactinoma undergoing FET-PET/MRICR between October 2020 and Amgust 2022 for either (1) additional information in case of difficult remnants after transsphenoidal surgery (TSS) or pharmacological treatment, or (2) diagnosis in absence of a (clear) adenoma on conventional MRI at diagnosis or after treatment.
Results
FET-PET/MRI^{CR} identified a lesion in 14/17 patients, yet failed to identify active lesions in 2 patients with negative conventional MRI but prolactin >7.5 times upper limit of normal. FET-PET/MRI^{CR} results were inconclusive in 1 patient due to diffuse tracer uptake 10 weeks post-surgery. Foci on FET-PET/MRI^{CR} corresponded completely with the lesion on conventional MRI in 10 patients, partially in 3 patients, and new foci were identified in 4 patients. Functional imaging influenced clinical decision making in 15/17 patients: 7 patients underwent TSS after functional imaging, and 8 patients did not. One patient underwent surgery despite negative FET-PET/MRI^{CR} due to a high need for alternative treatment, and 1 patient underwent additional diagnostics due to inconclusive FET-PET/MRI^{CR} results. FET-PET/MRI^{CR} results were confirmed in all patients undergoing surgery: intraoperatively by identification of adenoma tissue in 5/8 patients, by positive histopathology in 6/8 patients, and by significant decrease in prolactin postoperatively in 7/8 patients. The surgical goal was achieved in 7/8 patients.
Conclusion
FET-PET/MRI^{CR} can be of added value in the preoperative decision-making process for selected patients with difficult to localize prolactinoma (remnants), or patients lacking a substrate on conventional MRI.

[1]Amsterdam UMC location AMC, Endocrinology and Metabolism, Amsterdam, Netherlands; [2]Amsterdam UMC location VUMC, Endocrinology and Metabolism, Amsterdam, Netherlands; [3]Amsterdam UMC location AMC, Radiology and Nuclear Medicine, Amsterdam, Netherlands; [4]Netherlands Cancer Institute, Nuclear Medicine, Amsterdam, Netherlands; [5]Amsterdam UMC location AMC, Neurosurgery, Amsterdam, Netherlands; [6]Leiden University Medical Centre (LUMC), Endocrinology, Leiden, Netherlands; [7]Northwest Clinics location Alkmaar, Internal Medicine, Alkmaar, Netherlands; [8]Medical Spectrum Twente, Internal Medicine, Enschede, Netherlands; [9]Amsterdam UMC location AMC, Epidemiology and Data Science, Amsterdam, Netherlands

Background
Patients with non-functioning pituitary macroadenoma (NFMA) currently have no established medical treatment options. Somatostatin analogues may decrease tumour size, but randomised controlled trials are lacking. In vivo somatostatin receptor assessment with ^{68}Ga-DOTATATE PET could help in selecting patients for treatment. We aimed to determine the effect of the somatostatin analogue lanreotide on tumour size in patients with a ^{68}Ga-DOTATATE PET-positive NFMA.
Methods
The GALANT study was an investigator-initiated, multicentre, randomised, double-blind, placebo-controlled, phase 3 trial performed in the Netherlands and funded by Ipsen Farmaceutica BV (EudraCT 2015-001234-22; NTR NL5136). We included adult patients with a suprasellar extending NFMA (≥10 mm), either surgery-naïve or postoperative remnant. Important exclusion criteria were previous sellar radiotherapy and use of dopamine receptor agonists. Somatostatin receptor expression in the NFMA was determined by ^{68}Ga-DOTATATE PET/CT, co-registered with pituitary MRI. A predefined sample of 44 patients with PET-positive NFMA were randomly assigned (1:1) to lanreotide 120 mg or placebo subcutaneous injections every 28 days for 72 weeks. The primary outcome was change from baseline in cranio-caudal tumour diameter in the intention-to-treat population. Participants, investigators and outcome assessors were masked to treatment allocation.

Results
49 patients were included in order to randomise 44 PET-positive patients between lanreotide ($n=22$) and placebo ($n=22$). Study treatment was completed in 13 (59%) lanreotide and 19 (86%) placebo participants; outcome data were available for all participants. The mean (SD) change in cranio-caudal tumour diameter was +1.2 (2.5) mm with lanreotide and +1.3 (1.5) mm with placebo; ANCOVA adjusted mean difference vs placebo –0.1 mm (95% CI –1.3 to 1.2, $P=0.93$). Sensitivity analyses corroborated the main results. Treatment discontinuation due to tumour progression occurred in three lanreotide and three placebo participants. Four participants in the lanreotide group withdrew due to adverse events and two due to other reasons. Adverse events occurred in 22 (100%) lanreotide and 21 (95%) placebo participants. Gastrointestinal complaints were most common, reported by 18 (82%) lanreotide and 8 (36%) placebo participants. There were no treatment-related serious adverse events.
Conclusion
Compared with placebo, lanreotide treatment did not reduce tumour size or growth of ^{68}Ga-DOTATATE PET-positive NFMA. The results of this first successfully completed double-blind and placebo-controlled intervention trial in NFMA patients do not support the use of somatostatin analogues in these patients.

Hypogonadotropic hypogonadism in patients with non-functioning pituitary adenomas before and after transsphenoidal surgery – A prospective study

Victor Hantelius[1,2], Gudmundur Johannsson[1,2], Tobias Hallen[3,4], Thomas Skoglund[3,4] & Oskar Ragnarsson[1,2]
[1]Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Department of Internal Medicine and Clinical Nutrition, Gothenburg, Sweden; [2]Sahlgrenska University Hospital, Department of Medicine, Gothenburg, Sweden; [3]Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Department of Clinical Neuroscience, Gothenburg, Sweden; [4]Sahlgrenska University Hospital, Department of Neurosurgery, Gothenburg, Sweden

Background
Hypopituitarism is common in patients with pituitary tumors. Still, the influence of pituitary tumor surgery on gonadal function and reproductive health remains underexplored.
Objective
a) To assess gonadal function and its impact on quality of life (QoL) in patients with non-functioning pituitary adenomas (NFPA) before and after transsphenoidal surgery (TSS), b) to identify factors that predict recovery of gonadal function following TSS, and c) to investigate sex-specific disparities related to hypogonadotropic hypogonadism (HH).
Methods
From September 2015 to December 2021, 122 patients with NFPA planned for TSS were evaluated. Health related QoL was assessed with two questionnaires, EQ-5D and The Psychological General Well-Being (PGWB) Index.
Results
Before surgery, 74 (61%) of 122 patients had HH. Of 49 women, 24 (49%) had preoperative HH, of whom 9 (38%) had recovered 12 months after TSS. Similarly, 50 (68%) of 73 men had preoperative HH of whom four (8%) recovered. Of 48 patients without preoperative HH, 16 (33%) developed it postoperatively. Of 49 women, 13 (27%) were of reproductive age (<50 years). Eight of these 13 (62%) had preoperative HH, of whom 5 (63%) recovered postoperatively and regained regular menstrual cycles. In contrast, 10 out of 13 (77%) men <50 years of age had preoperative HH, of whom only one (8%) recovered. After 12 months following TSS, the mean EQ-5D-index for the whole cohort ($n=122$) increased from 0.86 (interquartile range (IQR): 0.77–0.96) to 0.90 (IQR: 0.85–0.98) ($P<0.001$) and their PGWB-index from 94 (IQR: 80–112) to 104 (IQR: 93–119) ($P<0.001$). There was no difference in QoL between patients with and without HH, neither before nor after surgery. In the group of 76 with postoperative HH the mean EQ-5D-index increased from 0.86 (IQR: 0.76–0.96) to 0.89 (IQR: 0.82–0.96) ($P=0.011$) and the PGWB-index increased from 96 (IQR: 84–113) to 103 (IQR: 90–119) ($P=0.003$). In a multivariable logistic regression analysis, male sex ($P=0.022$) and high BMI ($P=0.036$) were associated with postoperative HH, but central hypothyroidism, adrenal insufficiency and growth hormone deficiencies were not.
Conclusions
HH is common in both men and women with NFPA requiring surgical intervention. The recovery rate following TSS is higher in women than in men. The QoL improves for the whole group after surgery. Male sex and high BMI are predictors for persistent postoperative HH.

A phase 1 clinical study to evaluate the safety, tolerability, pharmacokinetics and pharmacodynamics of AZP-3813, a novel, small peptide growth hormone receptor antagonist, in healthy subjects

Soraya Allas[1], Guillaume Ravel[1], Colm Farrell[2], Sophie Fillon[1], Taha Ould Rouis[1], Michael Culler[3], Michel Ovize[1], Mark Sumeray[3] & Aart Jan van der Lelij[4]
[1]Amolyt Pharma, Ecully, France; [2]ICON PLC, Reading, United Kingdom; [3]Amolyt Pharma, Cambridge, MA, United States; [4]Erasmus University Medical Center, Rotterdam, Netherlands

Background
Acromegaly is a rare disease typically caused by a benign growth hormone (GH)-secreting pituitary adenoma that stimulates over-production of insulin-like growth factor-1 (IGF1) from the liver. Treatment with somatostatin analog (SSA) monotherapy does not provide optimal control of circulating IGF-1 levels in the majority of patients. AZP-3813, a 16-amino acid, bicyclic GH receptor antagonist (GHRA) binds to the GH receptor and prevents endogenous GH from stimulating the production of IGF-1. In normal animals, AZP-3813 potently decreases circulating levels of IGF-1 and further suppressive effects are observed when combined with the SSA, octreotide. AZP-3813 is being developed as an add-on therapy for the treatment of acromegaly in patients insufficiently controlled with SSAs.
Aim
To evaluate the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of AZP-3813 in healthy subjects.
Methods
Randomized double-blind placebo-controlled single and multiple ascending dose studies (SAD and MAD, respectively) are being conducted. In the SAD study, 5 subjects received a single subcutaneous administration of 3 mg AZP-3813 or placebo (3:2) and 8 subjects received 10, 20, 40, 60, 90, 120 mg AZP-3813 or placebo (6:2). In the MAD study, 8 subjects received 10, 20, 40 mg AZP-3813 or placebo (6:2) QD for 14 consecutive days.
Results
Treatment was well tolerated in all subjects with no safety concerns. Cmax and AUC increased in a dose-proportional manner. The half-life of AZP-3813 was estimated to be 18-22 hours. In the SAD study, AZP-3813 induced a dose-related decrease in circulating IGF-1 levels at doses of 10 mg and above with a more prolonged reduction up to 72 hours at higher doses. In the MAD study, AZP-3813 induced a gradual and sustained dose-related decrease in circulating IGF-1 levels at 20 and 40 mg/day, with a larger effect after 2 weeks of dosing as compared to single administration at the same dose, consistent with a cumulative effect of repeated administration. Mean placebo-adjusted % change from baseline for the 20 and 40 mg cohorts were 19% and 44%, respectively. This study is ongoing, and updates on additional MAD cohorts will be reported at the meeting.
Conclusion
These data clearly demonstrate that the novel GHRA, AZP-3813, substantially decreases circulating IGF-1 levels in healthy individuals, thereby supporting further testing in patients with acromegaly.

Introduction
Disruption of the hypothalamic/pituitary axes may lead to hypopituitarism. Anterior pituitary deficiencies (APD) and arginine-vasopressin deficiency (AVP-D) are well established and are treated with hormone replacement. Over the last decade, preliminary studies support the presence of an oxytocin (OXT)-deficient state that might be clinically relevant in patients with hypopituitarism and hypothalamic damage (HHD). Therefore, identifying a provocative test to diagnose an OXT deficiency will be important. The corticotropin-releasing hormone (CRH) – commonly used for the differential diagnosis of ACTH-dependent Cushing's syndrome – is a promising candidate for such a test as it increases peripheral OXT secretion in animal models. This study aimed at examining the effects of CRH on endogenous OXT release in patients with HHD compared to healthy controls (HC). We hypothesized that OXT release after CRH would be lower in patients with HHD compared to HC.
Methods
This single-blind, randomized, placebo-controlled proof-of-concept study (NCT 04902235) with crossover assignment (CRH:placebo) was conducted at an academic medical center. Nineteen patients with HHD (10 females) and 20 HC (11 females) completed two main visits. We randomly assigned participants to receive either CRH (1.0 µg/kg) or placebo (0.9% normal saline) in the first visit. After a washout of $\geq$48 h participants received the alternative treatment. Fasting AM samples were collected over 120 minutes (T0, T15, T30, T45, T60, T90, T120) to assess OXT levels. The primary outcome was the change in OXT levels over time in response to CRH vs placebo in patients with HHD and HC. We used three-way ANOVA (factors treatment*participant*time) to evaluate the effects of CRH on OXT levels.
Results
Participants were balanced by age (median (IQR) 50.3 (22.8) years) and body mass index (27.5(5.6) kg/m^2). HHD had more depression symptoms, alexithymia and impulsivity (all $P<0.05$), as well as worse quality of life ($P<0.001$) and sexual function ($P<0.025$) compared to HC; 80% of patients with HHD presented with $\geq$3 APD and 75% had AVP-D. Baseline OXT concentrations were similar across groups ($P=0.822$). CRH administration did not impact OXT levels across groups over time, three-way interaction was not significant ($P=0.524$). No significant differences in OXT levels overtime were observed in the subgroup of patients with HHD and AVP-D compared to those without AVP-D.
Conclusion
The response of OXT after CRH administration does not seem sufficient for CRH to be pursued as a provocative test to diagnose an OXT-deficient state in HHD. The identification of a safe and feasible provocative test is required.

Etiology, treatment, and outcomes of sellar metastases: A single-center institutional experience

Julia Breu, Yining Zhao, Michael Buchfelder & Natalia Kremenevski
Friedrich-Alexander-Universität Erlangen-Nürnberg, Neurosurgery, Erlangen, Germany

Background
Metastases to the sellar region are extremely rare tumours in surgical series. The reported incidence has recently increased with advances in neuroimaging. Survival of patients with metastatic cancer has improved due to progress in oncologic therapies and diagnostics. Patients with sellar metastases (SM) follow a variable disease course that is not well defined.
Objective
The objective was to evaluate the clinical characteristics, surgical approaches, and survival outcomes of SM diagnosed and treated at our institution.
Methods
56 patients (29/51·8% women and 27/48·2% men) with histologically confirmed SM were identified between the years 1982 and 2022. Their data were retrospectively collected and analyzed.
Results
Breast cancer in women (23·2%) and renal cell cancer in men (14·3%) were the most common primary malignancies. The median age at diagnosis of SM was 64·8 years (range 19·8-83·7). Patients presented with visual deficits (92·3% [36/39]), cranial nerve palsies (50·0% [28/56]), and headaches (23·2% [13/56]). Diabetes insipidus was noted in four patients (7%). The mean tumor volume was 9·4$\pm$10·8 cm^3 (median 6·0 cm^3 [range 0·04-52·9]). In 13 patients (23·2%), SM were found before the diagnosis of the primary cancer. These were all cases of lung cancer. The mean time in months from primary cancer diagnosis to SM was 96·7$\pm$61·5 for breast, 99·5$\pm$50·4 for renal cell, 37·0$\pm$31·1 for gastrointestinal, and 46·0$\pm$14·1 for prostate cancer. SM occurred intra- and parasellar (8, 14%), supra- (17, 30%), and intra- and suprasellar (21, 38%). In most cases, surgery was performed through a transsphenoidal approach (58·8%) and the transcranial approach was used in 17 cases (30·4%). Seven patients (12·5%) underwent other procedures. Gross total resection was achieved in only 5 patients (9%). 35 patients (62·5%) received adjuvant radiotherapy. One year after surgery, 26 of 53 patients (49·1%) were alive, 19 (35·8%) were alive after two years, and only one (1·9%) was alive after five years. The mean duration of follow-up in months was 23·4$\pm$39·5 (median 9·6 [range 0·3-265·5]).
Conclusions
The diagnosis of SM has always been delayed. Lung cancer patients are most at risk for sellar metastasis at primary tumor diagnosis. The overall survival of patients diagnosed with SM is poor. The extent of the resection of the SM does not affect survival. Surgery is effective for mass reduction and rapid symptomatic improvement of vision and headache. In some cases, it provides a definitive diagnosis of the primary tumor.

Overview
Despite marked insulin resistance, patients with active acromegaly have low hepatocellular lipid content (IHL) and an unfavourable hepatic lipid composition (UI). As previously shown, inadequate mitochondrial activity in the liver might counteract lipid accumulation in the liver. The purpose of this study was to understand changes in hepatic metabolism, and lipidomic profile with therapy of acromegaly.
Methods
We prospectively included thirteen subjects (5 female; age: 48.3$\pm$12.7 years) with active acromegaly, which was diagnosed by elevated serum IGF-1 concentrations and lack of GH level suppression ($>$1 ng/ml) after ingestion of 75 mg glucose during a standardized two-hour oral glucose tolerance test (OGTT). For further metabolic characterization, participants underwent 31P/1H-7T-MR-spectroscopy of the liver, an OGTT, as well as plasma metabolomic and lipidomic profiling at baseline and twelve months after inclusion.
Results
As expected IGF-I decreased in all patients after therapy with 7 out of 11 patients reaching biochemical control, defined as IGF-1 below age and sex specific upper limit of normal (IGF-I-ULN) of 120% (IGF-I ULN: before 296.1$\pm$119.7%; after 115.3$\pm$52.4%; $P=<0.001$). Two patients were lost to follow up after twelve months. Insulin resistance, measured with HOMA-IR decreased significantly (median difference -20; $P<0.01$). IHL increased (median difference: 0.92%; $P=0.016$), whereas UI decreased significantly after twelve months (median difference -3.6%; $P=0.016$). The hepatic mitochondrial ATP synthase activity parameter relative to the IHL content also decreased significantly after twelve months. The lipid classes of ceramides, sphingomyelins, as well as lysophosphatidylcholines decreased significantly, whereas alkyl-phosphatidyl-ethanolamines increased significantly with improvement of acromegaly.

Conclusion

This study shows that with biochemical improvement of acromegaly, lipid composition as well hepatic mitochondrial activity changes significantly and might therefore indicate a causal relation between growth hormone (GH) excess and hepatic lipid accumulation. Furthermore, a reduction in lipid classes, like ceramides and sphingomyelins, which are associated with insulin resistance gives a more detailed insight into mechanisms of insulin resistance associated with acromegaly. In conclusion, this study offers valuable insight into direct antisteatotic pathways of GH as well as the direct effects of GH on the metabolomic profile.

In our country, as in others, there is a lack of data on the success rate of transsphenoidal surgery for producing pituitary adenomas. We evaluated the results reported in TESSPAIN, a retrospective multicenter nationwide project that includes all the TSS performed in the participating centers in the period between 2018 and 2022, both included. Surgical treatment success is defined according to the published criteria for each disease: normal IGF-1 and GH after 75 g of oral glucose less than 0.4 ng/ml for GH-producing adenomas; adrenal insufficiency for Cushinǵs disease (CD); serum prolactin less than 10 ng/ml for prolactinomas; and resolution of hyperthyroidism for TSH-producing adenomas. We evaluated the global success rate in each center, its correlation with the volume of surgeries and with the number of neurosurgeons performing the surgeries, and the relative success rate including only adenomas retrospectively deemed as curable by an expert endocrinologist in each center, I.e. excluding those with unresectable invasion (Knosp 3b or 4). A total of 911 patients were enrolled in the study: 436 patients with acromegaly, 323 patients with CD, 127 patients with prolactinomas, and 25 TSH-producing adenomas. Overall, the rate of successful surgery was 58.5% for GH-producing adenomas (255/425), which increased to 85.0% when only those considered potentially curable were included (255/370). The surgical success rate for CD was 71.5% (231/323), increasing to 74.8% when only surgically resectable adenomas were included (231/309). The cure rates for PRL-secreting adenomas were 39.4% (50/127) and 76.9% (50 of 65 surgically resectable adenomas), and for TSH-secreting adenomas were 88% (22/25) and 92% (22 of 23 surgically resectable adenomas). The success rate did not correlate with surgical volume, although it showed a positive trend for GH-secreting adenomas (p: 0.43). Although the overall surgical success rate showed no statistically significant differences between centers with a dedicated neurosurgeon and centers with more than one neurosurgeon, the mean surgical success rates were not significantly higher in acromegaly (60.4 ± 11.0 vs 52.1 ± 26.1; *P*: 0.24) and Cushing's disease (74.8 ± 18.6 vs 55.5 ± 34.3; *P*: 0.06). We show the results of TSS for producing pituitary adenomas in our country, with success rates similar to those reported in other countries. We note the high success rate in TSH-secreting adenomas, which probably reflects the earlier actual diagnosis, before the tumor develops invasiveness, and the trend towards better results in centers with a dedicated neurosurgeon, probably not significant because of the low volume of surgeries.

Introduction

Thyroid disorders are generally diagnosed based on thyroid stimulating hormone (TSH) outside the reference interval (RI), and subsequent free thyroxine (FT4) concentrations. Most laboratories do not provide age-specific RIs for TSH and FT4 beyond childhood, although it is known that TSH concentrations vary with age which may be important to take into account. Therefore, we aimed to establish age-specific RIs for TSH and FT4 throughout life using an indirect method for four commonly used immunoassay platforms. Also, we determined whether using age-specific RIs would result in reclassification of thyroid disease diagnoses in adults.

Methods

Indirect RIs for TSH (TMC) and FT4 (RefineR) using four different immunoassay platforms (Roche, Abbott, Siemens, Beckman) were established using retrospective data from 13 Dutch laboratories (>7 million TSH and >2 million FT4 unique requests). RIs were evaluated per manufacturer. Age groups were established from 2 to 20 years by 2-year categories, followed by decade categories between 20 and 100 years.

Results

TSH upper reference limits (URLs) and FT4 lower reference limits (LRLs) were higher until the age of 10 to 12 years and decreased towards adulthood. The URLs of FT4 were stable with a dip during puberty. In adulthood, TSH URLs increased

from the age of 60 years onwards, and even from 50 years in women, while FT4 URLs increased from 70 years onwards. The LRLs of TSH and FT4 remained stable during ageing. The use of our adult age-specific RIs resulted in a decrease in diagnoses of subclinical and overt hypothyroidism in women above 50 (15.7 to 7.3% and 2.7 to 2.3%, respectively), and in men above 60 years of age (13.7 to 8% and 2.0 to 1.6%, respectively) in our Roche dataset.
Conclusion
This study stressed the known importance of using age-specific RIs in children. In adulthood, age-specific reference intervals are currently not used in clinical practice. However, this study showed an important clinical relevance by reducing the diagnoses of subclinical hypothyroidism, and to a lesser extent, overt hypothyroidism. Therefore, implementation of adult TSH age-specific RIs in clinical practice should be strongly considered. Data is less uniform regarding FT4 age-specific RIs and more research should be performed before implementing these in clinical practice.

Interpretation of TPOAb measurement in pregnancy: An individual participant data meta-analysis

Yindi Liu[1,2], Joris Osinga[1,2], group Consortium on Thyroid and Pregnancy working on TPOAb[3], Ulla Feldt-Rasmussen[4], Sofie Bliddal[4], Robin Peeters[1,2], Arash Derakhshan[1,2] & Tim Korevaar[1,2]
[1]Erasmus University Medical Center, Department of Internal Medicine, Rotterdam, Netherlands; [2]Erasmus University Medical Center, Academic Center for Thyroid Diseases, Rotterdam, Netherlands; [3]Multiple (see https://www.consortiumthyroidpregnancy.org); [4]Copenhagen University Hospital, Rigshospitalet, Department of Medical Endocrinology and Metabolism, Copenhagen, Denmark

Objective
Thyroid peroxidase antibody (TPOAb) positivity is the most important risk factor for overt/subclinical hypothyroidism and partly guides levothyroxine treatment indications during pregnancy. TPOAb positivity is usually defined by manufacturer cutoffs which are typically derived in non-pregnant populations with concentrations ≥95th percentile. Besides the general lack of assay uniformity, current TPOAb positivity cutoffs are likely to underestimate gestational thyroid autoimmunity due to immune tolerance of pregnancy. To improve the clinical interpretation of TPOAb measurement and cutoffs during pregnancy, we investigated the association of TPOAb concentrations and commonly used thresholds with maternal thyroid function during pregnancy.
Methods
This study was embedded in the Consortium on Thyroid and Pregnancy. Participants with multiple gestation, pre-existing thyroid diseases, thyroid (interfering) medication usage, or pregnancy by IVF/ICSI were excluded. We assessed the nonlinear association of TPOAb percentiles with SD-scores of thyroid stimulating hormone (TSH) and free thyroxine (FT4), which indicated an effect threshold between the 80th-85th percentile. With ≤80th percentile as the reference group, we assessed the association of each consequent TPOAb percentile with maternal thyroid function, the risk of TSH 2.5-4.0 mU/l, and the risk of TSH >4.0 mU/l.
Results
The final study population comprised individual-participant data of 69,713 pregnant women from 24 cohorts. For TPOAb concentrations from the 89th percentile and upwards there was a higher TSH (effect estimates, range +0.13 SD to +1.05 SD), and from the 91st percentile and upwards there was a lower FT4 (effect estimates, range -0.08 SD to -0.49 SD). Pregnant women with TPOAb concentrations ≥89th percentile had a statistically significant higher risk of TSH 2.5-4.0 mU/l (range ORs: 1.40 for the 89th percentile to 5.96 for the 100th percentile) and a higher risk of TSH >4.0 mU/l (range ORs: 1.92 for the 89th percentile to 38.46 for the 100th percentile). The associations of TPOAb percentiles with TSH and FT4 SD-scores were stronger during early pregnancy than during late pregnancy, fitting with patterns of hCG stimulation and immune tolerance (P for interaction <0.001 for TSH and <0.001 for FT4).
Conclusion
We show that TPOAb concentrations below the manufacturer cutoffs may already reflect clinically relevant thyroid autoimmunity during pregnancy. High normal TPOAb concentrations could be interpreted differently in pregnant women, especially for those in whom the TPOAb status could (partly) define a treatment indication.

Maternal thyroglobulin and thyroid function during pregnancy and offspring neurodevelopment

Tessa Mulder[1], Mònica Guxens[2], Sarah Bath[3], Mariana Dineva[3], Amaia Irizar Loibide[4], Nerea Lertxundi[4], Maria Luisa Rebagliato Ruso[5], Henning Tiemeier[1,6], Robin Peeters[1] & Tim Korevaar[1]
[1]Erasmus University Medical Center, Rotterdam, Netherlands; [2]ISGlobal, Barcelona, Spain; [3]University Of Surrey, United Kingdom; [4]Biodonostia Health Research Institute, San Sebastian, Spain; [5]Jaume I University, Castelló de la Plana, Spain; [6]Harvard T.H. Chan School of Public Health, Boston, United States

Background
Low maternal urinary iodine concentration (UIC) during pregnancy has been associated with lower child IQ and differences in brain morphology. However, UIC is highly variable as it is a reflection of 24-h urinary intake rather than long-term iodine status. Thyroglobulin (Tg) might be a more sensitive biomarker of the long-term maternal iodine status.
Aim
To study whether maternal Tg is associated with maternal and newborn thyroid hormone concentrations, offspring IQ and brain morphology and if these associations differ by UIC.
Methods
We selected participants from two population-based prospective cohorts: Generation R (the Netherlands) and INfancia y Medio Ambiente (INMA; Spain) with available measurements of maternal Tg and thyroid function at 13 weeks of gestation (n=4,438 women) or at birth (n=2,082 mother-child pairs), early childhood IQ (n=2,984; age 4.5 and 6 years) or late childhood IQ (n=2,569; age 9 and 13 years), and offspring brain morphology at 10 years (n=1,197). The associations of Tg with TSH and FT4 concentrations, IQ and brain MRI outcomes were studied with multivariable linear regression.
Results
Higher maternal Tg was associated with lower TSH (P<0.001), higher FT4 (P<0.001) and lower IQ in early childhood (-0.06 point per 1 ng/ml Tg, P=0.02). Tg was not associated with cord blood TSH or FT4, late childhood IQ or brain morphology. We found no clear evidence of effect modification by UIC.
Conclusions
Tg is associated with thyroid function during pregnancy and some markers of offspring neurodevelopment. However, further research should determine the added value of Tg in addition to UIC for defining iodine status.

Local treatment improves outcome of RAI - Refractory differentiated thyroid carcinoma (DTC) patients irrespectively of tyrosine kinase inhibitors (TKI) treatment: a single center experience

Olga Karapanou[1], Kanella Kantreva[2], Stavroula A. Paschou[2], Marina Michalaki[3], Maria Alevizaki[2] & Katerina Saltiki[2]
[1]Endocrine Department, 401 General Military Hospital of Athens, Athens, Greece; [2]Endocrine Unit, Department of Clinical Therapeutics, National and Kapodistrian University, Athens, Greece; [3]Division of Endocrinology-Department of Internal Medicine, School of Health Sciences, University of Patras, Patras, Greece

Purpose
Although the majority of differentiated thyroid cancer (DTC) patients have favorable outcome, approximately up to 20% of them may develop metastatic and/or locoregional disease persistence. One-third of those patients may not respond to the treatment with radioiodine (RAI refractory DTC, RAI-R DTC). There are few reports of real-life experience concerning the clinical course and the treatment modalities that have been used in patients with RAI-R DTC.
Methods
We conducted a retrospective study focusing on the clinical characteristics at diagnosis, the location and time interval of the appearance of metastatic lesions and the characterization of RAI-refractory tumors, the treatment modalities performed (local therapies and/or systemic treatment), the response to therapy and the disease progression rate.
Results
Patients with radioiodine refractory thyroid cancer (RAI-R DTC, n=122, 44.3% men, age-at-diagnosis 51.98±15.8 years, were followed-up for 9.5 years (1.4-50). Patients ≥55 yrs at-diagnosis had more frequently follicular/oncocytic DTC, increased tumor size, metastatic disease and worse outcome (P=0.015) compared to younger. Patients were divided in two groups: those with only cervical persistence (Group 1), n=27 (22.1%), and those with distant

metastases (Group 2), $n=95$(87.9%). In Group1 29.6% underwent >2 surgeries, 14.8% cervical external beam radiation therapy (EBRT), one radiofrequency-ablation (RFA), one sorafenib. The final outcome was: partial response (PR) 4(14.8%), stable disease (SD) 23/27(85.2%). In Group2 40% underwent >2 locoregional surgeries, 28.4% EBRT, 6.3% RFA. For distant metastases 42.1% received local therapies, 47.4% TKIs. Metastases stabilization with local procedures was achieved in 33.7% (18/45 while receiving TKI). Group1 patients were younger, with smaller tumors, had more frequently classical PTC ($P=0.005$) and more favorable outcome ($P<0.001$). In Group2 *sorafenib* was administered in 30 patients (median PFS 1.5 yrs, OS 2.7 yrs), lenvatinib in 31 (median PFS 2 yrs, OS 3.581 yrs), cabozantinib in 7. Overall, for *patients with metastatic disease* the final outcome was: PR 7/95 (7.4%) SD 38 (40%) PD 50(52.6%), 34/95 (35.8%) died of disease progression, 7/95 (7.4%) died of unrelated causes; in Cox-proportional-hazard analysis, for the total follow-up period, when age-at-diagnosis, TKI administration, local therapies, local surgeries, soft-tissue invasion, tumor size and histology were included in the analysis, the age-at-diagnosis and the administration of local therapies were predictors of more favorable OS and CSS ($P<0.02$).

Conclusions

In RAI-R thyroid cancer patients with metastatic disease younger age at diagnosis and the implementation of local therapies are associated with a more favorable outcome

Unusual manifestation of thyroid hormone receptor ß resistance

Dovile Denaite[1], Edward Visser[2] & Ruta Navardauskaite[1,3]
[1]Department of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Academic Center For Thyroid Disease, Department of Internal Medicine, Erasmus Medical Center, Rotterdam, The Netherlands; [3]Lithuanian University of Health Sciences, Medical Academy, Institute of Endocrinology, Coordinating center for rare and undiagnosed diseases Lithuanian University of Health Sciences hospital Kauno Klinikos, Kaunas, Lithuania

Introduction

Resistance to thyroid hormone beta (RTHβ) is a rare genetic disorder characterized by impaired responsiveness to thyroid hormone in tissues expressing TRβ. This case report explores the clinical manifestation of RTHβ in a 15-year-old male presenting with acute and intensive chest pain and subsequent diagnostic challenges.

Case Report

At midnight, a 15-year-old male reported acute, sharp chest pain, prompting medical attention. Elevated troponin I levels initially raised concerns about myocardial infarction, but electrocardiogram and echocardiography excluded it. The patient is the third child in the family, denied chronic illnesses, and reported regular physical activity in the swimming pool. Family history revealed an older brother's sudden cardiac death at 29 during cycling. Physical examination revealed an asthenic constitution (BMI: 16.2 kg/m^2, -2.18 SD), palpable goiter I grade, and a heart rate of 113 bpm. Holter monitoring detected 365 ventricular extrasystoles and normal arteries were determined in coronography on 1st day of investigation. A cardiac MRI excluded myocarditis on 4th investigation day. Troponin I peaked at 102.95 µg/l, decreasing to 0.09 µg/l (N <0.04). Creatine kinase MB and Lactate dehydrogenase were elevated but eventually stabilized. Coagulation parameters, including D-dimer levels, remained within normal limits. Hormonal investigation revealed elevated concentrations of circulating free thyroxine (fT4 33.99 pmol/l (N 10–19)) and free triiodothyronine (fT3 8.65 pmol/l (N 4.7–7.2)) in the presence of no suppressed thyroid stimulating hormone (TSH 2.05 mU/l (N 0.48–4.7)). Autoantibodies (TgAb, TRAb, TPOAb) were negative; catecholamines were normal. The coronary spasm and myocardial infarction with non-obstructive coronary arteries (MINOCA) related to thyrotoxicosis were considered. Methimazole 10 mg daily was initiated, which led to an increase in TSH with persistently elevated FT4 and FT3 levels A diagnosis of TSHoma was considered but brain MRI showed a normal pituitary gland. Next, RTHβ was suspected, and genetic testing (Rotterdam Thyroid Centre), revealed a known R320C mutation in the thyroid hormone receptor ß gene. The treatment with thyrostatics was stopped after confirmed RTHβ. The beta-blocker is used due to tachycardia up to now.

Conclusion

This case underscores the challenges in diagnosing thyroid hormone receptor resistance, emphasizing the importance of accessibility of genetic testing and a multidisciplinary approach for comprehensive patient care.

Introduction

Pheochromocytoma, a rare catecholamine-secreting adrenal tumor, can cause hypertension and life-threatening complications. Hereditary cases have an increased risk of developing bilateral disease. Standard treatment involves radical adrenalectomy, leading to adrenal insufficiency in bilateral cases. Partial adrenalectomy aims to preserve adrenal function but has higher recurrence rates. This study compares outcomes of partial vs radical adrenalectomy in hereditary pheochromocytoma, focusing on cases with initial unilateral disease.

Methods

Standard treatment involves radical adrenalectomy, leading to adrenal insufficiency in bilateral cases. Patients were categorized by initial disease presentation and type of surgery. Patients were categorized by initial presentation and surgery type. Outcomes included contra- and ipsilateral recurrence, adrenocortical insufficiency, metastasis, and disease-specific survival.

Results

256 patients with hereditary pheochromocytoma were included of which 108 (42%) with *RET*, 67 (26%) NF1, 62 (24%) VHL, 11 (5%) *TMEM127* and 8 (3%) *MAX* mutations. There were 191 (75%) patients that initially presented with unilateral tumors. Radical adrenalectomy was performed in 223 patients (87%), in 75 of whom bilaterally. A partial adrenalectomy was performed in 33 (13%). Median follow-up was 100 months. In 191 patients who presented with unilateral pheochromocytomas, 50 (26%) developed contralateral tumors, at a median follow-up time of 56 months. Incidence of metachronous contralateral disease was highest in *VHL*, *RET* and *MAX* mutations. Ipsilateral recurrence was low, 6% in the partial group and 3% in the radical group ($P=0.47$). In patients who developped contralateral pheochromocytoma, partial adrenalectomy as first intervention resulted in 3/4 (75%) adrenal insufficiency compared to 1/7 (14%) when the second adrenalectomy was partial ($P = 0.09$). Overall, 153 (60%) patients underwent unilateral surgery and 103 (40%) bilateral (synchronously or metachronous). Among 103 patients with bilateral adrenalectomies, adrenal insufficiency risk was 13/28 (46%) in partial cases and 75/75 (100%) in radical cases ($P < 0.001$). Recurrence rate was 5/28 (18%) for cases with partial adrenalectomy vs 7/75 (9%) those with radical operation ($P = 0.30$). In survival analysis time till ipsilateral recurrence was significantly shorter in the partial group ($P=0.035$). Metastasis and disease-specific survival did not differ between groups.

Conclusion

In hereditary pheochromocytoma, partial adrenalectomy offers lower rates of adrenal insufficiency compared to radical surgery, with slightly higher recurrence rate for the partial adrenalectomy. Risk of metastasis and disease-specific survival was similar between groups. In patients with metachronous bilateral disease,

preserving adrenal function possibly more succesful when partial adrenalectomy was performed as the second intervention.

The presence of abortive changes in thyroid tumors serves as a strong indicator of underlying DICER1 mutations

Vincenzo Condello[1], James Roberts[2], Adam Stenman[3], Catharina Larsson[1], Kartik Viswanathan[4] & Christofer Juhlin[1]

[1]Karolinska Institutet, Department of Oncology-Pathology, Stockholm, Sweden; [2]Children's Healthcare of Atlanta, Department of Pathology and Laboratory Medicine, Atlanta, United States; [3]Karolinska University Hospital, Department of Breast, Endocrine Tumors and Sarcoma, Stockholm, Sweden; [4]Emory University School of Medicine, Pathology and Laboratory Medicine, Atlanta, United States

Background

Somatic and bi-allelic DICER1 mutations have been reported in subsets of sporadic thyroid tumors, affirming a clear involvement of this gene in the development of thyroid tumors. As a recent study has highlighted associations between *DICER1* mutations and macrofollicular patterns, abortive changes, and papillary structures, we aimed to investigate these observations in a bi-institutional cohort.

Methods

A total of 61 thyroid lesions (54 tumors and 7 cases of thyroid follicular nodular disease; TFND), including 26 *DICER1* mutated cases and 35 *DICER1* wildtype controls underwent histological re-investigation and clinical follow-up.

Results

DICER1 mutated cases showed a statistically significant association with younger age at surgery (29.2 ± 12.5 vs 51.3 ± 18.8, $P = 0.0001$), a predominant macrofollicular growth pattern (20/26 mutated cases vs 18/35 wildtype; $P = 0.01$) and abortive changes (20/26 mutated cases vs 2/35 wildtype; $P = 0.0001$). Similar results were obtained when excluding TFND cases. We also present clinical and histological triaging criteria for *DICER1* sequencing of somatic tissues, which led to the identification of *DICER1* variants in 16 out of 26 cases (62%) when followed. In cases with available germline data ($n = 12$), 3 cases (25%) were found to carry germline *DICER1* mutations. This observation smggests that the majority of *DICER1* variants are somatic – however, it implies that sequencing of constitutional tissues could be clinically motivated.

Conclusion

We conclude that *DICER1* mutations are amassed in younger patients with macrofollicular-patterned tumors and, most strikingly, abortive changes. Considering the rate of germline involvement, our findings hold potential clinical value, allowing the pathologist to triage cases for genetic testing based on histological findings.

Activating the intratumoral IFNγR-pathway in adrenocortical carcinoma potently enhances antitumor functionality of CAR-T cells by modulating immune cell adhesion and responsiveness

Marc Philipp Schauer[1,2], Laura-Sophie Landwehr[1], Justus Weber[2], Barbara Altieri[1], Silviu Sbiera[1], Matthias Kroiss[1,3,4], Martin Fassnacht[1,4] & Michael Hudecek[2]

[1]University Hospital Würzburg, Department of Internal Medicine I, Division of Endocrinology & Diabetes, Germany; [2]University Hospital Würzburg, Department of Internal Medicine II, Chair for Cellular Immunotherapy, Germany; [3]LMU Hospital Munich, Department of Internal Medicine IV, Division of Endocrinology & Diabetes, Germany; [4]Comprehensive Cancer Center Mainfranken, University of Würzburg, Germany

Background

Adrenocortical carcinoma (ACC) is a rare and aggressive endocrine disease in which 60% of patients show endogenous glucocorticoid (GC) secretion that potentially contributes to a lack of immune cell infiltration and limited efficacy of immunotherapeutic approaches. In another study, we already demonstrated potent antitumor efficacy or ROR1 CAR-T cells in preclinical models of ACC. Nevertheless, solid tumors often show cell intrinsic resistance mechanisms to CAR-T cell cytotoxicity which recently could be attributed to a lack of IFNγR-signalling and immunogenic pathway activation. Here, we report of a new potent small molecule inhibitor* (SMI) that is able to modulate innate antitumor immune-response pathways and potently enhances CAR-T cell functionality by activating the IFNγR-pathway in ACC.

Methods

We evaluated target gene expression in 62 ACC patients at mRNA and protein level. We evaluated efficacy of our SMI in five ACC cell lines and activation of immunogenic proinflammatory tumor signalling pathways using RNA Nanostring nCounter analysis, qRT-PCR and Western Blot. Cytokine secretion was measured by Enzyme-linked Immunosorbent Assay (ELISA). We evaluated antitumour functionality alone and in combination with several CAR-T cell modifications using different preclinical models of ACC.

Results

We show significantly higher expression of our required target gene in five ACC cell lines and ACC tissues when compared to normal adrenal glands (0.073 vs 0.713; $P = 0.004$). Moreover, target expression strongly correlates with glucocorticoid secretion and other clinicopathological parameters including Ki67, Weiss-score and survival supporting its potential utility as biomarker in ACC. The SMI shows potent antitumor functionality alone (NCI-H295R: IC50 195 nM, respectively) by reshaping cell autonomous and immune-stimulating activity in ACC cell lines. We demonstrate strong intratumoral upregulation of PD-L1 (11.5-fold change; $P = 0.003$) and IDO1 (17-fold change; $P = 0.033$) as well as strong secretion of immunogenic upstream signals and a significant increase of IFNγR expression (2.9-fold change, $P = 0.019$) in all five ACC cell lines after co-culture for 48 hours (NCI-H295R cells shown respectively). Consistent with these findings, after selectively activating the IFNγR-pathway when combined with the SMI, we show enhanced immune cell adhesion and responsiveness of different CAR-T cell modifications in ACC upon antigen contact in preclinical models using subtherapeutic effector-to-target-ratios.

Conclusion

Our results illustrate an enhanced immunotherapeutic approach using the combination of a new potent SMI and CAR-T cells by activating immunogenic intratumoral signalling and the IFNγR pathway in adrenocortical carcinoma.

*The small molecule inhibitor will be kept confidential for patent law reasons

Decrease in anticortisolic drmg osilodrostat plasma exposure in patients treated with mitotane for adrenocortical carcinoma

Louis Thomeret[1], Alicja Puszkiel[2], David Balakirouchenane[2], Lucas Bouys[1,3], Jonathan Poirier[3], Annabel Berthon[1], Bruno Ragazzon[1], Anne Jouinot[1], Laurence Guignat[3], Laura Bessiene[3], Rossella Libe[3], Léopoldine Bricaire[3], Marie-Clémence Leguy[4], Jean Guibourdenche[4], Lionel Groussin-Rouiller[1,3], Guillaume Assie[1,3], Benoît Blanchet[2], Jérôme Bertherat[1,3] & Fidéline Bonnet-Serrano[1,4]

[1]Institut Cochin, INSERM U1016 - CNRS UMR8104, Université Paris-Cité, Team "Genomics and signaling of Endocrine Tumors", PARIS, France; [2]Hôpital Cochin, Assistance Publique - Hôpitaux de Paris, Department of Pharmacokinetics and Pharmacochemistry, PARIS, France; [3]Hôpital Cochin, Assistance Publique - Hôpitaux de Paris, Endocrinology department, PARIS, France; [4]Hôpital Cochin, Assistance Publique - Hôpitaux de Paris, Hormonology department, PARIS, France

Introduction

The steroidogenesis inhibitor osilodrostat (OSI), indicated for the medical treatment of endogenous Cushing's syndrome, exhibits significant interindividual variability regarding the response to treatment (*Pivonello et al*., 2020), *a fortiori* in the context of adrenocortical carcinoma (Tabarin et al., 2022). Plasma exposure may contribute to this variability. Our objective was to investigate the effect of concomitant use of mitotane (MITO), a potent inducer of CYP450 (3A4), on

circulating OSI concentrations in patients treated for an adrenocortical carcinoma (ACC).
Materials and Methods
Plasma OSI concentrations were determined every 4 hours over 24 hours (sampling at 8 h, 12 h, 16 h, 20 h, 24 h and 4 h) by LC-MS/MS (*Balakirouchenane et al*., 2023) in 29 patients treated for different etiologies of endogenous Cushing's syndrome: Cushing's disease ($n=19$), ectopic Cushing's syndrome ($n=4$), primary bilateral macronodular adrenal disease ($n=3$) and adrenocortical carcinoma ($n=3$). Twenty-seven patients were treated with OSI as a monotherapy ("OSI" group, 33 cycles) and 3 patients were treated ith OSI in association with MITO ("OSI-MITO" group, 8 cycles) for an ACC. OSI was administered twice daily in all patients. Daily doses of OSI and plasma MITO concentrations were expressed as median [min-max].
Results
Even after a long period of treatment (> 6 months), high fluctuations of OSI concentrations were observed along the day (median CV = 55%). The area under the OSI concentration curve (AUC-OSI) was thus used as pharmacokinetic endpoint. The AUC-OSI was well correlated with the daily dose of osilodrostat in both the "OSI" group (Spearman *r*0.84; OSI 10 [2-40] mg/day) and the "OSI-MITO" group (Spearman *r*0.85; OSI 60 [20-60] mg/day; plasma MITO concentration 14.1 [0.5-26.6] mg/l). However, the slope of the linear regression line was lower in "OSI-MITO" group. The AUC-OSI based on the daily dose was also statistically decreased in the "OSI-MITO" group compared to the "OSI" group (medians: 11.92 vs 26.81 ng/ml.h; $P<0.001$).
Discussion
Mitotane significantly decreases plasma exposure to Osilodrostat in patients treated for a cortisol-secreting ACC. This is likely explained by the induction of CYP450 by Mitotane and should be taken in account to adjust the Osilodrostat dose in patients treated with Mitotane.

Fibroblast-mediated modulation of GI-NETs: Implications for drmg response and tumor invasion
Eleonora Malavasi, Lara Toffoli, Marilyn Dainotto, Angeliki Ditsiou & Teresa Gagliano
University of Udine, Department of Medicine (DMED), Udine, Italy

Introduction
The intricate interplay between fibroblasts and cancer cells significantly contributes to cancer invasion, extracellular matrix (ECM) modulation, and the development of drmg resistance. This study delves into understanding the specific influence of fibroblasts on Gastro-Intestinal neuroendocrine tumor (GI-NET) cell lines.
Materials and Methods
Utilizing GOT1 and COLO320 cell lines, we incorporated Normal Human Dermal Fibroblasts (NF) in our investigation. Lipophilic tracers were employed in 3D co-culture to distinguish between cell types. FAK (BI-0319) and SYK (BI1002494) kinase inhibitors, previously identified as antiproliferative on GI-NET cells, were administered. Elisa assays were conducted to quantify protein secretion levels.
Materials and Methods
The study employed the GI-NET cell lines GOT1 and COLO320, alongside Normal Human Dermal Fibroblasts (NF). A 2D invasion assay was conducted using cell inserts, followed by crystal violet staining for visualization. Cell viability assessment in 3D cultures utilized the cell-titer glow method, with fluorescent lipophilic tracers distinguishing between cell types in 3D co-culture. FAK (BI-0319) and SYK (BI1002494) kinase inhibitors, recognized for their antiproliferative effects on GI-NETs cells, were administered as drmg treatment. Protein secretion levels were quantified using Elisa.
Results
In 3D culture, fibroblasts demonstrated a partial impact on the response to FAK and SYK inhibition. In 2D invasion assay, fibroblasts strongly stimulated cancer cell invasion, yet this effect was effectively counteracted by treatment with FAK (BI-0319) and SYK (BI1002494) inhibitors. Notably, fibroblasts were observed to diminish the secretion of TIMP2, a protein recognized for its anti-invasive propertie, preventing excessive extracellular matrix (ECM) degradation and hindering tumor cell migration.
Conclusion
Although fibroblast influence on cancer cells invasion and ECM remodeling is substantial, inhibiting the focal adhesion pathway was shown to partially counteract these effects. This dual role of fibroblasts, both influencing and being influenced by FAK and SYK inhibition, underscores the complexity of their interactions in the context of cancer invasion and highlights the potential therapeutic significance of targeting these pathways.

Insulinomas are rare insulin-producing pancreatic neuroendocrine tumours. Most insulinomas are non-metastatic and can be cured by surgery, but in 10% of the patients insulinomas metastasize, which is associated with a significantly impaired overall survival. As the metastatic potential of an insulinoma cannot be reliably predicted with the current biomarkers, we aimed to evaluate the expression of somatostatin receptors (SSTRs) and glucagon-like peptide-1 receptors (GLP-1Rs) in insulinomas and to analyse their association with clinicopathological features and long-term patient outcome[1,2]. The study material included formalin-fixed paraffin-embedded primary tumour tissue samples of 52 insulinoma patients diagnosed in Finland 1980–2010. Of these patients, 47 had a sporadic, non-metastatic insulinoma, 3 had a sporadic, metastatic insulinoma and 2 patients had a MEN1-syndrome-related, non-metastatic insulinoma. The median duration of the register-based follow-up was 10 (0–32) years after surgery. After histological re-evaluation, the samples were processed into tissue microarrays (TMA) and stained immunohistochemically with monoclonal SSTR1-5 and GLP-1R antibodies. The scoring was made manually and the immunoreactivity of the strongest stained TMA spot was scored based on membranous staining for GLP-1Rs and on both membranous and cytoplasmic staining for SSTRs. Of the somatostatin receptors, SSTR2 was expressed most frequently (71%), followed by SSTR3 (33%), SSTR1 (27%) and SSTR5 (6%). SSTR3 expression was associated with a larger tumour size, and SSTR3 and SSTR5 expression were associated with impaired overall survival. The expression of GLP-1Rs differed significantly between metastatic and non-metastatic insulinomas, as all sporadic, non-metastatic insulinomas expressed GLP-1R, while all metastatic insulinomas lacked the expression of GLP-1R. Of the two non-metastatic, MEN1-related insulinomas, one expressed GLP-1R and the other did not. In conclusion, the lack of GLP-1R expression is associated with a metastatic disease and impaired survival. Our results indicate that the lack of GLP-1R expression could be used as a negative prognostic marker in insulinomas but additional studies investigating a higher number of metastatic insulinomas are needed. Regarding SSTRs, most insulinomas were found to express SSTR subtype 2, which may be utilized in SSTR-targeted imaging and treatment, but further studies are needed to clarify the association between SSTR expression profile and overall survival.

Introduction
Multiple cancers have been described more commonly in patients with diabetes, and some exhibit increased aggressiveness of the tumor as well. This association has been debated with regard to thyroid cancer. With this work, we aim to clarify whether type 2 diabetes (DM2) or autoimmunity-related diabetes (type 1 diabetes + LADA = DM1) could coexist with thyroid cancers more aggressive as compared to those found in unaffected (non-DM) individuals.
Methods
We collected data from patients who underwent thyroid surgery in 10 referral clinics in Greece over 2 years. Our retrospective collection included the type of diabetes, pre-existing to the thyroid surgery, its treatments and duration, the preoperative thyroid function tests and the surgical pathology report. We compared the presence of different forms of thyroid cancer histology and the features of tumor aggressiveness between patients with and without diabetes.
Results
Overall, $n = 808$ subjects with thyroid cancer were included: $n = 571$ were females (70.7%), age 47.3 ± 14.3 years, BMI 27.0 ± 5.0 Kg/m^2, mean TSH 1.99 ± 2.21 mIU/l; $n = 692$ were non-DM, $n = 10$ had DM1 and $n = 107$ had DM2. Histology revealed $n = 5$ poorly differentiated / anaplastic, $n = 13$ medullary, $n = 12$ Hürthle cell, $n = 17$ follicular and $n = 773$ papillary thyroid cancers (PTC); $n = 20$ (2.5%) with aggressive histological subtypes of PTC, $n = 5$ (0.6%) with distant metastases (MET), $n = 199$ (24.6%) with extrathyroidal extension (ETE), $n = 419$ (51.9%) with capsular invasion (CI), $n = 225$ (27.8%) with lymph nodes involvement (LNi) and $n = 23$ with cancer recurrence (CR) (2.8%). The incidence of aggressive histological types, CR, MET or number of I-131 treatments were not different between groups ($p > 0.05$). ETE, CI and LNi were significantly more common in non-DM compared to both diabetes groups, while gross ETE was more common in DM2 over DM1 and non-DM ($P < 0.001$).
Conclusions
Some protective effects are observed in patients with DM1 more than DM2 on certain features of cancer aggressiveness in patients with diabetes. In addition, ETE seems more common in patients with DM2 compared to those with DM1. Aggressive histological types of thyroid cancer and aggressive variants of PTC incidence do not seem affected by the presence of diabetes. Obviously, the relatively small sample size of the present study limits the ability to detect effects of smaller magnitude, but an interplay between tumor biology, glucose homeostasis, insulin secretion and resistance and autoimmunity could have a significant effect on thyroid cancer development and aggressiveness.

Somatic RAS mutations in thyroid nodules: possible protective effect?

Martina Verrienti[1], Sabrina Lupo[2], Giacomo De Cao[1], Paola Franceschetti[2], Anna Crociara[2], Andrea Daniele[2], Stefania Bruni[2], Maria Rosaria Ambrosio[1] & Maria Chiara Zatelli[1]
[1]Ferrara, Dept of medical Sciences, Ferrara, Italy; [2]Ferrara, UOC of Endocrinology, AOU Ferrara, Ferrara, Italy

Introduction
Thyroid nodules (TN) may display somatic RAS mutations, that, however, lack of diagnostic value. In our experience, somatic RAS mutation evaluation could be useful since it has a very high negative predictive value. In the past, somatic RAS mutation had been associated with a good prognosis in thyroid cancer.
Objective
This study aims to evaluate whether somatic RAS mutation may associate with TN differential growth pattern.
Methods
Our study included 2174 patients referring our center for TN assessment by ultrasound (US), fine needle aspiration biopsy and subsequent cytological and molecular evaluation, represented by somatic BRAFV600E mutation by a CE-IVD Real-time PCR kit (DIATECH, Italy). In BRAF V600E negative TN displaying a non-malignant cytology, somatic RAS mutations were investigated by by a CE-IVD Real-time PCR kit (DIATECH, Italy). We selected 1092 TN undergoing somatic RAS mutations evaluation with a basal and at least one follow-up US evaluation (median follow-up 2 years) and calculated TN volume with the ellipsoid formula.
Results
Among the 1092 TN with US follow-up somatic RAS mutations were identified in 49 TN (RAS+), while 1043 TN where wild type for somatic RAS mutations (RAS-). Each group was divided in 3 categories: 1) TN displaying a volume increase, 2) TN displaying a volume reduction, 3) TN displaying stable volume during follow-up. We found that somatic RAS mutations were equally distributed among the 3 categories. On the contrary, initial volume was significantly higher in RAS- vs RAS+ TN in both category 1 (3.65 vs 1.08 ml) and 2 (4.71 vs 2.18 ml) ($P < 0.01$). In addition, volume variations RAS+ TN were not significant, while category 1 RAS- TN showed a ~twofold increase in volume ($P < 0.01$) and category 2 RAS- TN showed a ~1.5-fold reduction in volume ($P < 0.01$).
Conclusions
Our data smggest that somatic RAS mutations do not associate with TN volume variations. On the contrary, in our study they associate with a smaller and stable volume, supporting the hypothesis of a protective effect of these mutations.

Thyroid sequencing: What the cell am i using here?

Nuria Sánchez de la Blanca Carrero, Pablo Sacristán Gómez, Ana Serrano Somavilla, José Luis Muñoz de Nova, Miguel Antonio Sampedro Núñez, Mónica Marazuela Azpiroz & Rebeca Martínez Hernández
Hospital Universitario de La Princesa, Endocrinology, Madrid, Spain

Context
Pathological transcriptomic landscape has been the driver of the Molecular Biology in the recent years. Massive RNA sequencing techniques have been extended from bulk RNAseq, to single cell sequencing (scRNAseq) and spot-based spatial transcriptomics (ST), and sometimes laboratory cannot afford all of them. We tried to answer the question about which would be the best option in thyroid gland using Hashimoto's thyroiditis (HT) context.
Methodology
We performed RNAseq (5 HT, 5 controls) and Visium ST using the 10XGenomics platform (3 HT, 2 controls). We used scRNAseq from four HT patients from a public repository database. For ST, we followed a histological annotation classification and we analyzed each tissue compartment: thyrocytes, connective tissue, vessels, germinal center (GC) and immune infiltrated cells (TILs), separately. All the analysis were executed in R and Seurat package. DESeq was used for differential expression analysis (DEA) in RNAseq. In scRNAseq and ST, DEA was performed under the default option of Seurat.
Results
We first focused our analysis on the **ST** data separating the different tissue compartments. We found two thyrocytes subpopulations ("healthy" and "damaged"), three main fibroblasts subpopulations and a specific marker of vessels permeabilization, PLVAP, with their respective locations. Furthermore, we observed the spatial concentration of dendritic cell markers (such as FDCSP) in GCs, a main characteristic of HT histology. Nevertheless, TILs surrounding the GC were not properly estimated nor classified. In **scRNAseq**, we characterized different immune subpopulations which were not able to be observed in ST. However, it is critical to consider the low number of thyrocytes compared to other cells which smggests a non-uniform coverage of all representative cells in the thyroid tissue. This fact could interfere with the results of the analysis presenting limitations in the description of "damaged" and "healthy" thyrocytes subpopulations. We also found a lack of expression of FDCSP marker in GC cells represents the low capture efficiency or the damaged cells that results in the scRNAseq. In **RNAseq**, the upregulation of some genes is overshadowed by immune cell markers. In the top, we found genes such as CXCL13 and FDCSP. The analysis of pathogenic-fibroblasts markers and PLVAP did not reach statistical significance. It may be caused by the lack of depth/samples in the RNAseq analysis and the overrepresentation of immune cells transcriptomes.

Conclusions
ST provides a robust method to identify different cell type subpopulations similar that in scRNAseq in non-immune cells and offers higher depth than RNAseq.

The increased FCRL mRNA expression in patients with Graves' disease is associated with hyperthyroidism (but not with positive thyroid antibodies)

Katarzyna Wojciechowska-Durczyńska[1,2], Jan Stępniak[1], Andrzej Lewiński[2,3] & Małgorzata Karbownik-Lewińska[1,2]
[1]Medical University of Lodz, Department of Endocrinology and Metabolic Diseases, Lodz, Poland; [2]Polish Mother's Memorial Hospital, Research Institute, Lodz, Poland; [3]Medical University of Lodz, Department of Pediatric Endocrinology, Lodz, Poland

Fc Receptor-like (FCRL) genes play a role in the immune system by encoding proteins that function as receptors on the surface of immune cells. Peripheral blood B cells, which are positive for FCRL3 and FCRL4, are rarely found in healthy individuals. In previous studies overexpression of FCRL4 was observed in patients with Graves' disease (GD) but without association with thyroid peroxidase (TPOAb) or thyroglobulin (TgAb) antibodies. Nonetheless, the clinical significance of FCRLs expression in GD and Graves orbitopathy (GO) remains unclear. We decided to evaluate the expression of FCRL 2, 3, 4 mRNA in patients with GD and GO and its role in the development and severity of these diseases.
Methods
Peripheral blood samples from patients with GD (diagnosed on the basis of positive TSH receptor autoantibodies, TRAb; $n=26$) or GO (diagnosed on the basis of ophthalmic assessment and positive TRAb currently or in medical history; $n=49$) hospitalized in the Department of Endocrinology and Metabolic Diseases, Medical University of Lodz, were collected. Healthy individuals without thyroid diseases served as Control ($n=16$). Expressions of *FCRL2*, *FCRL3* and *FCRL4* were measured by real-time PCR and analyzed using the $2^{-\Delta\Delta CT}$ method.
Results
FCRL3 mRNA expression was higher in peripheral blood from patients with GD comparing to GO (1.375 vs 0.673, $P=0.004$), as well as comparing specifically to active GO (1.375 vs 0.639, $P=0.005$). Regarding FCRL4 mRNA expression, even more pronounced increase was found in GD patients. Namely, FCRL4 mRNA expression was higher in GD comparing to Control (3.078 vs 0.916, $P=0.003$), comparing to GO (3.078 vs 1.178, $P<0.001$), comparing to active GO (3.078 vs 1.186, $P=0.002$) and comparing to inactive GO (3.078 vs 1.171, $P=0.008$). In turn, FCRL4 mRNA expression was higher in patients with hyperthyroidism (subclinical+overt) than in euthyroid patients (2.509 vs 0.995, $P=0.001$ when the whole group of individuals was considered; 2.509 vs 1.073, $P=0.004$ when GO+GD was considered). This positive association of FCRL4 mRNA expression with hyperthyroidism was confirmed in univariate regression analysis (OR=1.561, 95%CI=2.213, $P=0.012$). No clear relationship was observed between FCRL mRNA expression and thyroid antibodies (TRAb included). FCRL mRNA expression was not related to active/inactive GO.
Conclusion
The increased FCRL mRNA expression in patients with GD is associated with hyperthyroidism (but not with positive TRAb) and our study is the first one to confirm this relationship.

Color Doppler ultrasound and real-time elastography in patients with hypothyroidism for the prediction of levothyroxine replacement: A cross-sectional study of 338 patients

Nikolaos Angelopoulos[1,2], Rodis Paparodis[2], Sarantis Livadas[2], Anastasios Boniakos[2], Ioannis Androulakis[2] & Ioannis Iakovou[1]
[1]AHEPA University Hospital, Faculty of Medicine, School of Health Sciences, 2nd Academic Department of Nuclear Medicine, Thessaloniki, Greece; [2]Hellenic Endocrine Network, Athens, Greece

Aims
While hormonal assays are commonly used for thyroid function assessment, Doppler sonography provides valuable information on vascularization and blood flow. This study aimed to examine the potential associations between Doppler parameters and clinical characteristics of hypothyroid patients, such as the autoimmune nature of the disease and adequacy of LT4 replacement.
Methods
A total of 338 patients with hypothyroidism, primarily caused by autoimmune thyroiditis (AT), were enrolled in this study. Exclusion criteria comprised specific medical conditions, medication history, and nodular abnormalities of the thyroid gland. Patient demographics (age, sex, BMI), treatment parameters (LT4 daily dose), and thyroid hormone levels (TSH, fT4) were recorded.
Results
Among the enrolled patients, 85.2% had autoimmune thyroiditis. Suboptimal levothyroxine (LT4) replacement was observed in 20.1% of patients at the time of enrollment. Patients with autoimmune thyroiditis had increased elastography ratios compared to those without autoimmune disease and present a positive association of elastography ratios with vascularity. In patients without autoimmune thyroiditis, those with suboptimal LT4 replacement had lower total thyroid volume. Patients with suboptimal LT4 replacement had higher peak systolic velocity (PSV) and end-diastolic velocity (EDV) in the inferior thyroid artery and lower resistive index (RI). The severity of hypothyroidism, as indicated by LT4 dose/body mass index (BMI), was negatively correlated with thyroid volume and EDV values of superior and inferior thyroid arteries. PSV of the inferior thyroid artery can predict suboptimal LT4 replacement (sensitivity 81.8%, specificity 42%).
Conclusions
In situations where obtaining blood tests may be challenging, utilizing color Doppler ultrasound can serve as an alternative method to assess treatment responses and identify patients who require further hormonal examinations.

Assessment of cardiovascular risk and coronary calcium deposits in women with hypopituitarism

Salma Salhi[1], Ibtissem Oueslati[1], Seif Boukriba[2], Emna Talbi[3], Meriem Yazidi[1], Moncef Feki[1], Habiba Mizouni[2] & Melika Chihaoui[1]
[1]La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia; [2]La Rabta University Hospital, Department of Radiology, Tunis, Tunisia; [3]La Rabta University Hospital, Laboratory of Biochemistry, Tunis, Tunisia

Introduction
Cardiovascular diseases are frequent in patients with hypopituitarism receiving conventional hormone replacement therapy. They represent the main cause of premature death in this population. Emerging evidence smggests that beyond traditional risk factors, evaluating coronary calcium score (CCS) and inflammatory markers such as high-sensitivity C-reactive protein (hs-CRP) provides valuable insights into cardiovascular health in this population. The aims of the present study were to assess the cardiovascular risk (CVR) and to determine CCS in women with hypopituitarism.
Methods
We conducted a cross-sectional study including 50 patients with complete anterior hypopituitarism secondary to Sheehan syndrome (SS), receiving conventional hormone replacement therapy (PG) and an equal number of age- and body-mass index (BMI)-matched women controls (CG). Participants underwent a clinical examination, laboratory tests, and a coronary computed tomography scan to calculate the CCS.
Results
The average age was 62.2 ± 9.4 years in the PG and 60.6 ± 8.4 years in the CG ($P=0.385$). The average delay between postpartum hemorrhage and the diagnosis of SS was 11.1 ± 9.4 years and its average duration was 31.6 ± 9.9 years. The prevalence of hypertension (PG: 78%, CG: 64%, $P=0.123$), insulin resistance (PG: 38%, CG: 56%, $P=0.070$), and diabetes (PG: 24%, CG: 14%, $P=0.202$) were comparable between the two groups. Dyslipidemia (PG: 66%, CG: 38%, $P=0.005$) and metabolic syndrome (PG: 64%, CG: 40%, $P=0.016$) were more prevalent in the PG. PG had higher hs-CRP levels (7.6 mg/l vs 2.5 mg/l, respectively; $P<0.001$) and higher CCS (47.3 vs 6.9, respectively; $P=0.009$) than controls. Two patients had coronary artery disease. No women from the CG had a cardiovascular accident. Based on a CCS > 10, 28% of PG had high CVR compared to 18% of controls ($P<0.001$). Factors associated with high CVR included age >55 years (OR= 1.5; IC95%: 1.25-1.95; $P=0.039$) and hypertension (OR=1.6; IC95%: 1.3-2.1; $P=0.016$). On the other hand, no relationship was observed between high CVR, disease-related parameters, and hormone replacement therapy.

Conclusion
Women with hypopituitarism secondary to SS had a higher CVR than controls. They necessitate a more exhaustive risk assessment strategy by incorporating CCS and inflammatory markers into the evaluation process. Preventive and therapeutic strategies should be early developed to mitigate the cardiovascular consequences associated with SS.

Elevated prolactin: Do not over investigate, cannulate!

Anna Hawkins, Nancy Enriquez, Raj Tanday, Usman Shah, Carmela Chan, Edel Casey & Khash Nikookam
Barking, Havering and Redbridge University NHS Trust, United Kingdom

Aim
Role of Endocrine Specialist Nurse (ESN) in performing cannulated prolactin and subsequent impact on outpatient clinic activities.
Introduction
Hyperprolactinemia is a common condition in endocrine clinical practice. It may occur in any sex, at any age and its prevalence and incidence depend on study population. The most common physiological causes of elevated prolactin are stress, lactation, pregnancy and exercise. Non-physiological causes include medications, pituitary and systemic disorders and medications[1]. Regardless of underlying aetiology hyperprolactinemia may cause galactorrhoea, amenorrhoea, infertility and erectile dysfunction in addition to several adverse health outcomes such as cardiac disease, cancer, osteoporosis, autoimmune conditions. 40 patients (11 men and 29 women) with a mean age of 32 yrs were referred by the consultant endocrinologists for cannulated prolactin over a 12-month period in 2023. All patients were originally referred by their GP with elevated prolactin following various presentations, pituitary adenomas (4), erectile dysfunction (3), irregular periods (3), fatigue (3), short stature (2), infertility (1), galactorrhoea (1), sweating (1), asymptomatic (22). Their elevated prolactin levels ranged 355 to 1281 miu/l in men and 499 to 2149 miu/l in women, with a mean prolactin of 891 miu/l in both sexes.
Method
All patients underwent a cannulated prolactin following our joint Endocrine guidelines. This involved placing a cannula in the arm and taking a sample of blood at insertion for prolactin. The patient was then left to sit and relax for 60 mins before a second sample of blood was withdrawn from the cannula for prolactin.
Results
21 patients (10 men and 11 women) had a normal cannulated prolactin at 60 mins with a range of 323 to 131 miu/l, mean = 244 miu/l in men and 435 to 260 miu/l, mean 360 miu/l in women. 21 (52%) of patient with normal cannulated prolactin were reassured and discharged back to their general practitioner (GP). 19 patients with non-suppressed prolactin (range of 409 to 1608 miu/l) were subsequently seen in consultant endocrine clinic for further investigation and treatment including two patients who were on Duloxetine and Olanzapine.
Conclusion
The above highlights the importance of a dedicated endocrine team with the role of the ESN being paramount to:
1) facilitate and ensure timely and accurate diagnostic testing.
2) ensure outcome follow up, improved patient care and satisfaction.
3) reduce referrals to Endocrine Clinics hence more capacity for urgent referrals.
4) cost effectiveness.
Prolactin normal reference range: men 86-324 miu/l, women 102-496 miu/l

Identifying potential small molecule "metabolites" as biomarkers for growth hormone deficiency (GHD): Insights from a novel mouse model

Sarmed Al-Samerria[1,2], Huiting Xu[3], Joseph Phelan[3], Maria Elena Diaz Rubio[3], Sayaka Yamada[1], Ariel Negron[1], Fredric Wondisford[4] & Sally Radovick[1]
[1]The University of Arizona Medical School, Department of Pediatrics, Phoenix, United States; [2]The University of Arizona College of Medicine - Phoenix, Phoenix, United States; [3]Rutgers University, Department of Medicine, New Brunswick, United States; [4]The University of Arizona Medical School, Department of Medicine, Phoenix, United States

Growth hormone deficiency (GHD) diagnosis poses a significant challenge since no test definitively diagnoses GHD. The current diagnostic approach for GHD relies on a determination of auxologic parameters followed by determining Growth Hormone (GH) levels and Insulin-like Growth Factor-I (IGF-I) in serum. However, clinical assessment and interpretation of GH and IGF-1 levels lack sensitivity. Further provocative studies of GH secretion do not have a precise cutoff level that discriminates a normal response from a deficient response; second, they have poor specificity. With the goal of determining biomarkers for GHD, our laboratory developed a unique mouse model, inspired by a severe GHD patient due to a mutation in the *PIT-1* gene, which provides a controlled setting for probing GHD intricacies, overcoming some challenges encountered in human studies. In this study, we utilized a metabolomic approach to analyze serum samples from both wild-type and mutant mice, both with and without GH treatment, aiming to identify potential biomarkers. Metabolomic analysis unveiled several impacted metabolic pathways associated with GHD in the developed mouse model. Among these pathways, the Purine metabolism pathway and Arginine and proline metabolism exhibited the most pronounced alterations, indicating their crucial involvement in GHD-related metabolic changes. Upon closer analysis, 3-hydroxy butyric acid, Glucose, and Hydroxyproline displayed distinctive patterns in male and female mutant mice, smggesting their potential as GHD biomarkers. Furthermore, we established a correlation between metabolomic changes and treatment response, enabling the monitoring of GH therapy effects. This research highlights the pivotal role of metabolomic analysis in identifying a unique biomarker for GHD and evaluating treatment response. Incorporating a novel mouse model with a *PIT-1* gene mutation enriches GHD research, contributing to enhanced diagnostic accuracy and improved monitoring of treatment outcomes in individuals with GHD.

Non-functioning pituitary neuroendocrine tumors (NF-PitNETs) are still orphan of medical therapy. The drmgs approved for the other types of PitNETs, e.g. somatostatin analogues (SSA) with high affinity for somatostatin receptors (SSTs) type 2 (SST2) and 5 (SST5) are poorly efficacious in NF-PitNETs. Among SSTs, NF-PitNETs express high levels of SST3, a receptor that can mediate antiproliferative and apoptotic signaling. ITF2984 is a pan-SST ligand with high affinity for SST3, able to induce SST3 internalization and phosphorylation, to trigger G-protein signaling in vitro and to exert antitumoral activity in MENX rat model. Aim of the present study was to test the antiproliferative and proapoptotic effects of ITF2984 in NF-PitNET primary cultured cells derived from surgically removed human tumors and to characterize their SSTs expression profile. We treated primary cells derived from 23 NF-PitNETs with ITF2984, octreotide (SSA with high affinity for SST2), pasireotide (SSA with high affinity for SST5) or cabergoline (DRD2 agonist) and we measured cell proliferation (by BrdU incorporation assay) and apoptosis (by caspase 3/7 activity assay). The expression of SST3, SST2 and SST5 in tumor tissues was analysed by qRT-PCR and western blot. Our results demonstrated that ITF2984 reduced cell proliferation (-40.8 (17.08) %, $P<0.001$ vs basal, $n=19$ NF-PitNETs) and increased cell apoptosis (+41.4 (22.1)%, $P<0.001$ vs basal, $n=17$ NF-PitNETs). On the contrary, in the same tumors no

effect was observed after octreotide, pasireotide, or cabergoline treatment. Receptor expression analysis revealed that SST3, SST2 and SST5 transcripts were expressed at similar levels in tumor tissues, and a positive correlation was found between SST3 and SST5 protein levels. In conclusion, our data support a possible use of ITF2984 in the pharmacological treatment of NF-PitNET.

Pregnancy and acromegaly: Clinical outcomes of retrospectively analysed data from the German Acromegaly Registry

Anke Tönjes[1], Marleen Würfel[1], Marcus Quinkler[2], Ulrich Knappe[3], Jürgen Honegger[4], Nina Krause.Joppig[5], Konrad Bacher[6], Jochen Schopohl[7], Sylvère Störmann[7] & Sebastian Meyhöfer[8]
[1]University of Leipzig Medical Center, Leipzig, Germany; [2]Endocrinology in Charlottenburg, Berlin, Germany; [3]Department of Neurosurgery, Johannes Wesling Hospital, Minden, Germany; [4]University of Tübingen, Department of Neurosurgery, Tübingen, Germany; [5]ENDOKRINOLOGIKUM Hannover, Hannover, Germany; [6]Practice for Endocrinology and Diabetes, Stuttgart, Germany; [7]Medizinische Klinik und Poliklinik IV, LMU Klinikum, München, Germany; [8]Institute of Endocrinology and Diabetes, University of Lübeck, Lübeck, Germany

Context
Acromegaly is a rare disease caused by excessive growth hormone (GH) secretion, mostly induced by pituitary adenomas. The care of pregnant women with acromegaly is challenging, in part due to existing clinical data being limited and not entirely consistent with regard to potential risks for mother and child.
Objective
To retrospectively examine data on pregnancy and maternal as well as neonatal outcomes in patients with acromegaly.
Design and Methods
Retrospective data analysis from 47 pregnancies of 31 women treated in centers of the German Acromegaly Registry.
Results
87.1% of the studied women underwent transsphenoidal surgery before pregnancy. In 51.1% a combination of dopamine agonists and somatostatin analogs were used before pregnancy. Three women did not receive any therapy for acromegaly. During pregnancy only 6.4% received either somatostatin analogs or dopamine agonists. In total, 70.2% of all documented pregnancies emerged spontaneously. Gestational diabetes was diagnosed in 10.6% and gravid hypertension in 6.4%. Overall, no preterm birth was detected. Indeed, 87% of acromegalic women experienced a delivery without complications.
Conclusion
Pregnancies in women with acromegaly are possible and the course of pregnancy is in general safe for mother and child both with and without specific treatment for acromegaly. The prevalence of concomitant metabolic diseases such as gestational diabetes is comparable to the prevalence in healthy pregnant women. Nevertheless, larger studies with more data in pregnant patients with acromegaly are needed to provide safe and effective care for pregnant women with this condition.

Prevalence and determinants of microvascular and macrovascular complications of diabetes in acromegaly patients: A prospective case-control cross-sectional study

Rosa Pirchio[1], Renata Simona Auriemma[1], Roberta Scairati[1], Antonella Tropiano[1], Ivan De Simone[1], Alice Vergura[1], Guendalina Del Vecchio[1], Claudia Pivonello[2], Rosario Pivonello[1] & Annamaria Colao[1]
[1]Università Federico II di Napoli, Naples, Italy, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy; [2]Università Federico II di Napoli, Dipartimento di Sanità Pubblica, Naples, Italy

Context
Although diabetes mellitus is a major complication in patients with acromegaly, prevalence and determinants of microvascular and macrovascular complications of diabetes remains unexplored in this population.
Aim
To investigate prevalence and determinants of microvascular and macrovascular complications in acromegaly patients with diabetes and to compare them with a group of diabetic patients without acromegaly.
Methods
Prospective case-control cross-sectional study evaluating 53 acromegaly patients with diabetes (ACRODIAB) and 53 diabetic patients (DIAB) similar for gender and age.
Results
No significant difference in age at diabetes diagnosis, diabetes duration, fasting glucose, and HbA1c levels were found between ACRODIAB and DIAB groups. Prevalence of retinopathy was similar between the two groups (18.4% vs 14.3%,$P=0.602$), whereas ACRODIAB patients had a significantly higher eGRF ($P=0.01$) and a significantly lower prevalence of chronic kidney failure ($P<0.001$) compared to DIAB group. Albuminuria was slightly but not significantly lower in ACRODIAB than in DIAB group (12.7 ± 18.4 vs 22.3 ± 38.3,$P=0.185$). Prevalence of ischemic heart disease (27.3% vs 41.5%, $P=0.03$) and cerebrovascular disease (1.9% vs 14.3%,$P=0.03$) were significantly lower in ACRODIAB than DIAB group. Similarly, atherosclerotic plaques (78.4% vs 95.2%,$P=0.09$) and lower limb peripheral arterial disease (14.7% vs 28.6%, $P=0.211$) were slightly less frequent in ACRODIAB than DIAB group. In ACRODIAB group, patients with retinopathy were significantly younger both at the evaluation ($P=0.02$) and at diabetes diagnosis ($P=0.009$) and had slightly higher IGF-I levels ($P=0.06$) as compared to those without retinopathy. In ACRODIAB group, patients diagnosed with diabetes before the age of 52 years (median) had a significantly higher prevalence of retinopathy (37.5% vs 4.3%,$P=0.008$), mainly proliferative (18.7% vs 4.3%, $P=0.07$), and a slightly higher prevalence of lower limb peripheral arterial disease (23.1% vs 9.5%, $P=0.278$) as compared to those diagnosed at older age. ACRODIAB patients in whom diabetes onset occurred before acromegaly exhibited a significantly higher prevalence of atherosclerotic plaques (55.5% vs 16.7%, $P=0.04$) and of lower limb peripheral arterial disease (32.3% vs 0%, $P=0.01$) as compared to those diagnosed with diabetes after acromegaly. Retinopathy was slightly more frequent in ACRODIAB patients diagnosed with diabetes before acromegaly than those in whom the diagnosis was simultaneous (42.8% vs 9.1%, $P=0.09$).
Conclusions
ACRODIAB patients are affected by a lower number of diabetes complications, particularly macrovascular, as compared to DIAB. So far, a protective role of GH and IGF-I on diabetes complications cannot be excluded. In ACRODIAB patients, age at diagnosis of diabetes and diabetes occurrence before acromegaly are the main determinants of diabetes complications.

Pituitary apoplexy: A retrospective canadian single center cohort study

Ellen Parker[1], S. Ali Imran[2], Andrea Hebb[1], Nelofar Kureshi[1] & David Clarke[1]
[1]Dalhousie University, Division of Neurosurgery, Halifax, Canada; [2]Dalhousie University, Division of Endocrinology and Metabolism, Halifax, Canada

Introduction
Pituitary apoplexy is a rare clinical syndrome that often involves headache, visual deficits, and endocrine dysfunction resulting from infarction or hemorrhage of a pituitary tumor. Due in part to the rare nature of this condition, there are few large studies on pituitary apoplexy described in the literature. Here, we present a large single center retrospective cohort study of patients with pituitary apoplexy managed surgically or conservatively.
Methods
This is a retrospective cohort study; data was collected from prospectively entered information in our Halifax Neuropituitary Clinic's database. Medical records of patients with symptomatic pituitary apoplexy treated at from January 2000 to October 2022 were reviewed. Patients treated surgically typically presented with deterioration of vision or loss of consciousness, whereas conservative management was typically selected for patients with no visual field deficits or who were otherwise unable to undergo surgery due to patient-specific medical factors. Patient demographics, endocrinologic values, clinical outcomes, and cases of tumor recurrence were analyzed. Descriptive statistics were reported as means, percentages, and standard error of the mean. Independent two-samples *t*-tests (and $\alpha=0.05$) were used for statistical analyses between patients treated surgically versus conservatively.
Results
Eighty-three ($n=83$) patients with symptomatic pituitary apoplexy met our inclusion criteria. The average age at diagnosis was 50.4 ± 1.6 years. Seventy-two percent of tumours ($n=60$) were non-functioning adenomas. Functioning (but hormonally uncontrolled) adenomas made up 8.4% of cases ($n=7$), and other parasellar lesions comprised 13.2% ($n=11$). Sixty (72.3%) patients were treated surgically, while the remaining twenty-three patients (27.7%) were treated conservatively. At time of initial presentation, mean endocrinological values were

as follows: GH 1.1 ± 0.6 µg/l (n = 28), IGF-1 155.1 ± 29.6 µg/l (n = 38), Prolactin 318.0 ± 286.1 µg/l (n = 49), FSH 7.6 ± 1.3 IU/L (n = 50), LH 3.8 ± 0.8 IU/L (n = 7), TSH 1.39 ± 0.17 mIU/l (n = 52), Cortisol 330.4 ± 35.8 nmol/l (n = 54). There were no significant differences in endocrinological values at time of presentation between patients treated surgically compared to those treated conservatively. At time of presentation, patients treated surgically had a tumor size in maximum dimension of 2.7 ± 1.4 cm vs 1.6 ± 0.5 cm for those treated conservatively (P = 0.0003). Fifteen percent (n = 9) of patients treated surgically underwent an additional surgery (mean 2.8 ± 2.0 years from index), of which 67% (n = 6) were secondary to tumor recurrence.

Conclusions

This is one of the largest reported series of pituitary apoplexy with long-term follow-up. A subset of surgically treated patients will require additional intervention, highlighting the importance of ongoing follow up in this population.

First-line F18-choline PET/CT Versus Tc99m-sestaMIBI SPECT/CT in the surgical management of primary hyperparathyroidism: a diagnostic randomized phase III trial

Elske Quak[1], Audrey Lasne-Cardon[2], Marie-Béatrice Cavarec[3], Barbara Lireux[1], Vianney Bastit[2], Nathalie Roudaut[4], Pierre-Yves Salaun[3], Nathalie Keromnes[3], Gael Potard[5], Patricia Vaduva[6], Annabelle Esvant[6], Franck Jegoux[7], Olivier De Crouy-Chanel[7], Anne Devillers[8], Clémence Guery[8], François Christy[9], Jean-Michel Grellard[9], Stéphane Bardet[1] & Bénédicte Clarisse[9]

[1]François Baclesse Cancer Centre, Nuclear Medicine and Thyroid Unit, Caen, France; [2]François Baclesse Cancer Centre, Head and Neck Surgery, Caen, France; [3]University Hospital of Brest, Nuclear Medicine, Brest, France; [4]University Hospital of Brest, Endocrinology, Brest, France; [5]University Hospital of Brest, Head and Neck Surgery, Brest, France; [6]Rennes University Medical Center, Endocrinology, Rennes, France; [7]Rennes University Medical Center, ENT, Rennes, France; [8]Emgene Marquis Cancer Institute, Nuclear Medicine, Rennes, France; [9]François Baclesse Cancer Centre, Clinical Research, Caen, France

Introduction

Whether F18-choline PET/CT (FCH PET/CT) should replace Tc99m-sestaMIBI SPECT/CT (MIBI SPECT/CT) as a first-line imaging technique for preoperative localisation of parathyroid adenomas in primary hyperparathyroidism (pHPT) is unclear.

Methods

We conducted a multicentre randomized open diagnostic intervention phase III trial in adults with primary hyperparathyroidism and indication for surgical treatment. Patients were assigned in a 1:1 ratio to receive first-line FCH PET/CT (FCH1) or MIBI SPECT/CT (MIBI1). In case of negative or inconclusive first-line imaging, patients received second-line FCH PET/CT (FCH2) after MIBI1 or MIBI SPECT/CT (MIBI2) after FCH1. The main aim of the trial was to compare the proportions of patients in whom the first-line imaging method resulted in successful mini-invasive parathyroidectomy (MIP) and normalisation of serum calcium levels at 1 month. We hypothesized a 30% superiority of FCH1 over MIBI1 for sample size determination (Quak et al, BMC Endocr Disord. 2021, PMID: 33413316).

Results

Overall, 57 patients received FCH1 (n = 29) or MIBI1 (n = 28). Baseline patient characteristics were similar between groups. Normocalcemia at 1 month after positive first-line imaging guided MIP was observed for 23 (85%) patients in the FCH1 group and 14 (56%) patients in the MIBI1 group (P = 0.022). Diagnostic performances were superior for FCH1 than for MIBI1: sensitivity was 82% and 63%, and diagnostic accuracy was 79% and 64%, for FCH1 and MIBI1, respectively. Follow-up at 6 months with biochemical measures was available for 43 patients, confirming normocalcemia for all patients with normocalcemia at 1 month post-surgery. Ten patients received FCH2 and 6 patients received MIBI2. FCH2 was positive in 8/10 patients, leading to 7/9 MIP and 2/9 bilateral cervical explorations (surgery recused in 1 patient), and normocalcemia in 9/9 patients. MIBI2 was positive in 2/6 patients, leading to 1 MIP and 1 VATS; normocalcemia was obtained in all 6 patients. No adverse events related to imaging and 4 adverse events related to surgery were reported.

Conclusions

First-line FCH PET/CT is a suitable and safe replacement for MIBI SPECT/CT. FCH PET/CT leads more PHPT patients to correct imaging-guided MIP and normocalcemia than MIBI SPECT/CT due to its superior diagnostic accuracy.

X-linked hypophosphatemia (XLH) is a rare genetic disease due to inactivation of the PHEX gene, which results in enhanced secretion of the phosphaturic hormone fibroblast growth factor 23 (FGF23); the latter induces renal phosphate wasting and hypophosphatemia. Skeletal and dental anomalies and recently described increase in cardiovascular risk are typical clinical findings. We retrospectively evaluated 58 adult patients with XLH from 9 Italian tertiary centres [34 females, 24 males, aged 42.6 ± 14.5 (19-72, min-max) years]. Median age at diagnosis was 4.0 (IQR, 2.0-14.0; min-max, 1-66) years; 12 patients (20.7%) were diagnosed in their adulthood. Twenty-six patients (44.8%) reported a family history of XLH and two females passed the condition on to their child. PHEX gene mutations or deletions were identified in 95% of patients. Circulating FGF23 levels were assayed in 23 patients (111.5 ± 71.5 pg/ml); FGF23 was increased in only 11 (47.8%) patients. Fractures or pseudofractures were reported in 30 patients (51.7%); 45 patients (77.6%) had marked signs of skeletal deformities, mainly varus of the lower limbs, or underwent multiple orthopedic surgeries; 18 (31.0%) patients had marked osteophytosis particularly affecting the spine. Enthesopathies were described in 16 (27.6%) patients, mostly affecting the knees. About two third of patients had severe dental disease, especially abscesses. Kidney stones/nephrocalcinosis developed in 6 patients. Regarding their cardiometabolic profile, 10 patients (aged 59.4 ± 10.6 years) had hypertension, and 7 patients were dyslipidemic. None of the patients had diabetes mellitus or a history of major adverse cardiovascular events. In the present series, 5 patients were diagnosed with hypoacusia. Autoimmune diseases, namely rheumatoid arthritis, Sjogren syndrome, thyroid diseases, and inflammatory bowel diseases, occurred in 17% of patients. About two third of patients were on conventional therapy with phosphate supplements and/or calcitriol, whereas 22 patients were on burosumab, a recombinant human IgG1 anti-FGF23 monoclonal antibody. Most patients proposed for treatment with burosumab, had experienced previous fractures/pseudofractures compared with patients on conventional therapy (82.6 vs 34.4% P = 0.0008), while they did not differ for age, age at diagnosis, and FGF23 levels. In conclusion, Italian adult XLH patients include lower limb deformities and severe dental disease as major clinical features; the presence of enthesopathies and ossifications that limit patients' quality of life is significant. Conversely, major cardiovascular events did not appear to be prevalent. Finally, Italian bone specialists propose burosumab to adult XLH patients with prevalent fractures/pseudofractures.

Autosomal dominant hypocalcemia type 1 (ADH1) is a genetic disorder characterized by low serum calcium and low or inappropriately normal levels of PTH. It is caused by a heterozygous activating mutation of the calcium-sensing receptor (*CASR*) gene, resulting in decreased sensitivity of the receptor to low serum calcium. The aim of our study was to describe a series of patients with ADH1 followed at our outpatient clinic from 2011 to 2023. A total of 7 patients (4 females and 3 males) carrying a missense variant of the *CASR* gene, were collected. Median age at diagnosis was 46 years (IQR 35-50), with only one patient diagnosed at birth. Two probands (71.4%) belonged to two kindreds with ADH1 and two (28.6%) were sporadic cases. Four patients (57%) were symptomatic at the time of the diagnosis (2 had recurrent kidney stones, 2 had cramp-like muscle pain with paresthesias and one recurrent hypocalcemic seizures since childhood). The remaining three patients were asymptomatic. At the time of our first evaluation, all patients had median albumin-corrected serum calcium of 7.72 mg/dl (IQR 6.9-8.1), PTH 17 ng/ml (IQR 15.5-20.7), phosphate 3.4 mg/dl (IQR 3.25-4.75), magnesium 1.9 mg/dl (IQR 1.68-2.0), creatinine 0.85 mg/dl (IQR 0.70-1.12), eGFR 90.8 mg/ml (89-105) and 24-h urinary calcium 202 mg IQR 179-225). Only one patient was on therapy with calcium carbonate, alfacalcidol and magnesium. Four of seven patients (57 %) had at least one target organ involvement (bilateral nephrolithiasis in three, nephrocalcinosis in four and reduced eGFR in two). One of six patients (17%) with available brain CT scan had basal ganglia calcifications. Bone mineral density at lumbar spine, femur and 1/3 distal radius was normal in five and low in two (median BMD 0.69; Z-score -2.2) at 1/3 distal radius. One patient started treatment with calcium carbonate and calcitriol and one also teriparatide. The median follow-up after our first evaluation was 5 years (IQR 4-8) and available only in five patients. Of the two patients on therapy, the median albumin-corrected serum calcium concentration was 8.9 mg/dl (IQR 8.9-8.9), phosphates 3.55 mg/dl (IQR 3.23-3.78), magnesium 1.85 mg/dl (IQR 1.77-1.92) and 24-h urinary calcium 345 mg/24 h (IQR 322-367). The three patients who were not on therapy had median values of serum calcium of 8.1 mg/dl (8.05-8.1), phosphate 3.85 mg/dl (3.78-3.92) and magnesium 1.9 mg/dl (1.85-1.95). Our data confirm a variable phenotype of ADH1 ranging from asymptomatic to mild-severe symptomatic profile.

Introduction
The HypoparaNet database includes 509 patients (110 men and 399 women) with chronic hypoparathyroidism (cHP), recruited and followed in 20 clinical centers in Italy from 2014 onwards. cHP etiology included 363 post-surgical cases (71.3%), 78 idiopathic cases (15.3%), and 64 patients with a genetic background (12.6%). Bone health is an important clinical aspect to be considered in patients with cHP, whose skeleton is exposed both to the cHP-induced alteration of bone mass and microarchitecture and to the occurrence/progression of osteopenia/osteoporosis related to ageing, specifically in post-menopausal (or over 50 years) women.
Patients and Methods
In the HypoparaNet cohort, dual x-ray osteodensitometry (DXA) was available in $n=173$ cHP patients. Among them, we specifically assessed the prevalence of osteopenia and osteoporosis in relation to menopause (or age below or above 50 years) in cHP women. Osteoporosis was defined as the presence of at least one of the measured bone sites presenting a *T*-score (or a *Z*-score for individuals <50 years) <-2.5. Osteopenia was defined as the presence of at least one of the measured bone sites presenting a *T*-score (or a *Z*-score for individuals <50 years) $<$-1.0, and all the measured bone site >-2.5.
Results
Female patients ($n=45$) at or below 50 years ($F\leq 50$) and female patients ($n=97$) above 50 years ($F>50$) showed comparable mean values of albumin-adjusted serum calcium, PTH, phosphate, 25(OH) vitamin D, $1,25(OH)_2$ vitamin D and magnesium. The overall prevalence of osteopenia was high, and it resulted to be comparable in the $F\leq 50$ and $F>50$ subgroups, averaging 38% and 34%, respectively. The prevalence of osteoporosis was clearly higher in the $F>50$ group with respect to the $F\leq 50$ group, averaging 4% and 24%, respectively.
Conclusions
These real-world data indicate that nearly half of cHP women, who represent the majority of the hypoparathyroid population, exhibit a high prevalence of osteopenia or osteoporosis that increases in relation to age. In this context, new treatment modalities (including PTH replacement therapy) for this patient population should aim at restoring a balanced bone turnover, preventing further bone loss and granting a better bone health at any age.

Management of skeletal fragility in women with early breast cancer (BC) under hormone-deprivation therapies (HDTs) may be a challenge and it is still unknown whether anti-osteoporotic therapies could be active in preventing fractures in pre-menopausal women exposed to HDTs. In this real-world, multicenter study, we evaluated the effectiveness of bone-active drmgs and determinants of vertebral fractures (VFs) in 306 pre-menopausal women (mean age 47.15 ± 5.09, range: 30-54) with early BC treated undergoing HDTs [gonadotropin-releasing hormone agonist (GnRHa) plus aromatase inhibitors (AIs) in 223 cases, GnRHa plus tamoxifene in 26 cases, AIs alone in 53 cases, tamoxifene alone in 4 cases]. In all 306 women, menopause was induced by treatment of BC (chemotherapy in 57 cases; GnRHa in the remaining 249 cases). All enrolled women were retrospectively evaluated for bone mineral density (BMD) and morphometric VFs by 12 months from starting of HDTs and after at least 24 months of

treatment. Treatment was guided by national guidelines, current Italian regulation for drmg reimbursement, patient's preference, comorbidities and overall clinical judgement. After the first bone evaluation, bone-active drmgs were prescribed in 237 women out of 306 (64 oral bisphosphonates, 28 zoledronate 5 mg iv yearly, 145 denosumab 60 mg every 6 months). At baseline, familiar history of osteoporotic fractures, personal history of clinical fractures, osteopenia, osteoporosis and morphometric VFs were found in 41 (13.40%), 21 (6.90%), 172 (56.20%), 39 (12.70%) and 19 (6.20%), respectively. After 47.01 ± 20.10 months of follow-up, 16 women (5.20%) experienced either new VFs or progression of pre-existing VFs. Incident VFs occurred more frequently in women who were untreated as compared to those treated with bone-active drmgs (14/69, 20.80% vs 2/237, 0.80%; $P<0.001$). Risk of VFs was associated with baseline diagnosis of osteoporosis [odds ratio (OR) 4.14, 95% confidence interval (C.I.) 1.10-15.58; $P=0.036$), familiar history of osteoporotic fractures (OR 3.19, 95% C.I. 1.05-9.73; $P=0.041$), baseline morphometric VFs (OR 25.36, 95% C.I. 8.03-80.13; $P<0.001$) and body mass index (BMI; OR 1.07; 95% C.I. 1.01-1.14; $P=0.034$). Duration of HDTs was significantly shorter in women experiencing incident VFs with vs those who did not fracture (38.00 ± 16.80 months vs 47.50 ± 20.10 months; $P=0.047$). In conclusion, risk of VFs in pre-menopausal women exposed to HDTs for early-BC could be effectively prevented by bisphosphonates or denosumab. This study smggests that bone-active drmgs might be indicated in women with pre-existing osteoporosis, familiar history of osteoporotic fractures and in those with higher BMI.

Changing clinical presentation of pheochromocytomas in a tertiary centre

Matej Rakusa[1], Gaj Vidmar[2], Ludemila Silva[3], Ursa Gerl[3] & Tomaž Kocjan[1]
[1]UMC Ljubljana, Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]University Rehabilitation Institute, Ljubljana, Slovenia; [3]Faculty of Medicine, Ljubljana, Slovenia

Context
Pheochromocytomas and paragangliomas (PPGLs) are rare tumours with potentially harmful cardiovascular complications. Traditionally, they were detected in patients with symptoms and signs of catecholamine excess or during genetic surveillance. However, according to recent reports, PPGLs are increasingly being diagnosed in the setting of incidentally discovered adrenal masses.
Aim
To assess the initial clinical presentation of our PPGL patients with emphasis on the characteristics of the incidental subgroup.
Methods
We retrospectively reviewed our cohort of patients diagnosed with and operated on PPGLs between January 2005 and December 2020 at the national tertiary care centre. The diagnosis was pathohistologically verified.
Results
We included 126 patients (68 women) with PPGL, mean age 55 years (range 16-80), mean BMI 26.1 (range 17.3-45.5). Most tumours were located in the adrenal (92%; right 52%, bilateral 2%), the remaining minority being paragangliomas (8%). Tumour size ranged from 10 to 121 mm (mean 47 mm). Overall, 80 PPGLs (63%) presented incidentally, 39 (31%) with adrenergic symptoms and signs, and 7 (6%) were diagnosed via genetic screening. Incidentally detected patients were older (mean age 58 years) on average than symptomatic individuals (52 years) and patients with hereditary syndromes (35 years; $P<0.001$). Annual number of PPGLs has been increasing over the studied period from about five to about 10. The presenting age has significantly increased since 2010 (mean 57 vs 48 years; $P=0.01$) in parallel with the proportion of patients with incidentalomas (69% vs 47%; $P=0.03$). However, targeted clinical assessment revealed that 48% of the incidentaloma group had at least one of the typical clinical manifestations (e.g. headache, palpitations, perspiration, pallor), and 37% had stage 2 or 3 hypertension. Genetically detected patients exhibited statistically significantly lower levels of urinary and plasma metanephrines, while values in symptomatic and incidentaloma patients were similar and varied widely. Five tumours appeared nonfunctional (2 hereditary and 3 incidental PPGLs). Imaging was mostly done by CT (120 patients or 94%). The density of the adrenal lesions ranged from 11 to 50 Hounsfield units. Nuclear medicine procedures were performed in 113 patients (89%). MIBG scintigraphy was used in 93% of these cases, the others had PET with positive findings in 91% overall.
Conclusion
Our observations are in line with recent reports that the majority of PPGLs are diagnosed incidentally. As a significant proportion of these patients were not truly asymptomatic, awareness of the clinical presentation of PPGLs still seems lifesaving.

Context
The role for hormone parameters at adrenal venous sampling (AVS) in predicting clinical and biochemical outcome remains controversial.
Objective
To investigate the impact of hormone parameters at AVS under cosyntropin stimulation on lateralization and on complete biochemical and clinical outcome.
Methods
We retrospectively evaluated 168 sequential AVS under cosyntropin infusion. Bilateral successful cannulation rate was 83.3% ($n=$ 140), 47.9% bilateral and 52.1% unilateral. The lateralization index (LI), aldosterone/cortisol ratio (A/C) in the dominant adrenal vein (AV), relative aldosterone secretion index (RASI = A/C in AV divided by A/C in inferior vena cava) were assessed. The contralateral suppression (CS) percentage was defined by (1 – nondominant RASI) ×100.
Results
A nondominant RASI <0.5 (CS >50%) had 86.84% sensitivity and 92.96% specificity to predict contralateral lateralization. An A/C ratio in dominant AV > 5.9 (74.67% sensitivity and 80% specificity) and dominant RASI >4.7 (35.21% sensitivity and 88.06% specificity) had a worst performance to predict ipsilateral lateralization. Complete biochemical and clinical cure were significantly more frequent in the patients with CS >50% [98.41% vs 42.86% (p <0.001) and 41.94% vs 0% ($P<0.001$)]. CS correlated with high aldosterone at diagnosis (p <0.001) and low postoperative aldosterone levels at 1 month ($P=0.019$). Postoperative biochemical hypoaldosteronism was more frequent in patients with CS >50% (70% vs 16.67%, $P=0.014$). In multivariable analysis, a CS >50% was associated with complete biochemical cure (OR 125, 95%CI 11.904–5,000; $P=0.001$) and hypertension remission (OR 12.19, 95%CI 2.074–250; $P=0.023$).
Conclusion
A CS >50% was an independent predictor of complete clinical and biochemical cure. Moreover, it can predict unilateral PA and postoperative biochemical hypoaldosteronism. Our findings underscore the usefulness of CS for clinical decision-making.

Light chromatography and mass spectrometry proteomic analysis of formalin fixed tissue of Bilateral Macronodular Adrenocortical Disease (BMAD) reveals various class correlating with molecular groups

Florian Violon, Anne Jouinot, Bruno Ragazzon, Patricia Vaduva, Lucas Bouys, Annabel Berthon, Mathilde Sibony & Jerome Bertherat
Cochin Institute, Endocrine tumor genomic and signaling pathway, Paris, France

Introduction
Bilateral macronodular adrenocortical disease (BMAD) is an adrenal cause of Cushing's syndrome explained in a subset of patients by inactivation of the tumor suppressor genes *ARMC5* or *KDM1A*. Genetic and transcriptomic studies cluster BMAD in 3 distinct molecular groups: one with *ARMC5* inactivation, one with *KDM1A* inactivation and a third group with no known genetic cause. Although *ARMC5* and *KDM1A* are involved in the post-translational regulation of proteins, the protein studies in BMAD tissues are mainly limited to immunohistochemistry targeted on steroidogenesis enzymes. The aim of this work was to study the proteomic heterogeneity in a BMAD cohort and its correlation with the molecular causes.
Patients and Methods
The cohort includes 24 BMAD (7 *ARMC5*-altered, 4 *KDM1A*-altered and 13 of unknown genetic cause) and 12 samples used as controls (10 adenomas and 2 normal adrenal glands). All patients underwent surgery in our center between 2006 and 2021. Samples were obtained from formalin-fixed and paraffin-embedded material by macrodissection. After protein extraction, identification and protein quantifications were performed by Light chromatography and mass spectrometry (LC-MS/MS) on the Cochin Institute Proteomic platform.
Results
PCA showed a rather homogeneity of *ARMC5* and *KDM1A*-altered BMAD, whereas BMAD with no known genetic cause were more heterogeneous. In accordance with *ARMC5* role in the regulation of the RNA polymerase II, several of its subunits including POLR2A are the most overexpressed proteins in ARMC5-mutated BMAD compared to the others BMAD groups. However, they have a low expression of several cholesterol biosynthesis enzymes (such as FDFT1 or NSDHL) compared to other BMAD. *KDM1A*-altered BMAD were also a homogeneous group characterized by the systematic loss of KDM1A protein and the overexpression of proteins involved in lipid metabolism (such as LDLR or SULT2A1).
Discussion
Our study is the first to explore the BMAD proteome using LC-MS/MS. We confirmed the high expression of ARN polymerase II subunits in *ARMC5*-altered BMAD and showed a high expression of ARN polymerase II partners smggesting its important role in the pathogenesis of BMAD mediated by *ARMC5* alterations. Compared to other BMAD, ARMC5-altered BMAD expressed lower levels of cholesterol biosynthesis enzymes that could partially explain the low cortisol production of cells with bi-allelic inactivation of *ARMC5*. *KDM1A* altered BMAD showed an overexpression of proteins involved in lipid metabolism that probably play a role in the production of cortisol dysregulation. BMAD with no known genetic cause showed various proteomic pattern smggesting different pathogenic mechanisms to be identified.

Background
Hypertension affects more than 30% of the adult population worldwide and is a major cardiovascular risk factor. Identifying secondary causes of hypertension is key to offering targeted treatments and mitigating adverse health outcomes. We tested the performance of urine steroid metabolomics (USM), the computational analysis of 24-hour urine steroid metabolome data by machine learning, for diagnosing endocrine forms of hypertension.
Methods
1400 hypertensive adults with and without endocrine causes were recruited through the ENS@T-HT EU-funded Horizon 2020 research and innovation project; of these, 351 and 1049 were collected retrospectively and prospectively, respectively. Liquid chromatography-tandem mass spectrometry (LC-MS/MS)-based multi-steroid profiling was used to quantify the excretion of 27 steroid metabolites in 24-hour urine samples. The prospective cohort underwent standardised measurement of the aldosterone-renin-ratio (ARR) to screen for primary aldosteronism (PA). Data were analysed by generalised matrix learning vector quantisation, a prototype-based algorithm of supervised machine learning, using the retrospective cohort (RC) for training and the prospective cohort (PC) for validation.
Results
We included 610 patients with PA (110 RC, 500 PC), 126 with phaeochromocytoma-paraganglioma (PPGL; 82 RC, 44 PC), 83 with Cushing's syndrome (CS; 48 RC, 35 PC), and 581 with primary hypertension (PHT; 111 RC, 470 PC). USM demonstrated high accuracy (area under the receiver-operating characteristics curve [AUC-ROC] 0.93) in identifying CS cases, which showed higher urinary excretion of glucocorticoid and glucocorticoid precursor metabolites. USM yielded moderate accuracy (AUC-ROC 0.73) in differentiating PHT from PA. However, the performance improved considerably (AUC-ROC 0.87) when comparing PA cases to low-renin PHT ($n=235$), with the major aldosterone metabolite – 3α,5β-tetrahydroaldosterone – being the most discriminatory. Within the prospective cohort, USM had similar accuracy to the ARR in differentiating PHT from PA (AUC-ROC 0.87 and 0.88, respectively). The performance improved when combining USM results with renin alone (AUC-ROC 0.90) or the ARR (AUC-ROC 0.93). Expectedly, USM could not reliably differentiate PHT from PPGL (AUC-ROC 0.57).
Conclusions
Urine steroid metabolomics is a non-invasive candidate test for accurately diagnosing hypertension secondary to cortisol and aldosterone excess and can improve diagnosis and delivery of appropriate treatment in affected individuals.

Introduction

Pharmacological glucocorticoid (GC) treatment may cause iatrogenic adrenal insufficiency (GIA), although the prevalence and clinical implications are debated. With 3% of the Danish population redeeming prescriptions of systemic GC annually, the number of patients at risk is potentially extensive. Taken together, there is an unmet need for a prospective and unbiased assessment of the GIA prevalence.

Materials and Methods

The data for this report stem from an ongoing randomized clinical trial – REPLACE. The study systematically investigates adrenocortical function in patients with polymyalgia rheumatica (PMR)/giant cell arteritis (GCA), 2-12 weeks after patients have stopped long-term (>12 weeks) prednisolone treatment. We used the standard 250 µg ACTH test (SST) and analyzed plasma cortisol at 0 and 30 minutes with Liquid Chromatography Mass Spectrometry and/or Electrochemiluminescence immunoassay (Roche Elecsys Cortisol II) with GIA defined as 30-minute cortisol <420 nmol/l. The participants also completed a 30-item disease-specific (AddiQoL-30) quality of life questionnaire with scores from 30 (worst) to 120 (best).

Results

Among 238 patients who were tested, four (1.6%) patients exhibited an insufficient response to the SST. 64/192 (33%) of patients with completed AddiQoL-30 displayed marked symptoms, with an AddiQoL-30 score ≤85 (average for AI patients in literature). AddiQoL-30 score ≤85 was related to lower basal plasma cortisol levels taken at median time 11:30 (IQR 10:09-12:50) of 261 (95%CI: 239-283) nmol/l vs 307 (95%CI: 292-322) nmol/l, $P<0.001$. Linear regression adjusted for age, sex, BMI and sample time revealed a positive correlation between AddiQoL-30 score and basal cortisol of 1.5 (95%CI: 0.3-2.9) points/50 nmol/l ($P=0.015$). Risk factors associated with low Addiqol-30 score included upper quartile body fat percentage (OR: 7.3, 95%CI: 1.8-30.7) compared to lower quartile, lower quartile hand grip strength (OR: 6.2, 95%CI: 1.9-20.6) compared to upper quartile and female sex (OR: 1.9, 95%CI: 1.0-3.7) compared to male (all $P<0.05$). There was no association with age, type of or duration of PMR/GCA, cumulative 6-month prednisolone exposure or levels of C-reactive protein.

Conclusions

- The risk of GIA defined by the SST after finished prednisolone treatment in patients with PMR/GCA is much lower than previously reported, but the prevalence of GIA symptoms is high and accompanied by lower cortisol levels.
- It remains to be experimentally tested, if patients with symptoms attributable to adrenal insufficiency after planned cessation of prednisolone treatment benefit from hydrocortisone replacement therapy.
- Our data add important information about the so-called steroid withdrawal syndrome, which merits future research.

Primary aldosteronism (PA) is the most frequent form of secondary hypertension and is due to autonomous aldosterone production by the adrenal gland. During the last decades, major advances have been made in our understanding of the disease with the identification of germline or somatic mutations in ion channels and pumps. These mutations enhance calcium signaling, the main trigger of aldosterone biosynthesis. The objective of our work was to elucidate, using chemogenetic tools, the molecular mechanisms underlying the development of PA by modulating sodium entry into the cells "on demand" leading to calcium signaling activation. We have developed an adrenocortical H295R-S2 cell line stably expressing a chimeric ion channel receptor formed by the extracellular ligand-binding domain of the a7 nicotinic acetylcholine receptor fused to the ion pore domain of the serotonin receptor 5HT3a named α7-5HT3. Its activation by a selective agonist, the PSEM-817, leads to sodium entry into the cells and activation of calcium signaling. In parallel, we have developed a mouse model expressing the α7-5HT3 receptor specifically in the adrenal cortex. The cells expressing the α7-5HT3 receptor recapitulated the major features of *KCNJ5* mutations, the most frequent genetic alteration identified in Aldosterone-Producing-Adenoma. Stimulation of the α7-5HT3 receptor by PSEM-817 resulted in a significant increase in intracellular calcium concentrations, *CYP11B2* mRNA expression, and aldosterone biosynthesis and was associated with a decrease in cell proliferation. RNA sequencing and steroidome analyses revealed unique profiles associated with sodium entry. Exploration of adult mice expressing the α7-5HT3 receptor specifically in the adrenal cortex, generated in our laboratory, is ongoing. Preliminary results revealed a significant increase in plasma aldosterone and 18-hydroxycorticosterone levels in male and female mice expressing the a7-5HT3 receptor after four weeks of treatment with PSEM-817 but no major adrenal abnormalities. Our results smggest that increased sodium influx leading to increased calcium signaling is not sufficient to promote both increased aldosterone production and cell proliferation, thus strongly supporting the requirement of additional mechanisms for the development of APA. Altogether, this work offers valuable insights into the role of sodium-induced calcium signalling in PA development and paves the way for developing new therapeutic strategies.

An artificial intelligence-based decision support system for classifying patients with adrenal tumors

Dimitrios Binas[1], Theodore Economopoulos[1], Grigoria Betsi[2], Paraskevi Xekouki[2], Anna Angelousi[3] & George Matsopoulos[1]

[1]National Technological University of Athens, Biomedical Engineering Laboratory, School of Electrical and Computer Engineering, Athens, Greece; [2]University of Crete School of Medicine, Endocrinology and Diabetes Clinic, Heraklion Crete, Greece; [3]National and Kapodistrian University of Athens, First Department of Internal Medicine, Athens, Greece

Background

Adrenal Incidentaloma's (AI) incidence has been increased 10-fold in the past two decades and more specifically, up to 7% in the general population and up to 9% in elderly patients. Determining whether an adrenal mass is malignant or hormonally active is of great clinical and socioeconomical importance, in order to select the best medical approach and follow up. Artificial Intelligence techniques could provide useful clinical tools for predicting the nature of AI with acceptable accuracy.

Methods

A total of 96 patients diagnosed with AI were selected from two tertiary centres. Their clinical data were collected and randomly grouped into training and validation sets in a ratio of 4:1. Two different experimental approaches were adopted. The first approach, concerned the analysis of twelve routine clinical features [functionality, age at diagnosis, hypokalemia, lateralisation, size max, baseline cortisol morning levels, adrenocorticotropic hormone (ACTH), 17-OH progesterone levels, 24 h urinary free cortisol, 1 mg overnight dexamethasone suppression cortisol levels, Hb1Ac, Computed Tomography imaging (baseline non-contrast Hounsfield)] for developing a predictive model for benign and non-benign adrenal tumors. The second approach included eight more features [age, gender, hypertension, hyperlipidaemia, anti-lipidemic therapy, Diabetes Mellitus (DM), anti-DM therapy, dehydroepiandrosterone (DHEAS)] for classifying

patients into the same groups (benign and non-benign tumors). Eleven Machine Learning (ML) models were applied and tested in each of the above-mentioned experimental approaches to construct the best performing predictive model. In order to evaluate the performance of the proposed classification systems, precision, sensitivity, F1-score and accuracy were examined.
Results
The first tested Machine Learning model, based on the combination of 12 features, resulted in predictions with an average accuracy of over 97% using a K-Neighbors classifier. Equally, the second tested model based on the combination of 20 features resulted in a prediction with an average accuracy of over 96%, using a Ridge classifier. The statistical comparison between the results of the two different experimental approaches did not show statistically significant difference, as verified through a Mann Whitney test.
Conclusion
This study proposes the use of Machine Learning methods to establish a prediction model for benign and non-benign adrenal tumors. A high predictive performance was achieved even based on relatively few clinical cases. This study provides a decision support model which could constitute a helpful and practical clinical tool, accelerating the decision process in the healthcare system resulting to early screening, which ultimately results in time and cost savings.

Effects of semaglutide, Peptide YY3-36 and empagliflozin on metabolic dysfunction associated fatty steatotic liver disease in diet-induced obese rats with chronic nitric oxide synthase-inhibition

Niklas Geiger[1], Simon Kloock[1], Jana Gerner[2], Aisha-Nike Landthaler[2], Alexander Nickel[2], Michael Kohlhaas[2], Andreas Geier[3], Martin Fassnacht[1] & Ulrich Dischinger[1]
[1]University Hospital Wuerzburg, Department of Internal Medicine, Division of Endocrinology and Diabetes, Wuerzburg, Germany; [2]University Hospital Wuerzburg, Comprehensive Heart Failure Center, Wuerzburg, Germany; [3]University Hospital Wuerzburg, Department of Hepatology, Wuerzburg, Germany

Background and Aims
Metabolic dysfunction-associated steatotic liver disease (MASLD) is a common comorbidity of obesity. In this study, we sought to determine hepatic metabolic and mitochondrial effects of the Glucagon-like Peptide-1-agonist semaglutide, the sodium-glucose linked transporter 2-inhibitor empagliflozin and Peptide YY_{3-36} in diet-induced obese rats with additional chronic inhibition of nitric oxide synthase via N^{ω}-nitro-L-arginine methyl ester (L-NAME), to induce accelerated liver injury.
Method
Following an eight-week feeding period with a high-fat/fructose-diet (HFD) and L-NAME, male wistar rats were randomized into the following treatment groups: semaglutide, empagliflozin, PYY_{3-36}, semaglutide in combination with empagliflozin or PYY_{3-36}, a food restricted body weight matched group (BWM) and saline control. After an additional 8 weeks, qRT-PCR was performed to quantify hepatic mRNA expression of metabolic and inflammatory marker genes. Serum was analysed for insulin, glucose, adiponectin and leptin levels. Moreover, in isolated mitochondria, mitochondrial respiration in different states using Oroboros O2K-FluoRespirometer was examined.
Results
In the liver, the de-novo lipogenesis regulating genes MLXIPL and SREBF-1 were downregulated in the BWM, semaglutide and PYY_{3-36} -mono groups and significantly lower in the semaglutide + PYY_{3-36} group ($P<0.05$) compared to saline treated controls. HOMA-index was significantly lower in PYY-mono treated animals ($P<0.05$) and in the semaglutide + empagliflozin- group ($P<0.05$), adiponectin-leptin-ratio was significantly higher in semaglutide + PYY_{3-36} ($P<0.01$) and BWM treated animals in comparison to saline ($P<0.01$). Moreover, there was a significant downregulation of IL-1b mRNA in the semaglutide-mono treated group ($P<0.05$). In the semaglutide + empagliflozin treated group, TNF-alpha-levels were lower compared to saline. Regarding mitochondrial respiration, fatty acid-dependent state 3 respiration, empagliflozin ($P<0.001$) as well as semaglutide + empagliflozin ($P<0.05$) decreased O_2-consumption significantly in comparison to controls. In the uncoupled state, empagliflozin and PYY_{3-36} mono-treatment decreased the O_2-rate significantly ($P<0.05$) compared to saline control. Moreover, semaglutide in combination with PYY_{3-36} or empagliflozin lowered O_2-consumption.
Conclusion
In summary, the presented data indicate a strong improvement of insulin sensitivity shown by presented metabolic parameters and associated genes. O_2-consumption of the respiratory chain in mitochondria is decreased in semaglutide, PYY_{3-36}, and empagliflozin treated rats, supposing reduced metabolic stress in these groups. The strongest effect was detected in semaglutide + PYY_{3-36} treated animals, which points towards PYY_{3-36} as a promising additive substance in the treatment of MASLD.

RC12.2

Predictors of poor response to semaglutide for weight management

Ploutarchos Tzoulis[1,2] & Michael Batavanis[3]
[1]UCL Medical School, London, United Kingdom; [2]IASO Hospital, Department of Endocrinology, Athens, Greece; [3]University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom

Introduction
The prevalence of obesity, a chronic disease with significant morbidity, has rapidly increased in recent decades. Semaglutide, an injectable glucagon-like peptide-1 agonist, has gained global popularity after its approval for weight management in 2021. All studies have reported marked variability in semaglutide response, with a small proportion of patients (10-16%) showing inadequate response. Data about the predictors of poor response to semaglutide for weight loss is lacking.
Methods
This is a retrospective case review of patients treated with semaglutide for weight loss in an endocrine clinic in Athens, Greece. This included 40 adults without diabetes mellitus who either had a body mass index (BMI) > 30 kg/m^2, or a BMI of 27-29.9 kg/m^2 and at least one weight-related co-morbidity. The aim was to assess the association of baseline characteristics with the magnitude of weight loss and determine predictors of poor response.
Results
This real-world chart review included 28 females and12 males with a median age of 47 years old, weight of 111.7 kg and BMI of 39.7 kg/m^2. The median weight reduction was 6.6% and 13.3%, following 3 and 6 months of semaglutide treatment, respectively. This study showed significant heterogeneity in response to semaglutide, with nine individuals (22.5%) being non-responders, defined as achieving a weight loss $<3\%$ at 3 months or $<5\%$ at 6 months. Baseline BMI was not associated with 3-month percentage weight loss ($P=0.086$). Regarding the effect of gender on semaglutide-induced weight loss, the median 3-month percentage weight loss was similar: 6.9% in females and 6.4% in males ($P=0.46$). However, the percentage of non-responders was higher amongst males (41.6% compared to 14.2% among females, but not statistically significant; $P=0.057$). Patients with a history of psychiatric illness were overrepresented in the non-responders group, with 4 out of 9 patients (44.4%) not showing a favourable response. The only three individuals who experienced weight gain at 3 months were all females with active major depressive disorder.
Discussion
This retrospective study confirmed the great variability in semaglutide-related weight loss outcomes, with males having a higher likelihood of suboptimal response compared to females. The novel finding was the link of psychiatric disease, especially active depression, with poor response to semaglutide, highlighting the need to evaluate the efficacy of semaglutide in patients with active psychiatric disease. Determining the predictors of response to semaglutide is essential to facilitate personalised treatment of obesity.

Adipose tissue analysis toolkit (ATAT) for automated analysis of adipocyte size and extracellular matrix in white adipose tissue

Jacob Robino[1], Alexander Plekhanov[2], Qingzhang Zhu[3], Michael Jensen[4], Philipp Scherer[3], Charles Roberts[1] & Oleg Varlamov[1,5]
[1]Oregon National Primate Research Center, Beaverton, United States; [2]California Institute of Technology, Pasadena, United States; [3]UT Southwestern Medical Center, Dallas, United States; [4]Mayo Clinic, Rochester, United States; [5]Oregon Health and Science University, Oregon Primate Research Center, Beaverton, United States

The pathological expansion of white adipose tissue (WAT) in obesity involves adipocyte hypertrophy accompanied by expansion of collagen-rich pericellular extracellular matrix (ECM) and the development of crown-like structures (CLS). Traditionally, WAT morphology is assessed through immunohistochemical analysis of WAT sections. However, manual analysis of large histological

sections is time-consuming, and available digital tools for analyzing adipocyte size and pericellular ECM are limited. To address this gap, we developed the Adipose Tissue Analysis Toolkit (ATAT), an ImageJ plmgin facilitating analysis of adipocyte size, WAT ECM and CLS. ATAT utilizes local and image-level differentials in pixel intensity to independently threshold background, distinguishing adipocyte-free tissue without user input. It accurately captures adipocytes in histological sections stained with common dyes and automates the analysis of adipocyte cross-sectional area, total-field, and localized region-of-interest ECM. ATAT allows fully automated batch analysis of histological images using default or user-defined adipocyte detection parameters. ATAT provides several advantages over existing WAT image analysis tools, enabling high-throughput analyses of adipocyte-specific parameters and facilitating the assessment of ECM changes associated with WAT remodeling due to weight changes and other pathophysiological alterations that affect WAT function.

Hypoglycaemia following the 2-hour 75g OGTT in pregnancy – investigating maternal and foetal outcomes

Edward Jude, Callum Blunt & Roopa Krishnamurthy
Tameside and Glossop Integrated Care NHS Foundation Trust, United Kingdom

Aims
To investigate differences in maternal and foetal outcomes in pregnancy, where patients developed hypoglycaemia following the 2-hour 75 g oral glucose tolerance test (OGTT).
Method
A retrospective cohort study of 200 pregnancies attending the Antenatal Clinic at Tameside General Hospital between 2018 and 2022. Outcomes were compared between 4 groups: normal OGTT [G1; ($n=39$, 20%], hyperglycaemia following OGTT [G2; BG $\geq$5.6 mmol/litre or 2-hour OGTT $\geq$7.8 ($n=41$, 21%)], hypoglycaemia [G3; 2 hr OGTT 3.0-3.9 mmol/l ($n=93$, 47%)], or clinically significant hypoglycaemia [G4; 2 hr OGTT $<$3.0 mmol/l ($n=27$, 14%)]. Maternal BMI, foetal body-weight (FBW), neonatal complications, neo-natal intensive care unit (NICU) stay and conversion to GDM were assessed.
Results
Maternal BMI was lower in G3 and G4 (27.3 kg/m^2 and 28.1 kg/m^2 respectively) compared to G1 (30.4 kg/m^2) ($P=0.02$). NICU stay was more frequent in G3 (12%, $n=11$) and G4 (8%, $n=2$) compared to G1 (5%, $n=2$). Foetal complications occurred in 39% of G3 ($n=36$) and 44% of G4 ($n=12$) compared to 23% in G1 ($n=9$) and 22% in G2 ($n=9$). FBW was similar in G1 when compared to G3 and G4 ($P=0.34$). Of the 120 patients in G3 and G4, 25 patients self-monitored blood glucose for two weeks. 28% ($n=7$) subsequently developed GDM.
Conclusion
Higher rates of NICU stay and foetal complications were seen in both hypoglycaemic groups. In patients with hypoglycaemia following OGTT there is evidence to support monitoring BG as a proportion were later diagnosed with GDM.

Effects of antagonists of the NPY-2 receptor, semaglutide, PYY3-36, and empagliflozin on metabolic dysfunction-associated steatotic liver disease in diet-induced obese rats

Simon Kloock[1], Niklas Haerting[1], Gloria Herzog[2], Marie Oertel[1], Niklas Geiger[1], Andreas Geier[3], Alexander Nickel[4], Kohlhaas Michael[4], Martin Fassnacht[1] & Ulrich Dischinger[1,4]
[1]Center for Internal Medicine at the University of Würzburg ZIM, Endocrinology and Diabetes, Würzburg, Germany; [2]Institute of Pathology at the University of Würzburg, Würzburg, Germany; [3]Center for Internal Medicine at the University of Würzburg ZIM, Hepatology, Würzburg, Germany; [4]Comprehensive Heart Failure Center, Cardiology, Würzburg, Germany

Metabolic dysfunction-associated steatotic liver disease (MASLD) frequently accompanies obesity, posing a significant health concern. The Neuropeptide Y (NPY) system, a key player in energy metabolism regulation, has implications for liver health, yet the impact of NPY receptor antagonists remains largely unexplored. This study investigates the effects of antagonists targeting the NPY-2 receptor (Y2R) in comparison to known MASLD-beneficial substances.
Methods
Diet-induced obese (DIO) male Wistar rats were divided into the following treatment groups: empagliflozin, semaglutide, semaglutide $\pm$PYY3-36, Y2R antagonist JNJ-31020028, a food-restricted group, and a control group. After 8 weeks of treatment, livers were assessed for weight and histology. QrtPCR was utilized to examine liver inflammation and de novo lipogenesis in both liver and adipose tissue. Serum samples were analyzed for metabolic parameters.
Results
The combination of semaglutide and PYY3-36 resulted in weight loss, significantly reducing liver steatosis compared to controls ($p = 0.05$). Markers of inflammation, insulin resistance, and leptin levels were also reduced. Empagliflozin exhibited limited impact on the measured parameters. JNJ-31020028 did not induce significant weight loss but prevented steatosis ($P=0.03$), with no effect on inflammation. The de novo lipogenesis regulating genes SREBP1 and MLXIPL were downregulated in livers of JNJ-31020028 treated DIO rats compared to controls ($p \leq 0.0001$), with no observed effect in visceral adipose tissue. Food restriction led to significant reductions in weight, steatosis, and de novo lipogenesis.
Discussion
Body weight reduction, achieved through methods like food restriction or drmgs such as semaglutide $\pm$PYY3-36, proved effective in ameliorating liver steatosis in DIO rats. Notably, the weight-neutral Y2R antagonists showed promise in preventing liver steatosis through a reduction in de novo lipogenesis. Further investigations are needed to elucidate the molecular impact of the NPY system on liver pathophysiology.

MTHFR 677 TT and CT genotype related epigenetic changes and hyperhomocysteinemia in Hypothyroidism and its management, a family case report

Tamar Kvaratskhelia[1], Elene Abzianidze[2], Sandro Surmava[2] & Eka Kvaratskhelia[2]
[1]New Vision University Hospital, Internal department, Tb, Georgia; [2]Tbilisi State Medical University, T'bilisi, Georgia

Introduction
Hypothyroidism is a clinical syndrome resulting from a deficiency of thyroid hormones, which in turn results in a generalized slowing down of metabolic processes. There are consistent reports demonstrating that many diseases, including the thyroid gland dysfunction are associated with changes of serum homocysteine (tHcy) level, with its genetic and epigenetic causes.
Case report
In 2018 we reported 51 and 52-year-old sisters diagnosed with subclinical and manifested hypothyroidism accordingly. One of them was enrolled to a research study related to the link between MTHFR gene polymorphisms, DNA methylation status and hypothyroidism (T. Kvaratskhelia et al.). Both siblings revealed MTHFR gene 677 TT genotype. We also investigated two other siblings from the same family without history of hypothiroidism: 54-year-old female and 47-year-old male who showed CC genotype and their 82-year-old mother with CT genotype and an episode of thyroid failure in the past. After 6 years we report 88-year-old mother who developed subclinical hypothyroidism soon after initial study and the results of hyperhomocysteinemia management with vitamin supplements in all effected family members.
Methods
MTHFR gene was investigated by the PCR-RELF method using HinfI (NEB Inc) enzyme. Levels of DNMT1-3a and DNMT1 were measured in nuclear extracts of PBMC (Abcam). Total serum homocysteine concentrations were also measured. DNA samples underwent bisulfite modification (Qiagen) and methylation levels of Alu and LINE-1 were examined by the combined bisulfite restriction analysis-interspersed repetitive sequences (COBRA-IRS). We have added vitamin B group supplements for hyperhomocysteinemia management.
Results
Family members with TT and CT genotype had elevated levels ofDNMT3a compared with CC genotype. There was no significant difference in DNMT1 levels. tHcy levels were significantly elevated in study subjects with TT genotypes and slightly elevated in the individual with CT genotype in initial measurement, which increased at the presentation of hypothyroidism. Hypermethylated loci (mCmC) at Alu elements were significantly lower and LINE-1 hypermethylated loci (mCmC) were also lower in TT and CT genotypes compared with CC family members. Hyperhomocysteinemia management with

supplemets lead to the reduction of levothyroxine replacement doses in sisters, it improved thyroid function test results in mother who was not initiated levothyroxine replacement treatment and significantly improved dyslipidemia in all study subjects.
Conclusions
We smggest that molecular studies of MTHFR gene and its related epigenetic changes could be valuable for refining the clinical diagnosis of hypothyroidism, leading to its more precise management.

Comprehensive genetic analyses of sporadic and seemingly idiopathic hypoparathyroidism by whole-exome sequencing: Identification of novel GCM2 and AIRE mutations

Saroj Sahoo[1], Takasi Anush Babu[1] & Kausik Mandal[2]
[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Endocrinology, Lucknow, India; [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Medical Genetics, Lucknow, India

Objective
We aimed to identify the genetic defect in patients labelled as sporadic and idiopathic hypoparathyroidism (HP) by using whole-exome sequencing (WES).
Methods
Patients with sporadic nonsurgical HP, aged <30 years were recruited. Those with a known genetic or autoimmune aetiology were excluded from the study. Thirty such patients were screened for antibodies against interferon-α, a highly sensitive and specific marker of autoimmune polyendocrine syndrome type 1 (APS1). Eight patients had an elevated titer and all of them carried double mutations in the *AIRE*, responsible for APS1. The remaining 22 were screened for DiGeorge syndrome via multiplex-ligand dependent probe amplification (MLPA) and five had deletions diagnostic of DiGeorge syndrome. The remaining 17 were subjected to WES. Mutations were confirmed by Sanger sequencing, and the pathogenicity of novel variants were confirmed by *in-silico* functional analyses.
Results
Of the 17 patients who underwent WES, pathogenic variants causing HP were detected in five (29%) patients. Patient #1 (current age 32 years, age of onset of disease 24 years) had a known pathogenic variant c. 1504A>C, Asn502His in the *GCM2* gene. Patient #2 (current age 19 years, age of onset of disease at 1 month) and patient #3 (age of onset of the HP 20 years, current age 32 years) had novel mutations in the *GCM2* gene; homozygous mutation c.391C>T, Arg131* and heterozygous variant c.319G>A, Asp107Asn, respectively. Patient #4 (current age 21 years, age of onset of disease 14 year) carried a heterozygous variant in exon 6 of the *AIRE* gene (c.739C>T, Arg247Cys). Patient #5 with HP and additional features such as sensory neural hearing loss and dysmorphic facies carried a heterozygous variant c.1608G>T (Met536Ile) in the *AIRE*. All the novel variants were pathogenic as assessed in the *in-silico* functional analysis. The patients carrying the *AIRE* mutations did not have other endocrine and ectodermal components on further investigations.
Conclusion
Muations in the *GCM2* and *AIRE* were common in patients with seemingly sporadic and idiopathic hypoparathyroidism. In contrast to the classic homozygous/compound heterozygous mutations in the *AIRE* which is responsible for childhood-onset APS1 and widespread endocrine and ectodermal manifestation, heterozygous mutations in the *AIRE* can manifest as isolated HP and negative for antibodies againt interferon-α. All young patients with sporadic and idiopathic hypoparathyroidism should be evaluated for genetic basis especially *GCM2* and *AIRE*.

Background
Metyrapone, osilodrostat, and ketoconazole are steroidogenesis inhibitors used as second-line treatment in endogenous Cushing's syndrome (CS). However, a direct comparison of these three drmgs is missing.
Objective
To compare the efficacy of the three drmgs after short-term therapy (≤ 12 weeks) for CS.
Methods
Multicenter, real-life retrospective study involving 20 centers worldwide. Patients with CS treated with metyrapone, osilodrostat or ketoconazole as monotherapy were included. Main outcomes were changes in 24 h urinary free cortisol (24 h-UFC) and morning serum cortisol, both normalized to upper limit of normal (ULN) for each measurement, after 2(T1), 4(T2), and 12(T3) weeks of treatment. Mixed-effects models were used to evaluate how drmgs influenced main outcomes over time, considering baseline values and controlling for dosage variations. The interaction between drmgs and time was tested.
Results
531 patients (76% women; 77% ACTH-dependent CS) were identified; 35 patients with adrenocortical carcinoma were excluded for this analysis. Among the remaining 496 cases, 199 (40%) were treated with metyrapone, 122 (25%) with osilodrostat, 175 (35%) with ketoconazole. Median daily dose of metyrapone and osilodrostat significantly increased from 750 (interquartile range 500-1000) mg and 3 (2-4) mg at baseline to 1000 (500-1250; $P<0.01$)mg and 6 (2-10; $P<0.0001$) mg at T3, respectively. No significant changes were observed for ketoconazole (median 400mg over time). Median baseline 24 h-UFC was slightly higher in patients under metyrapone (2.6×ULN, 1.5-7.9) than ketoconazole (2.1×ULN, 1.2-3.6, $P=0.04$), but not than osilodrostat (2.3×ULN, 1.3-4). The three drmgs showed same impact in decreasing 24 h-UFC over time (interaction $P=0.51$). Morning serum cortisol at baseline was not different among the groups. Osilodrostat reduced morning serum cortisol more than the other drmgs (interaction $P=0.002$), mostly at T3 (average mean difference: metyrapone/osilodrostat=0.23, 95%CI=0.07-0.38, $P<0.001$; ketoconazole/osilodrostat=0.28, 95%CI=0.45-0.12, $P<0.001$). No differences between ACTH-dependent and -independent CS were found regarding the efficacy of the three drmgs. At T1, the number of antihypertensives was reduced in 7% of patients under metyrapone, 17% under osilodrostat, and 7% under ketoconazole ($P<0.005$), whereas at T2-T3 no differences were found. At T3, 19% of patients under osilodrostat required potassium supplementation compared to 10% under metyrapone and 10% under

ketoconazole ($P=0.15$). Treatment was discontinued because of adverse events in 5% of cases under metyrapone, 10% under osilodrostat, 8% under ketoconazole.
Conclusion
Our results showed comparable efficacy of these three drmgs in decreasing 24 h-UFC. However, considering dose variations, osilodrostat might be more efficient in decreasing morning serum cortisol and faster in reducing blood pressure than metyrapone and ketoconazole.

Development and validation of an LC-MS/MS method to measure 7-alpha-hydroxy-4-cholesten-3-one (C4) for the assessment of bile acid dysregulation in PCOS

Jonathan S Atkins[1], Brian Keevil[1], Christian Ludwig[2] & James M. Hawley[1]
[1]Wythenshawe Hospital, Department of Clinical Biochemistry, Manchester, United Kingdom; [2]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom

Introduction
7α-Hydroxy-4-cholesten-3-one (C4) is the common intermediary of the primary bile acids (BAs). Its concentration in serum correlates with the rate of activity of hepatic CYP7A1 and therefore with the rate of hepatic BA production. Previous work has smggested a role for BA pool dysregulation in the metabolic syndrome and gut dysbiosis seen in polycystic ovary syndrome (PCOS). However, the mechanism of this is still to be elucidated. Here we report a novel LC-MS/MS method for the analysis of C4 for this purpose and an assessment of preanalytical stability to ensure reliable results.
Methods
The method was developed using a Waters TQS mass spectrometer. Accuracy was underpinned by calibrating to quantitative nuclear magnetic resonance analysis. C4 was analysed in a high-throughput 96-well plate format using deuterated C4 as an internal standard and liquid-liquid extraction for sample clean-up. The assay was validated according to 2018 FDA guidelines. To assess C4 stability, healthy volunteers ($n=12$) donated 8 samples each. Samples were incubated at 20°C for up to 72 hours and retrieved, centrifmged, aliquoted and frozen for storage at different time points prior to C4 analysis.
Results
The C4 method demonstrated excellent analytical performance and passed all validation criteria. The method was found to be accurate, precise, free from matrix effects and not susceptible to assay interference. Concentrations up to 1000 nmol/l could be reliably quantitated with an LOQ of 5 nmol/l. Over 72, hours concentrations of C4 gradually declined by up to 14% from their baseline concentrations. However, the change was not significant for up to 12 hours.
Conclusions
We present a robust method of analysing serum C4 that is metrologically traceable to SI units. C4 was found to be stable enough in unseparated serum for laboratory processing prior to analysis. This method is suitable for the assessment of BA production rate in patients with PCOS and may help to investigate the role this plays.

Dose response relationship between Denosumab treatment and germ cell proliferation of humanized RANKL mice in vivo and in testicular tissue cultures

Nadia Krarup Knudsen[1], Christine Hjorth Andreassen[1], Charles O'Brien[2], Anne Jørgensen[1] & Martin Blomberg Jensen[1]
[1]Herlev and Gentofte Hospital, Department of Endocrinology and Internal Medicine, Herlev, Denmark; [2]University of Arkansas

Today there exist no treatment that can improve semen quality in more than 85% of infertile men. Interaction between germ and Sertoli cells is critical for sperm production, and Denosumab, an inhibitor of RANKL, has previously been shown to stimulate sperm production in a fraction of infertile men. Here, we show in a humanized RANKL mouse that Denosumab dose dependently increase germ cell proliferation and testicular weight. RANKL was modified so it can be blocked by Denosumab. Fragments of mouse testis were cultured with the RANKL inhibitor Denosumab and compared with vehicle treatment. Testis tissue were cultured for 48 hours. Germ cell proliferation was assessed by BrdU incorporation and Denosumab treatment 1-100 ng/ml increased germ cell proliferation compared with vehicle although no effect on germ cell apoptosis was observed. This effect is physiologically relevant as the seminal fluid concentration reached 120 ng/ml following Denosumab injection of 60 mg dosing sc. once. Mice with humanized RANKL were treated with Denosumab 0,1-3 mg/kg once and sacrificed after 6 weeks. All mice treated with Denosumab had increased testicular weight and an increased serum AMH and Inhibin B although only statistically significant for 0.1 mg/kg. This shows that transient RANKL inhibition leads to increased germ cell output after 1 full spermatogenesis that takes 35 days in mice. This study smggests that even low doses of Denosumab can stimulate mouse spermatogenesis; however, further investigation is critical for understanding the interplay between Sertoli cell function, spermatogenesis, and RANKL inhibition in humans.

The clinical profile of silent and subclinical somatotroph PitNETs according to the immunohistochemical staining

Mariana Solovey[1,2], Olena Danevych[1], Mykola Guk[1] & Valeria Musulevska[1]
[1]Romodanov Neurosurgery Institute, Kyiv, Ukraine; [2]Komisarenko Endocrinology and Metabolism Institute, Kyiv, Ukraine

Background
Somatotroph PitNETs represent a polymorph group of GH-secreting pituitary neuroendocrine tumors with great variety of clinical presentation, which may graduate from totally silent without clinical and biochemical signs of hormonal hypersecretion to functioning with subtle or classic acromegaly symptoms. The grade of GH and somatostatin receptors expressoin as well as the other pituitary hormones and receptors co-expression may contribute to the tumor biological behavior.
Objective
To discover the clinical profile of silent and subclinical somatotroph PitNETs according to the immunohistochemical staining.
Materials and Methods
We have conducted a retrospective analysis of 33 cases of GH-immunopositive PitNETs surgically resected in our center without clinical signs of acromegaly. Tumors were classified according to the immunohistochemical staining: pure somatotroph, mammosomatotroph, mixed somatotroph-lactotroph, somatotroph-thyrotroph, plurihormonal Pit-1- lineage tumors. The clinical presentation and the grade of GH, somatostatin and estrogen receptors expressoin were compared in these groups.
Results
Silent somatotroph PitNETs represented 10·4% from all consecutive cases of nonfunctional PitNETs and 21.8% of all cases of GH-positive PitNETs. Pure somatotroph tumors constituted 48·5% of all GH-positive tumors, mammosomatotroph – 12·1%, mixed somatotroph-lactotroph – 21·2%, somatotroph-thyrotroph – 12·1%, plurihormonal Pit-1- lineage tumors – 6% respectively. Pure somatotroph tumors were divided into 2 groups: totally silent (24·25%) and subclinical (24·25%). The prevalent symptoms in cases of totally silent GH-tumors were visual disturbances and oligomenorrhea/amenorrhea. Headache was the most frequent presenting complaint in mixed somatotroph-lactotroph tumors. The presence of hypopituitarism and invasiveness depended on the immunohistochemical type of the tumor. The grade of GH expression didn't correlate with somatostatin receptors expression. The SSTR2 and SSTR5 expression was negative or lower than in acromegaly. All silent somatotroph tumors were negative for estrogen receptors.
Conclusions
Clinical presentation of silent somatotroph PitNETs is variable and depends on the variant of the immunohistochemical staining.

Reversal of cardiac damage after treatment for aldosterone-producing adenoma and idiopathic hyperaldosteronism – A Prospective Cardiac Magnetic Resonance Imaging study

Chenxiao Xu[1], Jiayu Sun[2], Tao Wu[2], Tao Chen[1], Lu Tang[2], Wei Wang[1], Fangli Zhou[1], Deying Wen[2] & Yan Ren[1]
[1]Department of Endocrinology and Metabolism, Adrenal Center, West China Hospital, Sichuan University, Chengdu, China; [2]Department of Radiology, West China Hospital, Sichuan University, Chengdu, China

Objective
At present, there are no studies in which authors report the use of cardiac magnetic resonance imaging (CMR) to evaluate the differences in myocardial strain between patients with aldosterone-producing adenomas (APAs) and those with idiopathic hyperaldosteronism (IHA) or the improvement in myocardial strain after treatment.
Methods
In this study, 71 patients with APA and 51 patients with IHA were prospectively enrolled from the Department of Endocrinology and Metabolism, West China Hospital, and all patients underwent CMR examination at the time of diagnosis. Differences in cardiac chamber volume, mass index and myocardial strain, including global radial strain (GRS), global circumferential strain (GCS) and global longitudinal strain (GLS), were compared between the two groups. Among them, 41 patients were re-examined via CMR one year after treatment, and the changes in cardiac parameters were also analyzed.
Results
Sex, duration of hypertension, blood pressure, fasting blood glucose, and lipid levels were comparable between the APA patients and the IHA patients at the time of diagnosis, and the IHA patients were older. There were no significant differences in the LVEF; native T1 time; or global radial, circumferential, or longitudinal peak strain (all $P>0.05$), but the APA patients had higher LV massi, LVEDVi, LVESVi, and RVEDVi (all $P<0.05$). Correlation analysis revealed that the log PAC and log ARR were positively correlated with the LV massi, LVEDVi, and LVESVi ($R=0.19$–0.27, $P=0.003$–0.042) and negatively correlated with the serum potassium concentration ($R=-0.24$–0.28, $P=0.002$–0.008). At the 1-year post-treatment follow-up assessment, patients showed significant decreases in the LVEDVi, LVESVi and LV massi and an increase in the global circumferential peak strain (all $P<0.05$).
Conclusion
Patients with APAs have more significant chamber enlargement and ventricular hypertrophy than patients without APAs, but the extents of myocardial strain and fibrosis may not be significantly different from those in patients with IHA. Improvements in the left ventricular structure and myocardial function 1 year after treatment are also noteworthy.
Key words: aldosterone-producing adenoma, idiopathic hyperaldosteronism, cardiac magnetic resonance, cardiac damage

Background
Ketoconazole is a steroidogenesis inhibitor approved in Europe for the treatment of endogenous Cushing's syndrome (CS) based on retrospective studies published over 3 decades. We present interim data from the first prospective observational, multicenter, international study on ketoconazole, a non-interventional PASS (Post-Authorization Safety study) requested by EMA at the time of registration to confirm ketoconazole good tolerance and effectiveness. This study is performed in collaboration with ESE owner of ERCUSYN (European Registry on CS).
Methods
Main inclusion criteria are: Patients (>12 years of age) with endogenous CS starting treatment with HRA ketoconazole® in routine clinical practice. The primary endpoint is to document liver (hepatotoxicity) and cardiac (QT prolongation, QTc >450 msec and/or QTc increase >60 msec tolerability profile of ketoconazole. The main secondary endpoints are overall safety of ketoconazole and effectiveness evaluations.
Results
Last interim results (August 2023) included 93 patients (73 Females, 20 Males) from 17 centers in 5 countries. At baseline, median age was 47 years (17–85), main etiology was pituitary-dependent CS and median final dose was 400 mg/day. Median treatment duration was 212 days (3 to 2160 days). No case of QTc prolongation was reported. Liver function tests (LFT) abnormalities were reported in 37.5% (33/88) patients, occurring up to 4 weeks after ketoconazole start. Only 10.2% (9/88) patients had AST ≥ 3 ULN (Upper Limit of Normal) without increase of Total Bilirubin (TB) >2×ULN. Among these patients, 7 had liver injury with ALT ≥5× ULN assessed as hepatocellular (4), cholestatic (2) and mixed injury (1), which resolved after ketoconazole discontinuation. In 5 patients concomitant medication was also suspected. For 5 patients, 9 study-drug related serious adverse events (SAEs) other than severe hepatotoxicity occurred (pneumonia, acute kidney injury (2), hypokalemia, acute adrenal insufficiency (2), hyperkalemia (2), angioedema). Among the 45/91 (49,4%) patients for whom urinary free cortisol (UFC) and/or serum cortisol data were available, 31/45 (47.2%) patients had normalized UFC levels and/or serum cortisol at the last visit. A treatment benefit was evaluated by the physician in 90/91 (98.9%) patients. At the last visit, twelve 12/91 (13.2%) patients had at least one less drug for comorbidities by drug class (antihypertensive, antidiabetics, anti-osteoporosis, lipid lowering, ischemic heart disease medications or other treatments for comorbidities).
Conclusions
This prospective observational study in patients with CS confirms that ketoconazole has a tolerability profile similar to the previously reported safety profile and effectively lowers cortisol levels.

Fingerprints of increased susceptibility to adrenal crisis in patients with chronic adrenal insufficiency

Janik Freytag[1], Irina Chifu[1], Sabine Herterich[2], Stefanie Hahner[1], Marcus Quinkler[3] & Burger-Stritt Stephanie[4]
[1]University Hospital Würzburg, Division of Endocrinology and Diabetes, Würzburg, Germany; [2]University Hospital Würzburg, Clinical Chemistry and Laboratory Medicine, Würzburg, Germany; [3]Endocrinology in Charlottenburg, Germany; [4]University Hospital, Uppsala, Sweden

Background
Potentially fatal adrenal crises (AC) still occur in educated patients with adrenal insufficiency (AI). Our study investigates clinical and biochemical fingerprints of increased susceptibility to AC.
Material and methods
199 patients with chronic AI (disease duration ≥6 years), classified into tertiles according to the frequency of AC/patient-years (group 1 no AC, group 2 ≤0.07 AC/py, group 3 >0.07 AC/py). Following parameters were assessed: 24 h urinary cortisol, salivary cortisol day profile, predefined glucocorticoid (GC) replacement score based on clinical and biochemical parameters of GC exposure, plasma and urinary catecholamines, polymorphisms (SNPs) of the glucocorticoid receptor

(*NR3C1*), mineralocorticoid receptor (*NR3C2*), *FKBP5*, HSD11B1 and HSD11B2 and crisis management.
Results
One-hundred patients (50%) never experienced AC, whereas sixty-seven patients (34%) had frequent AC (group 3). This group received significantly higher GC replacement doses (13 ± 5 mg hydrocortisone-equivalent /m^2/day) compared to group 1 (11 ± 3 mg hydrocortisone-equivalent /m^2/day, $P < 0.01$) and group 2 (11 ± 3 mg hydrocortisone-equivalent /m^2/day, $P < 0.01$). On the contrary, mean GC under-replacement score was lowest in patients with frequent AC (-2.3 ± 1.7) compared to both group 1 (-1.4 ± 1.4, $P = 0.017$) and group 2 (-1.0 ± 1.1, $P = 0.012$). 24 h-urinary metanephrine levels were lower, whereas 24 h-urinary normetanephrine levels were higher in patients from groups 2 and 3 compared to those without AC. Among patients with frequent AC, crises frequency correlated with HSD11B2 activity assessed by salivary cortisol/cortisone ratios Two *NR3C1* SNPs (rs1005297, rs860457) linked to glucocorticoid resistance and three *NR3C2* SNPs (rs6810951, rs11099680, rs4835493) linked to blood pressure regulation were associated with AC frequency. No significant differences in crisis management were observed between groups 2 and 3. Gastrointestinal and psychiatric comorbidities were more frequent among patients from group 2 (24% and 21%, respectively) and group 3 (22% and 21%, respectively) compared to patients without AC (10%, $P = 0.08$ and 7%, $P = 0.04$, respectively).
Conclusion
Higher glucocorticoid replacement doses in patients with frequent AC fit to previous observations and could simply reflect increased caution but might also be an indicator of increased vulnerability, as also suggested by the lower GC replacement scores and by the correlation with HSD11B2 activity. Gastrointestinal comorbidities might impair cortisol absorption and increase susceptibility to AC. The association between AC frequency and SNPs of *NR3C1* and *NR3C2*also implies a genetic susceptibility to AC. These observations require validation in prospective studies.

P4

The truth hidden behind a case of resistant hypertension

Xiaoxiao Song[1] & Xin Pan[1,2]
[1]The Second Affiliated Hospital, Zhejiang University School of Medicine (East Gate 1), Department of Endocrinology, Hang Zhou, China; [2]The First People's Hospital of Xiaoshan District, Department of Endocrinology, Hangzhou

Introduction
Resistant hypertension(RHTN) is an increasingly prevalent clinical condition associated with target organ damage and a poor prognosis, encompassing endocrine hypertension(EH). In this report, we describe a rare case of EH complicated by the application of a cytochrome P450(CYP450) enzyme inducer, which manifested as RHTN.
Case summary
A 56-year-old man with an 18-year history of hypertension and one month documented spontaneous hypokalemia(K+, 3.01 mmol/l),was admitted to the Endocrinology Department. The patient had undergone a 2-week washout period with double doses of doxazosin and diltiazem before admission. Physical examination revealed a BP of 170/85 mmHg and overweight. Screening investigations for EH showed abnormal response to the overnight 1 mg dexamethasone suppression test (DST) and low-dose 2-day dexamethasone test (cortisol of 113 nmol/l and 193 nmol/l, respectively), indicating Cushing's syndrome(CS) probably; secondly, a positive aldosterone–renin ratio(ARR) and a positive captopril challenge test(CCT) demonstrating primary aldosteronism(PA). Adrenal CT revealed slight nodular thickening of the bilateral adrenal glands. Pituitary MRI and renal artery ultrasound showed normal findings, leading to suspicion of EH as the underlying cause. Although spironolactone and amlodipine at near-maximum doses were added for the treatment of PA, there was no response. The BP sometimes still could achieve 200/100 mmHg. Subsequent treatment involved bisoprolol, terazosin, clonidine and olmesartan. However, systolic blood pressure had no significant change. MDT discussion and a review of medical history revealed that the patient had been taking rifampicin for brucellosis before being hospitalized. Previous research showed that almost all antihypertensive medications are substrates of CYP450 enzymes, which can be induced by rifampicin. This induction may lead to decreased blood concentration, diminished medicinal efficacy, and elevated BP. And the CYP-induction effect of rifampicin accelerates the metabolism of dexamethasone, rendering a false-positive DST. Consequently, we discontinued rifampicin, causing an improvement in BP control. During the 1-month follow-up, the patient's ARR and CCT were positive, and the overnight 1 mg DST (cortisol of 17.6 nmol/l) was negative. Further AVS supported idiopathic hyperaldosteronism (IHA). Thus, the etiology of the patient's RHTN was confirmed as IHA complicated by drug–drug interactions due to the CYP450 enzyme inducer, with CS excluded. Three months later, his BP was well controlled with serum potassium levels normal. The defined daily doses of antihypertensive medications had decreased by more than 50% compared with the previous treatment.
Conclusion
Drug–drug interactions caused by CYP450 inducers is prone to be neglected, especially when combined with another cause of EH, which complicates the etiology of RNTH further.

Introduction
Pheochromocytomas (PHEOs) are rare catecholamine-producing tumors with metastatic potential. Composite PHEOs are rare (3% of adrenal tumors) including components other than adrenal chromaffin cells. We report a case of a rare composite neoplasm with a very rapid disease progression.
Case report
A 57-year-old male was referred to the Endocrinology Department for investigation of a retroperitoneal mass. He presented with nonspecific symptoms and mild hypertension. Computed tomography (CT) of the abdomen revealed a left-sided $14.5 \times 12 \times 14$ cm mass with cystic, necrotic and hemorrhagic features. Investigation revealed elevated levels of 24-hour urinary metanephrine [690 μg/24 h (44–261)], normetanephrine [3471 μg/24 h (128–484)] and dopamine [998 μg/24 h (60–440)] and serum chromogranin A (CgA) [>9000 ng/ml (10–110)] suggestive of a PHEO. The ^{123}I-MIBG scintigraphy showed increased uptake in the left adrenal, multiple skeletal sites and the liver. He underwent left adrenalectomy and nephrectomy. The initial pathology report revealed a poorly differentiated PHEO (PASS score 17) composed of a high-grade spindle cell component and an epithelioid cell component. There was focal staining of CgA and Synaptophysin in the areas of better differentiation, while Ki-67 index was high (75%). Extensive necrosis and marked mitotic activity (>30 mitoses/HPF) were also observed. Postoperative 24 h urinary metanephrines decreased significantly although CgA levels remained high and CT scans showed disease progression with multiple liver and bone metastases. Treatment with cyclophosphamide, vincristine, dacarbazine (CVD) and concurrent radiation of left femoral metastasis was decided but after 3 CVD cycles further disease progression was noted. The patient died 6 months after diagnosis due to hepatic failure. Pathology review at the National Institutes of Health (NIH) concluded that this was a sarcomatoid, malignant spindle cell neoplasm immediately associated and commingled with a differentiated PHEO. Immunohistochemistry (IHC) was positive for CgA, S100, and Synaptophysin in the PHEO component. The partially retained expression of H3K27me3 on IHC did not support the possibility of a malignant peripheral nerve sheath tumor (MPNST). Exome sequencing was negative for germline pathogenic variants in genes associated with PHEO; Next generation sequencing performed on tumor tissue detected pathogenic (likely homozygous) deep deletions in *NF1*, *CDKN2A,* and *CDKN2B*.
Conclusion
Composite PHEOs are very rare and their clinical course depends on their components. MPNST is a rare component of composite PHEO with dismal

prognosis. In our case, histology and genetic variants indicated spindle cell sarcoma with no clear evidence of a neurogenic origin. Alternatively, this could represent a PHEO which partially dedifferentiated to a sarcomatoid neoplasm.

The differential impact of oral classic and 11-oxygenated androgen precursor administration on downstream androgen metabolism and insulin sensitivity in women with polycystic ovary syndrome

Tara McDonnell[1,2], Leanne Cussen[1,2], Clare Miller[2,3], Benson Jacob[3], Angela Taylor[4], Wiebke Arlt[4,5,6], Marie McIlroy[1], Karl Heinz-Storbech[7], Leanne Hodson[8], Jeremy Tomlinson[8], Mark Sherlock[1,2] & Michael W. O'Reilly[1,2]
[1]Royal College of Surgeons in Ireland, Academic Division of Endocrinology, Department of Medicine, Dublin, Ireland; [2]Beaumont Hospital, Department of Endocrinology, Dublin, Ireland; [3]Royal College of Surgeons in Ireland, Academic Division of Endocrinology, Dublin, Ireland; [4]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, UK; [5]MRC Laboratory of Medical Sciences, UK; [6]Imperial College London, Institute of Clinical Sciences, UK; [7]Stellenbosch University, Department of Biochemistry, Stellenbosch, South Africa; [8]OCDEM, Oxford Centre for Diabetes, Endocrinology, and Metabolism, Headington, UK

Polycystic ovary syndrome (PCOS) is the most common endocrine disorder in women. Androgen excess is a cardinal biochemical feature of PCOS and correlates closely with markers of insulin resistance. 11-oxygenated androgens are the predominant androgens in PCOS, however their relationship with metabolic dysfunction is unclear. The aims of this study were (i) to evaluate the downstream impact on androgen metabolism of oral classic and 11-oxygenated precursor administration and (ii) to delineate the differential impact of androgen excess on insulin sensitivity in women with PCOS. An interventional, open-label study was conducted in 20 women with PCOS. Metabolic phenotyping including hyperinsulinaemic–euglycaemic clamp (HEC) testing was carried out at baseline and after 7 days of androgen precursor administration. Participants were randomized 1:1 to receive 150 mg of either 11-ketoandrostenedione (11KA4) or dehydroandrostenedione (DHEA) for 7 days Serum and urinary multi-steroid profiling was performed by liquid chromatography–tandem mass spectrometry. Twenty women with PCOS were enrolled ($n=10$ in each intervention arm); 7 women crossed over to complete both study arms. Median age and BMI were 30.9 years (IQR 26–33) and 34.9 kg/m^2 (IQR 28.4–36.2), respectively. The intervention arms were matched for age and BMI. Following 7 days of 11KA4 150 mg daily, we observed priming of the 11-oxygenated pathway, with statistically significant elevations in serum 11KA4, 11β-hydroxyandrostenedione, 11β-hydroxytestosterone and 11-ketotestosterone ($P<0.05$ for each). Urinary 11-oxygenated androgen metabolites including 11β-hydroxyandrosterone and 11β-hydroxyetiocholanolone also increased significantly ($P<0.01$ for each). Serum classic androgens including testosterone did not change significantly after 11KA4. Oral DHEA 150 mg daily resulted in upregulation of classic androgens in both serum and urine, without any significant associated changes in levels of serum or urinary 11-oxygenated androgens. On HEC testing, glucose infusion rates, unadjusted for insulin, did not change significantly after either DHEA or 11KA4 administration (Table 1). Oral administration of the androgen precursors DHEA and 11KA4 is a powerful *in vivo* tool to study downstream classic and 11-oxygenated androgen metabolism, respectively. Further data and studies are required to delineate whether classic and 11-oxygenated androgens have differential effects on insulin sensitivity and metabolic risk in women with PCOS.

Table 1 The effect of androgen precursor administration on glucose metabolised (M-value) during a Two-Step Hyperinsulinaemic Euglycaemic Clamp.

Metabolic Variable	DHEA			11KA4		
	Before	After	P-value	Before	After	P-Value
M value, (mg/kg · min)						
Low insulin	1.71 [0.63–2.40]	1.51 [1.14–2.0]	0.41	1.88 [1.53–2.08	1.63 [1.11–2.03]	0.44

Inflammation-based scores in a large monocentric cohort of adrenocortical carcinoma and adrenocortical adenoma: role of the hormonal secretion pattern

Vittoria Favero[1,2], Alessandra Mangone[3,4], Alessandro Prete[5,6,7], YasirS Elhassan[5,6,7], Miriam Asia[7], Rowan Hardy[5,8], Giovanna Mantovani[3,4], Iacopo Chiodini[1,2] & CristinaL Ronchi[5,6,7]
[1]Ospedale Niguarda Ca' Granda, Endocrinology Unit, Milan, Italy; [2]University of Milan, Department of Biotechnology and Translational Medicine, Milan, Italy; [3]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [4]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [5]Institute of Metabolism and Systems Research, University of Birmingham, Birmingham, UK; [6]Birmingham Health Partners, Centre for Endocrinology, Diabetes and Metabolism, Birmingham, UK; [7]Queen Elizabeth Hospital, Department of Endocrinology, Birmingham, UK; [8]Institute of Clinical Sciences, University of Birmingham, Birmingham, UK

Background
Serum inflammation-based scores can predict clinical outcomes in several cancer types, including adrenocortical carcinoma (ACC). They may also be altered in benign adrenocortical tumours and correlate with cortisol excess. It is unclear whether the inflammation-based score alterations in ACC reflects malignancy, steroid excess, or both.
Methods
A total of 490 patients were included (429 [87.6%] with adrenocortical adenoma [ACA] and 61 [12.4%] with ACC) with available baseline full blood count and hormonal evaluation. We examined the relationship between different inflammation-based scores [neutrophil-to-lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), lymphocyte-to-monocyte ratio (LMR), systemic immune-inflammation index (SII), and prognostic nutrition index (PNI)] and both malignancy and steroid secretion patterns.
Results
All inflammation-based scores differ between ACC and ACA. Patients with ACC had higher levels of NLR, PLR, SII and lower levels of LMR and PNI compared to patients with ACA (all P values <0.001). This difference remained significant after adjusting for age, tumour size, and cortisol after the 1 mg-overnight dexamethasone suppression test (1 mg-DST). All the inflammation-based scores correlated with cortisol levels after 1 mg-DST in ACA and ACC patients. NLR showed a positive correlation with cortisol levels after the 1 mg-DST, both in ACC and in ACA ($P<0.001$). Among the inflammation-based scores, NLR demonstrated the highest accuracy in distinguishing ACC from ACA, with an area under the curve of 0.847 (95% CI 0.795–0.894) and an optimal cut-off value of 2.6. A logistic regression analysis showed that NLR >2.6 was independently associated with the presence of ACC, cortisol levels after 1 mg-DST, and age, but not with tumour size. The multivariate analysis showed that both the presence of malignancy (ACC vs ACA, $P<0.001$) and the presence of cortisol excess (cortisol after 1 mg-DST >50 nmol/l, $P<0.001$) were associated with higher NLR values. Considering ACC, NLR and SII were higher and PNI was lower in patients with cortisol excess compared to those without cortisol excess ($P=0.002$, $P=0.007$, and $P=0.044$ respectively). Finally, we studied the inflammation-based score in patients with hormonally inactive tumours; LMR and NLR were significantly different between inactive ACC (n = 10) and inactive ACA ($n=215$) ($P=0.040$ and $P=0.031$, respectively).
Conclusion
Inflammation-based scores are related to steroid secretion both in ACC and ACA. ACCs present a higher grade of inflammation regardless of their secretion, likely as a feature of malignancy *per se*.

Enhanced well-being in patients with congenital adrenal hyperplasia on modified-release hydrocortisone compared to conventional glucocorticoid replacement

Hannah Choi[1], Selina Ziegler[1], Hanna Nowotny[1], Lea Tschaidse[1], Matthias Auer[1], Ann-Christin Welp[1], Martha Merrow[2] & Nicole Reisch-Pawlu[1]
[1]LMU University Hospital, LMU Munich, Department of Medicine IV; [2]Faculty of Medicine, LMU Munich, Institute of Medical Psychology

Background
Conventional glucocorticoid (GC) replacement for congenital adrenal hyperplasia (CAH) induces unphysiological cortisol spikes. In contrast, modified-release hydrocortisone (MR-HC, Efmody) offers a more accurate imitation of the circadian cortisol release, particularly emphasizing the morning surge. The study

compares quality of life and sleep-wake cycles in patients with CAH with conventional GC treatment and after a switch to MR-HC.
Methods
In this single-center study we included 41 patients with CAH (28 females, 13 males; 34 classic CAH, 7 non-classic CAH) with a median age of 33 years (IQR 12,75) and a median BMI of 24.67 kg/m^2 (IQR 5.44). Baseline treatment distribution included 15 patients on HC with a median dose of 25 mg (IQR 10), 20 patients on prednisolone with a median hydrocortisone dose equivalence (HDE) of 27.5 mg (IQR 12.5), and 6 patients on mixed regimens with a median HDE of 30 mg (IQR 15). These patients were switched to MR-HC (Efmody) with a median dose of 25 mg (IQR 10). The following questionnaires were used to gather biopsychosocial data before and $\geq$3 months after the switch: a self-developed therapy-satisfaction survey, SF-36, Global Fatigue Index, WHOQOL-BREF, PSQI, and MCTQ. In addition, actigraphy watch data was collected from 12 patients using MotionWatch 8 (CamNtech), both before (8 patients with HC, 4 patients with prednisolone) and after the switch to MR-HC, for a median duration of 20 days.
Results
Patients on MR-HC showed significantly increased satisfaction with their replacement regimen, compared to those on conventional GCs (P=0,0048). Patients considered MR-HC more advantageous in managing CAH (P=0,0225). SF-36 survey results indicated less impairment due to mental issues (P=0,0041) and better mental well-being (P=0,0003). Additionally, patients reported an increased subjective health status after a switch to MR-HC compared to one year prior (P=0,0457). However, actigraphy watch data was not different between the two groups, neither the other surveys.
Conclusion
Patients seem to be more satisfied with MR-HC than conventional GC replacement regimen. This was further reflected in a subjective improvement in both physical and mental health status.

The cytoskeletal acting-binding protein filamin A (FLNA) is poorly expressed in adrenocortical carcinomas (ACC) compared to adenomas (ACA), and this might contribute to sustain the increased cell proliferation by upregulating IGF1R and its downstream signaling. An increased expression of the CDK1 kinase Wee1, a leading gatekeeper for G2/M transition, was shown in mouse neural progenitor cells after loss of FLNA. Wee1 is highly expressed in several tumor types and its pharmacological inhibitor AZD1775 is currently undergoing clinical trials. This project aims to investigate Wee1 expression in ACC, its regulation by FLNA, the anti-tumor effects of Wee1 inhibitor AZD1775, and the impact of FLNA levels on its efficacy in human H295R and MUC-1 cell lines. The analysis of FLNA and Wee1 protein expression in 6 ACC and 8 normal adrenal tissues revealed that ACC express increased levels of Wee1 (0.3-fold(0.2) vs 0.02-fold(0.05), $P<0.001$), while lower levels of FLNA (0.4-fold(0.1) vs 2.1-fold(1.7), $P<0.05$). FLNA silencing induced an increase of about 1.6-fold of Wee1 protein expression in MUC-1 and in primary ACC cultured cells. Accordingly, p-CDK1 and cyclin B1 levels were shown to be higher in FLNA-silenced MUC-1 cells. On the other hand, decreased Wee1 levels (0.4-fold(0.2), $P<0.001$), as well as those of p-CDK1 and cyclin B1, resulted after FLNA overexpression. Lactacystin treatment reverted Wee1 reduction in FLNA-transfected MUC-1 cells, suggesting that FLNA has a role in promoting Wee1 proteasomal degradation. AZD1775 treatment induced a dose-dependent reduction of cell proliferation in MUC-1 (-91(15%), $P<0.001$ vs bas at 500 nM), H295R (-52(28%), $P<0.05$ at 500 nM), and in primary cultured cells derived from 2 ACC (-86(3%), $P<0.05$ at 1 μM). In MUC-1, Wee1 inhibition increased both the early apoptotic (5.7-fold(2.9), $P<0.01$ at 1 μM) and necrotic (2.7-fold(3.1), $P<0.05$ at 1 μM) cell subpopulations. Furthermore, FLNA knockdown increased AZD1775 efficacy in reducing cell proliferation in MUC-1 (-85(8.0%) for FLNA siRNA vs 72(6.4%) for C-siRNA, $P<0.01$ at 250 nM) and in primary ACC cultured cells (-41.4 for FLNA siRNA vs -20.5 for C-siRNA, $P<0.01$ at 100 nM). Similarly, it also potentiated AZD1775 pro-apoptotic effect by increasing the early apoptotic cell subpopulation (3.1-fold(2.6) for FLNA siRNA vs 1.8-fold(2.1) for C-siRNA, $P<0.05$ at 500 nM). In conclusion, this work demonstrates that FLNA regulates Wee1 expression by promoting its proteasomal degradation, suggesting that the low levels of FLNA frequently found in ACC lead to an increase of Wee1 with consequent cancer cells growth. Moreover, it proposes Wee1 inhibition as a new potential therapeutic approach for ACC, particularly for those lacking FLNA.

Nausea and vomiting, a clue for the diagnosis of pheochromocytoma?

Ramona Teodora Catana, Adela Nechifor-Boilă & Angela Borda
George Emil Palade University of Medicine, Pharmacy, Science, and Technology of Targu Mures, Histology, Targu Mures, Romania

Background and Objective
Pheochromocytomas are rare tumors, originating from chromaffin cells of the adrenal medulla. The typical presentations include the Menard triad (headache, palpitations, sweating) accompanied by sustained or paroxysmal hypertension. Some studies on animals support that high levels of catecholamines have been implicated in the development of the vomiting responses, by activating the alpha-adrenergic receptors in the area postrema, which triggers the emetic cascade. Nevertheless, literature data on human studies is sparse. The aim of our study was to document and investigate nausea and vomiting as relevant and key-symptoms in patients diagnosed with pheochromocytoma.
Methods
We performed a 23-year retrospective study on all pheochromocytoma cases registered at Târgu-Mureş Pathology Departments, Emergency and County Mureş Hospitals, respectively, between 2000 and 2022. Demographic and pathological data were retrieved from institutional database registries and original pathological reports. All patients were subject to a phone questionnaire which provided data related to symptoms and body weight changes (before and after surgery for pheochromocytoma).
Results
Thirty-four patients (n=34) with pheochromocytoma were registered in our departments over the study period (women/men ratio:1.26, mean age: 51.66 years, mean tumor size: 67.83 mm). Subsequently, we were able to obtain clinical data for 25/34 of these patients. Approximatively half of them (n=13/25, 52%) complained of nausea and vomiting, symptoms that ceased following surgery for pheochromocytoma. The mean age of the symptomatic patients was 56.07 years, the majority were women (women/men ratio: 3.33) and the mean tumor size was 65.16 mm. When looking at the mean Body Mass Index for these patients we observed an increased postoperative value, from 27.34 kg/m^2 before to 28.84 kg/m^2 after surgery.
Conclusion
Although hypertension is the hallmark sign of pheochromocytoma, some patients complain of atypical symptoms, mimicking many other diseases. Our data revealed that nausea and vomiting could be considered as key-symptoms in the diagnosis of pheochromocytomas and should be documented in the history of these patients.

A rare case of testicular adrenal rest tumor associated to X-linked adrenoleukodystrophy

Marianna Torchio[1], Elena Pagin[1], Antonio Marzollo[2], Chiara Mainardi[2] & Chiara Sabbadin[1]

[1]University Hospital of Padua, Endocrine Unit, Italy; [2]University Hospital of Padua, Pediatric Hematology, Oncology and Stem Cell Transplant Division, Italy

Testicular adrenal rest tumors (TARTs) are benign masses causing testicular damage and infertility. Their development is attributed to chronic stimulation of elevated ACTH levels. Several diseases are characterized by an increase of ACTH, however TARTs have been described almost exclusively in patients with congenital adrenal hyperplasia (CAH), excluding only rare cases. X-linked adrenoleukodystrophy (X-ALD) is a rare cause of primary adrenal insufficiency (PAI). It is a genetic metabolic disorder of beta-oxidation with accumulation of very long chain fatty acids primarily in the adrenal cortex and central nervous system. In 2021, TARTs were reported for the first time in two patients with X-ALD associated PAI. In this article, we present two brothers with X-ALD-associated PAI. The youngest developed PAI first at the age of 10 after an adrenal crisis. Treatment with hydrocortisone was started with a median daily dose of 10 mg/m^2 body surface area. Following the patient's diagnosis, the oldest brother was also found to have X-ALD: at that time, he was 14 year old and presented symptoms of attention deficit hyperactivity disorder, but no previous episodes of possible unrecognized adrenal crisis. In fact, biochemical exams revealed only a moderate increase of ACTH levels and low normal values of cortisol; however, glucocorticoid treatment was prudently started. The younger brother was deemed eligible for hematopoietic cell transplant to prevent progression of cerebral disease, which was already detectable in his older brother. During screening programs, a left testicular lesion of 7×7 mm was accidentally discovered and then enucleated, resulting compatible with a TART. Even his older brother underwent testicular ultrasound, which resulted normal. This is the third case of TARTs described in a patient with X-ALD-associated PAI. The genetic factors may play a minor role in the onset of TARTs, as reported in these siblings. The development of TARTs seems to be more related to the early onset of the disease and poor hormonal control. Indeed, only the youngest showed a prepubertal onset of PAI, probably unrecognized for several months before the correct diagnosis. Testicular lesions should be always investigated in patients with PAI, regardless of the cause, to avoid misdiagnosis and unnecessary testicular surgery. Considering these recent findings, the prevalence of TARTs is underestimated and should be considered not only in CAH patients, but at least in those patients with an early onset of chronic ACTH elevation, a poor hormonal control, or fertility problems.

Background

Correctly identifying glucocorticoid-induced adrenal insufficiency in patients tapering prednisolone treatment to ≤5 mg daily is crucial. Pausing prednisolone before an ACTH-test is standard, yet the optimal pause duration is uncertain.

Aim

To determine the outcome of an ACTH-test after 1 vs 2 days' prednisolone pause before the test.

Methods

Baseline data from an ongoing randomised clinical trial (EudraCT:2021-002528-18) including 281 patients with polymyalgia rheumatica/giant cell arteritis receiving prednisolone treatment for >12 weeks, current dose ≤5 mg/day. Patients were instructed to pause prednisolone on the ACTH-test day, which was performed at any timepoint. Variation in pause duration resulted from different timing of regular prednisolone administration, ACTH-test timing, and compliance (some patients paused longer). A 1-day prednisolone pause was defined as last prednisolone dose taken the day before the ACTH-test (22–33 hours' pause); a 2-day pause as the last prednisolone taken 2 days before the test (34–54 hours' pause). P-cortisol was measured before (basal) and 30 min after (stimulated) 250 g ACTH injection. Adrenal insufficiency: stimulated P-cortisol <420 nmol/l (Roche Elecsys® Cortisol II assay or mass spectrometry); delta cortisol: stimulated minus basal P-cortisol concentrations. Subgroup analyses examined potential confounding from current prednisolone dose.

Results

Overall, 56/281 patients (20%) had an insufficient response to the ACTH-test. Patients who paused prednisolone for 1 day (n=251) vs 2 days (n=30) had 43 nmol/l lower mean basal cortisol [mean(s.d.) 262(86) vs 305(106), P=0.013]; 103 nmol/l lower mean stimulated P-cortisol [498(119) vs 601(140), P<0.0001]; and 61 nmol/l lower mean delta cortisol [235(91) vs 296(125), P=0.015]. The prevalence of adrenal insufficiency was 53/251 (21%) vs 3/30 (10%) in patients who paused prednisolone for 1 vs 2 days (P=0.22). Stimulated P-cortisol was positively associated with hours of prednisolone pause [5 nmol/l per hour, CI 95%: 2.6–6.8, P<0.0001]. There was no difference in current dose between groups (1-day vs 2-day). In the 172 patients treated with current dose 5 mg/day, mean basal, stimulated, and delta P-cortisol was 51 nmol/l, 111 nmol/l, and 61 nmol/l lower, respectively, after 1 vs 2 days' prednisolone pause (all P<0.05). Both after 1- and 2-days prednisolone pause, basal morning (before 0010 h) P-cortisol and random (any timepoint) basal P-cortisol >300 nmol/l provided 100% specificity for passing the ACTH-test.

Conclusion

During ongoing low-dose prednisolone treatment, a 1-day compared with a 2-day prednisolone pause before an ACTH-test resulted in lower basal, stimulated, and delta cortisol concentrations. The clinical implications remain to be examined, but awareness of the length of prednisolone withdrawal before an ACTH-test is important for proper interpretation.

Background

Primary adrenal insufficiency (PAI) is rare: prevalence ~100–140/million and incidence 4:1 000 000/year in Western societies [1]. The diagnosis of PAI is suggested by an early-morning cortisol <140 nmol/l (5 µg/dl) [1]. The commonest cause in adults is autoimmunity (~90% in Western countries) and it is generally considered progressive once the diagnosis is made, although it has been reported that residual cortisol secretion is present in ~30% of patients [2]. We have developed a modified-release formulation of hydrocortisone to replace the physiological cortisol circadian rhythm and are undertaking a Double-Blind, Double-Dummy, Two-Way Cross-Over, Randomised, Phase II Study of Modified-Release Hydrocortisones: Chronocort® Versus Plenadren®, in PAI. During recruitment, we were surprised by the number of patients who were ineligible as they had detectable morning cortisol levels.

Methods

Main inclusion criteria: Participants with known PAI on stable glucocorticoid replacement therapy and an early morning pre-dose cortisol <50 nmol/l

(1.8 μg/dl). Baseline serum cortisol was taken at ~0700 h and measured in a central laboratory by ADVIA Centaur® immunoassay with the lower limit of detection <14 nmol/l (<0.5 μg/dl).
Results
86 patients with PAI (autoimmune aetiology in 71), median age 52 years (range 20–73), 60 female, were screened in 8 centres in UK and Germany. 18 (21%) patients were excluded from the study based on morning cortisol >50 nmol/l (1.8 μg/dl), and of those 68 patients who qualified on the main inclusion criteria 51 (59% of screened) had a cortisol <14 nmol/l (<0.5 μg/dl). Of the 18 patients (autoimmune aetiology in 10) excluded based on their morning cortisol level, 9 (50%) were female and 11 (13% of screened), had morning cortisol ≥140 nmol/l (5.0 μ/dl). 12 patients with morning cortisol of >50 nmol/l (1.8 μ/dl) were retested and only 2 then qualified; their initial morning cortisol levels were 70 and 51 nmol/l. In patients retested the median difference between retest and the initial sample was 13 nmol/l (range 1–421 nmol/l).
Conclusions
In patients with an established diagnosis of PAI, the majority had undetectable morning cortisol, but cortisol was detectable in 41% of patients and above 140 nmol/l in 13% confirming previous publications [2]. Retesting patients with a cortisol >50 nmol/l showed very similar results suggesting that the detectable cortisol was not an artefact and likely due to background cortisol secretion.

Background
Current guidelines recommend adrenal vein sampling (AVS) for the identification of surgically treatable unilateral disease among patients with primary aldosteronism (PA). The cortisol-derived selectivity index (SI) is currently used to assess the success (or selectivity) of adrenal vein catheterization during AVS. However, AVS studies can be non-selective in many cases.
Aim
To examine whether the use of SI derived either from 11-deoxycortisol, DHEA or androstenedione assessed by liquid chromatography with tandem mass spectrometry (LC–MS/MS) could improve the selectivity rate of AVS compared to the cortisol-derived SI measured by immunoassay (IA) methods.
Design and methods
This prospective multicenter cohort study involved 160 patients from 7 centers located in 3 countries who underwent AVS without cosyntropin stimulation. Cortisol was assessed by IA and LC–MS/MS, whereas 11-deoxycortisol, DHEA and androstenedione were assessed only by LC–MS/MS. A SI of 3 was considered the cut-off for selectivity.
Results
The AVS selectivity rate was 76.9% (123/160) using the cortisol-derived SI assessed by IA. For the majority of patients with unsuccessful AVS, selectivity failed on the right side (21/37) or on both sides (12/37). Selectivity rates using cortisol-derived SI assessed by LC–MS/MS did not differ. Nevertheless, the use of SI derived by either 11-deoxycortisol, DHEA or androstenedione increased the selectivity success rate of AVS to 90.6% ($P<0.001$), 90% ($P<0.001$), and 90.6% respectively ($P<0.001$). DHEA showed the highest median SI values compared to all other steroids, with 4-fold higher median SI values for the left side and 8-fold for the right side compared to IA cortisol ($P<0.001$).
Conclusions
SI derived either from 11-deoxycortisol, DHEA, or androstenedione and assessed by LC–MS/MS yields a significantly higher selectivity rate for AVS than that derived from cortisol measured by both IA and LC–MS/MS. Our findings have immediate application in daily clinical practice.

Dysregulation of salivary cortisol rhythm in non-secreting and mild cortisol-secreting adrenal incidentalomas

Kimberly Coscia[1,2], Flaminia Fanelli[2], Lorenzo Tucci[1,2], Valentina Bissi[2], Greta Galante[2], Ilaria Improta[2], Francesca Donnarumma[1,2], Giacomo Colombin[1,2], Laura Rotolo[1,2], Claudia Lena[2], Sobia Noreen[2], Valentina Vicennati[1,2], Uberto Pagotto[1,2] & Guido DiDalmazi[1,2]
[1]Endocrinology and Diabetes Care and Prevention Unit, IRCCS Sant'Orsola-Malpighi Polyclinic, Bologna, Italy; [2]Department of Medical and Surgical Sciences, Alma Mater Studiorum of Bologna University, Bologna, Italy

Background
Adrenal incidentalomas (AI) are classified into mild autonomous cortisol-secreting (MACS) and non-secreting (NS) based on the 1mg-dexamethasone suppression test (DST). However, the latter test fails to detect alterations in the cortisol rhythm, which might be present in both MACS and NS.
Aim
To characterize the cortisol secretion in terms of daily rhythm and exposure in healthy controls (HC) and patients with AI.
Methods
Benign unilateral and bilateral adrenal adenomas and/or hyperplasia were included. AI were classified in NS ($n=25$) for post-DST serum cortisol values ≤18 ng/ml, and as MACS ($n=57$) for post-DST serum cortisol values >18 ng/ml. Twenty-eight HC with a regular wake/sleep cycle and no recent or chronic disease nor medications were recruited from the general population. On an ordinary day, each subject collected saliva samples at 0700 (awakening), 07:15, 07:30, 10:00, 12:30, 14:00, 16:00, 19:30, 21:00 and 23:00 h (bedtime). Salivary cortisol was measured by liquid chromatography–tandem mass spectrometry. Cortisol rhythmicity was evaluated by the repeated measurements ANOVA and compared among groups through the calculation of the cortisol dynamic range (CDR = log (peak value/nadir value)) between 07 00 and 23 00 h. Cortisol AUC was calculated to evaluate the daily glucocorticoid exposure.
Results
HC (age 29 ± 10 y) were younger than NS (age 61 ± 14 y) and MACS (age 65 ± 8 y) ($P<0.001$). Sex was evenly distributed in the overall cohort (51.8% females, n = 57) and among groups. Each group exhibited a significant cortisol reduction over the day ($P<0.001$). The CDR was significantly different between the 3 groups ($P<0.001$), with both NS (1.20 ± 0.30) and MACS (1.14 ± 0.35) having a lower CDR compared to HC (1.56 ± 0.26) ($P<0.050$). Cortisol AUC displayed an increasing trend in NS and MACS compared to HC ($P=0.012$). Cortisol levels among groups were similar from 07:00 h until 14:00 h, but different from 16:00 to 23:00 h (P: <0.001–0.044). Indeed, compared to HC, cortisol levels were higher at 21:00 h and 23:00 h in NS, and at 16:00, 19:30, 21:00 and 23:00 h in MACS. Moreover, values at 1930 and 2100 h were higher in MACS than NS (all $P<0.050$).
Conclusion
The salivary rhythm is preserved in both NS and MACS. However, we detected a reduced dynamicity in both AI groups. The overall glucocorticoid exposure increased with the functional status of the AI and is mainly related to the cortisol secretion from middle afternoon to evening. Notably, NS and MACS exhibited different secretion profiles before bedtime.

[1]Carl Gustav University Hospital, Endocrinology and Internal Medicine, Dresden, Germany; [2]University Hospital Wurzburg, Endocrinology, Würzburg, Germany; [3]Center for Interdisciplinary Digital Sciences, TU Dresden, Department Information Services and High Performance Computing, Dresden, Germany; [4]Institute for Laboratory Medicine, Dresden, Germany; [5]Prince of Wales Hospital, Pathology; [6]Hudson Institute of Medical Research, Center for Endocrinology and Metabolism, Melbourne, Australia; [7]Ludwig Maximiliam University Hospital Munich, Department of Medicine IV, München, Germany; [8]University Hospital Zurich, Department of Endocrinology, Zurich, Switzerland; [9]Radboud University Medical Center, Internal Medicine, Radboud, Netherlands

Background
Diagnostic stratification of patients with suspected primary aldosteronism (PA) is a multistep process reliant on tests that are not infallible. Only through prospective studies can diagnostic accuracy be appropriately assessed.
Methods
The PROSALDO trial enrolled 819 patients between 2019 and 2023 to assess steroid profiles against routine tests for diagnostic stratification. A combination of these tests and outcome assessments, including measurements of aldosterone by mass spectrometry (MS), was used to exclude and confirm PA.
Results
A diagnosis based on routine tests or outcome assessments could not be achieved in 97 patients, leaving 179 and 543 with and without PA. Screening with the aldosterone:renin ratio using a cut-off of 33 pmol/mU that provided 95% sensitivity revealed a false-positive rate (FPR) of 44% (56% specificity). Among 468 patients who underwent a saline infusion test (SIT), that test at a cut-off of 170 pmol/l for immunoassay measurements of aldosterone revealed a FPR of 48%. Even with MS-based measurements of aldosterone, that cut-off was associated with a 9% FPR (91% specificity). This was at a sensitivity of 98% due to three patients with false-negative results for the SIT, all who underwent adrenalectomy. Adrenal venous sampling (AVS) was carried out in 194 patients, including 69 (36%) without evidence of PA in whom subtyping largely reflected the 48% FPR for the SIT by immunoassay measured aldosterone. Among 167 selective AVS procedures, 52 of 62 patients (84%) without evident PA had non-lateralized aldosterone secretion, though 8 showed lateralization to the right and 2 to the left (16% FPR). Among 105 with PA, 78 (74%) showed lateralization; lack of lateralization in some of the other 27 patients may reflect false-negatives. Among 97 patients who underwent adrenalectomy, 87 were confirmed to have PA either by outcome assessments (n = 76) or when these remained unavailable (n = 11) by positive screening and confirmatory tests by MS. Among the 10 patients in whom PA was not confirmed, there were six in whom confirmatory tests by MS were negative and no outcome confirmation of PA was achieved. There were two others for whom masses in the resected adrenals were not aldosterone-producing adenomas and another two who had an alternative presurgical diagnosis.
Conclusions
The data indicate previously unrecognised inaccuracies in the diagnostic process for identification of patients with PA that in a substantial proportion of patients leads to unnecessary AVS and in some unrequired adrenalectomy. These findings emphasize the need for improved diagnostic strategies.

Plasma catestatin and relaxin-2 levels may predict impaired glucose metabolism in patients with primary hypertension

Olena Pankova & Oleksii Korzh
Kharkiv National Medical University, Department of General Practice – Family Medicine, Kharkiv, Ukraine

Background
Arterial hypertension (AH) and type 2 diabetes mellitus (T2DM) are common non-infectious diseases with a high tendency to co-exist. Catestatin (CTS) and relaxin-2 have antihypertensive, cardioprotective and metabolic effects and can be considered as biomarkers of these diseases.
Objective
To evaluate plasma CTS and RLN-2 levels in hypertensive patients and to investigate their associations with parameters of glucose metabolism and their predictive potential for impaired glucose metabolism.
Materials and methods
The present study was performed in accordance with all ethical principles of the Declaration of Helsinki. The study protocol was approved by the local ethics committee. Each study participant signed a written informed consent prior to any protocol procedures. 106 patients with AH stage 2 and 30 healthy volunteers were enrolled in the study. 55 hypertensive patients had comorbid T2DM. The clinical examination, medical history data and blood samples were collected from all study subjects. Plasma CST levels were measured by an enzyme-linked immunosorbent assay (ELISA), using a commercial kit (E4996Hu, BT Lab, China), RLN-2 (E-EL-H1582, Elabscience, USA). The data are presented as a mean ± S.D. or a median and interquartile range. Statistical significance was defined as $P < 0.05$. Statistical data were analyzed using SPSS statistical software (SPSS 25.0 for Windows, IBM, Armonk, NY, USA).
Results
Patients with AH and T2DM had significantly decreased plasma CTS (4.47 ± 1.16 vs 5.61 ± 0.61; $P < 0.001$) and RLN-2 levels (5.11 [4.97; 5.38] vs 6.71 [6.00; 7.14]; $P < 0.001$) than hypertensive patients without T2DM. CTS and RLN-2 levels are correlated with parameters of glucose metabolism, particularly glucose ($r = -0.45$; $P < 0.001$ and $r = -0.637$; $P < 0.001$), HbA1c ($r = -0.535$; $P < 0.001$ and $r = -0.704$, $P < 0.001$), HOMA-IR ($r = -0.481$; $P < 0.001$ and $r = -0.394$; $P < 0.001$), and lipid profile parameters, especially triglycerides ($r = -0.400$; $P < 0.001$ and $r = 0.480$; $P < 0.001$) and HDL-C ($r = -0.481$; $P < 0.001$ and r = 0.407; p < 0.001). Univariate binary logistic regression established that CTS (0.175 [0.099 − 0.312; $P < 0.001$) and RLN-2 (0.196 [0.095 − 0.405]; $P < 0.001$) are significant predictors of impaired glucose metabolism, as well as insulin levels (1.118 [1.065 − 1.174]; $P < 0.001$), HOMA-IR (2.020 [1.609 − 2.535]; $P < 0.001$) and BMI (1.108 [1.002 − 1.224]; $P = 0.045$).
Conclusions
In the present study, we determined the lower CTS and RLN-2 levels in patients with T2DM. Furthermore, we established that CTS and RLN-2 are significant predictors of impaired glucose metabolism. These findings suggest their possible diagnostic role as biomarkers of cardiometabolic diseases, especially AH with T2DM.

Clinical, biochemical, histopathological, and metabolic characteristics of patients with pheochromocytomas

Eleftheria Kakargia[1], Athanasios Fountas[1], Athina Markou[1], IRINI Giagourta[1], Dimitra Zerva[1], Theodosia Choreftaki[2], Giorgos Zografos[3], Chrysanthi Aggeli[3] & Labrini Papanastasiou[1]
[1]'G. Gennimatas' General Hospital of Athens, Department of Endocrinology and Diabetes Center, Athens, Greece; [2]'G. Gennimatas' General Hospital of Athens, Department of Pathology, General Hospital of Athens, Athens; [3]'G. Gennimatas' General Hospital of Athens, Third Department of Surgery, Athens General Hospital, Athens, Greece

Introduction
Pheochromocytomas represent a rare clinical entity with an incidence of approximately 0.8 per 100 000 person-years. Due to their rarity, the characteristics of patients with pheochromocytoma have not been thoroughly investigated yet.
Aim
The assessment of pre- and post-operative clinical and biochemical characteristics as well as the evaluation of imaging and histological data of patients with pheochromocytomas.
Design
Observational retrospective study of patients diagnosed with and treated for a pheochromocytoma in a tertiary general hospital between 2012 and 2022.
Methods
Medical records of patients with pheocromocytoma were reviewed and parameters related to patients' metabolic status (BMI, fasting glucose, HbA1c, total cholesterol, triglycerides, HDL, LDL), as well as pheochromocytoma characteristics [tumor size on imaging, 24 h urinary metanephrine (UMN) and normetanephrine (UNM) levels, phenoxybenzamine total daily dose (TDD) and total cumulative dose (TCD), histology PASS score] were recorded. In addition, comparison of patients' metabolic parameters (lipids and fasting glucose levels) at diagnosis and after surgical removal of the pheochromocytoma was performed.
Results
Overall, 48 consecutive patients (50% females, mean age 48 ± 15 years) with pheochromocytoma, diagnosed and surgically treated in our hospital, were included. Pheochromocytomas were incidentally detected in 46% of the patients, 57.4% were hypertensive (33% paroxysmal), 17% diabetic, 17% obese and 51% were symptomatic. At baseline assessment, no significant differences were found regarding the metabolic and tumor parameters between obese and non-obese patients, overweight and non-overweight ones, as well as between patients with incidentally detected pheochromocytoma and those presented with secondary hypertension or pheochromocytoma-related symptoms. Interestingly though, diabetic patients had larger tumors ($P = 0.048$) compared to those without diabetes. Regarding preoperational treatment symptomatic patients ($P = 0.013$)

required significantly higher TDD of phenoxybenzamine than asymptomatic patients. Univariate correlations demonstrated significant positive associations between UMN and both phenoxybenzamine TDD ($P=0.025$) and TCD ($P=0.05$). Larger tumors were associated with higher PASS scores indicating a more aggressive histology ($P=0.007$). Twenty patients were followed-up after adrenalectomy for a mean period of 36 ± 21 months. Follow-up assessment showed a significant improvement in fasting glucose values after pheochromocytoma resection ($P=0.001$), whereas lipid profile was not affected.

Conclusion

Our study demonstrates that the pheochromocytoma-associated metabolic alterations of glucose homeostasis improve after surgical removal of the tumor. Furthermore, tumor size seems to be a significant predictive factor of tumor aggressiveness.

Intra-tissular profile of adrenal steroids reveals variable levels associated with adrenocortical tumors (ACT) differentiation and suggests alterations in steroids export

[1]Institut Cochin, inserm u 1016, cnrs umr8104, Université Paris Cité, Equipe Génomique et Signalisation des Tumeurs Endocrines, Paris, France; [2]APHP-Cochin Hospital, Hormonology, Paris, France; [3]APHP-Cochin Hospital, Endocrinology, Paris, France; [4]APHP-Cochin Hospital, Visceral Surgery, Paris, France; [5]APHP-Cochin Hospital, Anatomopathology, Paris, France; [6]Institut de Chimie Physique, Université Paris-Saclay-CNRS, UMR8000, Orsay, France

Introduction

Adrenal steroidogenesis is alterated in adrenocortical tumors (ACT), leading frequently to abnormal steroid secretion. The development of steroid assays by mass spectrometry (MS) has greatly advanced the characterization of these alterations. However, steroid profiles are classically performed in blood and urine, providing a limited insight into adrenal steroidogenesis, altered by the mixing with gonadal steroids and by the steroid peripheral catabolism. The objective of our work was to evaluate the steroids tissue level in normal adrenals and ACT to better characterize adrenal steroidogenesis process dysregulation.

Materials and methods

Fifty-five samples of fresh-frozen adrenocortical tissue stored in liquid nitrogen in the COMETE tumor bank were included: 9 samples of normal adrenals, 22 samples from adrenocortical carcinomas (ACC) and 24 samples from adrenocortical adenomas (including 10 cortisol-producing adenomas (CPA) and 14 non/mild autonomous cortisol secreting adenomas (NFAT/MACS)). After tissue grinding in liquid nitrogen and sonication in methanol, tissue extracts were injected into a TSQ-ALTIS instrument to determine a profile of 13 steroids (cortisol, 11-deoxycortisol, 17-hydroxyprogesterone, cortisone, 21-deoxycortisol, androstenedione, testosterone, corticosterone, 11-deoxycorticosterone, progesterone, 11-hydroxyandrostenedione, 11-ketoandrostenedione, 11-ketotestosterone) in UPLC–MS/MS. Steroid intratissular concentrations were expressed in nmol/kg of tissue allowing the comparison with blood concentrations in nmol/l.

Results

In tissue of normal adrenals, cortisol was the most abundant steroid as in peripheral blood. However, the ranges of intratissular values observed (median [IQR] $=18790$ [5252–27987] nmol/kg) were 10 to 100 times higher than the usual value of cortisol blood concentration. The other most abundant steroids in normal adrenocortical tissue were corticosterone (6951 [1454–8840] nmol/kg) and 11OH-androstenedione (2189 [1323–9595] nmol/kg). The ratios of intratissular levels to usual blood concentrations were higher for precursors (progesterone, 17OH-progesterone and 11-deoxycortisol) than for cortisol, suggesting a facilitated export of bioactive products. In ACT, besides the high intratissular concentrations measured, the most striking observation was the lower steroid levels measured in ACC tissues in comparison to benign adenomas' tissues. Thus, intratissular cortisol level (nmol/kg) was lower in ACC (2655 [692–7933]) than in benign adenomas: CPA (27066 [21982–64731], Benjamini, Krieger and Yekutieli $q<0.0001$), MACS/NFAT (34241 [20425–43727], $q<0.0001$), and normal adrenals ($q=0.036$).

Discussion

This first study of tissue steroid assay in ACT reveals quantitative and qualitative differences among the tumor types. These differences are likely to be explained by the various mechanisms of tumor cells differenciation. The striking differences in the ratio of intratissular to blood levels between bioactive steroids and their precursors suggest differences in the regulation of steroids export.

Study on the pathogenesis of adrenocortical adenoma with bilateral independent secretion of aldosterone and cortisol: a case report and literature review

Yan Ren, Yan Xi Chen, Tao Chen & Lu Tan
West China Medical School, West China Hospital, Sichuan University, Endocrine, Cheng Du Shi, China

Aldosterone and cortisol coproducing adrenal adenoma is a rare type of primary aldosterone. Previous reports mostly describe single adrenocortical adenomas that simultaneously secrete aldosterone and cortisol. To date, only 7 cases of bilateral adrenocortical adenomas with independent functions of secreting different hormones have been reported in the published English literature. Here, we study an extremely rare case of a left adrenocortical adenoma secreting aldosterone and a right sebaceous adenoma secreting cortisol and explore the pathogenesis. The patient, a 29-year-old female, was diagnosed with gestational hypertension and hypokalemia. The examination showed that his PTC was significantly elevated (0 min PTC: 858 nmol/l) and ACTH was significantly suppressed (ACTH <1 ng/l). CT showed bilateral adrenal nodules/mass shadows, with the largest cross-sections on the right and left sides. They were 3.3×2.2 cm and 1.3×0.8 cm respectively. After the right adrenal tumor was removed, the pathology showed 'adrenal sebaceous adenoma'. Postoperatively, the patient developed cortical hypofunction, with a PTC of 109 nmol/l at 0800 h, and was given supplementary treatment with hydrocortisone. However, the patient still had hypertension and hypokalemia after the operation. Four months later, biochemical tests showed that the sitting plasma aldosterone and renin concentrations were 14 ng/dl and 0.51 uIU/ml respectively. The captopril test and saline test both showed aldosterone cannot be suppressed. CXCR4 imaging showed that the maximum SUV of the left adrenal adenoma was 8.75 and the maximum SUV of the left normal adrenal tissue was 2.7. Therefore, the left adrenal adenoma was diagnosed as an aldosteronoma and the left adrenal tumor was resected. After surgery, the patient's blood pressure and serum potassium returned to normal, and orthostatic aldosterone dropped to 10.5 ng/dl. Postoperative immunohistochemistry results showed: CYP11B1(+), CYP11B2(−) in the right tumor, and CYP11B2(+), CYP11B1(−) in the left tumor. Full-exome gene testing of the left and right tumors and peripheral blood revealed that the right cortisol tumor PRKACA c.167(exon7)T>G (p.L206R) and the left aldosteronoma KCNJ5 c.503(exon2)T> G(p.L168R) is considered pathogenic, but no abnormal mutations were found in the blood. At this point, through clinical manifestations and hormone testing, postoperative tumor tissue pathology and immunohistochemistry testing, and genetic testing of tumor tissue, we have identified a case of right-sided adrenal cortisoloma caused by PRKACA gene mutation and left-sided adrenal cortisoloma caused by KCNJ5 gene mutation. Adrenal aldosteronoma A case of an adrenocortical tumor secreting different hormones bilaterally.

Analysis of salivary dexamethasone does not improve the specificity of the dexamethasone suppression test

Marcus Imamovic[1], Nils Bäcklund[1], Staffan Lundstedt[2], Göran Brattsand[2], Tommy Olsson[1] & Per Dahlqvist[1]
[1]Umeå universitet, Public Health and Clinical Medicine, Umeå, Sweden; [2]Umeå universitet, Medical Biosciences, Umeå, Sweden

Objective

The low dose overnight dexamethasone suppression test (1 mg DST) is a sensitive screening test for Cushing's syndrome. The specificity of the test can be improved by simultaneous analysis of plasma dexamethasone concentrations. A simple and accurate alternative to analysis of plasma cortisol is analysis of salivary cortisone or cortisol following 1 mg DST [1]. We evaluated if analysis of salivary dexamethasone following 1 mg DST could further improve the specificity of the test. We also evaluated the stability of cortisone and cortisol in saliva samples stored 6–8 years in -80°C.

Design and methods

Saliva samples from 131 volunteers were collected with Salivette® Cortisol at 0800 h with simultaneous collection of plasma following 1 mg DST, between March 2015 and April 2016. Saliva samples were frozen at -20°C for at least

24 h and then thawed, centrifuged, aliquoted, and stored at −80°C. One aliquot of saliva was analysed for cortisone and cortisol with liquid chromatography tandem mass spectrometry (LC–MS/MS) in April–May 2016 and a second aliquot was analysed in November 2022 with the same LC–MS/MS method, slightly modified to also include dexamethasone. Plasma dexamethasone was analysed using a different LC–MS/MS assay. A lower reference limit (LRL) for salivary dexamethasone was defined as the non-parametric 2.5th percentile of all adequately suppressed saliva samples (cortisone <3.5 nmol/l [1]) after excluding outliers using Dixon's Q test ($n=3$), as recommended by the Clinical Laboratory Standards Institute. Spearman's rank correlation coefficients (r_s) were used to test associations between hormone concentrations.

Results

The LRL for salivary dexamethasone was calculated to 0.30 nmol/l (90% CI: 0.20–0.42). Among the samples with unsuppressed salivary cortisone following 1 mg DST (>3.5 nmol/l), four out of five had a plasma dexamethasone concentration below the LRL of 3.3 nmol/l. In contrast, none had a salivary dexamethasone concentration below the LRL of 0.30 nmol/l,. Salivary and plasma dexamethasone correlated moderately ($r_s=0.56$). There was a high correlation between saliva samples measured in 2022 and 2016 for both cortisone and cortisol ($r_s=0.98$ and 0.81, respectively).

Conclusions

Analysis of salivary dexamethasone does not reflect adequate circulating dexamethasone concentrations following 1 mg DST, potentially due to enzymatic conversion of dexamethasone in the salivary gland or tablet residuals in the oral cavity. Further studies are needed on alternative dexamethasone metabolites in saliva. Salivary cortisone and cortisol concentrations are essentially unaltered after longterm storage in −80°C.

Autoimmune Polyendocrine Syndrome type-1 (APS-1) is a rare monogenic disease (1:100 000 frequency), caused by mutations in the autoimmune regulator (AIRE) gene, which plays a crucial role in the thymus for negative selection of self-reacting T cells. With tissue damage caused by self-reactive immune cells from early stages of life and gradually presenting with symptoms in following years, APS-1 is clinically diagnosed by presence of minimum two components of the classical triad: primary adrenal insufficiency, hypoparathyroidism, and chronic mucocutaneous candidiasis. Although two criteria of the triad are enough to make a clinical diagnosis, APS-1 can also present with multiple additional autoimmunity-associated manifestations such as malabsorption, hypothyroidism, vitiligo, or enamel hypoplasia. In this study, our goal is to provide an update on the Norwegian APS-1 cohort, include longitudinal immune profiles and relate this to course of disease, age, additional manifestations, and demographic features. We explore the longitudinal changes in distribution and quantity of immune cell subtypes in peripheral whole blood samples of APS-1 patients using the well-characterized Norwegian biobank, known as Registry of Organ-specific Autoimmune Diseases (ROAS) to obtain longitudinal patient samples. Established in 1996, ROAS is among the biggest biobanks of endocrine autoimmune diseases, containing samples spanning 25 years. We analyzed 154 samples in total, including a collection of 106 samples from 27 APS-1 patients at multiple timepoints across 25 years with 47 age and sex matched controls. The new epigenetic immune cell quantification technology allowed us to explore the longitudinal immune cell profiles in APS-1 patients, by using a panel which includes 14 cell-type specific assays. Our panel includes cell groups such as neutrophils, B-lymphocyte subgroups, Natural Killer cells, monocyte subgroups and T-lymphocyte subgroups including cytotoxic, follicular helper and regulatory cells. Overall results showed that patients having classical triad's 3 components were diagnosed at the mean age of 7, whereas patients with less components of classical triad were diagnosed at age 11 on average. Among 27 patients, 11 had 3 components, 11 had 2 of 3 components, 5 had only 1 component of classical triad. Despite the large individual variety, the longitudinal changes in immune cell composition can be linked to clinical and genetic mutations and autoantibodies. In addition, candidiasis and hypoparathyroidism were observed more frequently than adrenal insufficiency.

Using basal cortisol cut-off to define adrenal sufficiency in a Southeast Asian population

Vijay Ramadoss[1], Lyeann Tan[1], AdaEeDer Teo[1], Kavita Narula[2], Kate Lazarus[2], Doddabele Srinivasa Deepak[1], LiZhen Ong[3], Karim Meeran[4], ChinMeng Khoo[1] & PeiChia Eng[1]
[1]National University Health Systems, Endocrinology, Singapore, Singapore; [2]Imperial College London, Hammersmith Campus, London, UK; [3]National University Health Systems, Laboratory Medicine, Singapore, Singapore; [4]Imperial College London, Hammersmith Campus, UK

Introduction

The short synacthen test (SST) is used in clinical practice to assess adrenal insufficiency (AI). However, the suggested threshold varies according to the patient cohort studied, assay variation and prevalence of the condition relative to the size of population tested. This study aimed to identify a threshold cortisol value to determine adrenal sufficiency in a Southeast Asian population and to investigate the utility of a stimulated 60-minute cortisol level in the diagnosis of AI.

Methods

We performed a retrospective analysis of 785 SSTs (250 micrograms) performed in our institution between 28 February 2022 to 28 February 2023. A normal response was defined as a stimulated cortisol value of ≥420 nmol/l at 30 or 60 min or at both time points, as measured by an Abbott Alinity Analyzer. Logistic regression analysis was performed to predict a normal response based on the baseline cortisol value.

Results

Median cortisol values at baseline, 30-min and 60-min after Synacthen stimulation were 254 (IQR 191–320) nmol/l, 499 (IQR 415–585) nmol/l, 574 (IQR 476–662) nmol/l respectively. Of the 785 SSTs, 83.0% of results were normal and 16.9% were abnormal. 55 SSTs (7.0%) would have been classified as AI if only the 30-min cortisol was assessed without the 60-min value, compared with 10 (1.4%) of patients would have failed using the 60-min cortisol without the 30-min value. An early morning basal cortisol (0800 h to 1200 h) cut-off value of <300 nmol/l identified a subnormal cortisol with 95% sensitivity and an afternoon cortisol (1200 h to 1700 h) of <312 nmol/l achieved 95.2% sensitivity. A basal cortisol level of <100 nmol/l will confirm AI with 97.3% specificity. Using a basal cortisol level of ≥300 nmol/l, 94.8% of individuals go on to pass the SST. Use of this basal cortisol value would have avoided 252 (32.1%) SSTs.

Conclusion

A single measurement of basal cortisol of ≥300 nmol/l, measured on the Abbott Alinity platform, has the potential to determine a normal response to an SST with 95% sensitivity on in our cohort of patients. Using a threshold cortisol level of 300 nmol/l, at least 32% of the SSTs could be avoided. Furthermore, a stimulated 60-min cortisol level identifies 55 (7%) of individuals who would otherwise be misclassified as AI. We believe this information may help clinician decide on situations where SST could be safely omitted, thus reducing unnecessary healthcare expenses.

Adrenocortical cells are prone to regulated cell death during *in vitro* septic conditions

Agnès Wlodarczyk[1,2], Uta Lehnert[1], Stefan Bornstein[1,2] & Waldemar Kanczkowski[1,2]
[1]University Hospital Carl Gustav Carus Dresden, Dresden, Germany; [2]TU Dresden, Dresden, Germany

Background

Sepsis is the primary cause of mortality in intensive care units. It is characterized by compromised function of several vital organs, including the adrenal glands. However, little is known about the mechanisms involved in this process. Recent experimental data demonstrated a potential role of iron overload and related iron-dependent, lipid peroxide driven form of regulated necrosis known as ferroptosis in sepsis-induced multiorgan damage. In a previous study, we demonstrated that human adrenocortical carcinoma cells NCI-H295R are sensitive to ferroptosis resulting from glutathione peroxidase 4 (GPX4) inhibition. However, whether sepsis also triggers ferroptosis in the adrenal gland remains unexplored until now.

Objectives

The main objective of this study was to investigate whether sepsis-associated conditions such as enhanced steroidogenesis and inflammation can induce ferroptosis in adrenocortical cells.

Methods

In order to mimic septic conditions *in vitro*, NCI-H295R cells were either exposed to forskolin, a well-known activator of steroidogenesis, or to inflammatory cytokine interleukin 6 (IL6). Necrosis induction (positive annexin V and PI

staining) as well as lipid peroxidation (C11-Bodipy staining) were analyzed 24–48 h thereafter. Furthermore, an expression of ferroptosis-relevant molecules was subsequently analyzed on gene and protein level by qPCR and western blot respectively. Finally, the expression those regulatory molecules was additionally assessed in the adrenals of mice treated with LPS.
Results
Our study demonstrated robust expression of two major modulators of ferroptosis, GPX4 and long-chain-fatty-acid-CoA ligase 4 (ACSL4), in the human and mouse adrenal cortex. Stimulation of NCI-H295R cells with either forskolin or IL6, as well as administration of bacterial LPS to mice, enhanced ACSL4 expression in adrenocortical cells. Furthermore *in vitro*results demonstrated that stimulation with forskolin and IL6 moderately increased lipid peroxidation and number of necrotic NCI-H295R cells, which indirectly suggested ferroptosis induction. However, while addition of the ferroptosis inhibitor ferrostatin-1 mitigated forskolin-mediated induction of lipid peroxidation, it rescued only a fraction of NCI-H295R adrenal cells from necrosis, suggesting potential involvement of a different form of cell death. Indeed, *in vitro* co-treatment of those cells with an apoptosis inhibitor fmk-zVad demonstrated a similar effect. In addition, we have found that IL-6 can decrease RSL3-mediated ferroptosis.
Conclusions
In summary, our findings suggest that septic conditions may promote ferroptosis and/or apoptosis in adrenocortical cells. However, further experiments, including the evaluation of GPX4 activity and caspase activation, as well as the validation of results using primary adrenal cells, are essential to gain a more thorough understanding of this process.

Prevalence and outcome of primary aldosteronism in PBMAH: A single center study and systematic review of the literature

Annalisa Panarelli[1,2], Elisabeth Nowak[1], Pia Adam[1], Junia Schweizer[1], Isabel Stuefchen[1], Stephanie Zopp[1] & Martin Reincke[1]
[1]Department of Medicine IV, LMU University Hospital, LMU Munich, Germany; [2]Department of Internal Medicine IV, Molinette University Hospital, Turin, Italy

Context
Patients with primary bilateral macronodular adrenocortical hyperplasia (PBMAH) usually present with bilateral benign adrenocortical macronodules at imaging and variable levels of cortisol excess. There is anecdotal evidence that, besides cortisol, other adrenal steroids, like mineralocorticoids, can be over-secreted.
Objective
To assess the prevalence, clinical, biochemical characteristics and imaging features of aldosterone excess leading to primary aldosteronism (PA) in patients with PBMAH.
Methods
We conducted a systematic review according to the PRISMA guidelines. We reviewed single case reports and case series of patients with PBMAH and coexistence of PA, in Pubmed, Embase and Cochrane from database inception to 17 December 2023. Two independent reviewers performed screening and data extraction. PBMAH was defined based on radiological features with ≥ 1 bilateral adrenal nodule ≥ 10 mm. We compared our findings to patients with PBMAH and PA derived from the LMU hospital Munich.
Results
1018 articles were screened, of which 36 articles were assessed for eligibility. We identified 18 articles (8 single case reports and 10 case series), resulting in 68 cases with PBMAH with PA. Of those, 14 had concomitant secretion of aldosterone and cortisol. The prevalence of a PA phenotype in patients with PBMAH in six studies with 166 patients ranged from 2 to 44%. The median age at diagnosis was 51.5 (47.5–56.2) with more male patients (18/26, 69%). Most patients were hypertensive, and the median duration of hypertension at referral was 108 months (48–135). 69.6% (16/23) of the patients were hypokalemic. The baseline aldosterone serum concentration and plasma renin activity (PRA) were 253 ng/l (159.8–436) and 0.25 ng/ml per hour (0.2–0.4), respectively. Treatment modality was reported in 30 cases: 28 patients underwent adrenalectomy (two bilateral, two subtotal, and 15 unilateral, 9 not reported) and two received mineralocorticoid receptor antagonists (MRA). In comparison, in the LMU cohort, fewer patients underwent adrenalectomy (12/20, $P=0.0088$) whereas 8/20 received MRAs. Outcome following surgery or MRA therapy was only described in eight cases derived from the literature (6 treated with surgery and 2 with MRA). Complete biochemical remission was obtained in 4 cases while complete clinical remission in 1 case. In the LMU cohort, 9 surgically treated patients went into complete biochemical remission and 2 obtained complete clinical remission.
Conclusion
Autonomous secretion of aldosterone in PBMAH appears to be more frequent than previously thought. Larger multicenter studies will help to clarify the association between these conditions as well as the most appropriate treatment modality.

Towards precision medicine in adrenocortical carcinoma; predicting response to mitotane using proteomics

Charlotte Vietor[1,2], Anand Iyer[1], Peter van Koetsveld[1], Fadime Dogan-Oruc[1], Lona Moradi-Zeyenedpour[3], Gaston Franssen[2], Cornelis Verhoef[2], Tessa van Ginhoven[2], Theo Luider[3], Richard Feelders[1] & Leo Hofland[1]
[1]Erasmus Medical Center and Erasmus MC Cancer Institute, Department of Internal Medicine, section Endocrinology, Rotterdam, Netherlands; [2]Erasmus Medical Center and Erasmus MC Cancer Institute, Department of Surgery, Rotterdam, Netherlands; [3]Erasmus Medical Center and Erasmus MC Cancer Institute, Laboratory of Neuro-Oncology/Clinical & Cancer Proteomics, Rotterdam, Netherlands

Background
Adrenocortical carcinoma (ACC) is a rare but devastating malignancy (5-year survival 18–57%), with limited treatment options. Currently, mitotane is the first-line medical treatment for metastatic ACC and is used in the adjuvant setting after surgery to prevent recurrence. Mitotane is an adrenolytic drug that is thought to act by disruption of mitochondria with subsequent activation of apoptosis. However, mitotane treatment comes with many drawbacks, such as severe side-effects and contralateral adrenal gland destruction, whilst both clinical and *in vitro*studies have shown that it is only effective in 25–30% of ACC tumors. We performed a proteomics-based analysis of ACC tissues previously characterized *in vitro*as responders, partial responders and non-responders to mitotane, with the aim of identifying tissue biomarkers to improve future patient selection for mitotane therapy.
Methods
Protein lysates were obtained from fresh-frozen ACC samples ($n=13$ responders, $n=10$ partial responders, $n=7$ non-responders). Label-free liquid chromatography–mass spectrometry shotgun proteomics was performed on these samples. Differential protein abundance was assessed using two statistical methods (DESeq2 and spectral index), followed by pathway analysis using STRING.
Results
On average, 2628 proteins were identified per tumor sample. We found 25 proteins (84% being mitochondrial(-related)) with lower expression in responders compared to non-responders with both statistical methods. Pathway analysis revealed involvement of these proteins in mitochondrial fusion, mitochondrial membrane organization and mitochondrial fatty-acid beta-oxidation. In contrast, only four proteins were higher expressed in responders compared to non-responders.
Conclusion
Mitochondria-associated proteins are differentially expressed in ACC of patients who respond well to mitotane therapy compared to non-responders, fitting well with mitochondria being the presumed target of mitotane. Immunohistochemical validation is necessary to further explore the potential of specific proteins to serve as a biomarker for mitotane treatment response. Furthermore, the mechanism behind the relative upregulation of mitochondrial proteins in non-responders and whether there is a causal relationship with mitotane sensitivity remains to be elucidated.

Impact on immunophenotype of switching from conventional gluco-corticoids to modified-release hydrocortisone in congenital adrenal hyperplasia

Selina Ziegler[1], Hanna Nowotny[1], Hannah Choi[1], Lea Tschaidse[1], Matthias Auer[1], Ann-Christin Welp[1], Adrian Gottschlich[2,3], Sebastian Kobold[2,4,5], Simon Rothenfusser[2] & Nicole Reisch[1]
[1]LMU University Hospital, LMU Munich, Department of Medicine IV; [2]LMU University Hospital, LMU Munich, Division of Clinical Pharmacology; [3]LMU University Hospital, LMU Munich, Department of Medicine III; [4]German Cancer Consortium (DKTK), Partner Site Munich; [5]Helmholtz Munich, Research Center for Environmental Health (HMGU), Neuherberg, Einheit für Klinische Pharmakologie (EKLiP)

Background
Previous research has revealed variances in the composition of immune cells among patients with congenital adrenal hyperplasia (CAH) on conventional glucocorticoid (GC) replacement therapy compared to healthy controls. Modified-release hydrocortisone (MR-HC) optimizes cortisol pharmacokinetics, aligning with a more physiological circadian cortisol rhythm. This study therefore aims to assess the impact on the immune cell profile when transitioning patients with CAH from conventional GCs to MR-HC.
Methods
A cohort comprising 25 patients with classic CAH, including 14 females and 11 males, with a median age of 37 years (IQR 14.25) and a median BMI of 25.29 kg/m^2 (IQR 3.72), was switched from conventional hydrocortisone ($n=13$) or prednisolone ($n=12$) treatment to an equivalent hydrocortisone dose (HDE) of MR-HC (median HDE 30 mg (IQR 10)). This cohort was compared to a group of 25 sex, age, and BMI matched healthy controls. Peripheral mononuclear blood cells were extracted before, 3 months and 6–10 months after the transition to MR-HC. Immune cell subsets were analysed through multicolour flow cytometry after a four-hour stimulation with PMI/ionomycin.
Results
Patients on conventional GCs exhibited a higher percentage of CD4+CD25+ lymphocytes ($P=0.0063$) compared to healthy controls and MR-HC-treated patients. The transition from conventional GCs to MR-HC resulted in a decrease in the percentage of CD4+CD25+ lymphocytes ($P=0,0327$). While patients under conventional GC treatment showed a smaller proportion of CD4+CD25+ Foxp3+T cells (Tregs) compared to controls ($P=0,0026$), the MR-HC cohort displayed comparable proportions to controls. Reductions in hydrocortisone doses by 5 mg, referable to efficient therapeutic control between 3 and ≥ 6 months post-transition to MR-HC, correlated with an increase in T helper cells ($P=0.0034$) and a decrease in CD94+ NK cells ($P=0.0312$).
Conclusion
Conventional GC substitution precipitates alterations in the immune phenotype of patients with CAH. In contrast, MR-HC, which more accurately imitates the physiological circadian release of cortisol, causes less changes in the immune cell profile. Additional functional analysis could help to draw further conclusions regarding the functionality of the immune system and its clinical impact.

Insulin tolerance test for the diagnosis of adrenal insufficiency
Sahar Abidi, Nadia Khessairi, Sabrina Ayari, Kammoun Elyes, Ibtissem Oueslati & Melika Chihaoui
Endocrinology Department, Rabta Hospital, Endocrinology Department, Tunis, Tunisia

Introduction
The insulin tolerance test (ITT) is the gold standard for hypothalamic–pituitary adrenal axis assessment. There are different protocols depending on the number and timing of serum samples. Our study aimed to investigate the kinetics of serum glucose and cortisol levels during ITT and to determine the most appropriate times for blood samples.
Methods
Our study was cross-sectional and descriptive. One hundred patients with suspected adrenal insufficiency (AI) were evaluated. The patients had 12 h fasting prior to the ITT. An intravenous rapid insulin bolus of 0.1 to 0.2 units/kg was administrated. Eight serum samples for glucose and cortisol measurements were taken: before the insulin injection (T0), at the time of hypoglycemia (Thypo) and samples every 10 min for 60 min after hypoglycemia (T10, T20, T30, T40, T50 and T60). We considered an adequate response a serum cortisol level above or equal to 18 µg/dl after a serum glucose level below 40 mg/dl.
Results
The mean age was 41.4±15.2 years and the sex ratio (F/H) was 0.2. The mean serum glucose lower cut point was 0.29±0.07 g/l and the mean time to achieve venous hypoglycemia (below 0.40 g/l) was 27.9±8.7 min. Forty-two patients (42%) had an adequate response and 58 patients (58%) had AI. Basal cortisol level was correlated with serum cortisol peak ($r=0.56$ $P<0.001$). A cutoff point of 9.75 µg/dl had a sensitivity of 59% and a specificity of 73% to predict an adequate response, it for. Twenty-six patients (62%) had an early response and 16 patients (38%) had a late response. A basal cortisol level ≤ 11.2 µg/dl had a sensitivity of 62% and a specificity of 82% to predict a late response. Finally, the most appropriate times for serum cortisol measurements were T30, T40 and T50 or T20, T30 and T50 with a sensitivity of 95%.
Conclusions
It is necessary to multiply the number of cortisol level samples after hypoglycemia, especially beyond 30 min, in order to increase the sensitivity of ITT and avoid misdiagnosis.
Key words
cortisol, insulin, hypoglycemia, adrenal insufficiency, diagnosis

Pheochromocytoma-induced pseudo-Cushing syndrome
Malgorzata Bobrowicz[1,2], Marek Roslon[1], Anna Karpilowska[3], Adrianna Gladka[3], Sadegh Toutounchi[4], Lukasz Koperski[5] & Urszula Ambroziak[1]
[1]Department of Internal Medicine and Endocrinology, Medical University of Warsaw, Warsaw, Poland; [2]Departament of Internal Medicine and Endocrinology, Medical University of Warsaw, Warsaw, Poland; [3]Department of Internal Medicine and Endocrinology, Medical University of Warsaw, Warsaw, Poland; [4]Department of General, Endocrine, and Vascular Surgery, Medical University of Warsaw, Warsaw, Poland; [5]Department of Pathology, Medical University of Warsaw, Warsaw, Poland

Introduction
Chronic catecholamine overproduction in pheochromocytoma may lead to a proinflammatory and hypermetabolic state characterized by increased resting energy expenditure and brown adipose tissue activation. Non-neoplastic hypercortisolaemia aka pseudo-Cushing syndrome (PCS) is a physiological overactivation of the hypothalamic–pituitary–adrenal axis by e.g. depression, eating disorders, extreme exercise, obesity, alcoholism, poorly controlled diabetes and cachexia. Here we describe an unusual case of pheochromocytoma-induced PCS.
Case report
A 66-year-old woman was referred to the hospital due to pronounced weakness, loss of appetite, apathy and weight loss of 5 kg within a month, a newly diagnosed diabetes mellitus and poorly controlled hypertension. Because of a rapid weight loss and suspicion of malignancy a chest and abdominal CT was performed, showing a heterogeneous, well-demarcated litho-cystic lesion (measuring 32× 25 mm) in the right adrenal gland, with inhomogeneous contrast enhancement. Metanephines' levels in serum were markedly elevated, as well as ACTH (535 pg/ml), highly increased 24 h urinary free cortisol excretion, high plasma DHEAS and testosterone. The initial differential diagnosis was as follows: a coexistence of pheochromocytoma or an ACTH-dependent hypercortisolemia or ectopic ACTH production by pheochromocytoma. An MRI ruled out pituitary tumors and a Ga^{68} DOTATE PET-CT scan showed a hypodense right adrenal nodule measuring 36×22 mm, probably litho-fluid with heterogeneous but high somatostatin receptor expression (with SUVmax 35.4). Considering clinical features, laboratory and imaging tests results, a suspicion of hypercortisolaemia due to ectopic ACTH-producing pheochromocytoma was raised. The patient was qualified for right adrenalectomy. Before the surgery the patient was treated with doxazosin and metyrapone, received enteral feeding and protein supplementation as well as intensive insulin administration. Interestingly, on this treatment we not only observed decreased cortisol levels (leading to a transient adrenal insufficiency), but also decreased levels of ACTH (150 pg/ml) and metanephrines. A right-sided laparoscopic adrenalectomy was performed. Post-surgery, the patient did not require further antidiabetic medication, experienced gradual weight gain, improved well-being, and did not need glucocorticoid supplementation. Histopathological examination confirmed a pheochromocytoma (pT1 NX, PASS 3, GAPP 2), and considering the immediate cortisol suppression with metyrapone, spontaneous ACTH decrease pre-surgery, absence of secondary adrenal insufficiency, and negative ACTH staining of the tumor, pheochromocytoma-induced PCS was diagnosed.
Conclusions
The case underscores the unique manifestation of PCS induced by pheochromocytoma, evident through clinical, laboratory, and histopathological findings, and highlights the successful resolution through adrenalectomy and supportive care.

An unexpected Adrenal Lymphangioma: A case report
Kouloud Boujelben, Samir Mkaouer, Dhoha Ben Salah, Rihab Khochtali, mouna mnif, fatma mnif, Faten Haj Kacem Akid, Mohamed Abid & NabilaRekik Majdoub
Hedi Chaker Hospital, Endocrinology Department, Sfax, Tunisia

Introduction
Lymphangioma is a rare benign malformation of the lymphatic system that typically affects the neck and head during childhood. Adrenal glands are an

uncommon and rare location for lymphangioma. Herein, we report an unusual clinical presentation of an adrenal lymphangioma revealed by Cushing syndrome.
Case report
A 69-year-old female was referred to our department for exploration of an adrenal incidentaloma. Her medical history was positive for dyslipidemia and depressive symptoms. She was admitted in the emergency department for a five-month history of diffuse abdominal pain. Clinical and biochemical findings were normal. Abdominal sonography was performed, revealing a large heterogeneous mass measuring 9×8 cm, located in the right adrenal gland. Then, an endocrine assessment was considered. On admission, physical examination revealed fragile skin, easy bruisability and normal blood pressure. Her laboratory results were within reference ranges. The endocrinlogical workup revealed a plasma adrenocorticotropic hormone (ACTH) at 8.17 pg/ml (normal <45 pg/ml), morning serum cortisol of 220 ng/ml and unsuppressed cortisol after 1 mg overnight dexamethasone suppression test. Low-dose dexamethasone suppression testing showed unsuppressed cortisol at 23.5 ng/ml. These results were compatible with ACTH independent Cushing syndrome. Serum metanephrines, normetanephrines and androgens levels were normal. On abdominal computed tomography (CT), there was evidence of a right giant heterogeneous mass with central and peripheral calcifications measuring 10×8 cm, suggestive of an adrenocortical carcinoma. Abdominal MRI confirmed CT scan' findings, showing large necrotic tissue. Fluorodeoxyglucose (FDG) Positron Emission Tomography (PET) scan did not demonstrate any metastasis. The patient underwent right adrenalectomy, under hydrocortisone coverage, through a right subcostal incision. Lumbo-aortic lymph node dissection was also performed. Unexpectedly, the histopathological examination was consistent with the diagnosis of a benign adrenal Lymphangioma. The postoperative period was uneventful, with pituitary–adrenal recovery.
Conclusion
Adrenal lymphangiomas remain extremely rare.However, they must be included in the differential diagnosis of adrenal mass.Clincial and radiological features are variable, leading to a misdiagnosis.Pathological examination is essential for the diagnosis.

Blood pressure changes during smoking cessation on dulaglutide and placebo treatment – a secondary analysis of the randomized, double-blind, placebo-controlled SKIP trial

Beck Julia, Flavia Hasenböhler, Sophia Lengsfeld, Thilo Burkard, Andrea Meienberg, Nica Jeanloz, Tanja Vukajlovic, Katja Bologna, Cemile Bathelt, Deborah Vogt, Laura Werlen, Mirjam Christ-Crain & Bettina Winzeler
Universitätsspital Basel, Basel, Switzerland

Objective
Smoking is an established major risk for atherosclerosis and cardiovascular mortality. However, the impact of smoking cessation on blood pressure remains controversial. Despite strong evidence linking smoking cessation to reduced cardiovascular risk, conflicting studies suggest potential increases in blood pressure after smoking cessation. Post cessational weight gain may contribute to these conficiting findings. We have recently shown that the glucagon-like peptide-1 (GLP-1) analog dulalgutide counteracts post-cessational weight gain. Therefore, the aim of this secondary analysis was to investigate blood pressure changes during smoking cessation in dulaglutide versus placebo treated individuals.
Design and methods
This is a predefined secondary analysis of the SKIP trial, a randomized, double-blind, placebo-controlled trial, conducted at the University Hospital Basel in Switzerland. Participants ($n=218$) underwent a 12-week smoking cessation program including standard of care and weekly injections of dulaglutide 1.5 mg or placebo. A mediation path analysis was performed to quantify the effect of predefined variables and relationships.
Results
In the short term (12 weeks), smoking cessation led to a weight gain of +0.96 kg [CI 0.23, 1.70, *P*-value =0.01], with each kilogram increase associated with a systolic blood pressure rise of +0.55 mmHg [−0.0, 1.11, *P*-value =0.055]. Dulaglutide treatment resulted in a weight reduction of −3.02 kg [CI −3.69, −2.63, *P*-value =0.001], and each kilogram decrease lowered systolic blood pressure by −1.66 mmHg [−3.40, 0.08, *P*-value =0.06]. No direct effect on systolic blood pressure was observed for smoking cessation or dulaglutide without weight influence. In the long term (52 weeks), smoking cessation led to a significant weight increase of +4.20 kg [2.67, 5.74, *P*-value <0.001]. No direct effect of smoking cessation on systolic blood pressure was observed, either independently or through weight change.
Conclusion
Our findings indicate that blood pressure changes during smoking cessation are primarily mediated by weight change. This underlines the importance of weight control and a potential beneficial role of GLP-1 analogues in the context of smoking cessation.

Physical activity after planned cessation of prednisolone treatment in patients with polymyalgia rheumatica and/or giant cell arteritis: baseline data from the double edge-replace study

Jelena Stankovic[1,2], MarieLouise Lund [3,4], AnjaFenger Dreyer[5,6], Hajir Al-Jorani[5,6], Victor Brun Boesen[3,4], StinaWillemoes Borresen[3,4], LouiseLehmann Christensen[5,6], Ulla Feldt-Rasmussen[3,4], Dorte Glintborg[5,6], Simon Bøggild Hansen[1,2], Richard Christian Jensen[5], NannaThurmann Jørgensen[3,4], LiseSofie Bisley[1], Randi Tei[1,2], Marianne Andersen[5,6] & JensOtto Jørgensen[1,2]
[1]Aarhus Universitetshospital, Department of Internal Medicine and Endocrinology, Aarhus, Denmark; [2]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [3]Rigshospitalet, Department of Endocrinology and Metabolism, København, Denmark; [4]The University of Copenhagen, Faculty of Health and Medical Sciences, Department of Clinical Medicine, Københavns, Denmark; [5]Odense University Hospital, Department of Endocrinology, Odense, Denmark; [6]University of Southern Denmark, Department of Clinical Research, Odense, Denmark

Introduction
Myopathy is a known and dreaded adverse effect of pharmacological glucocorticoid (GC) treatment, but its impact on daily physical activity is not known.
Aim
To measure spontaneous physical activity and musculoskeletal function in patients shortly after planned cessation of long-term (>12 weeks) prednisolone treatment.
Patients and methods
Baseline data from an ongoing nation-wide prospective study (DOUBLE EDGE – REPLACE) involving 49 patients [median (range) age 71 (51, 86) years, 29 females and 20 males] diagnosed with polymyalgia rheumatica (PMR) and/or giant cell arteritis (GCA) in GC free-remission for 2−12 weeks. Physical activity was assessed by ActiGraphy (wGT3X-BT, ActiGraph), a wearable wrist-device, capturing 7 consecutive days of activity data. Muscle function in terms of the short physical performance battery (SPPB) and time-up-and-go test (TUG) was also assessed. Finally, symptoms of GC-induced adrenal insufficiency (GIA) were assessed by a disease-specific questionnaire (AddiQoL-30 score), by which presence of GIA-symptoms were defined as a score of ≤85.
Results
Patients spent 57% (95%-CI: 55.0, 60.6) of the recorded time at sedentary activity (SA) levels and 10% (95%-CI: 8.1, 11.4) in moderate-vigorous physical activity (MVPA). The median (IQR) 6 month accumulated prednisolone-dose was 310 (208, 469) mg. Mean (s.d.) morning cortisol-level (nmol/l) was 246 (82) in patients with GIA-symptoms vs 315 (90) in the asymptomatic group ($P<0.001$). Patients who followed the WHO-recommendations of 60 min of MVPA daily performed better on the short physical performance battery (SPPB) (mean (s.d.) 10.3 (2.0) vs 8.4 (3.5)) and time-up-and-go (TUG) (mean (SD) 10.4 (6.4) vs 6.9 (1.7)), compared to those who did not meet the criteria ($P=0.03$ and $P<0.01$ respectively). The low-MVPA group was more comorbid measured by the Charlson comorbidity index ($P=0.03$). Multiple linear regression controlling for age and gender revealed no difference in SA or MVPA between patients with and without GIA-symptoms.
Conclusions
This is the first study to consecutively map spontaneous physical activity and muscle function in a population of PMR and GCA patients at risk of GC-induced myopathy. Only a small proportion of the patients met the WHO-recommendations of 60 min/day of MVPA. Low MVPA levels were associated with higher comorbidity, which illustrates broader health implications of inactivity. Higher GIA-symptoms did not correlate with objective activity measures. However, we hypothesize, that GC-related factors contribute to the so-called steroid-withdrawal syndrome. The ensuing prospective phase of the study will show if this is reversed by either time or low-dose hydrocortisone replacement.

Webinars for patient education on congenital adrenal hyperplasia

Ann-Christin Welp[1], Lea Tschaidse[1], Matthias Auer[1], Christian Lottspeich[1], Uta Neumann[2], Hanna F Nowotny[1] & Nicole Reisch[1]
[1]LMU Klinikum München, Medizinische Klinik und Poliklinik IV, Munich, Germany, [2]Institut Für Experimentelle Pädiatrische Endokrinologie, Charité – Universitätsmedizin Berlin, Berlin, Germany

Background
In 2020, DSD-Care, a collaborative project involving endocrine reference centres, support groups, and research institutes in Germany was launched funded by the German Ministry of Health. The aim of the project was to improve the quality of care for people with differences in sex development (DSD), who often report feeling poorly treated by healthcare providers and a lack of access to detailed information about their condition. Congenital adrenal hyperplasia (CAH) is one of the diagnoses that has been investigated in DSD-Care. According to current studies, patients with CAH often lack knowledge and education about their disease, which can have severe consequences. Proper treatment is crucial, as CAH is a life-threatening disease and patients must respond correctly in emergency situations.
Objective
To produce informative and objective webinars of high-quality for patient education that offer a structured and detailed overview of CAH for affected patients, their families, and those interested in the disease.
Design and methods
Endocrine specialists with extensive experience in CAH worked together to produce literature- and expert-based manuscripts. These manuscripts were transformed into video presentations for the webinars. The recorded videos present information in a clear and logical manner, using formal language that is still accessible to the layperson. Technical terms are introduced when first used, and current gender standards are adhered to.
Results
Experienced endocrinologists created and recorded seven evidence-based webinars for patient education on CAH. The webinars cover five main topics, providing a structured and detailed overview of CAH. The first topic is an introduction to CAH, presented in two videos. The second topic covers treatment and treatment monitoring of CAH, presented in two videos. The third topic presents the (side-)effects of CAH and emergency treatment. Topic four provides information on genetics in CAH and family planning, while topic five introduces CAH in childhood and adolescence. The videos will be freely available after registration on the LMU Klinikum learning platform for patients with CAH, their relatives and other interested viewers.
Conclusions
To serve the needs of people with CAH for better patient education we recorded webinars containing general information on CAH as well as on therapeutic concepts, side effects, sick day rules, genetics, family planning and CAH in childhood and adolescence. The videos are freely available for patients with CAH and all other interested parties. Evaluation of the webinars will be performed by surveys pre- and post-usage.

Impact of systematic screening of pheochromocytoma in patients with neurofibromatosis type 1

Audrey AGIUS[1], Abeillon Juliette[1], Mona Amini-Adle[2], Lasolle Hélène[1], Francoise Borson-Chazot[1], Patrick Combemale[2] & Lori Kepenekian[3]
[1]Hospices Civils de Lyon, Lyon, France; [2]Centre Léon Bérard, Lyon, France; [3]Infirmerie Protestante, Lyon, France

Background
In 2016, a prospective study conducted by our team found a prevalence of 7.7% of pheochromocytomas (Pheo) in patients with neurofibromatosis type 1 (NF1) if systematic screening including free metanephrines measurement (DMX) and abdominal imaging was performed. Half of Pheo were secreting, with 16% being symptomatic. This suggested the benefit of a systematic screening by abdominal imaging and DMX assay. The objective of this study was to evaluate the impact of systematic screening in a large cohort of NF1 patients.
Methods
This was an observational retrospective study of NF1 patients followed in the Lyon reference center Leon Berard since 1990 and explored at the Lyon university hospital until August 2023. The files were screened for a history of Pheo and diagnostic circumstances, biological and morphological characteristics, therapeutic modalities and evolution were collected.
Results
The whole cohort comprised 1594 NF1 patients, from whom 585 had undergone abdominal imaging at least once from the age of 25. Forty-eight patients were diagnosed with a Pheo and 1 with an extra-adrenal paraganglioma (PPGL). Prevalence of Pheo/PPGLs was 8.4% in the imaging population and 3% for the whole cohort. Nineteen Pheo/PPGLs were diagnosed on systematic screening (Screening Group (SG)) and 27 were diagnosed either incidentally ($n=10$) or because of symptoms ($n=17$) (Non Screening Group (NSG)). Median age at diagnosis was 44 years in both groups, with more men in SG (58%) than in NSG (26%; $p=0{,}037$). In SG, 26.3% of patients were symptomatic vs 84.6% in NSG, ($P<0.001$) while the proportion of secreting Pheo (DMX >2N) was 66.7% in SG, vs 86.4% in NSG ($P=0.253$). None patient of SG had a Pheo >4 cm vs 24% in NSG ($P=0.072$). Bilateral Pheo were found in 16.7% of cases in SG vs 42.9% in NSG ($P=0.489$), all were synchronous in SG vs 43% in NSG. None SG patient was metastatic vs 8% ($n=2$) in NSG. The number of surgeries was equivalent in both groups; four patients had not been operated on yet. Sparing surgery has been performed in 26.7% of patients in SG ($n=4$) vs 4.2% ($n=1$) in NSG ($P=0.062$).
Conclusion
Systematic screening for Pheo could allow diagnosis of smaller lesions, fewer metastatic and more often asymptomatic despite secreting. It led to more conservatives surgeries.

Incidence of adrenal crisis in Congenital Adrenal Hyperplasia (CAH) patients during a prospective monitored long-term study of modified-release hydrocortisone (MRHC) capsules, (Efmody)

Richard John M. Ross[1], DeborahP Merke[2], Ashwini Mallappa[2], Wiebke Arlt[3], AudeBrac DeLaPerriere[4], Angelica Hirschberg[5], JohnDC Newell-Price[1], Alessandro Prete[6], Aled Rees[7], Nicole Reisch[8], Marcus Quinkler[9], PhilippeA Touraine[10], Kerry Maltby[11], Jo Quirke[11], Naila Aslam[11], Helen Coope[11] & John Porter[11]
[1]The University of Sheffield, UK; [2]National Institutes of Health, Bethesda, USA; [3]MRC Laboratory of Medical Sciences, UK; [4]Louis Pradel Hospital, Bron, France; [5]Karolinska Institute, Sweden; [6]University of Birmingham, UK; [7]Cardiff University, UK; [8]Medizinische Klinik und Poliklinik I | LMU Klinikum, München, Germany; [9]Charlottenburg, Berlin, Germany; [10]University Hospitals Pitié Salpêtrière - Charles Foix, Paris, France; [11]Diurnal, UK

Background
Adrenal crisis is the leading cause of excess mortality in patients with CAH[1]. Retrospective studies report an adrenal crisis incidence of 5-10/100 patient years (PY), with mortality 0.5/100 PY[2]. Modified-release hydrocortisone (MRHC) capsules, (Efmody), replicate cortisol diurnal rhythm and improve androgen control in CAH compared to standard glucocorticoid therapy[2]. Here, we report the incidence of adrenal crisis in CAH patients from a prospective study of MRHC in CAH patients.
Methods
Patients completing MRHC Ph2 and Ph3 studies were eligible to enter a single-arm, open-label extension study. Study visits occurred at baseline, weeks 4, 12, 24 and 6-monthly thereafter. The primary endpoint was the safety of MRHC over time. Adrenal crisis was defined according to Allolio 2015[3]. MRHC doses were adjusted on the basis of an adrenal insufficiency checklist, and measurement of androstenedione (A4) and 17-hydroxyprogesterone (17-OHP) at 0900 and 1300 h.
Results
91 patients entered the study, mean age 37 years, 68% female, 32% male. 22 discontinued; 11 at patient request, 5 due to pregnancy, 2 undergoing fertility treatment, 2 at physician/sponsor request, 1 due to an AE (carpal tunnel syndrome), and 1 due to death (myocardial infarction). Median treatment duration was 1500 days, range 0.2 to 5.8 years. Median MRHC dose at study entry was 30 mg/day, reducing to 20 mg/day from 24-weeks until end of study. Signs and symptoms of adrenal insufficiency due to under-treatment were reported for 41 (45.1%) participants, most frequently fatigue which was reported at some point by 41.8% of all participants. Signs and symptoms of overtreatment were reported for 25 (27.5%) participants, most frequently sudden weight gain which was reported at some point by 16.5% of all participants. Signs and symptoms of both over- and undertreatment occurred predominantly during the first 24 weeks. The study encompassed 357 participant years, and 18 adverse events considered indicative of adrenal crisis occurred in 7 participants, giving an incidence rate of 5.043 adrenal crises/100 PY.
Conclusions
Data from this longest prospectively monitored study in CAH suggest that the incidence of adrenal crisis on MRHC is at the low end of that reported in retrospective studies and the safety profile of MRHC is otherwise similar to immediate release hydrocortisone.

Psychotropic drugs in patients with Addison's disease: A Swedish population-based cohort study

Sara Öster[1], Tim Spelman[2], Olle Kämpe[3,4], Sophie Bensing[1,4] & Jakob Skov[1,5]
[1]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden; [2]Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, Sweden; [3]Karolinska Institutet, Department of Medicine Solna, Stockholm, Sweden; [4]Karolinska University Hospital, Department of Endocrinology, Stockholm, Sweden; [5]Karlstad Central Hospital, Department of Medicine, Karlstad, Sweden

Objective
Several autoimmune disorders are known to be associated with an increased risk of psychiatric morbidity. Yet, the effect of autoimmune Addison's disease (AAD) on mental health is not well known. The aim of this study was to examine the use of psychotropic drugs around diagnosis in Swedish individuals with AAD.
Design and methods
In this population-based cohort study, The Swedish national patient register, and the Swedish Addison register were used to find cases with AAD. The Swedish population register was then used to find matched controls. Information on psychotropic drugs prescribed between July 2006 and December 2019 was retrieved from the Swedish prescribed drug register. The primary outcomes were dispensations of antipsychotics (ATC N05A), anxiolytics (ATC N05B), hypnotics/sedatives (ATC N05C) and/or antidepressants (ATC N06A), from three years before to three years after AAD diagnosis in the national patient register.
Results
963 cases of AAD and 9366 matched controls were identified. The most dispensed type of psychotropic medication was hypnotics and sedatives, with 14.2% of cases receiving it during the year of most use. The least dispensed group of psychotropics was anti-psychotics, with only 2.0% of cases and 1.8% of controls receiving it at most. Anti-depressants were prescribed at a lower frequency to the AAD group at all time points except for during the year before diagnosis, where the incidence was higher than in the control group (aOR 1.24; 95% CI 1.02–1.55; $P=0.040$). Patients also received more anxiolytics the year before diagnosis (aOR 1.28; 95% CI 1.03–1.62; $P=0.039$). Hypnotics and sedatives were significantly more common after diagnosis (aOR 1.29; 95% CI 1.02–1.64; $P=0.036$) and the increase did not subside during the study period.
Conclusion
Individuals with AAD receive more anxiolytics, anti-depressants, sedatives and hypnotics around diagnosis. While the dispensation of anxiolytics and anti-depressants return to pre-diagnostic levels after a while, the increased dispensation of sedatives and hypnotics remains elevated.

Brown adipose tissue activation on 18FDG-PET/CT scan in phaeochromocytoma: A case series

MuhammadNajmiBin MdNor[1], Kate Healy[1], Suzanne Egan[1], John Feeney[1], James Gibney[1], Agnieska Pazderska[2] & Aoife Garrahy[1]
[1]Tallaght University Hospital, Ireland; [2]St James's Hospital, Ireland

Introduction
Prior studies have demonstrated that individuals with phaeochromocytoma and paranganglioma may manifest activation of Brown Adipose Tissue (BAT) as a result of excess catecholamines secretion[1–2]. In this case series, we describe two cases featuring patients with phaeochromocytoma who exhibited increased uptake of BAT on ^{18}-FDG-PET/CT scans.
Case 1
A 74-year-old woman was referred to the Endocrinology department with a 7 cm right adrenal mass detected on CT imaging performed for the investigation of weight loss. Medical history included hypertension requiring three antihypertensives, type 2 diabetes and migraine. Blood work revealed elevated plasma normetanephrines, >25 000 pmol/l (0-1180), metanephrines, >16 000 pmol/l (0-510), and 3-methoxytyramine, 623 pmol/l (0-180). She subsequently had MRI Adrenal which showed 7 cm right adrenal mass and MIBG SPECT/CT which showed intensely MIBG-avid right adrenal mass. ^{18}-FDG-PET/CT arranged prior to the metanephrine results being available showed mild uptake in the right adrenal mass and intense uptake localising in thoracic paravertebral and perinephric fat indicative of BAT activation. Elective open right-sided adrenalectomy was performed, confirming a pheochromocytoma with Phaeochromocytoma Adrenal Scaled Score (PASS) of 7/20. Postoperatively, plasma metanephrines normalised and ^{18}-FDG-PET/CT showed a normalisation of perinephric FDG distribution and no FDG-avid disease.
Case 2
A 56-year-old woman was referred to Endocrinology department due to a 9 cm right retroperitoneal mass which was suspected to arise from right adrenal gland for investigation of recurrent vomiting. Medical history included hypertension and she reported having recurrent palpitations and anxiety. Blood work revealed elevated plasma normetanephrines >25 000 pmol/l (0-1180), metanephrines 1854 pmol/l (0-510) and 3-methoxytyramine, 731 pmol/l (0-180). Further investigations included MRI Adrenal, which identified well-circumscribed, peripherally enhancing 9 cm mass on right adrenal gland. She subsequently had ^{18}-FDG-PET/CT which showed partially cystic/necrotic right adrenal mass with intense FDG uptake in its solid component, with BAT uptake was observed in cervical, subclavicular and paraspinal stations. Subsequently, she had elective right-sided open adrenalectomy with histology confirmed phaeochromocytoma with PASS score of 11/20. Postoperatively, plasma metanephrines normalized and repeat CT TAP 6 months later showed no evidence of recurrence.
Discussions
Norepinephrine-induced beta-adrenoceptor activation in patients with phaeochromocytoma and paraganglioma may lead to brown fat activation, which is associated with increased energy wasting and cachexia[2]. In case 1, this manifested in weight loss and marked BAT activation on ^{18}-FDG-PET-CT, both of which were reversed following removal of the phaeochromocytoma.

Severe hyponatraemia and hyperkalaemia in pre-eclampsia due to hypoadrenalism/functional hypoadrenalism

Ffion Davies[1], Timothy Green[2], Rhiannon Berkeley[2], Genevieve Tellier[2] & Anthony Wilton[2]
[1]Bangor Hospital, Acute Intervention Team, Bangor, UK; [2]Bangor Hospital, Endocrinology, Bangor, UK

Pre-eclampsia is a life-threatening disease occurring in 4.6% of pregnancies characterised by multi-organ dysfunction. Placental dysfunction is implicated with release of factors causing systemic inflammation and endothelial dysfunction. Mild hyponatraemia (130–135 mmol/l) is regarded as physiological in normal pregnancy. Severe hyponatraemia (<125 mmol/l) is a rare life-threatening complication of pre-eclampsia. Severe hyponatraemia and hyperkalaemia has been reported on one occasion; we report a second case with endocrine data.
Case history
A 27 year old 34-weeks pre-eclamptic twin-pregnancy patient was referred to endocrinology with severe hyponatraemia, hyperkalaemia and metabolic acidosis: sodium 120 mmol/l, potassium 6.2 mmol/l, bicarbonate 16 mmol/l, creatinine 93 mmol/l, eGFR 63 ml/min. Five days earlier: sodium 131 mmol/L, potassium 4.5 mmol/l, creatinine 77 mmol/l, eGFR 78 ml/min. Two weeks earlier: sodium 135 mmol/l, potassium 5.1 mmol/l, creatinine 66 mmol/l, eGFR >90 ml/min. Insulin/dextrose was ineffective causing hypoglycaemia with little effect on potassium. Coincidental with deterioration in sodium and potassium levels a rise in creatinine, CRP and liver enzymes and decrease in eGFR, pH and albumin had occurred. Examination: ill, oedematous, blood pressure 140/90 mmHg on treatment with labetalol 200mg BD. Investigations at 0730 h: cortisol 483 nmol/l, ACTH 118 ng/l, PRA 1.7 nmol/l per hour, (aldosterone 2010 pmol/l, aldosterone/renin ratio 1182, results not immediately available). The abnormal electrolytes, pH and inappropriately normal cortisol level given clinical status, third trimester and elevated ACTH suggested hypoadrenalism. Hydrocortisone 100 mg IV followed by 200 mg/24 h continuous infusion did not prevent further biochemical deterioration: sodium 120 mmol/l, potassium 6.2–8.7 mmol/l, pH 7.23, creatinine 109 mmol/l and eGFR 52 ml/min. Urgent delivery was advised with a 2 healthy males outcome but a post-operative haemorrhage resulted in a hysterectomy. All laboratory data normalised post-delivery.
Conclusion
1) This case confirms severe hyponatraemia (+/− hyperkalaemia) as a risk factor in pre-eclampsia. Existing guidelines do not address this issue. 2) There is evidence of impaired cortisol synthesis/secretion with low cortisol and high ACTH level. The adrenal ACTH receptor is a 7-membrane-spanning G protein-coupled receptor which could be affected by endothelial dysfunction. 3) Angiotensin II is also a transmembrane G protein-coupled receptor which could also be affected by endothelial dysfunction. Hyperkalaemia is a highly potent aldosterone secretagogue acting by depolarisation of the cells of the zona glomerulosa. 4) Aldosterone upregulates and enhances gene transcription of the transmembrane sodium/potassium ATPase pump which again could be affected

by endothelial dysfunction explaining the lack of aldosterone effect on sodium and potassium levels.

11β-hydroxysteroid dehydrogenase type 1 inhibition unmasks multiple pathways that may mitigate the adverse effects of prescribed prednisolone

Riccardo Pofi[1], Sergi Coll[2], Nantia Othonos[1], Hamish Miller[1,3], Tom Potter[1,4], Jane Escott[5], Andrew Whittaker[6], Núria Monfort[2,7], Rosa Ventura[2] & Jeremy Tomlinson[1]

Background

Prednisolone is the most commonly prescribed exogenous glucocorticoid(GC) and its use is frequently associated with the development of iatrogenic Cushing's Syndrome. Once administered, prednisolone is rapidly converted to inactive prednisone by renal 11β-hydroxysteroid dehydrogenase type 2(11β-HSD2) and subsequently reactivated by 11β-HSD1. We have shown previously that 11β-HSD1 inhibition(with the selective 11β-HSD1 inhibitor, AZD4017) mitigates prednisolone-induced adverse effects[1]. Other enzymes, including AKR1C1(20α-hydroxylase), Carbonyl reductase 1(20β-hydroxylase, CBR1) and CYP3A4(6β-hydroxylase) are known to have a role in GC metabolism, but their contributions to prednisolone and prednisone metabolism are entirely unexplored.

Aims

To describe the patterns of unique metabolites(plasma and urine) associated with prednisolone and prednisone clearance, define the impact of 11β-HSD1 inhibition and assess correlations between plasma metabolites and clinically significant outcomes.

Methodology

Retrospective analysis of timed overnight urine collections alongside a detailed 8-h assessment period of 2-hourly plasma samples after administering prednisolone (20 mg) with either placebo or AZD4017. Plasma metabolites were quantified using LC–MS/MS. Specific enzyme activity was inferred using the ratio of target metabolite/substrate levels. We employed repeated measure ANOVA, Area Under the Curve(AUC) analysis as well as logistic regression.

Results

Urine sample analysis identified 20 discrete prednisolone metabolites. Following oral prednisolone administration (20 mg), timed (0–8 h) plasma metabolite analysis demonstrated that prednisolone (AUC = 820 ± 213 ng/ml) and prednisone (AUC = 154 ± 50 ng/ml) were the most abundant metabolites, followed by 20β-OH metabolites ($AUC_{20\beta\text{-OH-prednisolone}} = 69.5 \pm 71.2$; $AUC_{20\beta\text{-OH-prednisone}} = 24.8 \pm 16.8$ ng/ml). Inhibition of 11β-HSD1 activity with AZD4017 decreased prednisolone availability by 59% ($P < 0.001$). Interestingly, AZD4017 did not increase prednisone availability ($\Delta_{AUC} = -38.67$, 95%CI −84.42;7.08, $P = 0.113$). Furthermore, 8h after prednisolone administration, prednisone levels were lower in the AZD4017 treated group (Δ −14.88 ng/ml, 95%CI −18.94; −10.83, $P < 0.001$). This observation was driven, at least in part, through increased (+93%, $P = 0.007$) CBR-1 activity assessed by 20β-OH prednisone relative to prednisone concentrations. Logistic regression identified 20β-OH-prednisone(4h) as the only predictor of higher glucose disposal ($B = 0.382$, $P = 0.017$) and osteocalcin levels ($B = 0.727$, $P = 0.006$) after prednisolone, indicative of less significant adverse effects.

Conclusions

11β-HSD1 has a major role to regenerate active exogenous prednisolone. However, preferential prednisone clearance, principally through the activity of CBR1 (but also AKR1C1), further limits the potential for prednisone reactivation and may represent another important mechanism mitigating the adverse effects of prescribed GCs. Finally, 20β-OH-prednisone may emerge as predictor of prednisolone-related adverse effects that may lead to a more precise and personal approach to prednisolone prescribing.

Introduction

In patients with unilateral adrenal incidentaloma (AI) and mild autonomous cortisol secretion (MACS) the best therapeutic approach is still a matter of debate. The only available randomized study showed a short-term beneficial effect of surgery on diabetes and hypertension. Importantly, recent data demonstrated that MACS is associated to an increased risk of mortality, especially due to cardiovascular causes.

Study aim

to evaluate, in the medium term, the effect of adrenalectomy on blood pressure and glycometabolic control, in patients with AI and MACS.

Patients and methods

We performed a prospective randomized study on 62 patients with AI > 1 cm and cortisol after 1 mg dexamethasone suppression test (1 mgDST) between 1.8 and 5 μg/dl. Patients were randomized to adrenalectomy (operated) or conservative approach (non-operated). A total of 46 subjects (20 operated and 26 not operated) completed a 12 months follow-up. Blood pressure (BP), body weight, glycometabolic control, insulin secretion by homeostasis model assessment (HOMA-β) index and the medical therapy changes were assessed.

Results

At 12 months, the frequency of BP improvement was higher in operated (45%) than in non-operated patients (11.5%, $P = 0.01$), while the BP worsening was more frequent in the latter group (30.8%) than in the former one (10.0%, $P = 0.008$). Glycometabolic control ameliorated in the 25% and worsened in the 15% of surgically treated patients and in 11.5% and 30.8% of non-operated ones, respectively (P-for-trend = 0.300). The operated patients showed a significant increase in insulin secretion levels at 12 months compared to non-operated ones (HOMA-β 167.6 ± 79.4 vs 111.4 ± 47.7%, $P = 0.009$; fasting insulin 12.3 ± 4.6 vs 8.8 ± 3.9 μU/ml, $P = 0.018$; insulin AUC after OGTT 12817.1 ± 8006.1 vs 7912.5 ± 2397.0 μU/ml per 120 minutes, $P = 0.050$). BP and/or glycometabolic control improved more frequently in surgically treated patients (55.0%) than in non-operated ones (19.2%, $P = 0.015$), while BP and/or glycometabolic control worsened more commonly among non-operated patients (52.0%) than among surgically treated ones (20.0%, $P = 0.028$). The improvement of BP and/or glycometabolic control was 10.2-fold more frequent in operated patients (confidence interval, 2.82–37.1, $P < 0.001$), regardless for age, gender, and presence of glycometabolic alterations and hypertension at baseline.

Discussion

In patients with AI and MACS surgery leads to a persistent improvement of blood pressure control and insulin secretion and, in more than half of cases, it is beneficial in terms of BP and/or glycometabolic control. At variance, in more than half of patients a conservative approach seems to be deleterious in terms of BP and/or glycometabolic control.

Objective
We have described constitutional duplications of the *PRKACA* gene locus (encoding the catalytic subunit of the Protein Kinase A) in rare cases of bilateral nodular adrenocortical cause of Cushing's (Beuschlein et al, NEJM 2014). Its frequency in macronodular and micronodular adrenal diseases and the occurrence of others manifestation of Carney complex are not clearly established. This study performs its systematic screening in a large cohort of adrenocortical nodular disease patients and describes its phenotype.
Methods
Between 2020 and 2023, 487 consecutive index cases with bilateral macronodular adrenal hyperplasia ($n=442$) or Primary Pigmented Nodular Adrenocortical Disease (PPNAD)/Carney Complex (CNC) ($n=45$) were genotyped with a targeted NGS panel including the exonic and intronic flanking regions of the *ARMC5*, *MEN1*, *PRKAR1A* (CNC) and *PRKACA* genes. Familial screening was then offered to relatives. Whole genome sequencing was performed when accepted in index cases with *PRKACA* duplications.
Results
Constitutional duplications of *PRKACA* were identified in 5 index cases (representing 11% of patients with PPNAD or CNC) and 7 of the 11 screened relatives, supporting the involvement of the *PRKACA* oncogene through a constitutional copy gain mechanism. Sex ratio was 1 male/2 female. The whole genome sequencing performed for 4 index cases did not find any other gene involved in human disease in the duplicated region, nor any other alteration in genes implicated in adrenal tumors. All index cases had PPNAD responsible for Cushing's syndrome and ACTH-independent hypercortisolism, diagnosed at a median of 20 years (range: 9–32). The adrenals were described as normal on conventional imaging in 3/5 cases, but iodocholesterol scintigraphy showed diffuse bilateral uptake. They presented with high 24 h Urinary Free Cortisol (UFC) (range: 2.3 - 9.8 × upper limit of normal) and no response to Dexamethasone suppression test. A paradoxical rise in 24 h UFC after Dexamethasone (Liddle's test) was observed in 3 patients (1 index and 2 relatives). All patients with Cushing syndrome were treated by bilateral adrenalectomy. Almost no significant manifestations of CNC were observed apart from PPNAD (median follow-up of 10 years [5–16]): mainly lentigines and testicular calcifications in one male patient.
Conclusion
Constitutional duplication of *PRKACA* is a rare cause of PPNAD. It does not appear to be involved in other forms of adrenocortical nodular disease, nor is it frequently associated with other manifestations of CNC. Constitutional duplication of *PRKACA* should be searched in the absence of a pathogenic *PRKAR1A* variant in patients with PPNAD.

Lysophosphatidylcholines and acylcarnitines: Novel markers of physiological glucocorticoid action in adipose tissue

Kate Bennett[1], Terence Garner[1], Dimitrios Chantzichristos[2], Per-Anders Jansson[3], Adam Stevens[1] & Gudmundur Johannsson[3]
[1]The University of Manchester, Division of Developmental Biology and Medicine, Manchester, UK; [2]Sahlgrenska University Hospital, Department of Endocrinology-Diabetes-Metabolism, Sweden; [3]University of Gothenburg, Institute of Medicine, Sweden

Introduction
Glucocorticoids (GCs) play a crucial role in various physiological processes, with adipose tissue (AT) being an important target organ for their metabolic actions. Besides lipolytic action, the mechanistic regulation of GCs in human AT during physiological exposure is still unclear. We integrated transcriptomic and metabolomic data within the AT to identify mechanistic markers of GC action.
Methods
In a randomised, cross-over trial, ten patients with primary adrenal insufficiency received saline i.v. (GC withdrawal) or circadian infusion of hydrocortisone (GC exposure), with > two weeks in-between. At the end of each 26 hour period (0800 h), an abdominal subcutaneous microdialysis (membrane Asahi Kasei Medical, 3MDa) was performed, with dialysate analysed for metabolomics by LC–MS. Abdominal subcutaneous AT biopsy was collected for transcriptomics by Affymetrix Array. Hypergraph network models were used to identify changes in the metabolome between GC exposure and withdrawal, and integrate metabolomic and transcriptomic data.
Results
In subcutaneous dialysate, 22 metabolites were significantly different between GC exposure and withdrawal. The top five metabolites were lysophosphatidylcholine (lysoPC) (16:0(OH)/0:0), octanoylcarnitine, lysoPC(0:0/16:0(OH)), decanoylcarnitine, and hexanoylcarnitine. In near physiological GC exposure, we observed increased concentrations of five acylcarnitines, three fatty acids (FA), proteolytic metabolites such as gamma-glutamylleucine, and three lysoPCs with longer carbon chains (≥20C). Four lysoPCs with shorter carbon chains (<20C) were found at decreased concentration in GC exposure. We identified a relationship between a group of four acylcarnitines and two lysoPCs during physiological GC exposure. This relationship was disrupted in the withdrawal state, suggesting GC-dependent regulation. DEGs ($n=2048$ $P<0.05$) between the interventions were enriched in regulation of lipid metabolic processes by gene ontology. Hypergraphs highlighted a cluster of nine genes, the expression of which was linked to concentrations of acylcarnitines, FA and cortisol. These included several well-known GC-response genes, such as *KLF9*, *PDK4*, and *ZBTB16,* which share positive relationships with these lipolytic and proteolytic metabolites.
Conclusions
Near physiological GC exposure increased lipolysis pathways, with increased concentrations of acylcarnitines, FA, and lysoPCs. A GC-dependent relationship between acylcarnitines and lysoPCs was identified. Acylcarnitines act as transporters of FA across the mitochondrial membrane for beta-oxidation. We observed a shift from shorter chain (C14-16) to longer chain (C20-22) lysoPCs, suggesting increased lipolysis of shorter chain FA. Integration of metabolomics and transcriptomics showed relationships between expression of GC-response genes, and key metabolites in the dialysate, supporting methodology and suggesting an important role of lipolysis, beta-oxidation, and proteolysis in physiological GC action in AT.

Medication-associated false positive results for plasma normetanephrine, metanephrine and methoxytyramine

Lara Knigge[1], Kristin Potthoff[1], Georgiana Constantinescu[1], Francesco Alessi[1], Sybille Fuld[1], Karolina Zawadzka[2], Stefan Bornstein[1], Jacques Lenders[3], Graeme Eisenhofer[1] & Christina Pamporaki[1]
[1]University Hospital Carl Gustav Carus Dresden, Dresden, Germany; [2]Uniwersytet Jagielloński Collegium Medicum, Kraków, Poland; [3]Radboud University Medical Center, Nijmegen, Netherlands

Background
Measurements of plasma metanephrines provide a sensitive test for diagnosis of pheochromocytoma/paraganglioma (PPGL). However, false positive results can pose a diagnostic dilemma for clinicians. The aim of the study was to determine whether commonly prescribed drugs with potential action on the sympathetic nervous system can falsely elevate plasma free normetanephrine, metanephrine and methoxytyramine.
Methods
This retrospective study included 461 patients among who PPGL was excluded. Data on sex, age, plasma free normetanephrine, metanephrine and methoxytyramine concentrations, cardiometabolic comorbidities and/or seriouschronic illness (CCI), as well as a listing of all medications taken at the time of testingwere collected. Measurements of metabolites were by liquid chromatography with tandem mass spectrometry. For four patients under treatment with tricyclic antidepressants and/or serotonin-norepinephrine-reuptake blockers (NRBs), metabolites were measured at baseline and after discontinuation of the drug for at least five days.
Results
Among 461 patients, 408 were treated with various medications, including 23 with NRBs, 14 with selective-serotonin-reuptake-blockers, five with atypical antipsychotics, ten with anticonvulsants, 19 with hypnotics, 175 with diuretics, 187 with beta-blockers, 189 with dihydropyridines, 18 with non-dihydropyridines, 121 with angiotensin-converting-enzyme-inhibitors, 172 with angiotensin-receptor-blockers, 64 with alpha-blockers, 64 with central-agonists, 14 with vasodilators, and five with renin-inhibitors. Among 369 patients under antihypertensive treatment, 278 were treated with more than one antihypertensive drug. Rates of false positive results for plasma free normetanephrine, metanephrine and methoxytyramine in the entire cohort were 6% (29/461), 1% (4/461) and 1% (5/461) respectively. NRBs were responsible for 10% and 40% of all false positive elevations of normetanephrine and methoxytyramine respectively, whereas treatment with multiple antihypertensive drugs for 59% and 60% respectively. Nevertheless, for the vast majority of patients with multiple antihypertensive drugs and false positive elevations of normetanephrine(12/17), CCI were reported. Multivariable regression analysis after controlling for age, sex and the presence of CCI, indicated that only NRBs have significant impact on plasma free normetanephrine concentrations ($P=0.0014$). Among four patients under NRBs with paired metabolite measurements before and after discontinuation of treatment, all showed drops of normetanephrine levels below upper-cut offs after discontinuation of the medication, whereas for methoxytyramine all but one.

Conlcusion
Plasma free metanephrines and methoxytyramine is a test with a low rate of false positive results. Apart from NRBs, other medications have negligible impact on false positive results for plasma free normetanephrine.

Comparison of antihypertensive effects between eplerenone and esaxerenone, mineralocorticoid receptor antagonists, in patients with primary aldosteronism

Satoshi Morimoto, Saya Takebe, Kentaro Oyake, Saori Kitayama, Makiko Ikemoto, Yuko Inoue, Hisashi Sano, Kiyotaka Hirata, Noriyoshi Takano, Kaoru Yamashita, Yasufumi Seki, Kanako Bokuda, Daisuke Watanabe & Atsuhiro Ichihara
Tokyo Women's Medical University, Department of Internal Medicine, Tokyo, Japan

Objective
The efficacy of mineralocorticoid receptor (MR) antagonists has been demonstrated in MR-related hypertension, including primary aldosteronism (PA). Non-inferiority in 24-hour blood pressure reduction has been shown for esaxerenone 2.5 mg/day compared to eplerenone 50 mg/day in patients with essential hypertension. However, no trial has compared the antihypertensive effects of these drugs in patients with PA. This study aimed to investigate the effect of switching from eplerenone to esaxerenone and assess changes in various parameters, including blood pressure.
Methods
Patients with PA receiving eplerenone for at least 8 weeks underwent a switch to esaxerenone at 1/20th of the dose. Blood pressure measurements (office, 24-hour ambulatory blood pressure monitoring [ABPM]) and urine and blood tests were conducted before and 12 weeks after the switch, and the obtained data were compared before and after the switch.
Results
Forty-seven cases (21 males) with a mean age of 58±12 years and body mass index of 23.8 (21.7–25.3) kg/m^2 were included. Office blood pressure before the switch was 137±18/81±11 mmHg, 24-hour blood pressure 130 (123–140)/82±6 mmHg, diurnal blood pressure 133 (126–142)/84±6 mmHg, nocturnal blood pressure 119 (110–126)/73±6 mmHg, serum potassium 4.2±0.3 mEq/l, eGFR 70.1±14.3 ml/min per 1.73 m^2, and plasma renin activity (PRA) 0.9 (0.5–1.7) ng/mL per hour. After the switch, office systolic blood pressure was significantly decreased [130 (118–139) mmHg; p=0.002]. ABPM revealed significant reductions in both systolic and diastolic blood pressure over 24 h [127 (120–137) mmHg; P=0.008/80±6 mmHg; P=0.006], during the diurnal period [133 (126–142) mmHg; P=0.015/82±7 mmHg; P=0.009], and throughout the nocturnal period [115 (110–119) mmHg; p=0.039/71±7 mmHg; P=0.023]. Serum potassium did not show significant changes, but PRA [1.5 (0.7–2.1) ng/ml per hour; P<0.001] increased significantly, and eGFR (64.9±14.8 ml/min per 1.73 m^2; P<0.001) significantly decreased.
Conclusion
In PA patients, esaxerenone demonstrated a stronger MR antagonistic effect and a significant and sustained antihypertensive effect compared to eplerenone.

Objective
To describe the baseline characteristics of individuals enrolled in CAHtalyst Pediatric (NCT04806451), a randomized, double-blind, placebo-controlled, Phase 3 study evaluating the safety and efficacy of crinecerfont (a corticotropin-releasing factor type 1 receptor [CRF$_1$] antagonist) in children and adolescents with classic congenital adrenal hyperplasia due to 21-hydroxylase deficiency (21-OHD CAH).
Methods
Key eligibility criteria included: male or female, age 2-17 years; glucocorticoid (GC) dose >12 mg/m^2/day in hydrocortisone equivalents (HCe) adjusted for body surface area (BSA), on a stable dose for ≥1 month prior to screening; androstenedione (A4) greater than midpoint of reference range; and 17-hydroxyprogesterone (17-OHP) >2× upper limit of normal prior to morning GC dose. Baseline demographics and characteristics were summarized descriptively in all randomized participants.
Results
Of 103 enrolled participants at 46 study centers, 52% were male and 63% were White. Mean (±S.D.) age was 12±3 years (range: 4–17), with 54% ages 12–17 years. Overall, 58% were overweight/obese (body mass index [BMI] ≥85th percentile), BMI standard deviation score (SDS) was 1.2±0.9, height SDS was 0.3±1.3, and mean BSA was 1.5±0.3 m^2. Tanner stages (breast or testicular volume) were as follows: 1 (29%), 2 (12%), 3 (13%), 4 (18%), and 5 (28%). Mean (±S.D.) total daily GC dose was 16.4±3.9 mg/m^2/day HCe, with 92% on hydrocortisone and 8% on a predniso(lo)ne-containing regimen. 87% were taking fludrocortisone (mean dose: 1.1±0.5 mg/day), with 10% on GnRH agonists and 3% on aromatase inhibitors. Mean (±S.D.) hormone concentrations prior to morning GC dose were: ACTH, 329±344 pg/ml; 17-OHP, 8682±6847 ng/dl; A4, 431±461 ng/dl; testosterone (T) in females, 73±67 ng/dl; and A4/T in males, 3.5±7.6. Comorbidities included advanced bone age by ≥1 year (62%), early puberty (33%), irregular menstrual cycles (12% females), hirsutism (12% females), and testicular adrenal rest tumors (6% males). The mean ratio of bone age to chronological age was highest in males at Tanner stage 1 (1.4±0.4) and in females at Tanner stage 2 (1.2±0.2).
Conclusion
In a Phase 3 trial evaluating crinecerfont in children and adolescents with 21-OHD CAH on GC doses >12 mg/m^2/day HCe, there was clinical evidence of GC and androgen excess (e.g., overweight/obesity, advanced bone age, and early puberty). Androgen levels were elevated despite treatment with GC doses >12 mg/m^2/day HCe, highlighting the need for novel treatments for this condition.

Sphingosine kinase 1 inhibitor safingol as a new possible therapeutic strategy for adrenocortical carcinoma

Emma Nozza[1,2], Rosa Catalano[1], Emanuela Esposito[1,2], Serena Palmieri[3], Barbara Altieri[4], Laura-Sophie Landwehr[4], Hantel Constanze[5,6], Sandra Sigala[7], Emanuele Ferrante[3], Giovanna Mantovani[1,3] & Erika Peverelli[1,3]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]University of Milan, Phd Program in Experimental Medicine, Milan, Italy; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [4]University of Würzburg, Division of Endocrinology and Diabetes, Department of Internal Medicine I, University Hospital, Würzburg, Germany; [5]University Hospital Zurich (USZ) and University of Zurich (UZH), Department of Endocrinology, Diabetology and Clinical Nutrition, Zurich, Switzerland; [6]University Hospital Carl Gustav Carus Dresden, Medizinische Klinik und Poliklinik III, Dresden, Germany; [7]University of Brescia, Section of Pharmacology, Department of Molecular and Translational Medicine, Brescia, Italy

Sphingosine kinase 1 (SphK1) is the enzyme deputed to the phosphorylation of sphingosine in sphingosine-1-phosphate (S1P). S1P promotes ERK phosphorylation with increasing cellular proliferation, AKT phosphorylation, that induces apoptosis resistance and cell migration. It has been recently demonstrated that SphK1 is overexpressed in adrenocortical carcinoma (ACC) in comparison to adenomas (ACA) and that a high expression is related to worse outcome. Different SphK1 inhibitors have been developed to prevent S1P production and induce sphingosine accumulation resulting in cell apoptosis. Among these inhibitors, safingol was used in two phase I clinical trials on solid cancers, also including a small number of ACC patients, where it was clinically active in combination with other chemotherapies. Despite these interesting premises, safingol has never been tested on ACC *in vitro*models. Aim of this study was 1) to assess the expression of SphK1 in ACC, ACA, and normal adrenal tissues (NA) and in 4 human ACC cell lines; 2) to test the effect of safingol on

cellular viability, proliferation, and apoptosis in different ACC cell models. Western Blot analysis revealed that NA tissues ($n=8$) displayed the lowest SphK1 level ($P<0.001$ vs ACC or ACA), while SphK1 expression in ACC ($n=8$) was 2-fold higher than in ACA ($n=8$) ($P<0.05$). Among ACC cell lines, SK showed similarly greater levels in JIL-2266 and MUC-1 compared to H295R and TVBF-7. After 72 h of safingol treatment, all the cell lines displayed a significant reduction of cell viability [H295R safingol 5 μM -52.30 (32.51)%; JIL-2266 safingol 4 μM -51.96 (58.91)%; MUC-1 safingol 3 μM -30.38 (20.90)%; TVBF-7 safingol 8 μM -51.52 (57.50)%]. Cellular proliferation was assessed at the first dosage showing viability reduction, and it was decreased as well ($P<0.05$) in all cell lines [H295R safingol 5 μM -55.73 (57.52)%; JIL-2266 safingol 4 μM -64.53 (16.55)%; MUC-1 safingol 3 μM -51.53 (24.99)%; TVBF-7 safingol 8 μM -57.36 (35.52)%]. Pro-apoptotic effect of safingol was evaluated via caspases 3 and 7 activity quantification and found significantly increased ($P<0.05$) after 24 h of treatment [H295R safingol 7.5 μM + 146.73 (197.5)%; JIL-2266 safingol 4 μM + 141.6 (68.8)%; MUC-1 safingol 5 μM + 38.20 (61.6)%; TVBF-7 safingol 8 μM + 250.14 (258.6)%].
In conclusion, our data demonstrated an overexpression of SphK1 in ACC vs ACA and NA, suggesting that it may represent a novel diagnostic biomarker for ACC. Moreover, our results support the use of SphK1 inhibitor safingol as a novel possible therapeutic strategy for ACC.

CXCR4-directed [68Ga]Ga-PentixaFor PET/CT as a diagnostic modality in subtyping primary aldosteronism

AmirHosseinChaman Baz[1], Martin Gotthardt[2], Wilko Spiering[3], Jaap Deinum[4] & Johannes Langenhuijsen[1]
[1]Radboud University Medical Center, Urology, Nijmegen, Netherlands; [2]Radboud University Medical Center, Nuclear medicine, Nijmegen, Netherlands; [3]UMC Utrecht, Vascular medicine, Utrecht, Netherlands; [4]Radboud University Medical Center, Vascular medicine, Nijmegen, Netherlands

Introduction
Primary aldosteronism (PA) is a form of secondary hypertension, affecting 2.4% of the hypertensive population. It is caused by autonomous overproduction of aldosterone by either a unilateral aldosterone-producing adenoma (APA) or by bilateral adrenal hyperplasia (BAH). Subtyping is crucial, because PA is cured by adrenalectomy in APA and is treated by medication in BAH. The reference standard in subtyping PA is adrenal vein sampling (AVS). However, it is invasive, costly, has limited availability and is accompanied by risk of serious complications. We propose employing the positron emission tomography-computed tomography (PET-CT) tracer [68Ga]Ga-PentixaFor, which has high accuracy in detecting APAs in PA. The goal of this study is to determine concordance of [68Ga]Ga-PentixaFor PET-CT and AVS. Secondary outcomes are timepoint for scanning, criteria for lateralization and biochemical and clinical success after adrenalectomy.
Methods
This study is part of a two-step diagnostic trial. We included patients with PA from two academic centers, confirmed by an intravenous salt-loading test. Patients underwent AVS and [68Ga]Ga-PentixaFor PET-CT. Patients were treated based on the AVS results. A dynamic scan was performed to determine the optimal timepoint for scanning in the first 6 patients. The main outcome was the concordance of AVS and [68Ga]Ga-PentixaFor PET-CT. The SUVmax was used to determine lateralization in [68Ga]Ga-PentixaFor PET-CT. The PASO criteria for clinical outcomes were used to assess the surgical outcomes at 3 and 6 months post-surgery.
Results
Twenty-five patients underwent adrenal vein sampling and a [68Ga]Ga-PentixaFor PET-CT. The optimal timepoint of scanning was 1h post-injection. Using a cut-off of SUV-max-ratio of 1.4 we reached a concordance of 68%, sensitivity of 60% and specificity of 80%. Using a Bayesian prediction model, the predicted-concordance was: 67% (CI80% = 54–78). At 3 months post-surgery, complete biochemical success was observed in 100% (10/10) of patients and in 83% (5/6) at the 6-month mark. Clinical success rates were noted to be 70% (7/10) at 3 months and 67% (4/6) at 6 months.
Conclusion
[68Ga]Ga-PentixaFor PET-CT is an imaging modality with high concordance with AVS. With these results we have sufficient evidence to proceed to step-2: A randomized controlled diagnostic trial, where patients will be randomized in [68Ga]Ga-PentixaFor PET-CT or AVS.

Objectives
The clinical impact of glucocorticoid-induced adrenal insufficiency in patients on low-dose prednisolone is unclear. We investigated the influence of adrenal function on health-related quality of life (HRQoL) in patients tapering prednisolone.
Method
Baseline data from an ongoing prospective randomised clinical trial including 278 patients with polymyalgia rheumatica/giant cell arteritis treated with prednisolone for ≥12 weeks, current dose ≤5 mg. Adrenal function, evaluated with a 250 μg ACTH-test, remained blinded until after HRQoL assessments. Fatigue was assessed under unstressed conditions five times daily for three days using a smartphone-based momentary item version of the Multidimensional Fatigue Inventory's General Fatigue scale. Answers were provided on visual analogue 100-point scales and analysed with linear mixed models for repeated measures. Generic and disease-specific HRQoL was evaluated with SF36v2 and AddiQoL-30. Subgroup analyses of patients receiving i) 5mg and ii) <5 mg prednisolone/-day were performed.
Results
Of 278 patients 55 (20%) treated with prednisolone for median 18 months (3-271 months), median current dose 5 mg (0.36–5 mg) had adrenal insufficiency. Fatigue measurements were available for 120 patients [response rate 65% (1171/1800 questions)]. Overall, no difference in fatigue was found between patients with normal vs insufficient adrenal function [adrenal insufficient 4.6 points less fatigue, S.E.:5.1, $P=0.36$]. Patients experienced insignificantly more fatigue the higher stimulated P-cortisol [3.6 points/100 nmol/l, S.E.:1.7, $P=0.05$]. No effect of adrenal function on diurnal variation of fatigue was found [$P=0.81$]. Subgroup analyses of patients treated with 5 mg and <5 mg prednisolone/day showed similar results. Among 205 responses, total AddiQoL-30-scores did not differ in patients with insufficient vs normal adrenal function [mean(S.D.) 88.7(12.5) vs 87.9(10.9), $P=0.66$]. Similar results were found for all AddiQoL-30-subscales. For patients treated with 5 mg/day prednisolone ($n=121$), AddiQoL-30 Symptoms was correlated to stimulated P-cortisol (more symptoms with higher cortisol) [−0.58points/100 nmol/l, 95%CI: −1.1 to −0.05, $P=0.031$]. Among 202 responses, no significant difference in SF36v2 scores appeared between patients with normal vs insufficient adrenal function, except the subscale Role Emotion, which correlated with stimulated P-cortisol (worse the higher stimulated P-cortisol) [Spearman correlation coefficient −0.16, $P=0.020$]. Glucocorticoid-subgroup analyses showed similar results.
Conclusions
In patients tapering prednisolone to ≤5 mg/day, we did not find lower HRQoL in patients with adrenal insufficiency. In contrast, SF36v2 Role Emotion and AddiQoL-30 Symptoms scores were significantly worse with higher stimulated P-cortisol, but with small effect sizes and thus unlikely clinically relevant. Patients might experience symptoms during stress. The prospective part of our study will monitor symptoms of adrenal insufficiency during stress.

Benefits and harms according to intensity of statin therapy in Korean patients with dyslipidemia

SunOk Song[1] & Sunghwan Suh[2]
[1]National Health Insurance Service Ilsan Hospital, Division of Endocrinology and Metabolism, Goyang, Republic of South Korea; [2]Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, Division of Endocrinology and Metabolism, Changwon, Republic of South Korea

Background
This study aimed to investigate the association between the intensity of statin therapy and the development of cardiovascular disease (CVD) and diabetes in individuals without prior diabetes who were being treated for dyslipidemia with statins for the primary prevention of CVD, using the National Health Insurance Service-Health Screening (NHISHEALS) database.
Methods
The database is a longitudinal cohort study of Korean men and women 40 years of age or older who underwent comprehensive biannual screening health examinations by NHIS from January 1, 2002, to December 31, 2015. We included patients in the health screening checkup cohort who underwent health checkups in 2009 and 2010.The primary outcome was the occurrence of a first major cardiovascular or cerebrovascular event, new-onset diabetes.
Results
A total of 20 322 participants without prior diabetes at baseline from 2009 to 2015 were followed up for a mean duration of 81.2 ± 6.6 months. The mean age of all participants at baseline was 59.2 ± 8.4 years and 43.0% of them were male. Their index LDL-C level was 130.4 ± 36.2 mg/dl, the mean duration of taking statins was 337.4 ± 52.3 days, and 93.9% of them had been taking moderate-intensity statins. During follow-up, a total of 641 diabetes cases occurred, 41 from using low-intensity statins, 588 from moderate-intensity statins, and 11 from high-intensity statins. The results indicated no significant differences in the incidence of death, CVD death, or CVD among those in the strong statin group compared with the reference groups.
Conclusion
There was no difference in the occurrence of CVD or CVD death according to statin intensity for the primary prevention of CVD in Korean patients with dyslipidemia. In addition. there was a subtle difference in the incidence of diabetes.

Description of recreational male and female athletes illicitly using androgenic anabolic steroids

LaustF Buhl[1], LouiseL Christensen[1], Rikke Hjortebjerg[2], Selma Hasific[3], Clara Hjerrild[1], Stefan Harders[4], JonJ Rasmussen[5], Dorte Glintborg[1], MarianneS Andersen[1], Caroline Kistorp[5], JesS Lindholt[3], Axel Diederichsen[6] & Jan Frystyk[1]
[1]Odense University Hospital, Endocrinology, Odense; [2]University of Southern Denmark, KMEB, Odense, Denmark; [3]Odense University Hospital, Vascular Surgery, Odense; [4]Aarhus University Hospital, Radiology, Aarhus, Denmark; [5]Rigshospitalet, Endocrinology, København, Denmark; [6]Odense University Hospital, Cardiology, Odense

Background
The illicit use of androgenic anabolic steroids (AAS) has increased significantly and is nowadays used by many recreational athletes. This raises concerns about the AAS-associated health risks, particularly cardiovascular complications. Therefore, we studied cardiovascular health in the broad population of Danish AAS-using recreational male and female athletes.
Methods
We conducted a cross-sectional study of 107 AAS users (27 women) and 58 healthy, age-matched controls (16 women) ≥18 years of age. Athletes were categorized as active AAS users or previous AAS users. Primary outcome was ultrasound-detected plaques of the carotid and femoral arteries. Secondary outcomes were computed tomography angiography (CCTA)-determined non-calcified and calcified plaques and cardiac function measured by echocardiography.
Results
The prevalence of ultrasound-determined plaques in the femoral artery in controls vs previous vs active AAS users were 0.0%, 6.3%, 16.0%, $P=0.005$, respectively, and in the carotid artery 1.8%, 18.8%, 12.0%, $P=0.025$, respectively. In subgroup analyses, long-term AAS use (>5 years) was significantly linked to non-calcified plaques ($P=0.002$) and coronary artery calcium scores ($P=0.013$). Additionally, both active and previous AAS users had higher prevalence of cardiac hypertrophy (controls vs previous vs active: 3.5%, 21.3%, 32.0%, $P<0.001$). Furthermore, a consistent pattern of decline in biventricular systolic function was observed across groups (controls vs previous vs active), with active AAS users displaying the lowest left ventricular ejection fraction (LVEF) (58.7%, 56.8%, 53.8%; $P<0.001$), LV global longitudinal strain (LV-GLS) (−19.8, −18.8, −17.6; $P<0.001$) and RV-GLS (−22.8, −20.9, −20.2; $P<0.001$). Women showed quantitatively similar changes as men, although not all findings achieved significance, probably due to a lower number of participants.
Conclusion
Long-term AAS use was linked to the development of peripheral and coronary atherosclerosis, cardiac hypertrophy, and reduced systolic and diastolic function. Parallel trends in results were evident in both men and women, underscoring that women share the same risk of developing cardiovascular disease as men.

3D printed, personalized cortisol for cortisol deficiencies

Sejad Ayyoubi[1], Richard Feelders[2] & Liesbeth Ruijgrok[1]
[1]Erasmus MC, hospital pharmacy, Rotterdam, Netherlands; [2]Erasmus MC, Endocrinology, Rotterdam, Netherlands

Introduction
The current standard of care (SOC) for adrenal insufficiency (AI) is suboptimal due to fluctuating cortisol plasma concentrations. The sub- and supraphysiological cortisol levels, combined with the multi day tablet intake, are associated with negative health outcomes and a poor quality of life. Furthermore, there is a high interindividual difference in the cortisol need, demanding a personalized approach. 3D printing (3DP) has gained momentum within the pharmaceutical field, moving from conceptual products, to clinical trials. This technology makes it possible to adapt the drug dose, release profile, shape and taste, based on the individual patients' need. The aim was therefore to develop a 3D printed, personalized, sustained release (SR) hydrocortisone for patients with AI. Secondary aims were (1) to compare the quality of 3D medication to magistral capsules, which is the current standard of personalizing cortisol dose, and (2) to evaluate the manufacturing costs of 3DP.
Methods
10 mg hydrocortisone tablets were printed using semi-solid extrusion (SSE) and fused deposition modeling (FDM) 3DP. 5 mg Plenadren®, slow-release tablets, and manually filled 10 mg hydrocortisone capsules were purchased and analyzed, as comparators. Hydrocortisone content ($n=3$–10), weights of final products and drug release profiles ($n=3$–6) were determined for each formulation. A micro-costing study was performed to evaluate the manufacturing costs of FDM 3D hydrocortisone in an academic hospital pharmacy setting.
Results
The 3D tablets had a stable release profile, similar to the Plenadren, where >80% of hydrocortisone was released in 24 h. Drug content of 3D printed tablets were closer to 10 mg compared to the purchased capsules. 3D printed tablets contained 103 ± 5% and 98 ± 1% hydrocortisone respectively for SSE and FDM, while capsules contained 92 ± 1% – 94.5 ± 0.5%. Manufacturing costs of 3D hydrocortisone was €1.90–€3.20 per tablet, compared to a purchasing price of €9.00 per capsule.
Conclusion
A 3D printed SR, personalized hydrocortisone formulation was developed for patients with AI. The quality of 3D tablets is higher than the capsules, while the manufacturing costs seem lower compared to the purchase price of capsules. Therefore, 3DP should replace manually filling of capsules in AI. The 3D therapy is once-daily, compared to three times a day of the SOC, reducing pill-burden. Any desired dose can be printed, unlike the Plenadren®. The 3D printed formulation will be tested in a clinical setting. A personalized delayed release 3D product is under development for the morning cortisol need in AI.

Introduction
Real-world data on management of bone alterations in Cushing's syndrome (CS) are scanty. The aim of our study was to assess the prevalence of osteoporosis (OP) and bone fractures (BF) in CS patients included in the European Registry on Cushing's Syndrome (ERCUSYN), and to describe the diagnostic and therapeutic strategies adopted across Europe to address these comorbidities.
Patients and methods
In this retrospective, observational cohort study, we evaluated the prevalence of OP and BF in 1684 patients (81% females; mean age 44 (±14.1) years) of whom 1234 (73%) had a pituitary-dependent (PIT-CS) and 450 (27%) an adrenal-dependent (ADR-CS) CS from 60 European centers in 26 countries. In addition, we created a survey to collect real-life data on bone disease management in CS.
Results
A dual-energy X-ray absorptiometry (DXA) was performed in 766 (51%) patients at diagnosis. Lumbar and hip OP were found in 21% and 13% of patients, respectively. After treatment, lumbar and hip OP were found in 18% and 11% of patients respectively, after a median follow-up of 24 (36) months, with a similar prevalence between patients in remission (78%) and those with persistent disease (22%). Fractures were present in 17% of patients at diagnosis, most in the spine (30%). Patients with BF at the time of diagnosis were older than patients without [mean (± s.d.) age 48.3±13.1 vs 43.4±14.2 years; $P<0.001$] and were more often males ($P<0.001$). Median delay to diagnosis was longer in patients with BF as compared with those without [3 (3.5) vs 2 (2) years, $P=0.02$] at diagnosis. Most of the survey responders (87%) evaluate bone health using DXA in all newly diagnosed patients, whereas the remaining only assess it in high-risk patients. Forty-six percent of responders perform X-ray only in patients with fracture symptoms. Seventy-six percent of the centers start specific treatment in all patients with OP at diagnosis, 21% only treat patients with fractures. After successful treatment, 59% of the responders re-check bone status within two years,whereas the remaining individualize control based on fracture risk stratification. The most widely used medications to treat OP and/or BF are vitamin D with calcium (74%), zolendronate (72%), alendronate (59%), denosumab (49%), risendronate (25%) and teriparatide (25%).
Conclusions
There is a need to optimize the management of bone impairment across Europe. In the ERCUSYN cohort, older age, male sex and longer delay to diagnosis were associated with increased rate of fractures at the time of diagnosis.

Decoding adrenal marginal zone lymphoma's silent narrative

ShabbarAbbas Naqvi & SingYang Sim
Royal Sussex County Hospital, Endocrinology and Diabetes, Brighton, UK

An 80-year-old patient was referred due to an incidental finding of a right adrenal mass during investigation of Iron Deficiency Anaemia (Ferritin 11.7 µg/l). CT scan of abdomen and pelvis revealed a 10×5 cm ill-defined heterogeneous mass within the right supra-renal space with areas of enhancement in the arterial phase imaging without calcification. Clinically, the patient lacked signs of endocrinopathy, such as (catecholamine or corticosteroid excess). However, the history was positive for drenching night sweats, fatigue and abdominal discomfort for several months. The initial investigations were unremarkable. Plasma metanephrine 10 ng/l (<100). Normetanephrines 57 ng/l (<170), Overnight dexamethasone suppression 0900 h Cortisol-19 nmol/l (0–50), Urine steroid profile showed normal total cortisol metabolite output, ACTH 19 ng/l (<50), Renin 21 mU/l (5-60), Aldosterone 283 pmol/l (100-800), Renin aldosterone ratio <80, Androstenedione <0.5 nmol/l (2-5.4), Total testosterone 0.1 nmol/L (0.1-1.42), SHBG 91 nmol/l (17.3-125), DHEA <0.1 µmol/l (0.9-2.1), 17b Oestradiol 48 pmol/l (114-332),17 hydroxyprogesterone <1, FSH 55.3 iu/l (3.5-12.5) and LH 31 iu/l (2.4-12.6). A dedicated CT adrenal revealed a large right adrenal mass 10.4 cm×5 cm with pre-contrast density of 40 HU, Portal venous phase density approximately 80–100 HU and delayed post-contrast density approximately 60 HU. The case was discussed in the Adrenal MDT and differentials included lymphoma, Sarcoma or inflammatory condition. Patient underwent a CT guided biopsy which showed diffuse staining of monoclonal lymphoplasmacytic infiltrate. Immunohistochemistry revealed positive CD20 B-Cell markers in addition to other B cell marker (BCL2 and IgM) with low proliferation index and no staining for CD10, CD5 and BCL6. These features indicated extra-nodal marginal zone lymphoma. Staging PET CT displayed moderate to intense uptake (SUVmax 8) in the right adrenal mass with no active lymphoproliferative disease elsewhere. Patient was referred to haematology MDT and subsequently started on Rituximab monotherapy for adrenal marginal zone lymphoma. At the point of writing, patient remained under oncology follow up. Primary adrenal lymphoma (PAL) is rare (<1%) of all extranodal lymphomas. While diffuse large B cell lymphoma is more prevalent and associated with a poor prognosis, marginal zone lymphoma, a low grade B cell neoplasm can rarely occur presenting as a relatively indolent condition. The diagnosis is usually challenging and pathological examination is the only approach to establish the diagnosis. The role of surgery for the management remains controversial. Immunochemotherapy typically employing Rituximab, is the standard treatment for symptomatic patients with extra nodal Marginal Zone Lymphoma of various origins.

Fine needle aspiration cytology of adrenal lesions: A 22-year single center experience

AnaMariaCristina Carasel[1,2], CChristofer Juhlin[3,4], Jan Calissendorff[1,2] & Henrik Falhammar[1,2]
[1]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden; [2]Karolinska University Hospital, Department of Endocrinology, Stockholm, Sweden; [3]Karolinska Institutet, Department of Oncology-Pathology, Stockholm, Sweden; [4]Nya Karolinska, Department of Pathology and Cancer Diagnostics, Stockholm, Sweden

Background
The nature of adrenal tumors can occasionally be difficult to determine using only laboratory and radiological findings. In those rare cases, obtaining a cytological sample by fine needle aspiration (FNA) can be valuable. Transabdominal ultrasound, endoscopic ultrasound (EUS), and computerized tomography (CT) guided biopsy are the most used methods for obtaining a cytological sample from an adrenal lesion.
Methods
Adrenal FNAs performed between the years 2000–2022 at the Karolinska University Hospital were identified using a search function incorporated in our institutional pathology database. Clinical and histological data were retrieved from medical records.
Results
Of 241 adrenal FNAs identified, 113 (46.9%) were obtained by transabdominal ultrasound, 72 (29.9%) were obtained by EUS, 53 (22%) using CT-guided technique, one FNA was obtained during surgery (0.4%) and in two cases (0.8%) the modality was not mentioned in the available medical charts. Preceding imaging indicated suspected malignant lesions in 184 cases (76.3%). Malignancy was confirmed by cytology in 139 cases (57.6%). A new FNA was performed to obtain the correct diagnosis in 10 cases (4.1%). Adequate material for diagnosis

was retrieved in 98 cases (86.7%) by transabdominal ultrasound, 69 cases (95.8%) by EUS and in 47 cases (88.7%) by CT-guided biopsies. An endocrinological assessment of adrenal function was performed before cytology in 122 cases (50.6%). Using FNA, adrenal lesions were diagnosed as adrenal metastases in 127 cases (52.7%) and adrenocortical cells (indicative of an adrenal cortical lesion) were found in 92 cases (38.1%). Of the latter ones, 4 (1.7%) received a diagnosis of adrenal cortical carcinoma. The remaining FNAs showed lymphoma in 7 cases (2.9%), tuberculosis and acute myeloid leukemia in one case each (0.4%). The diagnosis was unclear in 13 cases (5.4%). Most metastases were from lung carcinoma (71 cases, 55.9%) followed by malignant melanoma (10 cases, 7.9%), renal cell carcinoma (9 cases, 7.1%), gynecological cancers (7 cases, 5.5%), and other malignancies (30 cases, 23.6%) (e.g., breast, prostate, hepatocellular, and gastrointestinal carcinoma). Complications due to the biopsy procedure, such as bleeding and pneumothorax, were reported in 19 cases (7.5%).
Conclusions
Complication rates for FNA were low and an adequate sample was obtained in most cases regardless of imaging method used. FNA of the adrenal glands is a useful tool for diagnosis of adrenal tumors, especially when a metastasis is suspected.

Keywords: fine needle aspiration, adrenal glands.

SIAH1, a regulator of the Wnt/β-catenin pathway in human adrenocortical cells

Pierre Puygrenier[1], Karine Perlemoine[1], Bruno Ragazzon[1], Anne Jouinot[1], Constantine Stratakis[2,3], Jérôme Bertherat[1] & Annabel Berthon[1]
[1]Institut Cochin, Paris, France; [2]Research Institute, ELPEN, Pikermi, Athens, Greece; [3]Human Genetics & Precision Medicine, Heraklion, Greece

The most frequent molecular alteration in adrenocortical tumors (ACT) is the activation of the Wnt/β-catenin pathway that is associated with poor prognosis in adrenocortical carcinoma. Activating β-catenin mutation (p.S31, p.S37, p.S45, T.41) inhibiting its proteosomal degradation by the canonical destruction complex is responsible for its abnormal activation in roughly 30% of ACT. However, the E3 ubiquitin protein ligase 1, SIAH1 is able to ubiquitinate β-catenin even while mutated in intestinal cells, we then, investigate if SIAH1 regulates both wild-type and mutant β-catenin in H295R human adrenocortical cells. We demonstrate that SIAH1 interacts with β-catenin and increases both wild-type and mutant β-catenin ubiquitination through its catalytic RING finger domain. Overexpression of SIAH1 results then, in a decrease in β-catenin half-life (−25%) that is sufficient to reduce β-catenin transcriptional activity (−50%) measured with the TOPFlash reporter even in presence of β-catenin mutation (p.S45) in H295R cells. However, the overexpression of SIAH1 deleted from its catalytic domain does not affect neither β-catenin activity nor its ubiquitination suggesting that the effect of SIAH1 on β-catenin activity depends on its E3 ubiquitin activity. Altogether, our results suggest that SIAH1 indirectly regulates β-catenin transcriptional activity and that promoting SIAH1 activity could limit the activation of this pro-oncogenic pathway while Wnt/β-catenin signaling is constitutively activated.

Background
Whether environmental pollution may influence adrenocortical carcinoma (ACC) development remains largely unknown. The aim of this study was to evaluate the impact of exposition to environmental pollutants on ACC presentation and prognosis in Italy.
Patients and methods
A retrospective analysis was done on 500 patients affected by ACC, who were diagnosed in 12 reference centers in Italy from 1990 to 2018 and followed-up for a median of 37.5 months (interquartile range, IQR, 11-83). Patients were stratified according to: i) residence in Sites of National Interest (SIN) which are areas with contaminated soil and water, classified as dangerous by the Italian Ministry of Environment and in need of remediation; ii) residence in areas with different degrees of urbanisation, considered as index of exposure to air pollution.
Results
At diagnosis, 50 (10%) patients were resident in SIN (Res-SIN) and 450 (90%) patients were not (Not-SIN). The two groups had similar characteristics in terms of age, ENSAT stage, tumor size, Weiss score and Ki67%. However, incidental diagnosis of ACC was more frequent in Not-SIN patients than in Res-SIN patients (40.0% vs 19.6%; $P=0.011$). Res-SIN patients showed shorter recurrence-free survival (RFS) than Not-SIN patients (21 months *vs* 41 months; $P=0.027$). In multivariate analysis, residence in SIN was an independent negative prognostic factor for RFS (HR 1.82, 95%CI 1.10–3.03; $P=0.021$). Overall survival (OS) showed a similar pattern although the difference between the 2 groups was not significantly different. At diagnosis, 205 (41%) patients were resident in 'cities' (>50% of population in urban centers, with density >1500 inhabitants/km^2 and population >50 000), 230 (46%) in 'towns' and 'suburbs' (>50% in urban clusters with density >300 inhabitants/km^2 and population >5000), and 65 (13%) in 'rural areas' (>50% of population not meeting the previous criteria). No statistically significant differences were observed among the three groups in terms of clinical presentation, RFS and OS.
Conclusions
The different clinical presentation and worse outcome of ACC in patients living in areas with contaminated soil and water suggest that environmental pollutants in these matrices may have a role in conditioning the behavior of this rare tumor. Conversely, air pollution does not seem to influence the ACC disease course.

Fertility outcomes in women with classic and non-classic congenital adrenal hyperplasia on modified-release hydrocortisone (MR-HC)

Lea Tschaidse[1], HannaF Nowotny[1], Matthias Auer[1], Christian Lottspeich[1], Ann-Christin Welp[1], Martin Bidlingmaier[1], JamesM Hawley[2], Brian Keevil[2] & Nicole Reisch[1]
[1]Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, München, Germany; [2]Manchester University Foundation NHS Trust, Manchester Academic Health Sciences Centre, Department of Clinical Biochemistry, Manchester, UK

Background
Women with classic and non-classic (NC) congenital adrenal hyperplasia (CAH) often struggle with fertility, due to androgen excess, elevated progesterone and 17-hydroxyprogesterone (17OHP) levels, causing anovulation, impaired endometrial development and menstrual irregularities. The typical approach to addressing infertility so far, often involves an increase in glucocorticoid (GC) doses, yet this strategy carries potential side effects. Limited observational data on modified-release hydrocortisone (MR-HC), which better replicates the natural diurnal cortisol rhythm, suggests improved fertility in both female and male patients with classic CAH. Therefore, the aim of this study was to investigate fertility in women with classic and non-classic CAH before and after switching to MR-HC.
Methods
A total of 28 adult female patients with CAH (18 classic; 10 NC), with a median (range) age of 32.0 (30.0) years, premenopausal, without hormonal contraception, participated in this prospective, observational, single-center study. The data

collection took place before (using conventional GC preparation) and after a switch to MR-HC. Clinical parameters, along with morning serum and daily saliva profiles were collected, measuring progesterone, 17OHP, androstenedione (A4), testosterone and 11-oxygenated androgens.
Results
Prior to study inclusion, 7/28 patients had an irregular cycle, 3/28 were amenorrhoeic, and 14/28 desired pregnancy. After switch to MR-HC, the patients received a significantly lower mean (SD) hydrocortisone equivalent dose (26.3 (12.0) vs 23.1 (8.3), $P = .038$). Median (range) morning serum concentrations between 0800 and 0010 h showed no significant differences for progesterone, 17OHP, A4, testosterone, and 11-oxygenated androgens. However, in early morning saliva, median (range) 17OHP levels were significantly lower (67.3 (693.2) vs 28.1 (572.8), $P = .006$) after switching to MR-HC. Menstrual regularisation occurred in 6/10 patients with menstrual disturbance, and 8/14 patients desiring pregnancy became pregnant under MR-HC.
Conclusion
Our preliminary data indicate a clinical improvement in fecundity and fertility in women with classic and non-classic CAH under MR-HC, with even a slight decrease in GC dose. Lower 17OHP concentrations in early morning saliva suggest improved hormonal control overnight, contributing to regulated ovulatory cycles and enhanced fertility.

Musculoskeletal health and body composition in patients discontinuing long-term prednisolone treatment – prospective data from the replace Study

LiseSofie Bislev[1], MarieLouise Lund[2], AnjaFenger Dreyer[3], Hajir Al-Jorani[3], VictorBrun Boesen[2], Stina Willemoes Borresen[2], LouiseLehmann Christensen[3], Ulla Feldt-Rasmussen[2], Dorte Glintborg[3], SimonBøggild Hansen[1], RichardChristian Jensen[3], NannaThurmann Jørgensen[2], Jelena Stankovic[1], Randi Tei[1], MarianneSkovsager Andersen[3], Marianne Klose[2] & JensOttoLunde Jørgensen[1]
[1]Palle Juul-Jensens Boulevard, Aarhus, Denmark; [2]Blegdamsvej 9, København, Denmark; [3]J. B. Winsløws Vej 4, Odense, Denmark

Background
Pharmacological glucocorticoid (GC) treatment exerts adverse effects on musculoskeletal health and may induce glucocorticoid-induced adrenal insufficiency (GIA), but these features have so far not been characterized in a prospective and unbiased manner.
Aim
To characterize a population, who recently discontinued long-term (>12 weeks) prednisolone treatment with particular emphasis on the presence or absence of symptoms.
Methods
A prospective nationwide study (REPLACE) including baseline data from 116 patients with polymyalgia rheumatica/giant cell arteritis in GC-free remission for 2–12 weeks. The participants completed a disease-specific questionnaire (AddiQoL-30) where a score <85 was defined as presence of GIA symptoms. Musculoskeletal health and body composition were assessed by DXA scans, functional tests, and in a subgroup HRpQCT scans ($n = 34$).
Results
The participant median (range) age was 73 (51-88) years (56% women) with a median [IQR] prednisolone treatment duration of 12.5 [10.0 -17.8] months and an accumulated dose of 323 mg [217 – 481] six months before inclusion. $n = 42$ (36%) reported symptomatic GIA. Median (range) morning basal cortisol (nmol/l) was 258 (101 – 470) in the symptomatic GIA group vs 291 (135-497) in the group without symptomatic GIA, $P = 0.01$. Median [IQR] adult fractures were 1 [1; 2]. Four out of five received calcium/vitamin D, and 38% anti-osteoporotic medication (all bisphosphonates). Only 18% of patients did not meet criteria for (prophylactic) bisphosphonate treatment, defined by a T-score <1 in hip/lumbar spine and/or a diagnostic fracture. Sarcopenia, defined as appendicular lean mass index <7.26/5.45 kg/m^2 for men/women, was present in 18%. Stratifying for GIA symptoms, patients showed no differences in bone health, fractures, anti-osteoporotic treatment, comorbidity or HbA1c. Patients with GIA symptoms had lower ionized calcium (1.23 vs 1.25 nmol/l, p = 0.04), reduced grip strength (19.5 vs 28.5 kg, $P = 0.05$), and a longer Time Up and Go test duration (7.7 vs 6.7 s, $P = 0.03$). No differences in muscle/appendicular lean mass were observed, but patients with GIA symptoms had a higher fat percentage (41.2 vs 36.5%, $P = 0.02$) and larger waist circumference (99.1 vs 93.8 cm, $P = 0.03$). The results on muscle function and body composition remained significant after adjusting for age and gender.
Conclusions
1) The majority of long-term prednisolone users requires (prophylactic) osteoporosis treatment. 2) GIA symptoms are accompanied by impaired muscle function and increased abdominal fat. 3) We hypothesize that GIA symptoms are a component of the steroid withdrawal syndrome, which merits clinical attention.

Peripheral cortisol concentration during adrenal vein sampling for primary aldosteronism

KarinZibar Tomšić[1], Ana Marija Alduk[2,3], Ivana Kraljevic[2,3], Tina Dusek[1] & Darko Kastelan[3]
[1]University Clinical Center Zagreb, Department of endocrinology, Zagreb, Croatia; [2]School of Medicine; [3]School of Medicine, Zagreb, Croatia

Background
Measurement of the peripheral cortisol concentration is necessary for calculating selectivity ratio (SR) based on which is AVS success evaluated.
Objective
The goal of this study was to assess the necessity for two peripheral cortisol measurements in sequential AVS, one after cannulation of the adrenal vein on one side, and the second after cannulation on the other side.
Methods
This retrospective study included 142 bilaterally successful AVS procedures in patients with primary aldosteronism. All procedures were performed by two experienced interventional radiologists. AVS was performed under continuous stimulation with adrenocorticotrophic hormone. Blood samples were taken sequentially, first from the right adrenal vein followed by the infrarenal segment of the IVC (time 1 = T1), then from the left adrenal vein followed by the infrarenal segment of the IVC (time 2 = T2). The AVS was considered technically successful if the SR (cortisol ratio of each adrenal vein to the IVC) was 5:1. The Wilcoxon paired test was used to assess differences.
Results
Median T1 and T2 cortisol concentrations were 743 (IQR 600-952) nmol/l and 760 (IQR 620-984) nmol/l, respectively ($P < 0.001$). Median T1 right SR was 30 (IQR 23-43), and T2 right SR was 29 (IQR 21-40), $P < 0.001$. Median T1 left SR was 15 (IQR 10-23), and T2 left SR was 14 (IQR 10-22), $P < 0.001$.
Conclusions
Although notable variations were observed in both absolute cortisol concentrations and SR at T1 and T2, these differences did not alter the overall conclusion regarding AVS accuracy in the patient group. Consequently, it might be considered that there is no imperative requirement for repetitive peripheral cortisol sampling during sequential AVS procedures under stimulation with adrenocorticotrophic hormone.

Management of Giant Pheochromocytomas: A single tertiary center experience

Furnica Raluca[1], StefanMatei Constantinescu[1], Damien Gruson[2], Mourad Michel[3] & Dominique Maiter[1]
[1]Cliniques Universitaires Saint Luc, Endocrinology, Bruxelles, Belgium; [2]Cliniques Universitaires Saint Luc, Clinical Biochemistry, Bruxelles, Belgium; [3]Cliniques Universitaires Saint Luc, Abdominal surgery and transplantation department, Bruxelles, Belgium

Introduction
Giant pheochromocytomas (PCs) are adrenal tumors greater than 7 cm. The incidence and presentation of these large tumors is not well known, with only a few case reports published in literature. The preoperative and surgical management of giant PCs is also not well established.
Material and methods
A retrospective monocentric study at a tertiary center of 80 consecutive patients operated for a PC between 1988 and 2018.
Results
Among the 80 patients, 20 (25%) had a giant PC (mean tumor diameter of 9.9 cm). There was no difference in the clinical manifestations at diagnosis of these patients compared to patients with a smaller tumour. A significant proportion of patients with giant PC had hypertension (17/20) and half had diabetes. The diagnosis was made because of PC-related symptoms in half of the patients, mass symptoms in 5 patients (25%), during familial genetic screening in 2 (10%) and incidentally in only 1 case. Giant PCs presented higher levels of 24-hour urine metanephrines ($P = 0.028$) and normetanephrine ($P = 0.001$) compared with tumors of less than 7 cm. Interestingly, noradrenergic PCs were the largest tumors ($P < 0.01$). The rate of perioperative haemodynamic

($P=0.008$) and surgical complications ($P=0.032$) was influenced by tumor diameter. When comparing patients with preoperative alpha-blocker treatment, there was no difference in cumulative dose according to the tumor size. As expected, giant PCs were more likely to have an open surgery (17/20; 85% vs 14/60; 23%). Also, giant PCs presented a higher rate of recurrence ($P=0.039$) and malignant behaviour ($P<0.001$).
Conclusion
We show that giant PCs are usually symptomatic and their presentation is not different from average-sized PCs, but they have a higher rate of perioperative hemodynamic and surgical complications and exhibit a more aggressive phenotype, thus requiring multidisciplinary management in an expert center.

Treatment outcomes in patients with recurrent adrenocortical carcinoma

Tamara Dojcinovic[1], KarinZibar Tomšić[2], IvanaDora Vodanović[2], Ivana Kraljevic[2,3], AnjaBarac Nekic[2], TanjaSkoric Polovina[2] & Darko Kastelan[2,3]
[1]University Clinical centre of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina; [2]University Hospital Center Zagreb, Zagreb, Croatia, Department of Endocrinology, Zagreb, Croatia; [3]School of Medicine, University of Zagreb, Zagreb, Croatia

Background
While a considerable body of literature exists detailing outcomes in patients with adrenocortical carcinoma (ACC), reports specifically addressing a cohort of patients with recurrent disease remain scarce. Therefore, the objective of this study was to evaluate treatment outcomes in patients with recurrent ACC.
Methods
In our cohort of 55 patients who underwent R0/Rx tumor resection between 2011 and 2022, 18 individuals (33%) exhibited recurrent disease and were consequently included in this study. Following disease recurrence, patients were treated with various modalities including surgery, mitotane, chemotherapy, locoregional therapy and radiotherapy. The main study outcomes were overall survival (OS) and progression free survival (PFS) following ACC recurrence.
Results
The median time from the initial surgery to ACC recurrence was 29 months (IQR 18–50), with three patients experiencing recurrence within 12 months post-surgery. Seven patients (39%) manifested local recurrence, while 11 patients (61%) developed distant metastases. Among those with distant metastases, seven exhibited lesions in a single organ, whereas four presented metastatic lesions in multiple organs. The median follow-up duration after tumor recurrence was 32 months (IQR 25–53). Regarding the treatment of ACC recurrence, 10 patients underwent a second surgery: surgery alone ($n=4$), surgery + mitotane ($n=4$), surgery + mitotane and chemotherapy ($n=1$) and surgery + radiotherapy and mitotane ($n=1$). Remaining patients were treated with chemotherapy ± mitotane ($n=4$) and locoregional therapy (microwave ablation (MWA), polyvynil alcohol (PVA) embolisation) ± chemotherapy ($n=3$). One patient chose not to proceed with further management and follow up. The median PFS was 17 (IQR 12-22) months while the median OS was not reached. Furthermore, the one, three and five-year OS rates were 94%, 68%, and 68%, respectively. In the multivariate model, increased mortality was associated with advanced age ($P=0.04$) and a shorter interval to ACC recurrence ($P=0.05$).
Conclusion
A significant proportion of patients with ACC recurrence experience disease progression or second recurrence, despite all treatment efforts. Nevertheless, by integrating diverse treatment modalities, many patients have the potential to attain long-term survival, underscoring the pivotal role of expert centers in their management.

Congenital adrenal hyperplasia and myelolipomas: A case report

Ana Paola Leon Ocando, OliverQuintero Rodríguez, Selena Rodríguez Fernández, KevinDiaz Gorrin, ItziarAznar Ondoño & JudithLópez Fernández
Hospital Universitario de Canarias, Endocrinology and Nutrition, San Cristóbal de La Laguna, Spain

Introduction
Adrenal myelolipomas are benign and fatty tumors usually detected incidentally in imaging tests. Their prevalence increases in patients with CAH, probably because corticosteroid deficiency causes high ACTH levels that stimulate adrenal growth, although their effect on the growth of adrenal tumors is not yet well established.
Clinical case
A 41-year-old man with classic 21 OH deficiency, losing salt since he was 10 months old,with stable doses of corticosteroids for approximately 15 years, under follow-up in another center. He was referred to our hospital in June 2020 due to evidence of bilateral AI on spinal CT (requested for low back pain). In turn, he was referred to Urology who asked for an MRI that reported a heterogeneous solid mass of 11×9 cm in the left adrenal gland and a mass with similar characteristics measuring 7×4 cm in the right adrenal, the etiology of which was 'undetermined'. Functionality was ruled out and finally, it was decided to perform a left adrenalectomy by laparoscopic in September 2020, with a pathological diagnosis of myelolipoma. The clinical committee, given the stable growth of the contralateral mass and similar imaging characteristics, decided to follow up with clinical and imaging tests.
Discussion
According to the literature, in our case, these tumors were diagnosed in the 5th decade of life and were bilateral. Although CAH is associated with the development of adrenal myelolipomas, screening using images is currently not recommended in affected patients. On the other hand, the Spanish Society of Endocrinology and Nutrition recommends to determine levels of 17-OHP in cases of bilateral AI.
Conclusion
In the context of following up on CAH, it is advisable to conduct both analytical and clinical monitoring. However, it should be noted that the progressive growth of the adrenal glands and the development of myelolipomas are currently not established as criteria for assessing undertreatment, despite their potential correlation.

Does 177Lu-DOTA-TATE works in metastatic cardiac paraganglioma?

Regina Medeiros[1], Ana Figueiredo[2], Tiago Silva[2] & Valeriano Leite[2]
[1]Hospital Divino Espírito Santo, P. Delgada, Serviço de Endocrinologia e Nutrição, Ponta Delgada, Portugal; [2]Instituto Português de Oncologia de Lisboa Francisco Gentil, Serviço de Endocrinologia, Lisboa, Portugal

Paraganglioma (PGL) are rare neuroendocrine tumors with an estimated prevalence of 1:6500, with cardiac PGL being even rarer. Although most PGL are benign, approximately 15–35% of PGLs have metastatic disease, with few effective treatment options. Novel therapeutic indications, such as 177Lu-DOTA-TATE for patients with PGL, has been investigated in several clinical trials. A 66-year-old woman was referred to Cardiology in 2011 due to an incidentaloma adjacent to the right atrium on a transthoracic echocardiogram, requested due to arterial hypertension. She underwent excision of the lesion, histology was compatible with paraganglioma, with no evidence of illness until 2021, when she began experiencing anterior chest pain, night sweats and fatigue. CT showed 2 suspicious nodules adjacent to the right superior vena cava (SVC) and a lesion causing extensive bone destruction of the right ischiopubic branch. All lesions show intense MIBG uptake. Analytically, increase (greater than 3× the upper limit) in norepinephrine, dopamine and normetanephrine in 24-hour urine and norepinephrine, dopamine and normetanephrine in plasma. A catecholamine-producing paraganglioma with bone metastasis was identified. Was referred to Endocrinology. Clinically with paroxysms of palpitations, sweating and high blood pressure and weight loss (6 kg in 1 month). She was subjected to alpha blocking. In 68Ga-DOTANOC PET, high-capture lesions: cervical in the carotid space on the right (SUV max 5.2), two mediastinal lesions adjacent to the right SVC (SUV max 89.5), bony in D3 (SUV max 133.7), L1 (SUV max 90.9), right ischiopubic branch (SUV max 118.8) and left pubic symphysis (SUV max 172.8). The genetic study revealed a pathogenic mutation in the SDHD gene. The patient was assumed to have no status for mediastinal surgery and underwent radiotherapy directed at the bone lesions (total dose of 30 Gy), with subsequent slow progression of all lesions, deciding to start therapy with 177Lu-DOTATATE. To date, she has undergone 4 PRRT therapies (total activity 800 mCi) with global clinical and imaging improvement, documented through both CT and PET. We report a rare silent paraganglioma adjacent to the right atrium. Having subsequently become productive and metastasized, leaving us with few treatment options. She responded well to PRRT, which went against the odds. The management of PGL is challenging due to the uncertain behavior during long-term follow-up, as demonstrated by our case.

Cardiovascular risk in patients with primary hyperparathyroidism

Raluca Trifanescu[1,2], Maria Mohora[2], Iustin Toma[1,2], Ileana Nitu[2] & Catalina Poiana[1,2]

[1]'Carol Davila' University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [2]'C.I. Parhon' National Institute of Endocrinology, Bucharest, Romania

Background
PTH is a hormone with vascular and cardiovascular properties, involved in the expression of endothelial pro-atherosclerotic and pro-inflammatory parameters. Both hypercalcemic and normocalcemic primary hyperparathyroidism (PHPT) were associated with increased cardiovascular risk.
Patients and methods
84 patients (6M/78F) with PHPT, aged 58.9 ± 12.7 years, were retrospectively reviewed. Serum calcium levels, PTH and 25 OH vitamin D levels were measured. ECG was performed in all patients and echocardiography was performed in selected cases.
Results
Mean serum total calcium was 11.2 ± 1.2 mg/dl (range: 9.3–18.4); median PTH level was 158.4 pg/ml (range: 64.2–1982) and mean serum 25 OH vitamin D levels was 18.3 ± 9.1 ng/ml (range: 5.8–37.7). Mean body mass index was 27 ± 5.1 kg/m^2. Arterial hypertension was present in 48 patients (57.1%) in whom plasma metanephrines and normetanephrines were normal; 2 additional patients were prior operated for an adrenal paraganglioma (pheochromocytoma) and for an extra-adrenal paraganglioma, respectively. Chronic stable angina or resting ECG ischemic features were present in 23 patients (27.4%), arrhythmias in 12 patients (14.3%); on transthoracic echocardiography, aortic and mitral valve calcifications were present in 9 patients (10.7%). Impaired glucose metabolism was present in 15 patients (17.8%): type 2 diabetes mellitus in 8 patients (9.5%) and impaired glucose tolerance in 7 patients (8.33%).
Conclusions
cardiovascular involvement is frequent in PHPT patients. A proper screening should be done both in patients with hypercalcemic PHPT who will be referred to surgery and in patients with normocalcemic PHPT to assess cardiovascular risk and to weight potential benefits of surgery.

β-estradiol contributes to sex differences in resilience to septic-induced cardiacdysfunction via GPER-1/PPARδ/NLRP3 signaling

Joseph Adu-Amankwaah, Lu Fu, Richard Mprah, Marie Louise Ndzie Noah, Zheng Gong & Hong Sun
Xuzhou Medical University, Xuzhou, China

Background and aim
Sepsis, a leading global cause of mortality, involves life threatening multi-organ failure triggered by a dysregulated host response to infection. Cardiac dysfunction significantly contributes to this failure, primarily influenced by septic-induced metabolic dysregulation. Clinical studies suggest a less favorable outcome for males in sepsis, potentially linked to hormonal disparities, which remains unclear. This study aimed to explore the sex-related cardiac mechanisms driving septic-induced mortality.
Methods and results
Here, we unveil that while sepsis induces dysfunction, metabolic dysregulation, oxidative stress, and apoptosis in the heart, these effects are notably more pronounced in males than females. Detailed mechanistic experiments employing ovariectomized mice, β-estradiol(E2) administration, GPER-1$^{+/+}$ (G protein-coupled estrogen receptor 1), and GPER-1$^{-/-}$ mice revealed that under lipopolysaccharide (LPS)-induced sepsis, E2 acting via GPER-1 enhances cardiac electrical activity, promotes PPARδ nuclear translocation, and subsequently ameliorates cardiac metabolism while mitigating oxidative stress and apoptosis in females. Furthermore, PPARδ specific activation using GW501516 in female GPER-1$^{-/-}$ mice reduced oxidative stress, ultimately decreasing NLRP3 expression in the heart. Remarkably, targeted GPER-1 activation using G1 in males mirrors these benefits, improving cardiac electrical activity and function and ultimately enhancing survival rates during LPS-induced sepsis. By employing NLRP3$^{+/+}$and NLRP3$^{-/-}$ mice, we demonstrated that the targeted GPER-1 activation mitigated injury, enhanced metabolism, and reduced cardiac apoptosis in the heart of male mice via the downregulation of NLRP3.
Conclusion
Our findings collectively illuminate the different sex-specific mechanisms influencing septic mortality, offering insights into physiological and pathological dimensions. From a pharmacological standpoint, this study introduces specific GPER-1 activation as a promising therapeutic intervention for males under septic conditions. These discoveries not only advance our understanding of sepsis regarding sex but also present a novel avenue for targeted interventions with potential translational impact.

Background and aim
Identifying patients with glucocorticoid-induced adrenal insufficiency poses a challenge. We investigated whether factors associated with exogenous hypercortisolism (as a proxy of overall elevated glucocorticoid exposure) could predict the risk of glucocorticoid-induced adrenal insufficiency in patients with polymyalgia rheumatica and/or giant cell arteritis during long-term low-dose prednisolone treatment.
Material and methods
Baseline data analysis of a nationwide prospective study (Double Edge/-RESCUE, EudraCT:2021-002528-18) of 133 participants with polymyalgia rheumatica/giant cell arteritis treated with prednisolone for ≥12 weeks, with a current daily dose of ≤5 mg, 58 participants with adrenal insufficiency and 75 participants with normal adrenal function evaluated with a 250 µg ACTH test. The participants were evaluated for factors associated with exogenous hypercortisolism. These factors included present diagnoses of diabetes, hypertension, dyslipidaemia, and osteoporosis documented by medical history and study examinations. Study examinations included anthropometric data, blood pressure, bone mineral density assessed by dual-energy X-ray absorptiometry (DXA) scans, and blood tests for fasting glucose, haemoglobin A_{1c} (HbA_{1c}), and lipids. Apart from medical history, the paraclinical diagnosis of diabetes was defined as HbA_{1c} ≥48 mmol/mol and/or fasting glucose >7.0 mmol/l; hypertension was defined as systolic and diastolic blood pressure >140/>90 mmHg; dyslipidaemia was defined as total cholesterol >5.0 mmol/l and/or low-density lipoprotein cholesterol >3.0 mmol/l; and osteoporosis was defined as a T-score ≤−2.5. Adrenal insufficiency was defined as ACTH-stimulated cortisol <420 nmol/l (Liquid Chromatography Mass Spectrometry and/or Electrochemiluminescence immunoassay Roche Elecsys Cortisol II). Logistic regression models were used to identify predictor variables.
Results
The cumulative prednisolone dose over the past six months (OR 2.9[95% CI 1.3–6.5]) and female sex (2.8[1.1–6.4]) were associated with increased risk of adrenal insufficiency, whereas this was not the case for age (1.1[1.0–1.1]) and BMI (1.0[0.9–1.0]). Neither diabetes (0.8[0.3–2.0]), dyslipidaemia (0.8[0.4–1.9],), or hypertension (0.5[0.3–1.0]) were associated with increased risk of adrenal insufficiency. However, data suggest a 3-fold increased risk in patients with osteoporosis (2.9[1.4–6.1]), also after adjusting for age, sex, and BMI (all OR 2.2–2.7), but not after adjusting for the cumulative prednisolone dose (2.2[1.0–4.8]).
Conclusion
- Accumulated prednisolone dose may be a major predictor of adrenal insufficiency during prolonged low-dose prednisolone treatment.
- The risk of glucocorticoid-induced adrenal insufficiency is higher in females and is associated with osteoporosis.
- The data may aid in providing evidence-based risk stratification and prevention programmes for prednisolone-treated patients.

Aldosterone:metanephrine ratio better predicts laterality in patients with primary aldosteronism and mild autonomous cortisol co-secretion than aldosterone:cortisol ratio

Zin Htut[1], Aditi Sharma[2], Daniel Foran[3], Fausto Palazzo[1], Aimee Dimarco[1], Karim Meeran[1], Ali Alsafi[1] & Florian Wernig[1]
[1]Imperial College Healthcare NHS Trust, UK; [2]Barts Health NHS Trust, UK; [3]Imperial College London, UK

Introduction
Adrenal Venous Sampling (AVS) is considered the gold standard to identify surgically treatable primary aldosteronism (PA) subtypes. Current guidelines suggest using plasma cortisol concentrations to confirm successful adrenal vein (AV) cannulation and lateralisation, but cortisol co-secretion by adrenal adenomas can lead to diagnostic misinterpretation. Plasma metanephrines (MN) have a half-life of 3 to 6 min and are not affected by cortisol co-secretion, and therefore may offer a more precise and sensitive approach when used as an alternative analyte to cortisol to diagnose unilateral PA.
Aim
This study aims to demonstrate superiority of measuring MN over cortisol in patients with PA and mild autonomous cortisol co-secretion.
Methodology
We studied 132 patients undergoing unstimulated AVS in a tertiary referral centre carried out by a single operator between January 2018 to May 2023. Plasma samples for MN were collected from both AV and PV. Cannulation success was determined by using AV/PV cortisol >2 or AV/PV MN >12. Unilateral disease was confirmed by an aldosterone/cortisol ratio >2, aldosterone/MN ratio >5 and contralateral suppression by a ratio below 0.5 of that in PV.
Results
The cannulation success rate was 98%. Among 132 cases, 73 underwent overnight dexamethasone suppression testing, which identified 14 patients with mild autonomous cortisol co-secretion (cortisol >50 nmol/l [53–201] post dexamethasone) and low or suppressed baseline ACTH. AVS results were discordant in 4 out of 14 patients with mild autonomous cortisol co-secretion as well as in one patient with post-dexamethasone cortisol of 36 nmol/l, with aldosterone/cortisol suggesting bilateral disease and aldosterone/MN indicating unilateral disease. Four out of those 5 patients with discordant results underwent unilateral adrenalectomy and histological analysis confirmed an adrenocortical adenoma in all cases. One patient opted for medical therapy. All surgically treated patients achieved complete clinical and biochemical remission according to PASO criteria.

Table 1 Patient baseline characteristics

Total number	132
Male	60%
Age (years)	50.0 ± 10.3
MAP (mmHg)	116.0 ± 14.2
Potassium (mmol/l)	3.0 ± 0.48
T2DM (prevalence)	15%
Number of antihypertensives	2 (1-3)

Conclusion
This study provides a further important addition to the current literature demonstrating superiority of aldosterone/MN over aldosterone/cortisol to distinguish unilateral from bilateral disease in patients with PA and cortisol co-secretion undergoing unstimulated AVS.

DOI: 10.1530/endoabs.99.P414

Bilateral adrenal haemorrhage secondary to heparin induced thrombocytopenia- a rare cause and presentation of adrenal crisis

Veronica Chirila, Beas Bhattacharya & Alexandra Ward
Royal United Hospital Bath, Diabetes and Endocrinology, Bath, UK

Case history
We present the case of a 73 year old lady who was admitted following a neck of femur fracture after a fall. She had surgery performed with no major complications. During her inpatient stay, she unexpectedly became very unwell, complaining of abdominal pain, low grade pyrexia, tachycardia, tachypnoea, hypotension, nausea and vomiting (1). Initial management was as sepsis of unknown source.
Investigations
Bloods on admission (23/08/23): Hb 132 g/l, MCV 95.7 fl, Plt 219 10×9/l, WCC 11 10×9/l, **Na 135 mmol/l**, potassium 3.8 mmol/l, eGFR ml.min/1.73 m^2, LFTs normal, CRP 3, TSH 2.06. Bloods (31/08/23): Hb 104 g/l, MCV 94.4 fl, Plt: 38 10×9/l, WCC 12.3 10×9/l, neutrophils 9.7 10×9/l, lymphocytes 1.2 10×9/l, **Na 125 mmol/**l, potassium 3.3 mmol/l, eGFR>90, LFTs normal, albumin 28, CRP 226 mg/l; SST (November 2023): baseline cortisol: 15 nmol/l; 30 min: 109 nmol/l. US abdomen (30/08/23) was normal CT abdomen and pelvis (03/09/2023): **bilateral adrenal haemorrhage (BAH)** and partial left renal vein thrombosis; subcutaneous haematoma associated with left THR. CTPA (03/09/23): bilateral segmental and subsegmental emboli with segmental infarct in RLL.
Conclusion and discussions
Our patient had BAH secondary to HIT (heparin induced thrombocytopenia). Platelets dropped 8 days later after she was started on dalteparin and her HIT screening came back positive. We discuss a rare but serious presentation of adrenal crisis which can be potentially fatal, if clinical suspicion is not high, and non-infective causes of shock are not considered. This is very relevant post-surgery, after anti-coagulant use and any major trauma. Therefore, it is essential that it is considered as a differential particularly by specialities not used to managing hypoadrenalism. Radiologically findings can often be difficult and need expertise in abdominal radiology as often represent a mass and can be mistaken as adrenal neoplasm(3). There are two proposed mechanisms involved in the pathogenesis of idiopathic haemorrhages (2) stress and adrenal medullary venous thrombosis. Other causes of adrenal haemorrhage in pheochromocytoma, metastatic lesions and adrenocortical carcinoma, which then will need to be investigated involving adrenal MDT with endocrinologist.

Increased cardiovascular risk in patients with germline VHL gene alterations – a UKBIOBANK-based genomic study

Reut Halperin[1,2,3,] & Amit Tirosh[1,2,3,]
[1]Sheba, Endocrinology, diabetes and metabolism, Ramat Gan, Israel; [2]Sheba, ENTIRE Endocrine Neoplasia Translational Research Center, Ramat Gan, Israel; [3]Tel Aviv University, Medicine, Tel Aviv-Yafo, Israel

Introduction
Von Hippel-Lindau (VHL) is an autosomal dominant disease associated with increased risk for developing hemangioblastomas of the central nervous system and retina, renal cell carcinoma (RCC), pancreatic neuroendocrine tumors (PNET), adrenal pheochromocytomas and paraganglioma (PPGL). Loss of function *VHL* alterations lead to pseudohypoxia and, consequently, to angiogenesis and metabolic derangements (e.g., increased glucose uptake). Little is known about the systemic effects of *VHL* alterations on the cardiometabolic system.
Aim
Study whether *VHL* gene variants are associated with increased cardiometabolic risk.
Methods
Data were extracted from the UK Biobank database, including demographic and anthropometric parameters, medical history, and lab testing. Whole exome sequencing data were available for all patients, and a focused variant calling and annotation of the *VHL* gene region was performed on the DNA-nexus platform. A composite of major adverse cardiovascular events (MACE) per patient consisted of ischemic heart disease (IHD), cerebrovascular accident (CVA), and peripheral artery disease (PVD). *VHL* variant severity was sub-categorized into low (silent or missense), intermediate (in-frame insertion or deletion and 5′ UTR variants), and high-risk (nonsense or frameshift).
Results
Data from 460 430 participants were analyzed (45.8% males, age at inclusion 73.6 ± 8.1 years). IHD, CVA, and PVD rates were 11.5%, 3.0%, and 1.8%, respectively. Germline *VHL* variants were detected in 2594 participants (0.45%), with 2073 low- (242 silent, 1830 missense), 505 intermediate- (18 in-frame deletion and 23 in-frame insertion and 464 5′ UTR variants), and 16 high-risk (3 frameshift insertions, one frameshift deletion, and 12 nonsense) *VHL* variants. In the multivariable logistic regression analysis, harboring a high-risk *VHL* variant was associated with an 11-fold increased risk of MACE (odds ratio [OR] 11.1, 95% confidence interval 1.5–54.1, $P=0.006$), after adjustment for age at inclusion, age at diagnosis with cancer, sex, kidney function, c-reactive protein plasma levels, and diagnosis status with diabetes mellitus, hypertension, dyslipidemia, obesity, and RCC.
Conclusions and discussion
VHL gene alterations are associated with an increased cardiometabolic risk. Metabolic changes or enhanced drive for angiogenesis might contribute to this association. Further research is needed to verify these results and to assess a possible benefit from early intervention in this population.

Background
The advances in next-generation sequencing (NGS) technologies and bioinformatic analysis have shed light on genetic alterations, either of germline or somatic origin, in many disorders, including adrenocortical diseases. However, our knowledge on genomic characteristics in benign adrenal tumors of serendipitous discovery (adrenal incidentalomas) remain scarce.The aim of this study was to understand the pathogenic role of germline variants in adrenal incidentalomas.
Methods
To identify disease-causing variants, in this multicenter study we performed targeted NGS of 191 patients with adrenal incidentalomas, using a custom panel of 21 genes potentially involved in the pathogenesis of adrenal tumors. Pathogenicity role of germline variants (GV) was assessed using ClinVar database or, in absence, using ACMG guidelines throw VarSome tool. Clinical and hormonal data were collected at diagnosis and at last follow-up visit. The median follow-up was 8.5 years (IQR 3–15 years).
Results
NGS analysis in 10 patients (5.2%) identified GV located in the following genes: ARMC5 ($n=3$), APC ($n=1$), CACNA1H ($n=2$), ZNRF3 ($n=2$), PDE11A ($n=1$), GNAS ($n=1$). We found two likely-pathogenic variants (LP) in ZNRF3 and GNAS genes and eight variants of suspicious pathogenicity (VUS/LP) in ARMC5, APC, CACNA11H, ZNRF3 and PDE11A genes. Two of the three patients with GV in ARMC5 gene had bilateral lesions at diagnosis and one of these developed hypertension during the follow-up despite the absence of cortisol autonomy. The patient with GV in APC gene did not present associated colon polyposis, significant changes of tumor characteristics and related comorbidities over time. None of the patients with GV in CACNA1H gene showed alterations in the aldosterone-renin ratio, whereas one was diagnosed with mild autonomous cortisol secretion and underwent adrenalectomy. Both patients with GV in ZNRF3 gene had unilateral adrenal lesions that did not changed their characteristics and developed hypertension during follow-up, despite the absence of mineralocorticoid and glucocorticoid excess. The patient with GV in PDE11A gene presented with unilateral lesions and hypertension, without significant changes of tumor characteristics and related comorbidities over time. A similar behavior was observed in the patient with a GV in GNAS gene (unilateral tumor, no significant radiological changes with time), who developed hypertension during follow-up.
Conclusion
GV with a pathogenic or potential pathogenic role were found in 5.2% of patients with benign adrenal incidentalomas. The small number of cases hampered the identification of a clear genotype-phenotype correlation; however, these data provide new insights for a better characterization of benign adrenal incidentalomas.

Gennimatas', Endocrinology, Athens, Greece; [2]Laiko Hospital, 1st Department of Propaedeutic Internal Medicine, Athina, Greece; [3]Henry Dunant, Department of Endocrine Surgery, Athina, Greece; [4]General Hospital of Athens "G. Gennimatas", Third Department of Surgery, Athens, Greece; [5]National and Kapodistrian University of Athens, University Research Institute of Maternal and Child Health and Precision Medicine, Athens, Greece; [6]Henry Dunant, Endocrinology, Athina, Greece

Introduction
Primary aldosteronism (PA), the most common endocrine cause of secondary hypertension, is generally underdiagnosed using current diagnostic tests.
Aim
To present our 14-year experience of prospective studies on the diagnosis, prevalence and treatment of PA.
Patients and methods
We studied 992 hypertensive patients and 278 age-, sex- and body mass index – matched controls (194 normotensive and 104 with essential hypertension), all with normal adrenal imaging. Participants underwent conventional confirmatory tests for PA modified by the addition of dexamethasone to exclude stress-induced aldosterone secretion including the Fludrocortisone Dex Suppression Test (FDST), the Dex Saline Infusion Test (DSIT) and the Dex Captopril Valsartan Test (DCVT). The normotensive controls underwent the FDST and the DSIT. Normal cut-offs of pre-FDST and pre-DSIT basal aldosterone to renin ratio (ARR) and post-FDST and post-DSIT aldosterone levels and ARR were calculated from this group of normotensive controls. Because the DCVT can only be applied to hypertensives, we used hypertensive individuals, in whom PA had been excluded by the FDST, as a control group for calculation of the normal cut-offs of pre-DCVT basal ARR and post-DCVT aldosterone levels and ARR. Hypertensive patients underwent the FDST, the DSIT and the DCVT. Failure to suppress aldosterone was demonstrated if the combination of post-test aldosterone levels and ARR were higher than the corresponding normal cut-offs for each test separately.
Results
Hypertensive patients of all three treatment groups had significantly higher blood pressure (BP) and lower serum potassium levels than their controls. Using the basal ARR, as a screening test, the prevalence of PA was 17.8%, but after applying the modified tests to all patients the prevalence of PA was 33.4%. Targeted treatment with Mineralocorticoid Receptor Antagonists was administered in 252 hypertensive patients with bilateral PA, with 188 (74.6%) obtaining a biochemical response (potassium >3.9 mmol/l, renin $>$ 7.5 mU/l) and a normalized BP ($<140/90$ mmHg). Forty-eight hypertensive patients with unilateral disease underwent laparoscopic adrenalectomy. Twenty-three of these had concomitant mild autonomous cortisol secretion. Postoperatively, three patients (6.2%) failed to suppress aldosterone, demonstrating a biochemical success rate of 94%.
Conclusion
Our modified methodology and the use of controls for each test separately (normotensives for FDST and DSIT and hypertensives for DCVT) for calculation of normal cut-offs of aldosterone suppression has never been reported before and significantly improves the sensitivity and specificity of the existing tests on the diagnosis of PA, allowing the detection of milder forms some with cortisol co-secretion.

Primary aldosteronism: Small molecule antagonists of mutant KCNJ5 potassium channels

Sanas Mir-Bashiri[1], Martina Tetti[2], Dennis Froebel[3], Dunja Reiss[1], Nicole Bechmann[3], Mirko Peitzsch[3], Graeme Eisenhofer[3], Martin Reincke[1] & Tracy Ann Williams[1]
[1]Klinikum der Universität München, Endocrine Research Unit, München, Germany; [2]University of Turin, Torino, Italy; [3]University Hospital Carl Gustav Carus Dresden, Dresden, Germany

Background
Primary aldosteronism (PA) is the most frequent cause of endocrine hypertension associated with excess aldosterone production from one or both adrenal glands. Somatic or germline mutations in the KCNJ5 potassium channel cause an imbalance in intracellular ion homeostasis. This ultimately drives aldosterone overproduction in some sporadic forms of PA and a familial form of the disease (familial hyperaldosteronism type 3). Our objective was to identify small molecule compounds that could be used in managing patients with PA driven by a *KCNJ5* mutation.
Methods
A virtual screening of $>$ 6 million low molecular weight compounds was used to identify candidate molecules potentially interacting with the KCNJ5 channel. Functional testing through WST-1 assays and flow cytometry was performed to quantify the inhibition of cell death mediated by high-level expression of KCNJ5 mutants in human adrenocortical cell lines (HAC15).

Results
In silico screening of the small molecule library identified 108 candidate molecules. One of these, referred to as C-81, was a spirocyclic molecule featuring an indene and pyrroloquinoline system that inhibited HAC15 cell death induced by mutant KCNJ5 overexpression by 34.95% (measured via flow cytometry, $P<0.001$). The effect of C-81 on different KCNJ5 mutations close to the channel pore was quantified by qPCR showing a 75% decrease in *CYP11B2* (aldosterone synthase) gene expression for KCNJ5 L168R mutations ($P<0.001$) and 91% decrease for T158A mutations ($P<0.001$). In contrast, C-81 only had a non-significant effect on *CYP11B2* gene expression levels in native HAC15 cells ($P=0.25$). Using a steady state system for *in vitro*evaluation of steroidogenic pathway dynamics, C-81 treatment resulted in up to a 50% reduction of aldosterone production.
Conclusion
C-81 is a candidate small molecule antagonist of mutated KCNJ5 which could have potential therapeutic use to decrease pathological aldosterone secretion in some sporadic and familial forms of PA.

Different metabolic pathways associated with total cortisol exposure and the cortisol time profile: A randomized cross-over clinical trial

Johanna McQueen[1,2], Terence Garner[3], Dimitrios Chantzichristos[1,2], Hans Lennernäs[4], Stéphanie Espiard[5], Oskar Ragnarsson[1,2,6], Ragnhildur Bergthorsdottir[1,2], Stanko Skrtic[1], Adam Stevens[3] & Gudmundur Johannsson[1,2]
[1]Institute of Medicine at Sahlgrenska Academy, University of Gothenburg, Department of Internal Medicine and Clinical Nutrition, Gothenburg, Sweden; [2]Sahlgrenska University Hospital, Gothenburg, Endocrinology, Diabetology, and Metabolism,, Gothenburg, Sweden; [3]Division of Developmental Biology and Medicine, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, UK; [4]Uppsala University, Department of Pharmaceutical Biosciences, Uppsala, Sweden; [5]Lille University Hospital, Department of Endocrinology, Diabetology and Metabolism, Huriez Hospital, Lille, France; [6]Wallenberg Center for Molecular and Translational Medicine, University of Gothenburg, Gothenburg, Sweden

Context
Excess cortisol exposure and disruption of the circadian cortisol profile are both associated with adverse clinical outcome.
Objective
The aim of this study was to identify unique metabolites and metabolic pathways associated with total cortisol exposure and the cortisol time profile.
Design
A randomized, 12-week, two period, cross-over clinical trial.
Patients and interventions
Eighteen adults with primary adrenal insufficiency received the same daily dose of dual-release hydrocortisone (HC) tablets once-daily (OD) and conventional immediate-release HC tablets 3 times daily (TID) during 12 weeks each.
Main outcome measures
Total cortisol exposure was calculated by the area under the concentration-time curve from pharmacokinetic sampling over 24 h ($AUC_{0\text{-}24}$). The variability of the serum cortisol time profile was quantified by calculating the lag–1 autocorrelation (AUTO) from serum cortisol concentrations over 24-hours. Metabolomic analysis in serum and urine were performed using gas chromatography–mass spectrometry (GC–MS) and liquid chromatography-mass spectrometry (LC–MS), respectively. The relationship between total cortisol exposure, the variability of the cortisol time profile and metabolite expressions were assessed using a Bayesian generalized linear model.
Results
During TID, cortisol exposure was 20% higher and the variability of the cortisol time profile was larger, compared to OD. In total, 2406 metabolites were detected. 109 metabolites in serum and 21 in urine were uniquely correlated with total cortisol exposure. These metabolites were involved in arginine biosynthesis and alanine–aspartate–glutamate and tryptophan metabolism. Further, 40 metabolites in serum and 2 in urine were uniquely correlated with the cortisol profile variability. These metabolites were involved in primary bile acid biosynthesis and cysteine–methionine metabolism.
Conclusion
We identified different groups of metabolites and metabolic pathways that specifically correlated with total exposure of cortisol and cortisol profile variability, respectively. These findings suggest that total exposure and the time profile of serum cortisol have independent metabolic and regulatory effects in the human body.

A case of reversible Brugada syndrome with severe hypothyroidism

Shyam Seshadri[1], Raja Nata[1], Firas Hadaddin[1], Manoj Thomas[1] & Frankie Swords[2]
[1]The Queen Elizabeth Hospital Foundation NHS Trust, Department of Endocrinology, Kings Lynn, UK; [2]Norfolk and Norwich University Hospital, Department of Endocrinology, Norwich, UK

A 23-year-old gentleman with a 9-month history of extreme tiredness, muscle aches and pains, weight gain, cold intolerance and constipation presented to hospital with severe lethargy and dizziness and vacant episodes of increasing frequency. Initial examination revealed him to have a pulse rate of around 66 beats per minute. He was haemodynamically stable. A resting ECG showed an elevated ST segment of more than 2 mm with descent to an upward convexity to an inverted T wave especially prominent in the precordial leads in keeping with type 3 Brugada ECG pattern. The patient was in sinus rhythm with no symptoms of cardiac sounding chest pain. Further investigations revealed raised creatine kinase, deranged liver function in the form of isolated elevated alanine aminotransferase and acute kidney injury. Thyroid function revealed a markedly decreased FreeT4 of 1.6 pmol/l and TSH of greater than 150 miu/l. An echocardiogram showed good left ventricular function and no significant pericardial effusion. The patient was commenced on levothyroxine initially followed by low dose liothyronine. An ultrasound of his kidneys to probe his renal function was normal. An autoimmune screen turned out to be negative. Patient was hospitalised for further management. A 24-h ECG trace showed him to be in sinus rhythm throughout with no cardiac arrythmias. Patient's stay in hospital was uneventful and he was discharged after 1 week with further review in the endocrine, renal and cardiology outpatient clinics. Endocrine review a month later showed him to have improved with his symptoms though not completely well yet and he had lost the 6 kg which he had gained prior to his hospital admission. He had ongoing muscle aches and tiredness and did not feel mentally sharp. He was asked to wean off his liothyronine over 2 weeks while his levothyroxine was increased. Further cardiology review 3 weeks later showed improving ECG changes especially with settling ST elevation. The patient also had a nephrology review in 2 months which was satisfactory. The raised alanine aminotransferase and creatine kinase was thought to represent metabolic changes due to severe hypothyroidism. A specialist opinion at the inherited arrythmia clinic 8 months later showed resolved ECG changes with now no evidence of Brugada ECG pattern and patient was reassured and discharged. We report on a rare cardiac manifestation of severe hypothyroidism which fortunately was reversible on successful correction of his endocrine abnormality.

Undertreated and undiagnosed adrenal insufficiency as a premature cause of death in glucocorticoid users

Margret J Einarsdottir[1,2], Penelope Trimpou[1,2], Gudmundur Johannsson[1,2] & Oskar Ragnarsson[1,2,3]
[1]Sahlgrenska Academy, Gothenburg, Sweden; [2]Sahlgrenska Hospital, Gothenburg, Sweden; [3]Wallenberg Center for Molecular and Translational Medicine, Gothenburg, Sweden

Objective
Whether glucocorticoid (GC)-induced adrenal insufficiency may cause premature mortality in GC-users is not known. We conducted a retrospective cohort study to investigate if undiagnosed and undertreated GC-induced adrenal insufficiency is a contributor to premature death.
Methods
Information on dispensed prescriptions in West Sweden from 2007 to 2014 was obtained from the Swedish Prescribed Drug Register. Cause of death was collected from the Swedish Cause of Death Register. Of 223 211 patients who received oral GC prescriptions, 665 died from sepsis within 6 months from their last prescription. Three hundred of these, who had died in hospital, were randomly selected for further investigation. The medical records were initially reviewed by one investigator. Two additional investigators independently reviewed the medical records of those whose deaths were suspected to be caused by GC-induced adrenal insufficiency.
Results
Of 300 patients (121 females, 40%), 212 (75%) were prescribed GC treatment at admission. The mean age was 76 ± 11 years (range 30–99). Undiagnosed or undertreated GC-induced adrenal insufficiency was considered a probable contributor to death by at least two investigators in 11 (3.7%) patients. In 5 of these 11 cases, long-term GC therapy was abruptly discontinued during the hospitalization. Undiagnosed or undertreated GC-induced adrenal insufficiency

was considered a possible contributing factor to death in a further 36 (12%) patients.
Conclusion
GC-induced adrenal insufficiency is an important contributor to premature death in GC users. Increased awareness of adrenal insufficiency during intercurrent illness and following cessation of GC treatment is essential.

Baseline characteristics of adults with classic congenital adrenal hyperplasia enrolled in CAHtalyst, a phase 3 study of Crinecerfont, a corticotropin-releasing factor type 1 receptor antagonist

Richard Auchus[1], Oksana Hamidi[2], Rosario Pivonello[3], Irina Bancos[4], Selma Witchel[5], Andrea Isidori[6], Patrice Rodien[7,8], Umasuthan Srirangalingam[9], Florian Kiefer[10], Henrik Falhammar[11], Deborah Merke[12,13], Nicole Reisch[14], Julia Sturgeon[15], Eiry Roberts[15], Vivian Lin[15], Jean L Chan[15] & Robert Farber[15]
[1]University of Michigan Medical School, Ann Arbor, USA; [2]University of Texas Southwestern Medical Center, Department of Internal Medicine, Dallas, USA; [3]University of Naples Federico II, Napoli, Italy; [4]Mayo Clinic, Rochester, USA; [5]University of Pittsburgh School of Medicine, Pittsburgh, USA; [6]Sapienza University of Rome, Roma, Italy; [7]Mitovasc, Angers, France; [8]Angers University Hospital Center, Angers, France; [9]University of College London, London, UK; [10]Medical University of Vienna, Wien, Austria; [11]Karolinska Institute, Stockholm, Sweden; [12]NIH Clinical Center, Bethesda, USA; [13]Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, USA; [14]Ludwig Maximilian University of Munich, München, Germany; [15]Neurocrine Biosciences, San Diego, USA

Objectives
To describe the baseline characteristics of individuals enrolled in CAHtalyst (NCT04490915), a randomized, double-blind, placebo-controlled, Phase 3 study evaluating the safety and efficacy of crinecerfont (a corticotropin-releasing factor type 1 receptor [CRF_1] antagonist) in adults with classic congenital adrenal hyperplasia due to 21-hydroxylase deficiency (21-OHD).
Methods
The study included adults (age $\geq$18 years) with classic 21OHD. Key eligibility criteria included glucocorticoid dose $>$13 mg/m^2/day in hydrocortisone equivalents (HCe; conversion factors: 4$\times$ for predni[so]lone, 60$\times$ for dexamethasone) adjusted for body surface area (BSA) with stable dose for $\geq$1 month prior to screening, and normal or elevated androstenedione (A4). Baseline demographics and characteristics were summarized descriptively in all randomized participants.
Results
Of 182 enrolled participants, 51% were men and 90% were White. Mean ($\pm$s.d.) age was 30.8$\pm$9.9 years (range: 18–58 years), mean BSA was 1.8$\pm$0.2 m^2, and mean body mass index (BMI) was 29.8$\pm$7.0 kg/m^2 (with BMI $\geq$30 kg/m^2 in 47% of participants). The mean total daily glucocorticoid dose was 17.6$\pm$4.9 mg/m^2/day (32.3$\pm$9.3 mg/day) HCe, with 57% on hydrocortisone alone, 30% on a predniso(lo)ne-containing regimen, and 13% on a dexamethasone-containing regimen. In addition, 86% of participants were on fludrocortisone (mean dose: 136$\pm$72 µg/day). Mean ($\pm$s.d.) hormone concentrations prior to the morning glucocorticoid dose were as follows: adrenocorticotropic hormone, 264$\pm$317 pg/ml; 17-hydroxyprogesterone, 9467$\pm$8829 ng/dl; A4, 620$\pm$729 ng/dl; testosterone (T) in females, 86$\pm$85 ng/dl; A4/T in males, 2.2$\pm$2.4; follicle-stimulating hormone in males, 6.3$\pm$9.4 IU/l; and luteinizing hormone in males, 4.6$\pm$5.0 IU/l. Among the 90 females, 42 (47%) reported a history of hirsutism; of the 66 females of childbearing potential not on hormonal or intrauterine contraception, 35 (53%) reported a history of amenorrhea or menstrual irregularities. Among the 92 males, 44 (48%) reported a history of testicular adrenal rest tumors (TARTs) while 53 (58%) had evidence of TARTs by ultrasound prior to study entry. Comorbidities included osteopenia (15%), hypertension (10%), osteoporosis (5%), and diabetes mellitus (2%).
Conclusion
In a Phase 3 trial evaluating crinecerfont (a CRF_1 antagonist) in adults with classic 21OHD, clinical evidence of glucocorticoid and androgen excess (e.g., high prevalence of obesity, hirsutism [females], and TARTs [males]) were observed at baseline. Androgens and other steroid biomarkers were elevated despite treatment with supraphysiological doses of glucocorticoids. These findings emphasize the urgent need for novel glucocorticoid-sparing treatments for this chronic condition.

Diagnostic performance of dehydroepiandrosterone sulfate in predicting adrenal insufficiency

Ashley Han[1], Sara J Achenbach[2], Elizabeth J (Beth) Atkinson[2] & Irina Bancos[3]
[1]Mayo Clinic, Internal Medicine, Rochester, USA; [2]Mayo Clinic, Rochester, USA; [3]Mayo Clinic, Division of Endocrinology, Diabetes, Metabolism, and Nutrition, Rochester, USA

Background
Diagnosing adrenal insufficiency (AI) often requires complex multi-step testing which can be expensive and time consuming. In this study, we evaluated the diagnostic performance of baseline dehydroepiandrosterone sulfate (DHEAS) level in identifying patients with AI.
Methods
A single-center retrospective cohort study was performed of patients who underwent Cosyntropin stimulation testing (CST) between 2005 and 2023 and had a baseline DHEAS level obtained within 3 months of CST. Patients were excluded if they had congenital adrenal hyperplasia (CAH), oral estrogen use at the time of lab testing, were hospitalized within 1 month after CST, or died within 6 months after CST. AI was defined as post-CST peak cortisol $<$18 µg/dl and DHEAS level obtained closest to the time of CST was utilized. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were determined using a receiver operating characteristic (ROC) curve. Optimal cutpoint was determined to maximize both sensitivity and specificity. For further analysis, patients were stratified by gender and age; women $\geq$50 years old were assumed to be post-menopausal.
Results
Out of 1245 patients included in this study, 204 (16.4%) had an abnormal CST result. In these patients with AI, median DHEAS level was lower compared to patients without AI (21.2 vs 96.0 µg/dl, $P<0.001$). Similarly, patients with AI had a lower median baseline cortisol level than patients without AI (4.3 vs 8.0 µg/dl, $P<0.001$). Among all patients, baseline DHEAS level predicted an abnormal CST result with an accuracy rate of 73.7%. The optimal DHEAS cutoff point was determined to be 51 µg/dl with a sensitivity of 73.0%, specificity of 73.9%, PPV of 35.4%, and NPV of 93.3%. In our subgroup analysis, men had an optimal DHEAS cutpoint of 59.2 µg/dl with an accuracy rate of 72.2%, sensitivity 73.0%, specificity 72.0%, PPV 45.1%, and NPV 89.4%. While women $<$50 years old had an optimal DHEAS cutpoint of 63.9 µg/dl with an accuracy rate of 75.9%, sensitivity 75.9%, specificity 75.9%, PPV 29.2%, and NPV 96.0%, post-menopausal women had a lower optimal DHEAS cutpoint of 21.3 µg/dl with an accuracy rate of 71.1%, sensitivity 70.7%, specificity 71.2%, PPV 41.0%, and NPV 89.6%.
Conclusions
DHEAS is a valuable diagnostic test which can effectively rule out AI in many patients due to its high negative predictive value. For the majority of patients, a baseline DHEAS level $>$51 µg/dl makes a diagnosis of AI unlikely and additional dynamic testing may not be necessary.

Income and work loss in patients with Addison's disease in Sweden: A nationwide population-based study

Stavros Stergianos[1,2], Åsa Hallqvist Everhov[3,4], Jonas Söderling[3], Ragnhildur Bergthorsdottir[5,6], Jeanette Wahlberg[7], Olle Kämpe[1,8], Jakob Skov[2,9] & Sophie Bensing[1,2]
[1]Karolinska University Hospital, Department of Endocrinology, Stockholm, Sweden; [2]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden; [3]Karolinska Institutet, Clinical Epidemiology Division, Department of Medicine Solna, Stockholm, Sweden; [4]Karolinska Institutet, Department of Clinical Science and Education, Södersjukhuset, Stockholm, Sweden; [5]University of Gothenburg, Department of Internal Medicine and Clinical Nutrition, Institute of Medicine at Sahlgrenska Academy, Gothenburg, Sweden; [6]Sahlgrenska University Hospital, Department of Endocrinology, Gothenburg, Sweden; [7]Örebro University, School of Medical Sciences, Faculty of Medicine and Health, Örebro, Sweden; [8]Karolinska Institutet, Department of Medicine (Solna), Center for Molecular Medicine, Stockholm, Sweden; [9]Karlstad Central Hospital, Department of Medicine, Karlstad, Sweden

Background
Previous studies have found reduced health-related quality of life and employability in patients with autoimmune Addison's disease (AAD). However, there are no large studies examining the economic cost of illness for the individual.

Objective
To study differences in income and work loss between patients with AAD and matched comparators.
Methods
In this cross-sectional study we linked the Swedish Addison Register and several Swedish national health registers to identify individuals of working age (18–64 years) with AAD and comparators from the general population, matched 1:5 by sex, age and region of residence. The study outcomes were taxable earnings, disposable income and mean annual days of work loss (sick leave or disability pension) during 2019. Quantile regression was used to calculate adjusted median differences in taxable earnings and disposable income (adjusted for age and sex), while linear regression was used to obtain adjusted mean differences in work loss days.
Results
We identified 1140 patients with AAD and 5700 comparators (51.6% female), with mean age 46.1 years. Type 1 diabetes was present in 15.7% of patients with AAD and 1.1% of the comparators. We found no significant difference in taxable earnings ($P=0.48$) or disposable income ($P=0.43$) between patients with AAD and their matched comparators. However, patients with AAD had significantly higher mean annual work loss, adjusted mean difference 14.4; 95% CI, 8.6–20.3 days, $P<0.001$. Subgroup analysis revealed that patients with short education (<9 years) or co-existence of type 1 diabetes had lower taxable earnings ($P=0.02$ and $P=0.006$), lower disposable income ($P=0.007$ and $P=0.02$) and higher mean annual work loss ($P=0.004$ and $P<0.001$).
Conclusion
Overall, patients with AAD have more work loss, but similar taxable earnings and disposable incomes compared to matched population comparators. One possible explanation is that the Swedish social welfare system partly compensates for the work loss financially. However, patients with AAD with lower levels of education or co-existent type 1 diabetes appear to be socioeconomically vulnerable.

Evaluation of quality of life by AddiQoL-30 compared to SF-36 in patients with previous long-term prednisolone treatment

Hajir Al-Jorani[1,2], Stina Willemoes Borresen[3], Lise Sofie Bislev[4,5], Richard Christian Jensen[1], Anja Fenger Dreyer[1,2], Simon Bøggild Hansen[4,5], Victor Brun Boesen[3], Louise Lehmann Christensen[1,2], Dorte Glintborg[1,2], Nanna Thurmann Jørgensen[3,6], Marianne Klose[3], Marie Louise Lund[3,6], Jelena Stankovic[4,5], Randi Tei[4,5], Ulla Feldt-Rasmussen[3,6], Jens Otto Jørgensen[4,5] & Marianne Andersen[1,2]
[1]Odense University Hospital, Department of Endocrinology, Odense, Denmark; [2]Research Unit OPEN, University of Southern Denmark, Department of Clinical Research, Odense, Denmark; [3]Copenhagen University Hospital, Rigshospitalet, Department of Endocrinology and Metabolism, Copenhagen, Denmark; [4]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [5]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus, Denmark; [6]Faculty of Health and Clinical Sciences, Copenhagen University, Department of Clinical Medicine, Copenhagen, Denmark

Background
Long-term prednisolone therapy may lead to subtle changes in circadian oscillations of the hypothalamic-pituitary-adrenal axis, which can affect quality of life of the patient. Low score of the Addison's disease-specific quality-of-life questionnaire (AddiQoL-30) could be a method to assess functional glucocorticoid-induced adrenal insufficiency.
Objective
To compare scores from AddiQoL-30 with generic Short Form (SF-36) questionnaire in patients terminating long-term prednisolone therapy.
Methods
This study is part of REPLACE, an ongoing multicenter, randomized, double-blinded placebo-controlled study, and sub-study of The Double Edge Study. We included 140 patients (72 women) with median age of 73 years, diagnosed with polymyalgia rheumatica and/or giant cell arteritis, where prednisolone was terminated during 2–12 weeks. AddiQoL-30 and SF-36 questionnaires as well as a clinical examination were carried out, and baseline standardized fasting cortisol levels were assessed. Multiple linear regression models were used to evaluate associations between AddiQoL-30 and SF-36.
Results
Patients with low AddiQoL-30 scores ($\leq$85) had significantly lower baseline cortisol levels ($P=0.03$) (abstract ID: 5059). In patients with low AddiQoL-30 scores, baseline cortisol showed positive association with the four SF-36 domains vitality, role limitations physical, social and physical functioning. The estimate for vitality in patients with AddiQoL-30 scores $\leq$85 was significantly different from patients with AddiQoL-30 scores >85 (P-interaction $=0.01$). In patients with AddiQoL-30 scores >85, associations between SF-36 and cortisol were not significant.
Conclusion
A low AddiQoL-30 score $\leq$85 may align with the SF-36, especially regarding the vitality dimension, in patients with previous long-term prednisolone use. The REPLACE sub-study (abstract ID: 4814) is still recruiting, and baseline and follow-up investigations of AddiQoL-30 and SF-36 questionnaires are ongoing.
Funding: The Double Edge Study is funded by the Novo Nordisk Foundation as part of a collaborative grant entitled 'double edge – Characterization and mitigation of adverse effects of glucocorticoid treatment' (NNF20OC0063280). Disclosure of interest: None declared.

First report of inclisiran utilization for hypercholesterolemia treatment in real-world clinical settings in a middle east population

Tanveer Ashraf[1], Sajid Iqbal[1], Hani Sabbour[2], Nader Lessan[1] & Adam Buckley[1]
[1]Imperial College London Diabetes Centre, Research Department, United Arab Emirates; [2]Imperial College London Diabetes Centre, Cardiology, Abu Dhabi, United Arab Emirates

Purpose
Inclisiran is the first small interfering RNA (siRNA)-based treatment approved to reduce pro-atherogenic lipoproteins in patients with heterozygous familial hypercholesterolemia (HeFH) or clinical atherosclerotic cardiovascular disease (ASCVD), who require additional lowering of low-density lipoprotein cholesterol (LDL-C). We report, to the best of our knowledge, the first evaluation of its effects in a Middle Eastern population.
Methods
Retrospective review of patients initiating inclisiran treatment at an outpatient Diabetology/Endocrinology and Cardiology Centre between May 2021 and December 2022. All individuals followed up for $\geq$90 days or with at least one lipid determination post-initiation were included. Participants were categorized into primary ($n=57$) and secondary prevention ($n=89$) groups according to previous ASCVD.
Results
Inclisiran was initiated in 146 individuals, mean $\pm$ S.D. age 54.8 $\pm$ 12.12 years, 82 (56.2%) males, 28 (19.2%) with FH diagnosis, 89 (61%) with Diabetes Mellitus (DM) and 35 (23.9%) with statin intolerance. Median follow-up was 137 (90–193) days. At 90 days, median (IQR) reductions in serum LDL-cholesterol (LDL-C), and triglycerides were respectively −37.9% (−9.5%; −51.2%), −12.0% (−9.8%; −40.5%) in primary prevention, and −54.1% (−17.1%; −71.4%), and −15.3% (−14%; −38.8%) in secondary prevention (all P-values < 0.001). LDL-C goals were attained in 110 (75.3%) patients. Non-attainment of LDL-C goal was attributed to system effect in 26 (72.2%), biological effect in 5 (13.9%), and discontinuation of treatment in 5 (13.9%) patients. Therapy was well tolerated.
Conclusion
To the best of our knowledge, this current study is the first from the Middle East and North Africa (MENA) region that reports the real-world efficacy and safety of inclisiran in a mixed-risk population of individuals with HeFH and other non-FH indications. Clinically meaningful and sustained reductions in pro-atherogenic lipids with good tolerability were observed after inclisiran initiation.

Development and validation of LC–MS/MS assay for simultaneous determination of thirteen steroid hormones and two synthetic steroids in saliva: potential utility for pediatric population and beyond

Sandra R Dahl, Liv Hanne Bakke, Per Medboe Thorsby & Svetlana Zykova
Hormone Laboratory, Department of Medical Biochemistry, Oslo University Hospital, Oslo, Norway

Background
Saliva samples offer the possibility to obtain stress-free non-invasive samples, also for home-testing, especially useful when blood collection is either undesirable or difficult.
The aim of this work was to develop an LC–MS/MS method for the determination of clinically relevant steroid hormones cortisol, cortisone, 11-deoxycortisol, 21-deoxycortisol, 17OH-progesterone, aldosterone, corticosterone, deoxycorticosterone, betamethasone, dexamethasone, testosterone, androstenedione, DHEAS, DHEA and 17OH-pregnenolone. A special effort was made to adopt the method to neonatal population with respect to low sample volumes and multiplexing.
Results
Ten microliters were acceptable but 50 µl preferable sample volume for all the analytes. Cortisol, cortisone, aldosterone, 11-deoxycortisol, deoxycorticosterone, dexamethasone, betamethasone, 17OH-pregnenolone and DHEAS could be determined in as little as 2–5 µl saliva. Total analytical variation was $<15\%$, except for 17OH-progesterone, deoxycorticosterone, 17OH-pregnenolone, 21-deoxycortisol, androstenedione, DHEA and betamethasone, that could only be determined semi-quantitatively or qualitatively. The minimum turnaround time is 3–4 h. Recovery from the best-performing sample collection swab SalivaBio ranged from 83 to 127%. Aldosterone, cortisone and DHEA were more stable in saliva compared to serum when stored at ambient temperature for one week. Corticosterone and 17OH-progesterone needed immediate freezing.
Conclusion
The non-invasiveness, small saliva volume requirement, on-swab stability and analytical performance make the method relevant for both research and diagnostics, above all in the setting of neonatal intensive care unit.

Establishing cut-off values for late-night salivary cortisol and cortisone measured by LC–MS/MS in the diagnosis of endogenous hypercortisolism

Karlijn Koops[1,2,3], Peter H Bisschop[2,4], Annemieke C Heijboer[1,2,3,5] & Jacquelien Hillebrand[2,3]
[1]Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Laboratory Medicine, Endocrine Laboratory, Amsterdam, Netherlands; [2]Amsterdam Gastroenterology, Endocrinology & Metabolism, Amsterdam, Netherlands; [3]Amsterdam UMC location University of Amsterdam, Department of Laboratory Medicine, Endocrine Laboratory, Amsterdam, Netherlands; [4]Amsterdam UMC location University of Amsterdam, Department of Endocrinology and Metabolism, Amsterdam, Netherlands; [5]Amsterdam Reproduction & Development Research Institute, Amsterdam, Netherlands

Background
Diagnosing endogenous Cushing's syndrome (CS) is often challenging because of the difficulty in interpreting results of dynamic endocrine tests. One of the recommended initial tests is the measurement of late-night salivary cortisol (LNSaCl). Some articles describe added value of late-night salivary cortisone (LNSaCn) measurements. However, published cut-off values of LNSaCl and LNSaCn vary widely between studies, which may be related to different experimental set-ups.
Aim
The aim of this study was to establish the cut-off values for LNSaCl and LNSaCn that differentiate between patients with and without endogenous hypercortisolism using LC–MS/MS.
Methods
The study included data from consecutive patients who underwent dynamic endocrine function tests to evaluate endogenous hypercortisolism at Amsterdam UMC between December 2015 and February 2022. The indications for testing included clinical suspicion, adrenal or pituitary incidentalomas, or evaluation in the context of genetic diseases. Endogenous hypercortisolism was diagnosed or excluded based on follow-up of more than 12 months, histology, symptom reduction, and the need for hydrocortisone supplementation postoperatively. Salivary samples were collected between 2200 and 2359 h on two consecutive days and analyzed for cortisol and cortisone using an in-house developed and well standardized liquid chromatography coupled to mass spectrometry method (LC–MS/MS). Data analysis was based on the lowest of the two LNSaCl and LNSaCn measurements. The test's diagnostic accuracy was evaluated using ROC curve analysis.
Results
Twenty-nine patients with endogenous CS (21 of pituitary and 8 of adrenal origin) and 497 patients without endogenous hypercortisolism were included. The median LNSaCl was 7.8 nmol/l (IQR: 8.5) for patients with CS ($n=25$ eligible measurements), and 1.0 nmol/l (IQR: 0.9) for patients without CS ($P=<0.001$, $n=430$ measurements). The median concentration of the LNSaCn measurements was 35.5 nmol/l (IQR: 30.8) for patients with CS ($n=16$ measurements), and 5.3 nmol/l (IQR: 4.5) for patients without CS ($n=311$ measurements, $P=<0.001$). For LNSaCl, a cut-off of 2.25 nmol/l provided the optimal diagnostic accuracy for endogenous hypercortisolism with a sensitivity of 96% and a specificity of 86% (positive predictive value (PPV) = 28.6%, negative predictive value (NPV) = 99.7%). For LNSaCn this was 15.5 nmol/l with a sensitivity of 93.8% and a specificity of 94.5% (PPV = 46.9%, NPV = 99.7%).
Conclusion
We established optimal cut-off values for cortisol and cortisone in saliva measured by LC–MS/MS. The cut-off of LNSaCn provided the highest accuracy. Using these cut-off values will add to the performance of screening for endogenous hypercortisolism and these can be used by other laboratories following method comparison.

Holistic nursing care in acromegaly: A case report

Nermin Olgun[1], Selda Çelik[2] & Merve Murat[2]
[1]Hasan Kalyoncu University, Şahinbey/Gaziantep, Türkiye; [2]Health Sciences University

Background
Acromegaly is an uncommon metabolic condition characterized by the excessive secretion of growth hormone after the closure of epiphyseal plates. The onset of acromegaly is gradual, and its progression is slow. Manifestations of elevated growth hormone levels may remain inconspicuous for an extended period. Clinical indications include enlarged jaw, swelling in the hands and feet, pronounced facial bones, roughened facial features, nasal enlargement, tongue enlargement, deepening of the voice, snoring, sleep apnea, skin thickening, and excessive and unpleasant sweating.
Objective
This nursing case report aims to describe the comprehensive care provided to a 64-year-old male diagnosed with acromegaly and other chronical health care problems, emphasizing the collaborative approach among healthcare professionals to address the unique challenges associated with health conditions.
Methods
The patient presented with characteristic features of acromegaly, including acral enlargement, facial changes, and visual disturbances. A multidisciplinary healthcare team, comprising endocrinologists, other specialties such as neurosurgeons, ophthalmologists, and nurses, collaborated to formulate and implement a tailored care plan. The nursing care focused on symptom management, psychoeducation, and emotional support.
Results
The nursing interventions encompassed monitoring and managing the patient's physical symptoms, such as pain and discomfort related to acral enlargement, as well as addressing psychosocial aspects such as body image concerns and emotional well-being. Education about medication adherence, self-care strategies, and the importance of regular follow-up appointments was integral to empowering the patient in managing his chronic conditions.
Conclusion
This case report illustrates the pivotal role of nursing care in the holistic management of acromegaly. By providing patient-centered care that addresses both physical and emotional aspects, nurses contribute significantly to enhancing the overall well-being and quality of life for individuals with acromegaly. The collaborative effort among healthcare professionals is essential in ensuring comprehensive and effective care for patients with this rare endocrine disorder.

Cognitive functions in patients with mild autonomous cortisol secretion: Is it related with the serum brain-derived neurotrophic factor level?

Tugba Barlas[1], Muhammed Aksu[2], Ethem Turgay Cerit[1], Mehmet Muhittin Yalcin[1], Mujde Akturk[1], Fusun Toruner[1], Ayhan Karakoc[1] & Altinova Alev[1]
[1]Gazi University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey; [2]Gazi University Faculty of Medicine, Department of Psychiatry and Behavioral Sciences, Ankara, Turkey

Context
The impact of abnormal cortisol secretion on cognitive functions in patients with mild autonomous cortisol secretion (MACS) remains uncertain.
Objective
To assess cognitive functions, determine serum brain-derived neurotrophic factor (BDNF) concentration in patients with MACS, and investigate the possible association between cognitive subdomains and BDNF after minimizing the impact of body mass index (BMI) and visceral adiposity.

Methods
We included 84 participants: 28 patients with MACS, 28 patients with nonfunctional adrenal adenoma (NFAA), and 28 control subjects matched for age, gender, BMI, visceral fat and educational level. The serum BDNF concentration of participants was measured. DSM-5-focused interviews and Montreal Cognitive Assessments (MoCA) were carried out by an experienced psychiatrist.
Results
Patients with MACS had a higher BDNF concentration than the NFAA ($P=0.001$), while that of patients with NFAA was lower than the controls ($P=0.044$). There was a positive correlation between BDNF concentration and BMI ($r=0.227$, $P=0.038$), waist circumference ($r=0.248$, $P=0.042$), abdominal fat ($r=0.248$, $P=0.038$), visceral fat ($r=0.272$, $P=0.023$), LDL concentration ($r=0.486$, $P<0.001$), whereas HDL concentration was negatively correlated with BDNF concentration ($r=-0.349$, $P=0.003$) in the whole group. Furthermore, there was a positive relationship between BDNF concentration and the largest adenoma diameter ($r=0.311$, $P=0.020$) and cortisol level after 1 mg overnight dexamethasone (DST) ($r=0.292$, $P=0.032$) in patients with adrenal adenoma (MACS and NFAA groups). BMI and cortisol level after 1 mg DST were found to be the parameters most associated with BDNF concentration in linear regression analysis. No significant difference was found in total MoCA scores between MACS and NFAA groups ($P=0.967$), whereas those were lower than the control group ($P=0.016$, $P=0.008$ respectively). When the cognitive subdomains were examined seperately, MACS group performed higher memory score than NFAA group, but lower language scores than both the NFAA and control groups ($P=0.024$, $P<0.001$). In the whole group, there was a positive correlation between BDNF concentration and memory ($r=0.337$, $P=0.002$). DST and language were also negatively correlated ($r=-0.355$, $P=0.008$), while DHEA-S level was positively correlated with attention ($r=0.310$, $P=0.043$), language ($r=0.303$, $P=0.048$), as well as visuospatial and executive functions ($r=0.317$, $P=0.038$) in the whole group.
Conclusion
Chronic low-grade hypercortisolism is associated with elevated BDNF concentrations, which might be a protective factor for memory function in patients with MACS compared to NFAA.

Role of ccfDNA-based biomarkers in classification of adrenocortical adenomas

Mengjie Xu[1,2], David S Tourigny[3], Juliane Lippert[4], Ana Crastin[1], Silke Appenzeller[5], Miriam Felicitas Asia[6], Oskar Podstawka[1], Yasir Elhassan[6], Kassiani Skordilis[7], Alessandro Prete[1] & Cristina L Ronchi[1]
[1]University of Birmingham, Institute of Metabolism and System Research, Birmingham, UK; [2]Taihe Hospital, Hubei University of Medicine, Department of Endocrinology, Shiyan, China; [3]University of Birmingham, School of Mathematics, Birmingham, UK; [4]University of Wuerzburg, Institute of Human Genetics, Wuerzburg, Germany; [5]University Hospital of Wuerzburg, Core Unit Bioinformatics, Comprehensive Cancer Center Mainfranken, Wuerzburg, Germany; [6]Queen Elizabeth Hospital Birmingham NHS Trust, Department of Endocrinology, Birmingham, UK; [7]Queen Elizabeth Hospital Birmingham NHS Trust, Department of Renal Histopathology, Birmingham, UK

Background
Adrenocortical adenomas (ACA) can be associated with different degrees of cortisol excess. Genetic alterations in the cAMP/PKA pathway are observed in up to 60% of cases with overt Cushing syndrome (CS-ACA) and 15% of cases with mild autonomous cortisol secretion (MACS-ACA), while variants in the gene coding for β-catenin (*CTNNB1*) are more frequent in MACS-ACA and non-functioning adrenal tumours (NFAT). We aimed to test whether somatic variants could be detected in circulating cell-free DNA (ccfDNA) from patients with adrenal CS or MACS and potentially contribute to management strategies.
Methods
We investigated 44 patients, including 17 with MACS-ACA, 9 with CS-ACA, 12 with aldosterone-producing adenomas (APA), and 6 with NFAT. A total of 23 healthy subjects (HS) were used as controls. ccfDNA was extracted from EDTA blood samples with commercially available kits and ccfDNA concentrations quantified with fluorimeter. Tumour-DNA (T-DNA) was isolated from paraffin embedded tissue samples in 14/44 cases. Matched ccfDNA/T-DNA were sequenced using a customized panel including 32 genes (Cell3™ Target by Informed Genomics) and Illumina platform. Leucocyte DNA was used to filter out germline variants using TNhyplotyper2 (Sentieon) with an additional orientation bias model to remove strand bias artefacts. Only variant candidates that passed stringent filters were retained (read depth greater than 10, variant allele frequency greater than 0.1 in ccfDNA/T-DNA and less than 0.02 in paired leucocyte DNA).
Results
Patients with ACA had higher total ccfDNA concentrations than HS (0.155 ± 0.147 vs 0.052 ± 0.048 ng/μl, $P<0.001$), with CS-ACA showing the highest ccfDNA levels (0.267 ± 0.143 ng/μl, $P<0.005$ *vs* HS). ccfDNA concentrations did not correlate with age, sex, and maximum tumor diameter, but there was a trend toward a positive correlation with cortisol levels after overnight dexamethasone suppression test ($P=0.0641$, $R=0.29$). At T-DNA level, somatic variants were identified in 50% of ACA (i.e., *PRKACA* in 2/6 CS-ACA, *CTNNB1* in 2/4 MACS-ACA and 1/6 CS-ACA, and *KCNJ5* in 2/4 APA). Somatic mutations were not detected in any of the investigated ccfDNA samples.
Conclusions
Total ccfDNA concentrations are higher in patients with adrenal CS, likely due to an impact of the excessive circulating cortisol levels. Despite the presence of somatic variants in 50% of tumor samples from our ACA cohort, we did not detect any at ccfDNA level. Therefore, this approach appears ineffective for pre-operative evaluation of genetic alterations and clinical decision making.

Prediction of endogenous mineralocorticoid receptor activity by depressor effects of mineralocorticoid receptor antagonists in patients with primary aldosteronism

Makiko Ikemoto, Satoshi Morimoto & Ichihara Atsuhiro
Tokyo Women's Medical University, Department of Internal Medicine, Japan

Objective
Patients with primary aldosteronism have an increased risk of developing cardiovascular disease. The response to mineralocorticoid receptor antagonists (MRAs) varies among individuals, indicating diverse mineralocorticoid receptor activities in these patients. This study explored the factors linked to the efficacy of blood pressure reduction through MRAs in patients with primary aldosteronism.
Methods
We retrospectively investigated patients with primary aldosteronism who were newly administered MRA and had no changes in other antihypertensive medications during a 6-month treatment period. We assessed age, estimated daily salt intake, body fat percentage, clinic blood pressure, electrolytes in urine, eGFR, HbA1c, plasma renin activity, and plasma aldosterone concentration. The association between the reduction in blood pressure and patient characteristics before and after undergoing treatment with MRAs was examined. The blood pressure-lowering effect of MRAs was defined as the decrease in systolic BP (ΔsBP) divided by the spironolactone-equivalent dose of MRA at 3 and 6 months (ΔsBP 3M and ΔsBP 6M). The MRA dosage was based on the equivalent spironolactone dosage, with 100 mg spironolactone equal to 100 mg eplerenone or 5 mg esaxerenone.
Results
We examined the relationship between the reduction in blood pressure and patient characteristics in a group of 41 patients with primary aldosteronism (24 males, mean age 55 ± 13 years, including 34 patients diagnosed with bilateral primary aldosteronism) before and after undergoing treatment with MRAs. Significant reductions in office blood pressure were observed 3 and 6 months after treatment initiation. Single correlation analyses showed that the urinary chloride-to-potassium ratio displayed the strongest positive association with blood pressure reduction, surpassing plasma aldosterone concentration, plasma renin activity, and urinary sodium-to-potassium ratio, at 3 and 6 months. Multiple correlation analyses revealed a consistent and independent positive correlation between the urinary chloride-to-potassium ratio and blood pressure reduction at 3 and 6 months. The optimal threshold for the urinary chloride-to-potassium ratio with respect to its ability to lower blood pressure, was determined as 3.18. These results imply that the urinary chloride-to-potassium ratio may be independently associated with the effectiveness of blood pressure reduction facilitated by mineralocorticoid receptor antagonists.
Conclusion
The urinary chloride-to-potassium ratio could potentially serve as a valuable predictor of the effectiveness of MRAs and function as an indicator of endogenous mineralocorticoid receptor activity in patients with primary aldosteronism. Further investigation is needed to determine if similar associations exist in essential hypertension.

Even a nonfunctional adrenal incidentaloma carries a higher metabolic disease risk: Cross-sectional controlled study

Hyo-Jeong Kim[1], Kyong Yeun Jung[1] & Kil-Young Kwon[2]
[1]Nowon Eulji Medical Center, Eulji University, Department of Internal Medicine, Seoul, Republic of South Korea; [2]Nowon Eulji Medical Center, Eulji University, Department of Family Medicine, Seoul, Republic of South Korea

Background
Although metabolic syndrome was prevalent in patients with autonomous cortisol secretion, there are limited data for those with nonfunctioning adrenal incidentaloma (NFAI). This study aimed to compare metabolic features and body composition of patients with NFAI to referent subjects without adrenal mass.
Methods
This study included 141 patients with biochemically confirmed NFAI and 1:3 age and sex matched controls without adrenal incidentaloma ($n=420$) among subjects who underwent both abdominal computed tomography and dual-energy X-ray absorptiometry (DEXA) at a Eulji healthcare center in 2013-2020. Among 141 patients with NFAI, 48 patients underwent DEXA, so we evaluated body composition of these patients compared to 1:3 age, sex and underlying metabolic disease matched controls ($n=143$).
Results
Mean age was 56.5 ± 12.0 years and 52% were women in 141 patients with NFAI. The NFAI group had a higher body mass index compared to control group (25.1 ± 4.1 vs 24.1 ± 3.4 kg/m^2, $P=0.011$). Age, sex and BMI adjusted logistic regression showed significantly higher odds ratios (ORs) for diabetes, hypertension and dyslipidemia in NFAI (OR [95% confidence interval], 2.33 [1.45–3.74], 1.92 [1.22–3.03] and 2.26 [1.48–3.45], respectively. The body fat index (8.0 ± 0.3 vs 7.1 ± 0.1 kg/m^2, $P=0.027$) and total fat mass (20.7 ± 0.5 vs 18.5 ± 0.3 kg, $P=0.005$) were higher and skeletal muscle index was lower (6.4 ± 0.1 vs 6.7 ± 0.1 kg/m^2, $P=0.042$) in NFAI group compared to control.
Conclusion
Patients with NFAI were associated with higher risk for diabetes, hypertension and dyslipidemia and demonstrated abnormal body composition. Even a non-functioning hormone status may impact metabolic feature in patients with adrenal incidentaloma.

Performance of plasma cortisol at 1600 hours for the diagnosis of Cushing syndrome

Hippolyte Dupuis[1], Merlen Emilie[1], Elices Diez Julien[2], Balaye Pierre[2], Cortet Christine[1], Jannin Arnaud[1], Do Cao Christine[1], Douillard Claire[1], Ramdane Nassima[3], Soudan Benoit[4], Marie-Christine Vantyghem[1] & Stéphanie Espiard[1]
[1]Lille University Hospital, Department of Endocrinology, Diabetology and Metabolism, Lille, France; [2]Lille University Hospital, Include – INtegration Center of the Lille University hospital for Data Exploration, Lille, France; [3]Lille University hospital, Department of statistics and data management, Lille, France; [4]Lille University Hospital, Biology Department, Lille, France

Introduction
Guidelines recommend using first-line tests, including 24-hour urine-free cortisol (UFC), overnight 1-mg dexamethasone suppression test (DST), and late-night salivary cortisol (LNSC) for the positive diagnosis of hypercortisolism. Unfortunately, LNSC access is constrained in certain institutions, requiring, as an alternative, hospitalization for midnight plasmatic cortisol (F00h) measurement. This study explores the diagnostic potential of afternoon plasma cortisol (F16h), aligning with the contemporary shift toward outpatient care.
Materials and methods
Patients assessed for suspicion of Cushing's syndrome at a single center from September 2017 to Jully 2021. Plasma cortisol at 8h (F8h), 16h (F16h), and midnight (F00h), DST, and UFC performed in a single center were extracted via the Integration Center of the Lille University Hospital for Data Exploration. Two endocrinologists reviewed electronic patient's medical files to establish the positive diagnosis of CS. Patients with interfering treatment, including oestrogen therapy, and patients assessed for adrenal incidentalomas or recurrence of Cushing's disease were excluded.
Results
Among 1922 cortisol cycles, 589 patients (41.3% women, mean age 50.7 ± 16.30 years) were included, with 49 (8.3%) diagnosed with CS. There were no significant differences between age and sex between patients with CS (CS group) and patients without CS (no-CS group). The F00h, F16h, 24h-UFC and DST were significantly higher in the CS group compared to the no-CS group (F00h: 8.60 µg/dl [5.60–11.50] vs 2.65 µg/dl [1.70 to 4.10], $P<0.001$; F16h: 10.80 µg/dl [8.40–14] vs 6.40 µg/dl [4.70–8.60], $P<0.001$; UFC: 71 µg/24h [38.4–116] vs 30 µg/24h [21–45], $P<0.001$; DST: 4.4 µg/dl [3 to 9.3] vs 1 µg/dl[1–1.3], $P<0.001$). F16h significantly correlated with DST, 24h-UFC and F00h in both groups, with a stronger correlation in the CS group. The area under the ROC curve (AUC) for the F16h did not differ from UFC yet its sensitivity was higher using the optimal diagnostic threshold. The AUC for the F16h was significantly lower than that for F00h and DST. The optimal cut-off of the F16h was 7.9 µg/dl, achieving 83.7% sensitivity and 67.4% specificity.
Discussion
If LNSC should remain the first-line test for evaluating the circadian rhythm of cortisol, when not available, the F16h could be an interesting alternative for diagnosing hypercortisolism in an ambulatory setting. Further studies are required to assess its variability and confirm its utility in different situations, with a specific focus on evaluating recurrences of Cushing's disease.

Different modes of cell death induced by chemotherapeutic agents in treatment resistant and sensitive models of adrenocortical carcinoma

Sarah Feely[1], Nathan Mullen[1], Cong Hong[1], Constanze Hantel[2], William Rainey[3] & Michael Dennedy[1]
[1]Discipline of Pharmacology and Therapeutics, School of Medicine, Galway, Ireland; [2]Department of Medicine IV, University Hospital, Ludwig Maximillan University of Munich, Munich, Germany; [3]Department of Molecular and Integrative Physiology, University of Michigan, Ann Arbor, USA

Adrenocortical carcinoma (ACC) is a rare aggressive cancer with poor survival. Adjuvant mitotane is the only approved drug for treatment of ACC. It improves survival but its use is limited by poor tolerability and drug resistance. For metastatic ACC, combination chemotherapy, using mitotane and etoposide, doxorubicin, and cisplatin improves survival, but efficacy is limited. Better understating the cytotoxic mechanisms of mitotane offers potential to develop improved therapeutic options for ACC. To investigate the underlying mechanisms in vitro, human ACC cells (HAC15 and H295R), in monolayer cell culture were treated with increasing concentrations of mitotane. Cell death was evaluated at 6 and 24 h using flow cytometry analysis of Annexin V and Sytox Blue. This was complemented by Incucyte ® Live-Cell Analysis System imaging of annexin V and Sytox Blue staining. Expression of the markers of apoptosis, cleaved caspase 3, and necroptosis, phosphorylated MLKL and RIPK1 was measured at 6 and 24 h. Mitotane significantly reduced the viability of H295R cells at 6 and 24 h at the therapeutic concentration of 50 µM ($P>0.0001$), thereby demonstrating treatment-sensitivity. In HAC15 cells, a supratherapeutic dose of 200 µM was needed to significantly reduce viability ($P>0.05$) at 24 h, indicating resistance to mitotane treatment at therapeutic concentrations. There was increasing Annexin V fluorescence with increasing mitotane concentration in H295R and HAC15 cells ar 6 and 24 h without higher coinciding staining with Sytox Blue. Video analysis demonstrated these findings. Cleaved caspase 3 expression was associated with mitotane-induced cell death in H295R cells at 6 and 24 h, indicating apoptosis. HAC15 cells demonstrated cleaved caspase 3 expression only at the highest concentration of mitotane exposure (600 µM) at 6 h, without appreciable expression at 24 h. Phosphorylated-MLKL and RIPK1 expression was seen in controls and all mitotane doses in both cell lines at both timepoints, indicating necroptosis. In this study, H295R cells, representing a treatment-sensitive model of Mitotane undergo both apoptotic and necroptotic cell death at 6 and 24 h of mitotane exposure. In contrast, HAC15 cells, demonstrated relative treatment resistance to mitotane, and undergo necroptotic cell death only. These results highlight the importance of understanding and targeting non-apoptotic and necroptotic cell death pathways, particularly when evaluating mechanisms of treatment resistance in ACC. Given the difference in the mechanism of cell death in treatment-sensitive and treatment-resistant cells, further exploration of necroptosis is necessary to better understand how ACC cells may manifest treatment resistance.

Adrenocortical activity in patients with vasovagal syncope

Barbora Bačkorová[1], Zora Lazúrová[2], Monika Lukáčová[3], Peter Mitro[3] & Ivica Lazúrová[1]
[1]Louis Pasteur University Hospital, 1st Department of Internal Medicine, Košice, Slovakia; [2]Louis Pasteur University Hospital, 4th Department of Internal Medicine, Košice, Slovakia; [3]East Slovak Institute of Cardiovascular Diseases, 1st Department of Cardiology, Košice, Slovakia

Background
Syncope is a transient loss of consciousness resulting from cerebral hypoperfusion. Despite the extensive efforts by the scientific community over decades, the pathophysiology remains unclear. Although syncope itself is a reversible, short-lasting, benign condition, it negatively impacts quality of life. Vasovagal syncope (VVS) is a form of orthostatic intolerance (OI). Its clinical signs such as dizziness and hypotension may mimic symptoms of adrenal insufficiency. The objective of this study was to evaluate the adrenal gland function in patients with vasovagal syncope after stimulation with synthetic ACTH.
Methods and results
The study involved 42 participants (33 females and 9 males, aged 22–82 years, median 51 years), including 27 patients diagnosed with vasovagal syncope using the head-up tilt (HUT) test. The control group consisted of 15 healthy individuals with no history of syncope. Serum cortisol and aldosterone concentrations were measured under basal conditions and at 30 and 60 min after intramuscular ACTH stimulation. Patients with VVS had significantly higher cortisol levels at baseline (441 ± 143 vs 331 ± 84.7 nmol/l, $P = 0.01$), at 30 min (802 ± 143 vs 686 ± 105 nmol/l, $P = 0.009$) and at 60 min (931 ± 141 nmol/l vs 793 ± 147 nmol/l, $P = 0.005$) after ACTH administration (Synacthen 250 μg). Plasma aldosterone increased after ACTH stimulation, but did not show significant differences between the two studied groups. There were no significant differences in measured hormones between males and females. Furthermore, there was also no significant correlation between cortisol levels and systolic or diastolic blood pressure or heart rate.
Conclusion
Patients diagnosed with VVS have higher cortisol levels both at baseline and after ACTH stimulation. This finding indicates that individuals with VVS have a hyperactivated adrenal cortex potentially as a response to the orthostatic stress induced by syncope, which acts as a stressful stimulus on the autonomic nervous system.
Key words: orthostatic intolerance, vasovagal syncope, adrenal cortex, cortisol, aldosterone

A service review of phaeochromocytoma management at the regional adrenal referral centre

Hina Aslam[1], Katherine Alington[1], Ma'en Al-Mrayat[1], Diane Bray[1], C Richard W Lockyer[2] & Jana Bujanova[1]
[1]University Hospital Southampton NHS Foundation Trust, Department of Diabetes and Endocrinology, Southampton, UK; [2]University Hospital Southampton NHS Foundation Trust, Department of Urology, Southampton, UK

Aims
The aim of this project was to conduct a service review of ph*a*eochromocytoma management and to benchmark local practice against national guidelines and recommendations defined in the 'Getting It Right First Time' (GIRFT) national report.
Methods
Electronic patient records were searched for patients referred to our centre, within our catchment area and from peripheral centres, with phaeochromocytoma between 2017 to February 2023. Data on their presentation, treatment, perioperative complications and follow-up were collected.
Results
Forty patients were identified during this period (average 6.5 patients/year). 21 (52.5%) of patients were referred from peripheral centres and 19 were internal referrals. Twenty-three (57.5%) presented incidentally, 11 (27.5%) with typical symptoms and 6 (15%) identified on surveillance of genetic syndromes. Twenty-five (65%) had tumour size between 2 and 6 cm and 5 (12.5%) >6 cm. Ninety-five percent were discussed at the adrenal multidisciplinary team meeting (MDT). 30 (75%) had adrenalectomy (80% laparoscopic, 20% open), 8 were managed conservatively, one received MIBG therapy for metastatic disease and one had no follow-up data. None of those managed conservatively were hospitalised for reasons related to their phaeochromocytoma during period covered by this review. Ninety-five percent of patients received preoperative medical preparation, with twice as many patients treated with doxazosin (57.5%) than phenoxybenzamine (27.5%). 57% received concomitant beta-blocker. Most achieved blood pressure (86%) and heart rate (93%) targets preoperatively. Sixty-seven percent of surgically treated patients, had uneventful intraoperative period, 33% experienced haemodynamic instability, mainly labile BP and intraoperative hypotension. 43% had a postoperative haemodynamic complication, mostly hypotension requiring inotrope support. 45% receiving phenoxybenzamine preoperatively experienced intraoperative complication versus 33% of those on doxazosin. 45% receiving phenoxybenzamine experienced postoperative complication versus 40% receiving doxazosin. 19 (63%) had a PASS score included in their histology report (PASS < 4 in 14 and PASS > 4 in 5 patients). 83% of patients had metanephrines performed 12 weeks postoperatively, whilst only 47% of patients had postoperative surveillance imaging at 3–6 months. 63% underwent annual metanephrines screening. 63% of surgically treated patients were offered genetic testing.
Discussion
Our review showed effective collaborative working of the adrenal MDT with peripheral centres. Doxazosin performed slightly better in terms of risk of peri/postoperative complications and was better tolerated. We identified developmental opportunities for perioperative and follow-up phaeochromocytoma pathways led by a specialist endocrine nurse with an independent prescriber qualification. We also identified a need for a standardised postoperative follow-up across the peripheral hospitals including consideration of genetic testing.

NFAT and risk of dementia

Hadis Mirzaei[1,2,3,3], Jekaterina Patrova[1], Buster Mannheimer[4], Jonatan Lindh[5] & Henrik Falhammar[6,7]
[1]Department of Endocrinology, Södersjukhuset, Stockholm, Sweden; [2], [3]Karolinska Institute, Department of Clinical Science and Education, stockholm, Sweden; [4]Department of Clinical Science and Education, Södersjukhuset, Karolinska Institutet, Stockholm, Sweden; [5]Department of Laboratory Medicine, Division of Clinical Pharmacology, Karolinska Institutet, Stockholm, Sweden, stockholm, Sweden; [6]Karolinska Institutet, Department of Endocrinology, stockholm, Sweden; [7]Karolinska Institute, Stokcholm, Sweden

Importance
It is not known if non-functional adrenal tumors (NFATs) are associated with dementia.
Objective
To analyze incidence and prevalence of dementia in individuals with NFAT.
Design, setting and participants
A national retrospective register-based study in patients with NFAT diagnosed in Sweden 2005–2019 and controls without adrenal tumors followed until death or end of 2019 was conducted. Individuals with a diagnosis of adrenal hormonal excess or previous malignancy were excluded.
Exposures
NFAT diagnosis.
Main outcomes and measures
Main study outcomes were prevalence and incidence of dementia, after adjustment for sex, age and comorbidities. Secondary outcomes were Alzheimer's and vascular dementia.
Results
Among 20390 cases, 12 120 (59.4%) were women, and the median (IQR) age was 66 (57; 73) years. Among 125 392 controls, 69 994 (55.8%) were women, and the median (IQR) age was 66 (57; 73) years. Previous dementia was less common in patients diagnosed with NFAT compared to controls (odds ratio (OR) 0.59, 95% CI 0.50–0.69, adjusted OR 0.47, 95% CI 0.56). We obtained similar results för Alzheimer's dementia (odds ratio (OR) 0.48, 95% CI 0.38–0.62 adjusted OR 0.44, 95% CI 0.34–0.57). Vascular dementia were also less common in patients with NFAT compared to controls (odds ratio (OR) 0.71, 95% CI 0.52–0.94, adjusted OR 0.48, 95% CI 0.35–0.64). During the follow-up period (5.4years (IQR 2.5–8.8)) dementia incidence was similar in patients with NFAT and controls (hazard ratio (HR) 1.06, 95% CI 0.97–1.15, adjusted HR 1.06). For Alzheimer's and vascular dementia the incidences were also similar between patients with NFAT and controls (HR 0.86, 95% CI 0.73–1. 00, adjusted HR 0.94, 95% CI 0.8–1.1 and HR 1.29, 95% CI 1.08–1.53, adjusted HR 1.13 (95%CI 0.95–1.35)).
Conclusions and relevance
NFAT was not associated with increased risk for all-cause dementia, Alzheimer's or vascular dementia.

The challenges of adrenal incidentaloma evaluation in dialysis patients

Mihaela Florea, Stefana Bilha, Viviana Popa, Irina Puscasu, Alexandru Florescu, Anca Matei, Letitia Leustean & Cristina Preda
'Grigore T. Popa' University of Medicine and Pharmacy Iasi, Endocrinology, Iasi, Romania

Introduction
Chronic kidney disease (CKD) is associated with alterations in endogenous glucocorticoid regulation through various mechanisms: longer plasma cortisol half-life, reduced renal cortisol clearance, loss of 11b-HSD type 2 activity in the kidney contributing to an elevated cortisol/cortisone ratio, less effective hepatic metabolism of cortisol and, finally, hyperactivation of the hypothalamus-pituitary-adrenal axis due to acidosis, chronic stress, and inflammation.
Case report
We present the case of a 63-year-old woman, with cardiovascular, renal, and gastrointestinal comorbidities (arterial hypertension, heart failure, end-stage chronic kidney disease undergoing hemodialysis for 5 years, chronic hepatitis C) that was referred to the Endocrinology Department for uncontrolled blood pressure (220 mmHg) and an incidentally discovered right adrenal mass of 22/11 mm, with radiological features suggestive of adenoma. Clinical examination revealed a BMI of 33.9 kg/m^2, blood pressure of 160/80 mmHg, pale, dehydrated skin and anuria. Hormonal evaluation revealed normal 0800 h ACTH (21.5 pg/ml) and cortisol levels (19.8 µg/dl), normal free plasma metanephrine levels, elevated late-night salivary cortisol (LNSC):85.1 nmol/l (reference range, <11.3) and lack of suppression of serum cortisol on 1 mg, 2×2 mg and 8 mg dexamethasone suppression tests. DHEAS levels were in the low-normal range. Despite biological tests suggesting autonomous cortisol secretion, the patient did not exhibit glucose and lipid metabolism abnormalities (normal plasma glucose, HbA1c, lipid profile), therefore periodic follow-up was recommended. At one-year follow-up, biochemical testing showed a normal LNSC (8.5 nmol/l), normal 0800 h ACTH and cortisol and lack of adequate suppression after 8 mg overnight dexamethasone suppression (cortisol level of 5.79 µg/dl). Follow-up adrenal CT scan didn't show any significant changes. In the absence of significant metabolic disturbances and considering the limitations of hypercortisolism assessment in CKD, we opted for periodical follow-up.
Discussions
One particular feature of investigating adrenal incidentalomas in dialysis patients is the difficulty to distinguish autonomous cortisol secretion from the impact of chronic kidney disease on cortisol metabolism. False-positive results may occur at screening investigations for hypercortisolism, such as late-night salivary cortisol or low-dose dexamethasone tests. In our case, a repeated value of LNSC within the normal range was not in favor of a definitive diagnosis of Cushing syndrome. More so, metabolic complications, such as dyslipidemia and glycemic abnormalities, were lacking. In such patients, clinical and biological follow-up and evaluation of comorbidities potentially attributable to cortisol excess (diabetes mellitus, dyslipidemia, osteoporosis) is recommended.

Association between endothelial dysfunction and androgen levels in men with coronary artery disease

Shafaat Talib[1], Pooja Alipuria[2] & Atush Alipuria[3]
[1]MGM Medical College & Hospital, Internal Medicine, Aurangabad, India; [2]Yashoda Super Speciality MediCentre, Karkardooma, Internal Medicine, New Delhi, India; [3]Yashoda Super Speciality Hospital, Ghaziabad, India

Background
The available literature is meagre on relationship of Androgen levels in Coronary Artery Disease (CAD).
Objective
The current study analyzes the androgen levels (Total Testosterone, Free Testosterone, and Dehydroepiandrosterone sulfate (DHEA-S)) in relation to endothelial dysfunction and graded coronary artery disease.
Design
Serum androgen levels were measured in 112 angiographically proven, stable CAD male subjects, who were assessed by flow mediated dilatation (FMD) of brachial artery using angiodefender device. Estimation of DHEA-S & Total Testosterone (TT) were carried out by electrochemiluminescent immunoassay and Free Testosterone (FT) by enzyme linked immunosorbent assay. Pearson Correlation, t-Test and multivariate analysis were applied for the analysis of risk factors of coronary artery disease. The Mann–Whitney *U* test and Kruskal Wallis test were applied with 95% confidence interval wherever necessary. Probability value of less than 0.05 was considered statistically significant.
Results
In our study, FMD provides the information on the extent and the severity of CAD ($P<0.0001$).The low serum total testosterone level though correlates with cardiovascular risk factors but do not correspond to the severity of CAD viz. single, double and triple vessel disease. Multivariate analysis was applied to analyze the correlation of risk factors of CAD with Model A and B as dealt in methodology. The multivariate results revealed Model A was significant predictor of Dheas and total testosterone values of the patient, whereas the other model was statistically inconclusive. The results also showed significant association between androgen levels and endothelial dysfunction, wherein age being a confounding independent parameter.
Conclusion
It is concluded that age adjusted androgen levels remained confounding factor in atherogenesis, hence also a cardiovascular risk factor of CAD. The subject needs more focus with larger group of patients.

Premature Adrenarche and metabolic dysfunction – a systematic review and meta-analysis

Wogud Ben Said[1,2,3], Ioannis Lempesis[3], Silvia Fernandez Garcia[3], Shakila Thangaratinam[2,3], Wiebke Arlt[4] & Jan Idkowiak[1,2,3]
[1]Birmingham Women's and Children's NHS Foundation Trust, Department of Endocrinology and Diabetes, Birmingham; [2]Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners.University of Birmingham, Birmingham, UK; [3]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, UK; [4]MRC London Institute of Medical Sciences (New building), London, UK

Background
Androgen excess frequently manifests in pre-pubertal children as premature adrenarche (PA). PA is characterised by the development of pubic and axillary hair, adult-type body odour in girls <8yrs and in boys <9yrs. PA may be a forerunner condition of polycystic ovary syndrome (PCOS), a complex metabolic disorder characterised by androgen excess. It is well established that women with PCOS have high risk of insulin resistance and frequently develop type 2 diabetes, dyslipidaemia, hypertension, and fatty liver disease. Importantly, androgens are identified as independent drivers to accelerate metabolic risk in PCOS. Whilst the link between PCOS and metabolic risk is well established, there is paucity of data on the risk for children with PA to develop metabolic dysfunction.
Objective
We conducted a systematic review and meta-analysis on metabolic disturbances in children with PA.
Methods
Published cross-sectional case/control studies were identified using Medline, Embase and Cochrane Library. Key outcome measures: Mean difference in anthropometric measures (height SDS, BMI SDS), indices of glucose metabolism (fasting insulin/glucose, HOMA-IR, HbA1c) and measures of lipid metabolism in children with PA compared to healthy controls.
Results
From 4640 records identified via electronic databases, 25 cross-sectional studies were selected, reporting on 823 children with PA and 707 healthy controls. Height SDS (mean difference [MD] 0.66; 95% confidence interval [CI_{95}] 0.36–0.95; $I^2=79\%$) and weight SDS (MD: 0.63; CI_{95} 0.33 −0.93; $I^2=53\%$) were significantly higher in PA group. These findings persist with subgroup analysis by PA definition, sensitivity analysis for gender and risk of bias assessment. PA children also have higher fasting insulin levels than controls (MD: 15.04; CI_{95} 5.27–24.81 pmol/l; $I^2=91\%$). Fasting glucose levels, HOMA-IR, mean serum glucose, mean serum insulin and HbA1c did not differ between PA and controls. Total cholesterol, LDL, HDL and VLDL were similar in both groups.
Conclusion
Our systematic review and meta-analysis with a pooled sample of more than 800 children with PA revealed higher fasting insulin levels but no other significant metabolic disturbances. However, we observed statistical and methodological heterogeneity. A unified approach in the assessment of metabolic risk in children with idiopathic early-onset androgen excess is needed, as well as long-term follow-up studies to identify children who might be at higher risk of developing metabolic dysfunction and PCOS.

Elevated serum uric acid in asymptomatic primary hyperparathyroidism: a biomarker of disease severity?

Matteo Malagrinò, Nicolò Bisceglia, Giulia Vandi, Anna Piazza, Uberto Pagotto & Guido Zavatta
Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna

Context
Numerous studies propose a potential role of PTH in uric acid (UA) metabolism, particularly through its impact on the ABCG2 transporter, which is responsible for UA excretion in the intestines and kidneys. Another suggested mechanism involves increased tubular reabsorption of UA due to hypercalcemia-induced extracellular volume contraction. Elevated UA levels constitute a well-established risk factor for cardiovascular disease, nephrolithiasis, and chronic kidney disease – conditions prevalent in individuals with primary hyperparathyroidism (PHPT). Despite current international guidelines not advocating routine UA-level measurements in PHPT, addressing hyperuricemia could potentially safeguard renal and cardiovascular health in these patients.
Objective
To assess UA levels in patients with PHPT.
Design
Case-control study.
Setting
Academic, outpatient.
Patients
From February 2021 to December 2023, we consecutively evaluated 206 women with classical hypercalcemic asymptomatic PHPT. These underwent comprehensive assessments, including blood and urinary analysis, dual-energy X-ray absorptiometry (DXA), and renal ultrasound. From this group, 116 patients with thorough testing, including UA measurement, were selected. Of these, patients with known interfering drugs (e.g. diuretics) or drugs affecting PTH or serum calcium (bisphosphonates, denosumab, and cinacalcet) were excluded, obtaining a final cohort of 59 patients. Women without primary or secondary hyperparathyroidism enrolled during the same period ($n=251$), without interfering medications, and with full mineral, serum UA, and DXA evaluation were used as controls.
Results
Both groups had similar age, BMI, and blood creatinine levels, but showed significant differences in biochemical and densitometric parameters as expected. UA level proved notably higher in PHPT patients than controls (5.0 mg/dl vs 4.6 mg/dl, $P=0.015$). Correlation analyses unveiled an inverse relationship between elevated UA and reduced eGFR ($\rho=-0.809$, $P<0.001$), and a positive correlation emerged with PTH levels ($\rho=0.217$, $P<0.001$). Univariate analysis in PHPT individuals identified significant associations of UA levels with eGFR ($P=0.012$), and serum calcium levels ($P=0.007$). Instead, in the control group, UA levels showed significant associations with BMI ($P<0.001$) and eGFR ($P<0.001$), but not with serum calcium levels ($P=0.725$). In a logistic multinomial regression model, hyperuricemia was predicted by higher BMI (OR = 1.087, CI:1.005–1.167, $P=0.037$), serum creatinine (OR = 67.949, CI:6.745–684.535), and serum calcium (OR = 2.371, CI:1.348–4.172, $P=0.003$), regardless of age, PTH levels or diagnosis of PHPT.
Conclusions
Asymptomatic PHPT is associated with elevated serum uric acid, which seems dependent on the degree of hypercalcemia and renal dysfunction, irrespective of PTH levels. Further studies are needed to determine if uric acid levels might have an impact on the clinical management of PHPT.

Extensive scalp calcification in pseudohypoparathyroidism type 1A: A case report and genetic insight

Ho-Cheol Kang & HeeKyung Kim
Chonnam National University – Hwasun Campus, Internal Medicine, Hwasun, Republic of South Korea

Subcutaneous ossifications (SCO) represent a recognized manifestation of pseudohypoparathyroidism type 1A (PHP1A) and pseudopseudohypoparathyroidism (PPHP), posing significant morbidity to affected individuals. This report details the case of a 37-year-old woman with PHP1A with extensive scalp calcifications, an unusual and unexpected finding. The patient presented with multiple firm skin nodules on the right knee and dorsum of both hands. Having been diagnosed with hypothyroidism and hypocalcemia five years prior, she was receiving levothyroxine (50 μg/day), alfacalcidol (1 μg/day), and calcium carbonate (1 g/day). Despite a stature of 148 cm and displaying typical Albright hereditary osteodystrophy (AHO) features, she maintained regular menstrual cycles. Genetic analysis identified a c.85C>T mutation in the GNAS, confirming the suspicion of PHP1A. To assess extraskeletal calcifications (ESO), a brain CT scan was conducted, revealing basal ganglial calcifications and unexpectedly extensive scalp SCO. Notably, the patient remained asymptomatic with regard to these calcifications. A skin biopsy from a knee nodule confirmed osteoma cutis. Subsequently, the patient's identical twin daughter, born three years later, exhibited hypocalcemia and seizures, leading to the identification of PHP1A. Genetic testing revealed a shared GNAS mutation in both the patient and her daughters. This case aligns with previous observations suggesting that patients with frameshift and nonsense mutations in GNAS tend to manifest more severe SCO compared to those with missense mutations. The identification of SCO in conjunction with AHO phenotypes underscores the importance of GNAS mutation analysis, not only for diagnostic purposes but also for facilitating genetic counseling. This emphasizes the need for a comprehensive approach in managing patients with SCO and AHO phenotypes, ensuring a more accurate diagnosis and informed genetic guidance.

Utility of 18F-choline PET-CT in the localization of adenomas in primary hyperparathyroidism

Elena Martínez Silla, Migueluesada Charneco, Javier García Sánchez, Raúl Rodríguez Juárez, Juan Luis Delgado Montoya & Pablo José López-Ibarra Lozano
San Cecilio Clinical University Hospital, Endocrinology and Nutrition, Granada, Spain

Objective
The definitive treatment of primary hyperparathyroidism (PPH) is the removal of the affected gland(s). However, its localization can be complicated. The usefulness of 18F-Choline PET-CT versus classical techniques is unknown. The aim of this study was to evaluate the results of 18F-Choline PET-CT in the detection of hyperfunctioning parathyroid tissue with respect to conventional imaging tests and to analyze the relationship between its findings and the levels of calcium and parathyroid hormone (PTH) prior to surgery.
Material and methods
Retrospective observational study of a sample of 30 patients with PPH candidates for surgery, assessed in consultation between 2020-2023, who underwent 18F-Choline PET-CT after negative or discordant conventional localization tests.
Results
Twenty-two females and 8 males were studied. Mean age: 55.6±12.1 years. Surgical criteria were: osteopenia/osteoporosis (73.3%), renal lithiasis (53.3%), serum calcium (50%), age (33.3%), elevated calciuria (20%) and glomerular filtration rate (3.5%). Eighty percent met 2 or more surgical criteria. Parathyroid ultrasound and/or MIBI scintigraphy had been performed in 96.7% of patients, with a concordance with 18F-choline PET-CT results of 40% and 17.2%, respectively. Parathyroid 4D-CT was performed in 19 patients, with a concordance with PET-CT results of 36.8%. In 100% of the sample the 18F-choline PET-CT was positive, with the most frequent localization being the right lower gland (36.7%). Ectopic gland was reported in 10%. The mean diameter of the lesions on PET-CT was 12.58 mm. 15 patients had already undergone surgery, and parathyroid adenoma was found in 13 of them and parathyroid hyperplasia in the remaining 2. There was 100% concordance between the PET-CT findings and the anatomical location of the hyperfunctioning gland in the pathological anatomy study. No association was found between serum PTH and/or calcium levels with the diameter of the lesion on PET-CT or with its weight on anatomic pathology.
Conclusions
18F-Choline PET-CT was useful in cases where ultrasound, scintigraphy or CT-4D had negative or discordant results. It presents a high detection rate of parathyroid hyperfunction and concordance with the surgical location of the affected gland. In addition, it offers benefits in the planning of surgery in patients in whom a good preoperative localization of the lesion was not achieved and in patients with persistent or recurrent PPH.

Impact of parathyroidectomy on calcium metabolism, bone mineral density and trabecular bone score in patients with non-syndromic primary hyperparathyroidism

Efstratios Kardalas, Georgia Ntali, Panagiotis Mouxtouris, Aglaia Papachristou & Marinella Tzanela
Evangelismos General Hospital, Department of Endocrinology 'D. IKKOS', Diabetes Center European and National Center of Excellence for Rare Endocrine Diseases, Greece

Background/aim
Primary hyperparathyroidism (pHPT) is a relatively common endocrine disorder, which is associated with severe disruption of calcium metabolism and deterioration of bone density and quality. Our study aimed at examining the effect of parathyroidectomy on bone mineral density (BMD), T-Score in both the femoral neck (FN) and the lumbar spine (LS) and on trabecular bone score (TBS).
Materials and methods
A cohort of 280 adult patients (195 males and 85 females), diagnosed with non-syndromic pHPT (from 1998 to 2023), who underwent parathyroidectomy and were followed-up post-surgically in our endocrine center, was retrospectively evaluated. Demographic, clinical and laboratory data of these patients at the time of diagnosis of pHPT and 1 year after parathyroidectomy were evaluated.
Results
Mean age and body mass index of the patients at diagnosis were 54.1 years and 28.6 kg/m^2 respectively. Mean PTH and corrected serum calcium values decreased significantly 1 year after parathyroidectomy (PTH: 65.3 ± 44.3 vs 307.5 ± 284.9 ng/l, $P<0.01$; corr Ca: 9.2 ± 0.6 vs 11.9 ± 1.8 mg/dl, $P=0.014$, respectively). BMD values were dramatically increased 12 months after parathyroidectomy in both the FN and the LS (LS BMD: 0.792 ± 0.133 vs 0.731 ± 0.105, $P < 0.01$, FN BMD: 0.611 ± 0.123 vs 0.544 ± 0.110, $P=0.022$ respectively). The same positive observation applied in case of T-Score values in both sites post-parathyroidectomy (LS T-score: -1.3 ± 0.9 vs -2.2 ± 1.3, $P<0.01$; FN T score: -1.5 ± 0.6 vs -2.3 ± 0.9, $P=0.016$). Interestingly, pre-operative PTH values were found to be moderately and inversely associated with the post-operative BMD and T-Score values in both the LS ($r=-0.44$, $P=0.013$; and $r=-0.56$, $P=0.022$ respectively) and the FN ($r=-0.52$, $P=0.018$; and $r=-0.58$, $P=0.015$ respectively). Finally, the evaluation with TBS pre- and post-operatively identified no significant alterations (TBS pre- and post-operatively: 1.23 ± 0.12 vs 1.25 ± 0.15, $P=0.37$).
Conclusions
The results of our study indicate that the surgical treatment of pHPT can potentially lead to significant improvement of BMD and T-Score values already after 1-year time. Nonetheless, higher biochemical severity of pHPT could be associated to limited recovery of bone metabolism post-surgically. Unfortunately, bone microarchitecture seems to remain relatively unaffected from the parathyroidectomy, thus possibly indicating irreversible effects of pHPT on bone structural integrity. Further long-term study and evaluation of the impact of parathyroidectomy on bone metabolism and quality of patients with pHPT is needed.

Intrathyroidal parathyroid adenoma: Two case reports

Anca Maria Andrei[1], Andreea Manole[1], Alicia Ungureanu[1], Delia Varlan[1], Ramona Dobre[1,2], Iulia Burcea[1,2] & Catalina Poiana[1,2]
[1]'C.I.Parhon' National Institute of Endocrinology, Bucharest, Romania; [2]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania

Introduction
The basis of treatment of primary hyperparathyroidism (pHPT) is parathyroidectomy of the responsible lesion, and thus, preoperative localization is important. Ectopic parathyroid adenomas are rare, and they can be accounted for persistent or recurrent hyperparathyroidism. An intrathyroidal parathyroid adenoma (IPA) is an ectopic variant where the adenoma is either partly (>50%) or completely enveloped by the thyroid gland. The incidence of IPAs ranges from 0.7% to 6%. We herein report two cases of primary hyperparathyroidism due to intrathyroidal parathyroid adenomas (IPA).
Case presentation
The first patient, a 60-years-old woman, was referred to our clinic for hypercalcemia. She was not experiencing any symptoms of hypercalcemia. The laboratory investigations showed an elevated serum calcium level of 12 mg/dl (normal range: 8.5–10.2) and parathyroid hormone level of 148.3 pg/ml (normal range: 15–45). The anterior cervical ultrasound revealed an intense hypoechoic, homogenous, with well-defined margins mass of 17/15 mm localized in the right thyroid lobe. A fine needle aspiration with PTH washout was performed indicating a PTH level of 2213 pg/ml. She underwent surgery and postoperative levels of calcium and PTH normalized. The histopathological evaluation confirmed the diagnosis of parathyroid adenoma. The second patient, a 30-year-old male, with history of autosomal dominant tubulointerstitial kidney disease and renal transplant, was admitted for a routinely endocrinological check−up. His laboratory results showed a serum calcium level of 11.5 mg/dl and a parathyroid hormone level of 200.5 pg/ml (normal range: 15–45). A homogenous, clear borderline, hypoechoic mass of 21.5/5.6 mm located in the left thyroid lobe was found at the neck ultrasound. The ^{99}mTc−estamibi scintigraphy did not find images suggestive of parathyroid adenomas, but fine needle aspiration with PTH washout from the intrathyroidal nodule revealed a PTH of 1215 pg/ml, which confirmed the parathyroid origin of the nodule. He is scheduled to undergo a left hemithyroidectomy.
Conclusion
It is difficult to make a definitive diagnosis of IPA before surgery, although the accuracy of diagnosis of IPA can be increased by combining various techniques, such as imaging and fine needle aspiration biopsy. The optimum technique likely depends on a variety of patients, surgeons, and center-dependent factors. The presented cases had completely enveloped parathyroid adenomas, one was cured after surgery and the other will undergo the same treatment. A thorough search for other adenomas and at other ectopic sites before thyroid lobectomy is associated with higher success rates.

Hypoparathyroidism following thyroid surgery: Risk factors and the role of early postsurgical PTH determination

Tânia Matos[1], Daniela Dias[1], Catarina Silvestre[1], Filipa Serra[1], Pedro Marques[1,2], Carlos Leichsenring[3], Nuno Pinheiro[3] & Inês Sapinho[1]
[1]Hospital CUF Descobertas, Endocrinology, Portugal; [2]Universidade Católica Portuguesa, Faculdade de Medicina, Portugal; [3]Hospital CUF Descobertas, General surgery, Portugal

Introduction
Hypoparathyroidism is one of the most common complications following thyroidectomy and it is associated with significant morbidity. It usually occurs within the first 48 h after thyroid surgery, however hypocalcemia symptoms may only begin up to 64 h after surgery. Therefore, early detection of hypoparathyroidism is essential to a secure postsurgery discharge.
Objectives
We aimed to evaluate the potential risk factors for postsurgical hypoparathyroidism and to determine the role of early determination of serum parathyroid hormone (PTH) following thyroid surgery to predict the occurrence of postsurgical hypoparathyroidism.
Methods
Retrospective analysis of patients submitted to thyroid surgery between August/22 and July/23 at Hospital CUF Descobertas, Lisbon. Serum PTH and calcium levels were determined 6 hours postoperatively. Hypoparathyroidism was defined as an inappropriately low PTH level (PTH normal range 18.5–88 pg/ml) in the context of hypocalcemia (calcium normal range 8.5–10.1 mg/dl), and it was classified as definitive if persisted longer than 6 months. Patients with a follow-up <6 months and with pre-operative abnomal phospho-calcium metabolism were excluded.
Results
We included 76 patients, 82% female ($n=62$), with an average age of $52 \pm$ 12years (23–75). 74 patients were submitted to thyroidectomy (lymph node dissection: 7 unilateral, 2 bilateral and 2 central) and 2 to thyroidectomy completion. Thyroid cancer was present in 24 patients (32%). Nineteen patients developed hypoparathyroidism (25%): 14 transient (18%) and 5 definitive (7%). These patients had lower early postoperative PTH levels (5.6 ± 3.8 vs $21.3 \pm$ 16.4 pg/mL, $P<0.001$), lower postoperative calcium levels (8.3 ± 1.1 vs $8.7 \pm$ 0.5 mg/dL, $P=0.026$) and had incidental parathyroidectomy more frequently (66.7% vs 19.4%, $P=0.002$). There were no significant differences among patients with or without postsurgical hypoparathyroidism regarding sex, age, type of thyroid disease (benign or malignant), neither on surgery type (with or without lymph node dissection). ROC-curve analysis revealed a good accuracy for PTH levels measured 6 hours after surgery to rule out the late occurrence of transient or definitive hypoparathyroidism (AUC 0.908 (CI 95% 0,832-0,983)). In all patients with postoperative PTH levels below 4pg/mL hypoparathyroidism was confirmed (29% of these corresponding to definite hypoparathyroidism), while for 6h-postoperative PTH levels above 18.75 pg/ml transient or definitive hypoparathyroidism has never occurred.
Conclusion
Early postsurgical PTH levels represent a simple and useful tool for a rapid evaluation of hypoparathyroidism risk following thyroid surgery. It allows for

selective and appropriate calcium and vitamin D supplementation, preventing symptomatic hypocalcemia and reducing delays on hospital discharge.

Co-morbidities in adults with hereditary hypophosphatemia compared to controls – a retrospective Danish register study

Signe Beck-Nielsen[1], Ulla Ege Johansen[2], Rikke Faergemann Hansen[2], Jennifer Gleisner[3] & Angela Williams[4]
[1]Aarhus University Hospital, Aarhus, Denmark; [2]Signum Life Science Aps, København, Denmark; [3]Kyowa Kirin AB, Sweden; [4]Kyowa Kirin International, HEOR, Marlow, UK

Background
Hereditary hypophosphatemia (HH) are rare diseases, characterized by excessive renal phosphate wasting and inappropriately low 1,25-dihydroxy-vitamin D causing hypophosphatemia. In children, the disease manifests as rickets and osteomalacia, in adults osteomalacia.
Aim
The study aims to describe the co-morbidities more prevalent in adults (18y+) with HH and the median age at first diagnosis compared to controls.
Methods
The case population was identified in the Danish National Patient Register based on five diagnostic codes referring to rickets or hypophosphatemia. A journal audit was performed based on all cases identified in Region of Midt Jutland and on available medical files from the remaining four regions in Denmark to verify the diagnosis of HH based on predefined diagnostic criteria. The background population (control) matched by gender, birth year and month, was randomly selected using the Danish Civil Registration System matching fifty controls to each adult with HH. Data on co-morbidities were retrieved from the Danish National Patient Register.
Results
The dataset comprised 98 adults with HH matched with 4.893 controls. Arthrosis was significantly more prevalent in adults with HH compared to controls ($P<0.001$) and first diagnosed at a significantly earlier median age (37.5y vs 55.5y, $P<0.001$). Knee prosthesis and osteotomy were significantly more prevalent in adults with HH ($P<0.001$ both); although younger in age at first registered contact, it was not significant. Hyperparathyroidism, renal failure, and hypertension were more prevalent in adults with HH ($P<0.001$, $P<0.001$, and $P=0.002$, respectively), also being diagnosed significantly earlier in adults with HH (median age 35.0y vs 62.0y, $P=0.010$; 40.5y vs 62.0y, $P=0.027$; and 41.5y vs 58.0y, $P=0.027$, respectively) compared to controls. Chiari I malformation, spinal stenosis, hearing loss, obesity and diseases of pulp and periapical tissues were more prevalent in adults with HH compared to controls ($P<0.001$, $P<0.001$, $P<0.001$, $P=0.002$ and $P=0.001$ respectively), but with no difference in age at presentation. Depressive episode(s) were of similar prevalence, but the median age at presentation was younger for adults with HH (26.0y vs 34.0y [$P=0.008$]).
Conclusion
This retrospective analysis revealed a significantly higher prevalence of co-morbidities already well-known in adults with HH, identifying that in some cases a first contact was at a significantly earlier age compared to controls. Clinicians taking care of adults with HH need to be aware of co-morbidities occurring at an earlier age to identify and initiate correcting actions to limit progression of morbidities in adults with HH.

Comparative effects of vitamin D supplementation on serum calciotropic hormone profile, in orthodox nuns with hypovitaminosis d in different regions of greece, versus intermittent fasting and western diet in lay women

Spyridon Karras[1,2], Neoklis Georgopoulos[3], Zadalla Mouslech[2], Georgios Koukoulis[4], Filotas Talidis[5], Stefan Pilz[6] & Martin Hewison[7]
[1]Thessaloniki, Aristotle University Medical School, Thessaloniki, Greece; [2]Thessaloniki, Greece; [3]Patras, Greece; [4]Larissa, Greece; [5]Kastoria, Greece; [6]Graz, Austria; [7]Birmingham, UK

Introduction
Greek Orthodox monasteries due to their sartorial habits, comprise a population with high prevalence of hypovitaminosis D. Intermittent religious fasting is adopted by this population, as well as from a large part of general lay Greek population. Comparative effects of vitamin D supplementation and intermittent fasting on vitamin D equilibrium and calciotropic profiles remain scarce.
Aim
To comparatively evaluate effects of vitamin D supplementation in two different forms (drops and pills at 2.500 IU daily) in Orthodox nuns from different regions of Greece, versus Orthodox fasting and Western diet patterns in women from general population on vitamin D and calcium homeostasis.
Methods
Two groups of 25 women from two Orthodox monasteries in Northern Greece (Groups A and B) and two groups of 25 healthy women (Groups C and D) were included. During enrollment a detailed recording of demographic, dietary habits and anthropometric characteristics (via bioimpedance) was conducted. We evaluated calciotropic profiles [Calcium-Ca, Albumin, Parathyroid hormone-PTH, 25(OH)D] at baseline and after 12 weeks. Groups A and B received vitamin D supplementation with 2.500 international units of cholecalciferol daily (in the form of drops - Group A- and tablets - Group B). Groups C and D adopted a dietary pattern of Orthodox intermittent fasting [daily feeding window (1000 h–1800 h)] (Group C) and a diet based on the recommendations of the American Heart Association (AHA) for the management of overweight and obesity in adults (Group D).
Results
All groups were comparable at baseline for calcium, PTH and 25(OH)D concentrations. All groups demonstrated significant increases of 25(OH)D [Group A (21.68 vs 31.05 ng/ml),(Group B 25.78 vs 38.35 ng/ml),(Group C 17.31 vs 24.32 ng/ml),(Group D 17.62 vs 24.12 ng/ml), with no significant between group differences. PTH concentrations decreased significantly in Group C (42.18 vs 25.89) pg/ml and Group D (34.22 vs 17.68) pg/ml, whereas PTH changes in groups A and B were non-significant after 12 weeks of supplementation compared to baseline, with no effects of anthropometric measures of body fat,as well as type of supplementation.
Conclusions
Intermittent fasting and AHA dietary patterns were equally effective with equal moderate doses of vitamin D supplementation in improving vitamin D status, in different groups of Greek nuns and lat women.

Frequency and causes of hypophosphatemia in internal medicine patients

Lisa Hübener[1], Christian Haas[2] & Birgit Harbeck[3]
[1]University of Lübeck, Lübeck, Germany; [2]University Hospital of Marburg, Department of Nephrology, Marburg, Germany; [3]University Hospital of Hamburg, Department of Medicine III, Hamburg, Germany

Background
Hypophosphatemia is of relevant clinical importance, especially in its severe form. Hypophosphatemia occurs when serum phosphate levels are below 0.84 mmol/l. It can be divided into a mild form (serum phosphate between 0.5 and 0.83 mmol/l), a moderate form (serum phosphate between 0.3 and 0.5 mmol/l) and a severe form (serum phosphate <0.3 mmol/l). Approximately 2.2 to 3.1% of hospitalized patients not requiring intensive care are affected (Brunelli et al., 2007). There are multiple causes such as chronic alcohol consumption, parenteral nutrition or sepsis. However, it has been observed that a mostly mild form of hypophosphatemia often occurs in routine laboratory controls. Aim of the study was to assess the frequency of subtypes of hypophosphatemia and to identify their causes.
Methods
In a retrospective analysis between March 2014 and March 2016, laboratory values from a total of $n=34103$ patients were collected and statistically evaluated. The parameters tested were phosphate, calcium, alkaline phosphatase, creatinine and albumin.
Results
A very high prevalence of hypophosphatemia (23.9%) was demonstrated. The mild form is by far the most common, while the severe form is, as expected, rare. In numbers: the mild form of hypophosphatemia occured in 21.3% ($n=7920$) of all patients, the moderate form in 2.1% ($n=705$) and the severe form in 0.5% ($n=165$) of patients. The further results were obtained using correlation matrixes. According to initial findings, hypophosphatemia may not occur when creatinine

levels are elevated. In the severe form hypophosphatemia can be associated with hypocalcemia.

Unveiling unique clinical phenotypes of hip fracture patients and the temporal association with cardiovascular events in Hong Kong and the United Kingdom: A retrospective study

Ching-Lung Cheung[1], Warrington Hsu[1], Xiaowen Zhang[1], Chor-Wing Sing[1], Kathryn Tan[1], Ian Wong[1] & Wallis Lau[2]
[1]The University of Hong Kong, Pok Fu Lam, Hong Kong; [2]University College London, London, UK

Major adverse cardiac events (MACE) are the leading cause of death among hip fracture patients. This study aimed to: (1) identify hip fracture subphenotypes using LCA and (2) evaluate the prognosis of the hip fracture subphenotypes on CVE-related outcomes in two extensive hip fracture cohorts from Hong Kong (HK CDARS; $n=78,417$) and the United Kingdom (UK THIN; $n=27,948$), employing both the conventional cohort (between-individual comparison) design and the self-controlled case series (SCCS; within-individual comparison) design. The latent class analysis (LCA) revealed three distinct clusters in the HK cohort: Cluster 1 had cerebrovascular and hypertensive diseases, hyperlipidemia, and diabetes; Cluster 2 had congestive heart failure; Cluster 3 consisted of relatively healthy patients. In the UK THIN dataset, Cluster 1 consisted of a high prevalence of CVE including coronary heart disease, congestive heart failure, and arrhythmia and conduction disorders, and with a higher prevalence of most clinical conditions studied when compared with the relatively healthy Cluster 2. In the HK cohort, the risk of 180-day all-cause mortality and MACE were significantly higher in Clusters 1 (all-cause mortality: HR 1.35, 95% CI 1.28 to 1.42; MACE: HR 1.97, 95% CI 1.83 to 2.12) and Cluster 2 (all-cause mortality: HR 2.22, 95% CI 2.10 to 2.34; MACE: HR 4.06, 95% CI 3.78 to 4.35) compared to Cluster 3. For the secondary outcomes, both Clusters 1 and 2 were associated with a higher number of hospital visits, A&E visits, and total length of hospital stays in the 180-day period after hip fracture. In the between-individual analysis, an immediate risk of overall MACE was observed in the Clusters 1 and 2 in the HK cohort, using the relatively healthy cluster as the reference. SCCS analysis (the within-individual analysis) showed a significantly elevated risk of MACE within 60 days post-hip fracture. Similar associations were observed in the UK cohort in all analyses. In conclusion, this study identified distinct subphenotypes of hip fracture in both the Hong Kong and UK older adult populations using LCA. Temporal associations with MACE were observed in all hip fracture patient clusters. Notably, heart failure consistently emerged as a key characteristic associated with poor prognosis in hip fracture patients. Personalised care of hip fracture patients, considering their specific subphenotypes, is required to prevent MACE.

The association between the 'time to first fracture' and imminent fracture risk – data from the FRISBEE cohort

Jeroen M.K. de Filette[1], Alexia Charles[2], Amélie Bellanger[2], Iconaru Laura[1], Felicia Baleanu[1], Murielle Surquin[3], Bergmann Pierre[2,4] & Jean-Jacques Body[1,2,3]
[1]CHU Brugmann, Endocrinology, Bruxelles, Belgium; [2]CHU Brugmann, Laboratoire de Recherche Translationnelle, Bruxelles, Belgium; [3]CHU Brugmann, Internal Medicine, Bruxelles, Belgium; [4]CHU Brugmann, Nuclear Medicine, Bruxelles, Belgium

Background
Risk factors for fragility fractures were assessed in several prediction models (e.g. FRAX®, Garvan, FRISBEE, …). The predictors of a shorter 'time to first fracture' and its impact on imminent fracture risk, however, remain to be determined.
Methods
The concept of 'time to first fracture' between inclusion in the FRISBEE cohort ('Fracture RIsk Brussels Epidemiological Enquiry'; 3560 postmenopausal women; median follow-up time of 10.1 ± 2 years) and first fragility fracture was studied. Subjects with validated fractures were divided into 3 groups: first fracture $<$ 2 years, 2-5 years, and >5 years after inclusion. Cox proportional hazard modeling using uni- and multivariate analysis was performed to evaluate factors associated with first fracture risk in these groups. Furthermore, the association between a short 'time to first fracture' as a risk factor for imminent fractures was analyzed. Differences between groups were evaluated by chi^2-test.
Results
Classical risk factors (age, prior fracture, fall history and low BMD) were associated with first fracture in all groups. Previous glucocorticoid use and rheumatoid arthritis (RA) were predictors for early fracture (<2 years), consistent with the concept of very high risk. The 'time to first fracture' was not an independent risk factor for subsequent imminent fractures as FRAX® at baseline was significantly different between groups. Imminent fractures were similar in subjects with/without osteoporosis treatment (16.3 vs 15.5%) despite a higher estimated 10-year risk of fragility fracture in those treated, suggesting that treatment was efficient.
Conclusion
Among the risk factors considered, only previous glucocorticoid use and RA were specific predictors for early fracture. The 'time to first fracture' was not an independent risk factor for imminent fractures. Patients with a first osteoporotic fracture should thus be considered at very high risk for re-fracture, independent of the 'time to first fracture'.

Risk of sarcopenia can predict quality of life in Primary Hyperparathyroidism

Christina Manani[1], Georgios Tzikos[2] & Theodosios S Papavramidis[2]
[1]Aristotle University of Thessaloniki, 1st Propedeutic Department of Surgery, AHEPA University Hospital, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki, 1st Propedeutic Department of Surgery, AHEPA University Hospital

Background
A specific self-administered health-related quality of life questionnaire for sarcopenia, the sarcopenia and Quality of life (SarQol®) has been recently developed. The questionnaire is composed of 55 items and organized into seven domains of quality of life. The Pasieka Quality of life questionnaire (PAS-Qol) is a specific self-administered quality of life questionnaire that has been developed for patients with primary hyperparathyroidism. The questionnaire has been developed as an assessment tool to find out how primary hyperparathyroidism affected patients' lifestyle and wellbeing. Many of these symptoms develop insidiously and are not easily recognized. If you have primary hyperparathyroidism and your score is over 200 then you are likely to be symptomatic and affected by the disorder. Sarcopenia and low quality of life are widely found among patients suffering from primary hyperparathyroidism.
Aim This study aims to verify whether risk of sarcopenia can predict quality of life in patients with primary hyperparathyroidism.
Methods
The study included both men and women diagnosed with primary hyperparathyroidism and community-dwelling adults with no known hyperparathyroidism disorder. Both groups were assessed with the SarQol questionnaire, and the hyperparathyroidism group was also assessed with the PAS-Qol questionnaire.
Results
Of the 100 included individuals 80% were women with a mean age of 63.8years. Increased age is associated with a lower quality of life (<-1.160, $P<0.001$) in the community-dwelling adults, and gender, with females as the reference is also a significant negative predictor (-11.323, $P=.010$).Neither age ($B=4.845$, $P=.219$) nor gender ($B=-37.816$, $P=0.685$) significantly predicted quality of life in hyperparathyroidism group using the PAS-Qol scale. The mean overall scores of the SarQol scale for patients of the normal group was 72.6 (s.d. = 14.9) and for the hyperparathyroidism group 63.7 (s.d. = 15.1). There was a statistically significant difference ($P=0.006$), suggesting that individuals with hyperparathyroidism generally had lower quality of life scores compared to those without the condition. Between the quality-of-life scores as assessed by the SarQol scale and the PAS-Qol scale there is a significant negative correlation suggesting that as the SarQol score increases PAS-Qol score tends to decline in primary hyperparathyroidism (negative correlation -0.444^{**}, $P=0.001$).
Conclusion
The study highlights the potential interconnectedness between these two conditions, sarcopenia and primary hyperparathyroidism, and their impact on patients' overall well-being. The study emphasizes the need for comprehensive management strategies addressing both sarcopenia and hyperparathyroidism to enhance patients' quality of life.

Education, and early retirement in patients with hereditary hypophosphatemia compared to controls – a retrospective Danish register study

Signe Beck-Nielsen[1], Ulla Ege Johansen[2], Rikke Faergemann Hansen[2], Jennifer Gleisner[3] & Angela Williams[4]
[1]Aarhus University Hospital, Centre for Rare Diseases, Aarhus, Denmark; [2]Signum Life Science Aps, København, Denmark; [3]Kyowa Kirin AB, Sweden; [4]Kyowa Kirin International, HEOR, Marlow, UK

Background
Hereditary hypophosphatemia (HH) are rare diseases, characterized by excessive renal phosphate wasting and inappropriately low 1,25-dihydroxy-vitamin D causing hypophosphatemia. In children, the disease manifests as rickets and osteomalacia, in adults osteomalacia. Complications from the disease appear with increasing age, in adults characterized by pain, arthrosis, persisting deformities of long bones if not corrected during childhood causing compromised functions of daily living and decreased health-related quality of life.
Aim
In this study, we aimed to investigate if patients with HH achieved the same educational level as the background population and if the ability to work with increasing age was comparable.
Methods
The case population was identified in the Danish National Patient Register based on five diagnosis codes referring to rickets or hypophosphatemia. A journal audit was performed based on all cases identified in Region of Midt Jutland and on available medical files from the remaining four regions in Denmark to verify the diagnosis of HH based on predefined diagnostic criteria. The background population (control) matched by gender, birth year and month, was randomly selected using the Danish Civil Registration System matching fifty controls to each patient with HH. Data on highest educational attainment and employment information were retrieved from the Educational Register and the Ministry of Employments database, respectively.
Results
The dataset comprised 120 patients with HH matched with 6000 controls. We found no difference in the highest obtained educational level between patients with HH compared to controls. A significantly lower proportion of patients with HH aged 40–49y were employed compared to controls ($P=0.012$), and a significantly larger proportion aged 30-49y were in flexible job, in rehabilitation or on flexible benefits compared with controls ($P<0.05$). From age 60+y, a significantly larger proportion of controls were unemployed ($P<0.001$). There was no difference in early retirement in age groups 18–29y, but from age 30–59y, a significantly larger proportion of patients with HH were early retired ($P<0.05$). The mean age at early retirement was 38.7y for patients with HH compared to 45.1y for controls (Δ 6.4y, $P=0.015$).
Conclusion
Patients with HH achieved a comparable educational level compared with the background population, but a significantly larger proportion of patients with HH had the need for a flexible job, rehabilitation or flexible benefits in addition to early retirement. There is a need for identifying and addressing the possible causes for well-educated patients with HH leaving working life too early.

A rare cause of bone pain: Fibrodysplasia ossificans progressiva

Gökçen Nailer Ertuna[1], Feride Pınar Altay[1], Fatih Gürbüz[2], Abbas Ali Tam[3], Didem Ozdemir[3], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yıldırım Beyazıt University Faculty of Medicine, Pediatric Endocrinology, Ankara, Turkey; [3]Ankara Yıldırım Beyazıt University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey

Introduction
Fibrodysplasia ossificans progressiva (FOP), also known as stone man disease, is a rare connective tissue disorder with a prevalence of 1 in 2 million. It is caused by a mutation in ACVR1 gene, usually sporadic and sometimes with autosomal dominant (AD) inheritance. These patients are normal at birth except for the short great toes and hallux valgus. Over time soft tissues such as ligaments, skeletal muscles or tendons ossify. Diaphragm, tongue, extraocular and cardiac muscles are spared.
Clinical case
A 32-year-old female with severe bone pain and hip contracture applied to our clinic. In her history, at age 8 she was admitted to hospital due to lump on her back. The biopsy result of the lesion was reported as fibrotic fat tissue and she was discharged. Two years later at age 10 she was admitted to hospital again due to protrusion and pain in the area where the biopsy was taken. The second biopsy taken from the left thoracic wall was reported as heterotopic endochondral ossification. Further examination of the case for FOP was recommended. Genetic testing could not be done due to the family's financial difficulties. Over the years, painful swellings continued to develop in various regions. When the patient's daughter was 5 years old, the same painful swellings began to occur. This time genetic testing was done on both. Mutation was detected positive for ACVR1 gene for both. (NM_001105.5, c.617G>A (p.R206H) (p.Arg206Pro) (Heterozygote)). During our examination, many painful ossification areas were detected in different regions such as the back, dorsum of foot and chest wall. In addition, contracture of the left hip joint occurred in external rotation and abduction. She also had short big toes and hallux valgus. No abnormalities were detected in laboratory tests. In plain radiographs, pseudoexostoses were seen in various parts such as left sided thoracic wall, left iliopsoas muscle and adductor magnus muscle. Also, monophalangic great toes were noted (Figure 1). Since there was no treatment to prevent the progression of the disease, we administered ibuprofen for symptomatic treatment and glucocorticoid to use during painful flare-ups.
Conclusion
FOP is a rare disease that reduces quality and duration of life. Where heterotopic ossification is detected clinically or radiologically, FOP should be kept in mind. Since it can be inherited AD, genetic testing and counseling should be provided in case of clinical suspicion.

More potent antiresorptive effect of denosumab versus zoledronate in osteoporotic postmenopausal women with primary hyperparathyroidism

Katarina Mlekus Kozamernik[1,2], Luka Ležaić[2,3], Marko Hočevar[2,4] & Tomaž Kocjan[1,2]
[1]UMC Ljubljana, Endocrinology, Ljubljana; [2]Faculty of medicine, University of Ljubljana, Ljubljana; [3]UMC Ljubljana, Department of nuclear medicine, Ljubljana; [4]Institute of Oncology, Department of Surgical Oncology, Ljubljana

Introduction
Primary hyperparathyroidism (PHPT) is a state of increased bone turnover that can result in secondary osteoporosis. Antiresorptive treatment can be used to preserve bone mineral density (BMD). We compared the impact of zoledronate and denosumab on bone-related biochemical parameters.
Methods
We analyzed interim data from our ongoing randomized trial on osteoporotic postmenopausal women with PHPT who are being treated with either zoledronate 5 mg i.v. once a year (ZOL group) or with denosumab 60 mg s.c. every six months (DMAB group) (ClinicalTrials.gov Identifier NCT04085419). Here, we compare the serum calcium levels (S-Ca), intact parathyroid hormone (iPTH), and bone turnover markers at baseline and 3 months after the start of the treatment.
Results
We enrolled 40 female patients with a mean age of 73.0 (7.8 s.d.) years and 22.6 (10.0) years from menopause with a BMI of 27.77 (5.1) kg/m^2 and with osteoporosis: BMD at a lumbar spine (LS) 0.833 (0.134), total hip (TH) 0.736 (0.117), femoral neck (FN) 0.624 (0.084), distal third radius (1/3R) 0.494 (0.069) g/cm^2 and trabecular bone score (TBS) 1.190 (0.127). After randomization, 20 women received zoledronate (ZOL group) and 20 denosumab (DMAB group). Three months (3M) after the treatment, there was a statistically significant decrease of serum calcium (S-Ca) in both groups (DMAB: baseline S-Ca 2.72 (0.16) vs 3M S-Ca 2.65 (0.18) mmol/l; $P=0.045$, ZOL: baseline S-Ca 2.72 (0.1) vs 3M S-Ca 2.64 (0.12) mmol/l; $P<0.01$). No significant difference in S-Ca decrease between the groups was detected. Similarly, there was a significant increase in iPTH levels in both groups but no statistically significant difference between the groups: (DMAB Δ iPTH 61.91 (126.93) vs ZOL Δ iPHT 30.24 (56.84) ng/l; $P=0.31$). Bone turnover markers decreased significantly in both groups with greater decline of CTX and bone-specific alkaline phosphatase (BAP) in DMAB group (DMAB Δ CTX 0.952 (0.639) vs ZOL Δ CTX 0.556 (0.439) µg/l; $P=0.03$ and DMAB Δ BAP 19.92 (8.51) vs ZOL Δ BAP 12.99 (9.3) µg/l; $P=0.03$). The apparent numerical difference in P1NP was not statistically significant: DMAB Δ P1NP 75.45 (33.87) vs ZOL Δ P1NP 55.12 (32.52) µg/l; $P=0.06$.
Conclusion
Within the first three months of treatment, our data show a greater reduction in bone turnover markers in the DMAB group than in the ZOL group. S-Ca decreased, and iPTH increased in both groups without significant differences between the groups.

Comparison of fractional excretion of calcium from different urine samples in the differentiation between primary hyperparathyroidism and familial hypocalciuric hypercalcemia

Markus Koster[1], Siegenthaler Martin[1,2] & Bilz Stefan[1]
[1]Kantonsspital St. Gallen, Division of Endocrinology and Diabetes, St. Gallen, Switzerland; [2]Charité Universitätsmedizin Berlin, Department of Endocrinology and Metabolic Disease, Berlin, Germany

Background
Calculation of the fractional excretion of calcium (FECa) from 24-hour (24h) urine collections is recommended to identify patients with suspected familial hypocalciuric hypercalcemia (FHH) during the work-up of primary hyperparathyroidism (pHPT). The current study was designed to test whether calculating the FECa or calcium-to-creatinin clearance obtained from 24h urine specimen can be substituted by results obtained from second morning or spontaneous void urine samples.
Methods
Ninety-one patients subsequently referred for the workup of PTH-dependent hypercalcemia (albumin-corrected and/or ionized calcium $\geq$ 2.6/1.3 mmol/l, PTH $\geq$ 30 ng/l, 25-OH vitamin D3 $\geq$ 50 nmol/l) were included and provided two independent 24h urine collections (groups D1 and D2), one second morning urine (MU) and one spontaneous void urine sample (SU). FECa (%) was calculated from paired blood and urine samples. Patients with a FECa $<$1% were categorized as suspicious for FHH (sFHH), the remaining considered to have pHPT. Descriptive statistics (median, IQR), Kruskal Wallis and McMemar tests were used to test whether FECa results or the proportion of sFHH patients were different across the four urine collections.
Results
The median FECa in the 4 samples were D1: 2.1% (1.2, 2.7), D2: 2.2% (1.6, 2.8), MU: 1.6% (1.0, 2.4) and SU: 2.1% (1.2, 2.7). FECa derived from the MU was significantly lower when compared to D1 and D2 ($P=0.04$ and <0.001, respectively). The proportion of patients assigned to the sFHH category were D1: 0.23 (95%CI 0.14–0.32), D2: 0.10 (95%CI 0.03–0.16), MU: 0.24 (95%CI 0.15–0.33), SU: 0.21 (95%CI 0.13–0.30). The proportions of patients assigned to sFHH were significantly different between D1 and D2 ($P=0.027$), D2 and MU ($P=0.006$) and D2 and SU ($P=0.027$). 7/91 subjects had a FECa $<$1% in all samples and 3 of them received a genetically confirmed diagnosis of FHH.
Conclusion
Considering the inherent variability of FECa derived from 24h urine collections using spontaneous void urine samples may be an adequate alternative to identify patients with possible FHH. Based on our preliminary data, we hypothesize that repeated testing of FECa in spontaneous void urine samples rather than relying on single 24h urine collection may aid to reduce the number of patients in whom genetic testing is required to rule out FHH.

Burosumab treatment for FGF23-related hypophoshatemia in an adult patient with severe fibrous dysplasia in McCune-Albright syndrome

Maria Stelmachowska-Banaś[1], Karolina Cylke-Falkowska[1], Wojciech Zgliczyński[1] & Waldemar Misiorowski[1]
[1]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland

Background
McCune Albright syndrome (MAS) is a rare mosaic genetic disorder affecting 1/100 000 to 1/1 000 000 of the population. It arises from a somatic gain-of-function mutation in GNAS gene. The clinical picture is complex and includes fibrous dysplasia (FD), café-au-lait spots, precocious puberty and other hyperactive endocrinopathies. The degree of FGF23 overproduction is correlated with FD severity, and frank hypophosphatemia occurs only in patients with extensive skeletal involvement, resulting in frequent fractures, pain, increased propensity for deformities, and muscle weakness. Burosumab is a monoclonal antibody that targets FGF23, indicated for the treatment of hypophosphatemic rickets and tumor-induced osteomalacia caused by overproduction of FGF23. To date, there is no evidence on the effectiveness and safety of burosumab treatment in adults with FD/MAS.
Case presentation
A 27-year-old male with MAS was under the care of the Endocrinology Department for persistent hypophosphatemia despite treatment with oral phosphate supplements and alfacalcidol. MAS was diagnosed at the age of 6 years and his medical history included precocious puberty, multiple fractures, skeletal deformities, muscle weakness and exacerbated skeletal pain due to severe FD. The patient was diagnosed with GH excess at the age of 22 years and has been treated with pasireotide 40 mg every 4 weeks i.m. with normalization of IGF-1 level for age and sex. Because of persistent hypophosphatemia (serum phosphate 0.38 mmol/l) resulting from FGF23 excess (serum FGF23 495kRU/L normal $<$100), bone pain and frequent fractures, the treatment with burosumab has been attempted (1 mg/kg body weight s.c. every 4 weeks). Over the 10-month course of treatment, the patient reported improved general well-being, reduced bone pain and increased muscle strength. Normalization of serum phosphate 0.87 mmol/l, PTH 51.6 pg/ml and significant reduction in alkaline phosphatase levels from 1022.2 U/l to 592.6 U/l were achieved. No adverse effects of the short-term therapy were observed.
Conclusions
This is the first reported case of burosumab treatment in an adult patient with FGF23-related hypophosphatemia in MAS. In our case, positive effects of the therapy were observed, both in terms of the patient's reported well-being and in terms of calcium-phosphate balance and bone markers. However, a longer follow-up in a larger group of adult patients with MAS seems necessary.

Cystic parathyroid adenomas – a rare case of primary hyperparathyroidism: Two case reports

Katja Veraguth[1], Walter Kolb[2], Ole Maas[3] & Stefan Bilz[1]
[1]Kantonsspital St.Gallen, Klinik für Endokrinologie, Diabetologie, Osteologie und Stoffwechselerkrankungen, St. Gallen, Switzerland; [2]Kantonsspital St.Gallen, Klinik für Allgemein-, Viszeral-, Endokrin- und Transplantationschirurgie, St. Gallen, Switzerland; [3]Kantonsspital St. Gallen, Klinik für Radiologie und Nuklearmedizin, St. Gallen, Switzerland

Less than 0.5% of parathyroid lesions are cysts out of which only 10–20% are endocrine active. Depending on their localisation, the most frequent symptom of a parathyroid cyst (PC) is neck mass (41.7%) with possible compressive symptoms. Women are more frequently affected and tend to have hormone-inactive PCs. Men tend to have endocrine-active PCs. The best diagnostic approach is still under debate as PCs are relatively rare.
Case report 1
A 68-year-old man was referred by the rheumatologists for primary hyperparathyroidism, which had been diagnosed as part of the extended investigations for CPPD arthritis. His history revealed recurrent kidney stones, chronic kidney disease and osteopenia (T-score minimal -2.0 s.d.) as possible associated secondary diseases. There were no local complaints or compression symptoms. The albumin-corrected calcium was 2.8 mmol/l and the PTH was 200 mmol/l. Ultrasonography showed a large cystic lesion (58 mm) caudal to the left lobe of the thyroid gland. The cyst fluid obtained by fine needle aspiration was hemorrhagic and contained high concentrations of PTH (305 000 ng/l). Intraoperatively, most of the cyst was retrosternal and could be removed intact. Histopathologically, the specimen weighed 28 g and could be clearly assigned to a cystic parathyroid adenoma.
Case report 2
A 74-year-old female patient was diagnosed with primary hyperparathyroidism as part of a search for secondary causes of osteoporosis (T-score minimal -4.5 s.d.). The serum calcium was 2.7 mmol/l, the PTH was 177 mmol/l. Sonography revealed a predominantly cystic mass with solid margins (max. 37 mm) in the area of the caudal right lobe of the thyroid gland, which could not be clearly differentiated from the thyroid gland. The choline PET/CT showed a choline-enriched lesion with strong margins dorsally adjacent to the right lobe of the thyroid gland. The findings could be surgically resected and histopathologically corresponded to a 5 g cystic parathyroid adenoma. A low normal PTH was measured in both patients on the 1st day postoperatively, the Calcium normalized in the following investigations.
Conclusion
The diagnosis of cystic parathyroid adenomas can be made by imaging or fine needle aspiration. To date, the diagnostic value of Tc-99m MIBI SPECT/CT in primary hyperparthyroidism caused by cystic parathyroid adenomas is unclear (no data for choline PET), and minimally invasive FNA appears to be very useful for the diagnosis and differentiation of other neck cysts due to the highly elevated PTH level in both endocrine active and inactive PCs, what is very characteristic.

Age-associated changes of fast-twitch skeletal muscle fibers in male rats

Branko Filipović[1], Branka Šošić-Jurjević[1], Svetlana Trifunovć[1], Natasa Ristic[1], Milica Manojlović-Stojanoski[1], Nataša Nestorović[1] & Vladimir Ajdžanović[1]

[1]University of Belgrade, Institute for Biological Research "Siniša Stanković", National Institute of Republic of Serbia, Citology, Belgrade, Serbia

Aging process is accompanied by structural and functional changes in different organs including bone and muscle tissues. Between these tissues there is a mutual interaction mediated by endocrine factors such as the peptide hormone osteocalcin, produced by osteoblasts. Since the skeletal muscles is composed of two basic fiber types, slow-twitch (type I) and fast-twitch (type II), the aim of this study was to examine the age-related changes in rat fast-twitch skeletal muscle fibers using morphometrical, immunohistochemical and biochemical analysis. Experimental animals included three age group of male Wistar rats: young adult (3-months old), middle-aged (16-months old) and old (24-months old). For immunohistochemical characterization of fast myosin heavy chains (MHC-fast) in skeletal muscle fibers, anti-fast myosin skeletal heavy chain served as primary antibody. Morphometric analysis of muscle fibers was performed using Olympus microscope (BX-51), equipped with a microcator, a motorised stage and a CCD video camera, and controlled by the newCAST stereological software package. Blood serum was used for determination of serum osteocalcin (OC) and testosterone (T) concentrations. Morphometric analysis of fast-twitch muscle fibers, in gastrocnemius muscle cross-sections, showed a significant reduction in mean MHC-fast fiber perimeter (MHC-fast FP) by 15% ($P<0.01$) and 10% ($P<0.05$) in old rats compared to the young adult and middle-aged rats, respectively. The value of MHC-fast fiber cross-sectional area (MHC-fast FCSA) was markedly reduced by 27% ($P<0.01$) and 19% ($P<0.05$) in the old rats, related to young adult and middle-aged groups, respectively. The MHC-fast fiber minimal Feret's diameter (MHC-fast FMFD) in old rats decreased by 17% ($P<0.01$) when compared to young adult. Evaluation of the biochemical parameters showed a significant reduction in serum OC concentration by 61% ($P<0.0001$) and 63% ($P<0.0001$), when the middle-aged and old rats were compared to the younger animals. Serum T was significantly lower by 26% ($P<0.05$) and 56% ($P<0.0001$) in the middle-aged and old groups respectively, compared to young adults. The reduction of serum T measured 40% ($P<0.01$) when old rats were compared to middle-aged animals. These findings indicate age-related changes in the morphometric parameters of fast-twitch muscle fibers, as a consequence of their size reduction in the rat gastrocnemius. This is supported by the decline in serum levels of osteocalcin and testosterone, which may contribute to the reduction of their muscle anabolic effects in old age.

Osteoporosis causes bone fragility usually affecting the elderly. Genetic susceptibility plays a crucial role in determining the risk of fragility fractures and is involved in early-onset osteoporosis. When fragility fractures or low bone mineral density (BMD) occur in young adults without evident secondary osteoporosis, an underlying monogenetic bone disease should be assessed. The list of genes related to low BMD and their mutations is increasing. Nevertheless, little is known about the role of Variants of Uncertain Significance (VUS). We retrospectively evaluated 65 adult patients undergoing Next Generation Sequencing analysis for osteogenesis imperfecta/lowBMD panel including the following genes: COL1A1, COL1A2, BMP1, CRTAP, FKBP10, IFITM5, P3H1, PLOD2, PLS3, PPIB, SERPINF1, SERPINH1, WNT1, LRP5. The indication for genetic analysis was prompted by multiple fragility fractures or low BMD in premenopausal/perimenopausal women and in men aged less than 55 years, in the absence of a clear phenotype of monogenetic bone disease and after exclusion of secondary causes of osteoporosis. Gene variants were detected in 37 (57%) out of 65 enrolled patients: 3 patients, mean aged 47.3 years, had pathogenic mutations in COL1A1 and COL1A2, therefore being diagnosed with osteogenesis imperfecta. They denied dental diseases, while two of them had moderate-severe scoliosis and hearing loss, and one reported ligament laxity; each reported a mean of 5 fractures, more commonly appendicular. One patient had densitometric osteoporosis. The remaining 34 patients harboured VUS: they did not significantly differ from wild-type patients regarding age, sex, age at first fracture, presence of low BMD and circulating markers of mineral metabolism and C-terminal telopeptide. Of note, though the prevalences of dental disease and hearing loss were similar, VUS patients had more commonly a family history of fragility fractures (56.2 versus 24.0%, $P=0.015$), and a higher number of axial fractures (2.9 versus 1.0%, $P=0.01$), whereas the number of appendicular fractures was comparable with wild-type subjects. Moreover, moderate-severe scoliosis showed a trend to be more common in the VUS group (20.6 versus 3.6%, $P=0.087$), and the median levels of alkaline phosphatase and its bone isoenzyme were higher in VUS patients (81.8 versus 55.0 U/l, $P=0.01$; 20.3 versus 9.8 µg/l; $P=0.02$, respectively). In conclusion, VUS in low BMD related genes may associate with a family history of fragility fractures, moderate-severe scoliosis, high number of axial fractures and relatively high bone turnover. These findings suggest the need to extend genetic diagnosis and to investigate the role of VUS.

Alterations in phosphate metabolism in patients with Klinefelter's syndrome

Rita Indirli[1,2], Valeria Lanzi[1,2], Iulia Petria[1,2], Giovanna Mantovani[1,2] & Emanuele Ferrante[1]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

Background
Patients with Klinefelter's syndrome (KS) present a high prevalence of osteopenia, osteoporosis and fragility fractures. Several factors may contribute to skeletal fragility, e.g. hypogonadism, derangements in vitamin D metabolism, reduced testicular secretion of Insulin-like Factor 3. However, phosphate metabolism has never been investigated.
Methods
A retrospective analysis was conducted to investigate prevalence and characteristics of hypophosphatemia (HypoP, serum phosphate $\leq$2.7 mg/dl) among adult KS patients followed-up at a tertiary endocrinology center in Milan, Italy. Among 100 patients, 86 had at least one phosphate assessment and were included in the analysis. HypoP was defined as recurrent/persistent if confirmed in $\geq$2 assessments. Moreover, 36 KS patients (age 32 [26–43] years) were consecutively enrolled in a cross-sectional study and compared to 32 male healthy controls (age 29 [26–40], $P=0.49$). Blood and urine parameters of phosphate metabolism, including tubular resorption of phosphate (TmP/GFR), were assessed in both groups. Hip, femoral neck and lumbar spine bone mineral density (BMD) was evaluated in KS patients by dual-energy X-ray absorptiometry.
Results
In the retrospective analysis, 20 out of 86 (23%) patients presented mild-moderate HypoP in at least one assessment. HypoP was recurrent/persistent in 9 patients (10%). No apparent causes of HypoP were identified. Patients with HypoP were older (43 [40–53] vs 31 [26–46] years, $P<0.001$) and had a greater phosphate urinary loss (TmP/GFR 3 [2.7-3.7] vs 2.4 [2.2-2.9] mg/dl, $P=0.002$) than patients with normal phosphate, but prevalence of low BMD was similar (5/21 vs 14/66, $P=0.9$). In the cross-sectional study, KS patients displayed lower testosterone concentrations than controls (4.8 [3.4–5.6] vs 5.1 [4.6–7.2] ng/ml, $P=0.03$), but comparable levels of phosphate (3.4 [0.7] vs 3.6 [0.6], $P=0.18$), 25OH-vitamin-D, parathyroid hormone and alkaline phosphatase. HypoP was observed in 7/36 KS (19%) and 3/32 controls (9%, not-significant). However, KS patients displayed a statistical trend for greater urinary phosphate excretion (TmP/GFR 2.9 [2.6–3.3] vs 3.3 [2.9–3.8], $P=0.07$). Phosphate metabolism parameters were not associated to testosterone concentrations or BMD. TmP/GFR correlated inversely with 25OH-vitamin-D ($r=-0.34$, $P=0.046$).
Conclusion
Persistent/recurrent, unexplained hypoP can be observed in 10% of KS patients. In KS a trend to increased urinary phosphate excretion is observed. However, these mild derangements in phosphate metabolism are not associated with BMD. Interestingly, the finding that phosphate urinary excretion is associated with 25OH-vitamin-D may suggest a role for FGF-23. This phosphatonin, indeed, inhibits both renal 1alpha-hydroxilaton of 25OH-vitamin-D and tubular resorption of phosphate, and should be evaluated in further studies.

Hypocalcemia after hyperthyroidism surgical treatment: Besides iatrogenic hypoparathyroidism

José Vicente Rocha[1], Marta Vaz Lopes[1], Mariana de Severino[1], Carolina Peixe[1], Ana Gomes[1], Maria Inês Alexandre[1] & Maria João Bugalho[1]
[1]ULS Santa Maria, Endocrinology, Diabetes and Metabolism, Lisboa, Portugal

Introduction
Hypocalcemia is a possible complication of thyroid surgery, usually assumed in the context of iatrogenic hypoparathyroidism. On the other hand, Hungry Bone Syndrome (HBS) is a complication classically described after surgical correction of primary hyperparathyroidism. It is characterized by hypocalcemia with normal or elevated PTH values (usually accompanied by hypophosphatemia and hypomagnesemia) and occurs consequently to a compensatory bone formation after a period of increased resorption. As increase bone resorption is present in hyperthyroidism, HBS can also follow hyperthyroidism surgery.
Methods
We retrospectively reviewed patients submitted to hyperthyroidism surgery in our center between 2020 and 2023. Exclusion criteria included concomitant hyperparathyroidism, bisphosphonate treatment, or previous therapy with radioactive iodine. Patients were subdivided into 2 subgroups; those who developed HBS (HBS+) and those who did not (HBS-). A comparative analysis including demographic, clinical and laboratory data was performed.
Results
A total of 98 patients were included. Thirteen patients underwent lobectomy (corresponding to toxic adenomas) and the remaining total thyroidectomy. The median age was 51 ± 14 years, 85% were female patients ($n=83$). Thirty-five out of forty-seven patients (74%) who developed hypocalcemia (calcium <8,4 mg/dl) had normal or high PTH values (HBS+). Subgroups were similar for age at diagnosis, hyperthyroidism duration, medical treatment duration, initial values of TRABs (in patients with Graves' disease), calcium, phosphorus and alkaline phosphatase. HBS + patients had higher fT4 (3.29 vs 2.6 ng/dl, $P=0{,}06$), ft3 (12.16 vs 10.78 ng/dl, $P=0.29$), and PTH (63 vs 48 pg/ml, $P=0.037$, $n=25$). Moreover, HBS+ patients needed higher doses of tiamazol (13 mg vs 9 mg, $P=0{,}014$).
Conclusion
In the current study, postoperative hypocalcemia was a common occurrence with most cases corresponding to HBS. Among those with hypoparathyroidism, there was recovery of hypocalcemia likely to correspond to transient hypoparathyroidism. Maximum needed tiamazol dosages and pre-operative PTH values were significantly different between HBS + and HBS- patients, suggesting that more severe hyperthyroidism is associated with HBS development.

Evaluating novel bone biomarkers (FGF2, lipocalin, sclerostin) in patients with tumor induced osteomalaî ia (TIO) and acromegaly

Sofia Gronskaia[1], Zamira Zuraeva[1], Larisa Nikankina[1] & Zhanna Belaya[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation

Background
Bone tissue is a non-classical endocrine organ, which controls phosphate metabolism through production of fibroblast growth factor 23 (FGF-23) mainly by osteocytes. Recent studies have demonstrated that specific proteins involved in paracrine regulation of bone remodeling can be measured in serum samples and may be involved in human metabolism.
Aims
To evaluate serum biomarkers related to endocrine and paracrine function of bone tissue in patients with phosphate metabolism disturbances such as FGF-23 hyperproduction in patients with tumor induced osteomalacia (TIO) or FGF-23 resistance due to acromegaly.
Materials and methods
This is a case-control study. Fasting serum samples were taken between 0800 and1000 h from patients with TIO, acromegaly and age- sex-matched healthy volunteers and stored at −40°C. Commercially available kits for enzyme-linked immunosorbent assay (ELISA) were used to determine the serum levels of iFGF-23 (Biomedica BI-20700), cFGF-23 (Biomedica BI-20702), FGF2 (R&DDFB50), lipocalin (Biovendor RD191102200R) and sclerostin (Biomedica BI-20492). Insulin-like growth factor-1 (IGF-1) was measured by immunochemiluminescence assays (Mediagnost E20). Non-parametric tests (the Kruskal-Wallis test and the Mann-Whitney test) were used to assess the differences between the groups of patients. One-way ANOVA and Bonferroni criterion were utilized to assess the differences between groups.
Results
We enrolled 71 subjects (mean age 48 ± 12 years): 23 patients suffered from TIO (group 1), 24 patients with acromegaly (group 2) and 24 matched healthy controls (group 3) with no differences among the groups in sex and age ($P=0.328$, 0.959 respectively). Patients with TIO had significantly higher iFGF-23 serum (median 86 [28;736]) and cFGF-23 (5 [3;14]) as compared to the other groups ($P=0{,}003$, $P<0{,}001$). Phosphorus (Pi) serum levels in subjects with TIO were significantly lower as compared to the other groups (median 0.49 [0.46;0.53] ($P<0.001$)). Patients with acromegaly had higher Pi - 1.4 [1.3; 1.6] ($P<0.001$) and IGF1 - 780 [650;810] ($P<0.001$) vs control. Nevertheless, we did not find statistically significant differences in the measured biomarkers: FGF2 ($P=0.38$), Lipocalin ($P=0.16$), sclerostin ($P=0.12$) within the three investigated groups.
Conclusion
TIO and acromegaly are associated with phosphate metabolism disturbances with no detected changes in the serum levels of FGF2, lipocalin or sclerostin.

The association of vasomotor symptoms with fracture risk and bone mineral density in postmenopausal women: a systematic review and meta-analysis of observational studies

Panagiotis Anagnostis[1,1], Konstantinos Lallas[2], Anna Pappa[1], Georgios Avgeris[1], Kristina Beta[1], Dimitrios Damakis[1], Eirini Fountoukidou[1], Maria Zidrou[1], Irene Lambrinoudaki[3] & Dimitrios Goulis[1]
[1]Aristotle University of Thessaloniki, 1st Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki, Department of Medical Oncology, School of Medicine, Thessaloniki, Greece; [3]National and Kapodistrian University of Athens, 2nd Department of Obstetrics and Gynecology, Athens, Greece

Purpose
Vasomotor symptoms (VMS) adversely affect postmenopausal quality of life. However, their impact on bone health has not been elucidated. This study aimed to systematically review and meta-analyze the evidence regarding the association of VMS with fracture risk and bone mineral density (BMD) in peri- and postmenopausal women.
Methods
A literature search was conducted in PubMed, Scopus and Cochrane databases until 31 August 2023. Fracture, low BMD (osteoporosis/osteopenia) and mean change in lumbar spine (LS) and femoral neck (FN) BMD were assessed. The results are presented as odds ratio (OR) and mean difference (MD), respectively, with a 95% confidence interval (95% CI). The I2 index quantified heterogeneity.
Results
Twenty studies were included in the qualitative and 12 in the quantitative analysis ($n=49\,659$). No difference in fracture risk between women with and without VMS was found ($n=5$, OR 1.04, 95% CI 0.93–1.16, I2 16%). However, VMS were associated with low BMD (n=5, OR 1.54, 95% CI 1.42–1.67, I2 0%). Patients with VMS had lower LS BMD than those without VMS (MD -0.019 g/cm^2, 95% CI -0.03 to -0.008, I2 85.2%). In contrast, there was no difference in FN BMD between groups (MD -0.010 g/cm^2, 95% CI -0.021 to 0.001, I2 78.2%). These results were independent of VMS severity, age and study design. When the analysis was confined to studies that excluded menopausal hormone therapy use, the association with BMD remained significant.
Conclusions
The presence of VMS compromises bone health in postmenopausal women, since it is associated with low BMD.

22q11.2 deletion syndrome diagnosed in the context of seizure and hypocalcemia in adulthood

Maria Galani[1], Grigoris Effraimidis[1,2], Ioannis Gkountios[1], Eleni Georgiou[1], Anastasia-Konstantina Sakali[1], Dimitra Pappa[1], Eleftheria Barmpa[1], Nektarios Adamopoulos[1] & Alexandra Bargiota[1,2]
[1]Larissa General University Hospital, Department of Endocrinology and Metabolic Disorders, Larissa, Greece; [2]University of Thessaly, School of Health Sciences, Faculty of Medicine, Larissa, Greece

Introduction
The 22q11.2 deletion syndrome (22q11.2DS) caused by a microdeletion of the 22q11.2 region of chromosome 22 is the most common deletion in humans causing a variety of disorders, including DiGeorge syndrome (OMIM #188400), velocardiofacial syndrome (OMIM #192430) and distal chromosome 22q11.2 deletion syndrome (OMIM #611867). Most individuals diagnosed with this condition are identified in early childhood and the diagnosis in adults is uncommon. It is characterized by a specific facial phenotype, and structural and functional abnormalities in the cardiac and endocrine systems.
Case
A 42-year-old female was admitted in the emergency room due to loss of consciousness followed by grand mal epileptic seizure. Prior to the episode the patient felt dizziness and nausea. Clinical examination revealed postural hypotension, systolic murmur 1-2/6, strabismus, dental deformities, and numbness of the upper limps, while Chvostec and Trousseau's sign were not present. Chest X-ray showed an increased cardiothoracic index and no electrocardiographic or echocardiographic abnormalities were found. Laboratory tests revealed primary hypoparathyroidism with total calcium 5.1 mg/dl [ref. range: 8.8–10.4], phosphorus 5.76 mg/dl [2.5–4.5], parathyroid hormone 6.8 pg/ml [15–65] and 25(OH)D3 11.5 ng/ml. On admission she was treated with IV calcium gluconate and fluids, and during hospitalization she was started on oral calcium, magnesium, alfacalcidol and cholecalciferol. The patient had a history of epilepsy on systematic medication since childhood. She displayed a mild intellectual disability, speech sound disorders and history of anxiety and psychosis. She had slight facial dysmorphia (long face, hypertelorism, ear helix folded) and normal stature and had performed surgical extraction of the majority of her teeth, due to jaw malocclusion and enamel hypoplasia. No history of cervical surgery or irradiation, heart disease or recurrent infections was reported. Basal ganglia calcification was shown in brain CT. Taken into consideration the patient's history, facial features and clinical and biochemical (primary hypoparathyroidism) manifestations, 22q11.2DS was suspected. Fluorescence in-situ hybridization (FISH) revealed deletion of 22q11.2 (46,XX.ish del(22)(q11.2)(D22S75 -), confirming the diagnosis.
Discussion
We report the case of an adult woman diagnosed with 22q11.2DS at the age of 42 in the context of syncope and seizures due to severe hypocalcaemia, highlighting the need for clinicians to be aware of the manifestations of the syndrome in adults, as well as the role of endocrinologists in the correct diagnosis and treatment of these patients. Confirmation of the diagnosis allows the initiation of appropriate treatment and multidisciplinary follow-up.

Hyperostosis frontalis interna – a case of Morgagni–Stewart–Morel syndrome

Vlad Radulescu[1], Anastasia Stanescu[1], Cristina Stancu[1] & Corin Badiu[1,2]
[1]C.I. Parhon National Institute of Endocrinology, BucureŞti, Romania; [2]Carol Davila University of Medicine and Pharmacy, BucureŞti, Romania

Introduction
Morgagni–Stewart–Morel syndrome is defined as the absolute presence of hyperostosis *frontalis interna*, associated with metabolic, endocrine, and neuropsychiatric disorders. There are very few cases reported in the literature and some experts do not even recognize it but the exact etiology of the syndrome remains unclear; some theories relate to estrogen dysfunction, obesity and leptin dysfunction, and genetic alterations.
Case report
We present the case of a 33 year old, Caucasian woman, referred to us for frontal cranial hyperostosis associated with intense, invalidating headaches with nausea, vomiting, tremor and palpitations. She was seen by the neurology department that confirmed the frontal cranial hyperostosis with CT and MRI imaging. She was already in treatment with Tramadol 150 mg 4 times a day, Carbamazepine 200 mg twice a day, Metamizole 400 mg + Caffeine 60 mg + Drotaverine 40 mg three times a day, Sumatriptan one administration when needed. From the patient's history we note a lost pregnancy due to oligohydramnios at 30 weeks, allergic bronchitis, left micropolycystic ovary and secondary amenorrhea for 2 years at the moment of her presentation in our clinic. The clinical exam showed an altered general state due to constant multidrug resistant headache, photophobia, hyperemic face, grade II obesity (BMI = 39 kg/m^2), acanthosis nigricans in the nucal area, accelerated intestinal movements, normal blood pressure and pulse with no other modifications. She had hypercolesterolemia, HbA1c = 6.1% and an insufficient status of vitamin D3 = 17.2 ng/ml, with no other modified parameters on lab work. The bone resorbtion and formation markers were in the normal range. As far the treatment is concerned, we had to choose between neurosurgery of the frontal bone to reduce the frontal hyperostosis or to find a medical approach, to stop the bone formation process. We decided to administer one vial of zolendronic acid 4 mg/5 ml, with benefit in pain reduction and mild flu-like syndrome 24 h after administration. Six months later, the patient comes for a check-up and we note a BMI = 32.08 kg/m^2, a significant decrease in the headaches intensity with a significant reduced use of pain medication, no more tremors, normal menstrual cycles and a CT that showed stationary frontal hyperostosis.
Discussion
Morgagni–Stewart–Morel syndrome is a rare entity, mostly diagnosed on the clinical setting, with speculative theories about its pathogenesis. Its management is usually symptomatic, but in this particular case we needed a more specific approach as the use of the pain medication was very high and the quality of life was severely affected.

Clinical characterization of a cohort of patients with multiple endocrine neoplasia syndrome type 1 (MEN1): role of the MEN1 gene mutation on the phenotypic expression of the syndrome

Laura Pierotti[1], Elena Pardi[1], Chiara Sardella[2], Simone/////Della Valentina[1], Anna Dal Lago[1], Paolo Piaggi[3], Fausto Bogazzi[2], Maria Adelaide Caligo[4] & Filomena Cetani[2]
[1]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [2]University of Pisa, Unit of Endocrinology, Pisa, Italy; [3]University of Pisa, Department of Information Engineering, Pisa, Italy; [4]University of Pisa, Laboratory of Molecular Genetics, Pisa, Italy

The clinical diagnosis of MEN1 is established when a proband manifests at least two of the manifestations of the triad (Primary Hyperparathyroidism (PHPT), Pituitary adenoma, Gastroenteropancreatic Neuroendocrine Tumor (GEP-NET)). Typically, it is a familial disease (F-MEN1), while in about 10% of cases the disease is sporadic. In sporadic forms (S-MEN1), up to 70% of patients may exhibit a negative genetic analysis (*MEN1*-negative). These patients seem to have distinct features compared to those who carry *MEN1* mutation (*MEN1*-positive). This study aims to assess the clinical phenotype of *MEN1*-negative and *MEN1*-positive patients in terms of endocrine and non-endocrine manifestations and survival. This is a retrospective study including 187 patients (105 index cases and 82 relatives) with S-MEN1 and F-MEN1 followed at our clinic from January 1993 to January 2023. One hundred-forty (75%) were *MEN1*-positive and 47 (25%) MEN1 negative. The median observation time was 120 months (IQR 60-190) for *MEN1*-positive and 122 months (IQR 75-178) for *MEN1*-negative. *MEN1*-positive exhibited a significantly lower mean age of onset of PHPT (36.3 + 14.2 vs 49.5 + 13 years; $P < 0.00001$), pituitary adenoma (36.2 + 13.5 vs 44.2 + 14.4 years; $P = 0.006$), and GEP-NET (39.7 + 13 vs 47.8 + 11 years; $P = 0.008$). None of the *MEN1*-negative patients had GEP-NET before 30 years. *MEN1*-positive patients also displayed a significantly lower age of onset of the first (36 + 14.3 vs 46 + 14.8 years; $P < 0.0001$), second (39.7 + 14.1 vs 50.2 + 13.1 years; $P < 0.0001$), and third (42 + 14 vs 54.4 + 11.4 years; $P = 0.001$) endocrine manifestations. A higher prevalence of GEP-NET was found in *MEN1*-positive than *MEN1*-negative (61% vs 29%; $P = 0.02$). Additionally, none of the *MEN1*-negative presented metastatic GEP-NET (0% vs 16%; $P < 0.001$). Although no difference in the median number of manifestations was observed between the two groups ($P = 0.06$), *MEN1*-positive exhibited a greater distribution of the number of manifestations compared to *MEN1*-negative (1 to 6 vs 2 to 4, respectively; $P = 0.005$). *MEN1*-positive had a higher prevalence of lipomas ($P = 0.01$) and angiofibromas ($P = 0.01$) compared to *MEN1*-negative. No difference in survival rate was found between the two cohorts. However, in *MEN1*-negative patients none died for MEN1-related causes, whereas in *MEN1*-positive 7 patients died for MEN1-related causes. The overall findings suggest that *MEN1*-negative patients exhibit a less aggressive phenotype than *MEN1*-positive. Consequently, they may benefit from a less intensive follow-up. This underscores the need to update the MEN1 guidelines to differentiate the diagnostic and therapeutic workout in *MEN1*-negative and MEN1-positive.

Investigating the etiology of non-surgical hypoparathyroidism: insights from a sponsored genetic testing program

Michael Mannstadt[1], Claudio Marelli[2], Ananth Sridhar[3], Lyndsay Smith[3], Mary Scott Roberts[3], Scott Adler[3] & Arun Mathew[3]
[1]Massachusetts General Hospital and Harvard Medical School, Endocrine Unit, Boston, USA; [2]BridgeBio Pharma Inc., Sestri Levante, Italy; [3]Calcilytix Therapeutics Inc., San Francisco, USA

Hypoparathyroidism is a rare endocrine disorder characterized by inadequate production of parathyroid hormone to maintain normal blood calcium levels. Hypoparathyroidism is most frequently caused by damage to or removal of the parathyroid glands but can also be associated with genetic etiologies. Genetic forms of hypoparathyroidism can present as isolated or as part of a syndrome and include disorders of parathyroid gland formation, parathyroid hormone secretion, and damage to the parathyroid gland through autoimmunity. A sponsored genetic testing program in the United States was made available for patients with suspected genetic hypoparathyroidism who met program eligibility criteria and included those with an idiopathic diagnosis. The next-generation sequencing panel leveraging a whole exome backbone with copy number variant detection has evolved to include 26 genes known to be associated with hypoparathyroidism: *ACADM*, *AIRE*, *ATP1A1*, *CASR*, *CHD7*, *CLDN16*, *CLDN19*, *CNNM2*, *DHCR7*, *EGF*, *FAM111A*, *FXYD2*, *GATA3*, *GCM2*, *GNA11*, *HADHA*, *HADHB*, *KCNA1*, *NEBL*, *PTH*, *SEMA3E*, *SLC12A3*, *SOX3*, *TBCE*, *TBX1* and *TRPM6*. A total of 169 samples over a 2-year period were tested from participants with a mean±SD age of 23.4±20.4 (range 0-81). With the multi-gene panel, 77 variants were identified in 64 individuals (37.9%) which have been classified as pathogenic, likely pathogenic, and variants of uncertain significance. In order of frequency, the number of individuals with detected variants are as follows: *CASR* 56.3% (36/64), *AIRE* 12.5% (8/64), *TBX1* 9.38% (6/64), *GATA3* 7.8% (5/64), *GNA11* 6.25% (4/64), *CHD7* 3.13% (2/64), *FAM111A* 3.13% (2/64), *PTH* 3.13% (2/64), *ACADM* 1.6% (1/64), *GCM2* 1.6% (1/64), *HADHB* 1.6% (1/64) and *TBCE* 1.6% (1/64). Of note, 5 individuals had variants identified in more than 1 gene. Within this group of participants, the most frequent genetic form of hypoparathyroidism was found to be autosomal dominant hypocalcemia type 1 (ADH1), caused by gain-of-function mutations in the *CASR* gene (21.3%; 36/169). An ongoing global Phase 3 study is investigating an oral calcilytic that functions as a negative allosteric modulator of the calcium-sensing receptor, potentially the first targeted treatment for ADH1, which affected over half of individuals with identified variants. Genetic testing should be considered for all patients with non-surgical hypoparathyroidism as identified variants in known genes can inform medical management of patients. Genetic testing may uncover the underlying etiology of nonsurgical hypoparathyroidism and can help confirm clinical diagnosis, guide medical treatment, identify affected family members, and assist in determining eligibility for participation in clinical studies.

Optimal strategies for vitamin D supplementation in the management of severe vitamin D deficiency

Ashraf Soliman, Fawzia Alyafei, Nada Alaaraj, Noor Hamed & Shayma Mohamed
Hamad General Hospital, Pediatric Endocrinology, Doha, Qatar

Introduction
The uncertainty surrounding the optimal dose to rectify severe vitamin D deficiency (VDD) necessitates further investigation.
Aim
To review and analyze various vitamin D (VD) supplementation doses, durations, and their effects on 25-hydroxyvitamin D (25OHD) levels, along with their biochemical and clinical outcomes, in the management of VDD.
Methods
We reviewed intervention studies targeting VDD from databases (PubMed, Google Scholar, ResearchGate, and Scopus, focusing on studies published after 2010.
Results
Twenty-two studies were reviewed. Comparing different regimens, VD3 showed superiority over VD2 in doses of 1600 IU and 50 000 IU once daily and once monthly, respectively, at the conclusion of a year. For adults, the widely adopted 'loading dose' approach (50 000 IU VD orally once weekly for 2–3 months) indicated a minimum cumulative dose of 600 000 IU for achieving an end-of-treatment 25OHD level exceeding 30 ng/ml. The average daily dose for significant serum 25OHD increase was 4707 IU/day for a large adult population. A predictive equation for VD dosage suggested that the required dose = [(8.52 – Desired change in serum 25OHD level) + (0.074 × Age) - (0.20 × BMI) + (1.74 × Albumin concentration) - (0.62 × Starting serum 25OHD concentration)] / (−0.002). Another simplified equation for adults proposed a loading dose formula: IU = 40 × (75 nmol/l – serum 25OHD) × body weight. Two prospective studies involving infants and adolescents who received intramuscular cholecalciferol injections (10 000 IU/kg) demonstrated significant improvements in biochemical and clinical outcomes, with most achieving serum 25OHD levels ≥ 20 ng/ml three months post-injection. In older women, a daily oral dose of 50 000 IU calciferol for ten days elevated 25OHD from 8 ng/ml to 21 ng/ml. Patients treated with cumulative doses of 100 000, 150 000, and 200 000 IU displayed corresponding increases in mean serum 25OHD levels. Reviews of 49 and 76 trials indicated an increase of 2 ng/ml per 100 IU/d of ingested VD and an average rise of 0.78 ng/ml per 40 IU of VD3 supplement daily, respectively. In a study with sixty adolescents, those receiving 300 000 IU VD3 followed by 50 000 IU monthly, or 100 000 IU every three months had higher 25OHD levels (30 ng/ml) than those receiving 50 000 IU every three months or 100 000 IU every three months (15 ng/ml).
Summary
Utilizing a megadose oral or intramuscular loading regimen of VD (300 000 IU, 10 000 IU/kg) followed by daily doses of 1000–2000IU or 50 000IU monthly seems effective for managing severe VDD.

Formation of new bone lesions in an adult patient with fibrous dysplasia/McCune–Albright syndrome over 19 years and the effect of postoperative hypoparathyroidism on bone turnover markers – case report

Katerina Zajickova[1] & Josef Vcelak[2]
[1]Institute of Endocrinology, Clinical endocrinology, Prague 1, Czech Republic; [2]Institute of Endocrinology, Molecular endocrinology, Prague 1, Czech Republic

Introduction
Fibrous dysplasia (FD) is a rare mosaic disorder originating from the activating mutation in the gene encoding the alpha subunit of the Gs stimulatory protein (*GNAS*) in multipotent skeletal stem cells that cannot differentiate into bone-forming osteoblasts. FD is thought to be a self-limited disease with a peak of activity in childhood and a waning of activity in adulthood.
Case presentation
We report a 39-year-old woman with mild polyostotic FD and precocious puberty in her history. At the age of 31, the patient underwent total thyroidectomy for papillary thyroid cancer, complicated by postoperative permanent hypoparathyroidism. The ^{18}F- NaF PET/CT, carried out to monitor skeletal activity, showed several new skeletal lesions that were not documented on the original PET/CT with ^{18}F-fluorodeoxyglucose performed 19 years ago when FD was diagnosed. Four new lesions were localized in the ribs, two in the vertebrae and one in the symphysis, with corresponding changes in the CT image characteristic of FD. The patient had no clinical evidence of fractures and the thyroid cancer was in remission at the time of the scan. In contrast to polyostotic FD, osteocalcin, alkaline phosphatase and collagen beta crosslaps, which reflect bone remodeling and should correlate with disease extent, were within normal ranges in our patient. The only exception was procollagen 1 N-terminal propeptide (P1NP), which was consistently 3–4 times higher (mean value of P1NP in years 2021–2023: 219.2 ng/ml, normal values 15.3–58.8 ng/ml).
Conclusion
The present case documents the evolution of new skeletal lesions on ^{18}F-NaF PET/CT imaging in an adult patient with mild FD/ McCune-Albright syndrome and shows that the skeletal burden in FD may not be completely stable in adulthood. Furthermore, concomitant postoperative hypoparathyroidism modulates the patient's bone turnover and may highlight a possible role of parathyroid hormone in skeletal involvement in FD. Supported by MH CZ - DRO (Institute of Endocrinology – EÚ, 00023761).

The incidence of fractures in cancer patients initiating immune check-point inhibitors

Ruth Karov, Eugene Feigin, Etty Osher, Yona Greenman & Vanessa Rouach
Tel aviv Souraski medical center, Institute of Endocrinology, Diabetes, Metabolism and Hypertension

Introduction
Immune check-point inhibitors (ICI) can cause adverse events in many organs due to the activation of T-cells. Data on the effect of ICI on bones and incidence of fracture is still scarce.

Aim
To quantify the rate of osteoporotic fracture before and after the use of ICI in cancer patients.
Methods
We retrospectively retrieved pertinent data of all patients who were treated with ICI between 2015 and 2023 at the Tel-Aviv Souraski Medical Center. Healthcare administrative databases were assessed for the presence of fracture diagnostic codes in the year prior to and up to two years after ICI initiation. Fracture rate was stratified based on the time-period before and after ICI initiation.
Results
The study cohort consisted of 1349 ICI users. The mean age was 67.7 (10.9) years, 58% were male, 35.5% were active smokers, 18% were diabetics, mean BMI was 25.7 (6.8) and mean Charlson Comorbidity Index was 4.2 (2.3). Most patients were treated with an anti-PD-1 agent (82.1%), for 17.6% it was the only therapy. The fracture rate in the year prior to ICI initiation was 8.9 per 1000 patient-years. The fracture rate in the year after ICI initiation was 12 per 1000 patient-years. The fracture rate in the second year after ICI initiation was 18.9 per 1000 patient-years. In the first and second years after ICI treatment initiation, incidence rates of fractures were higher compared to the last year prior ICI treatment, IRR = 1.34 (95% 0.64–2.85) and IRR = 2.13 (95% 1.02–4.41), respectively. Only 12.5% of the patients who sustained a fracture received an antiresorptive treatment.
Conclusions
Fracture risk may be increased in cancer patients after initiation of ICI. Prospective studies monitoring BMD in addition to fracture rate are needed. An effort should be made to identify patients at risk for fractures and offer adequate therapy.

Background
Primary hyperparathyroidism (PHPT) is the third most common endocrine disease and the most frequent cause of hypercalcemia in outpatients with an estimated incidence of 20/100 000/year and prevalence in the general population of 0.1%–0.4%. Parathyroidectomy (PTX) is the only treatment that can achieve PHPT cure but a few medications can be used to control calcium levels, bone and kidney impairment.
Aims
1) To assess costs associated with the different treatment options for PHPT (PTX, cinacalcet, bisphosphonates, denosumab, and thiazides); 2) To assess the cost-utility profile of the alternatives to inform the policy making; 3) To provide comprehensive recommendations for the most cost-utility and efficient approaches to managing PHPT in the Italian healthcare setting.
Method
A systematic literature review and a survey among the panel were performed to address drivers that contribute to each therapeutic option. Economic analysis was carried out with Activity Based Costing methodology.
Results
The estimated cost of PTX arm amounts to an average of € 4588. This amount includes: diagnostic assessment, surgery, post-operative follow-up, indirect costs for patient and caregiver, and costs due to the acute and chronic post-operative complications (added for the fraction of patients undergoing those complications). Taking into account the expected additional costs in the first year for the complementary services, the total expenditure is € 5714. In the case of non-surgical policy, the estimated annual cost is a mean € 197 and € 953 for surveillance and drug treatments (including cost of drugs and follow-up in the proportion of patients treated with each drug), respectively. As surgery for sporadic PHPT is performed at a mean age of 55 years, the residual time horizon points to about 30 years. The estimated cost for the same 30-year time horizon amounts to € 28 590 for the patients followed up with medications and to € 5910 for surveillance alone (Table 1).

Approach	Annual cost	30-year cost
Surgery	€ 5116	€ 5116
Surveillance	€ 197	€ 5910
Medication	€ 953	€ 28 590

Conclusions
Despite limitations of this analysis, we can believe that the 30-year excess costs for patients who are managed pharmacologically in comparison to those who are surgically treated is € 23 474 (28 590 – 5116). If we assume that at least 10% of patients currently treated pharmacologically (estimated to be near 1500 in Italy) could be switched to surgical strategy, we can estimate an annual saving for National Health System exceeding € 3 500 000 (23 474 × 150 = 3 521 100).

Bone responsiveness in PTH resistance syndromes: preliminary data of a single centre retrospective study

Giulia Del Sindaco[1,2], Angela Pagnano[1,2], Arianna Cremaschi[2] & Giovanna Mantovani[1,2]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Ern Bond, Milan, Italy

Inactivating PTH/PTHrP signaling disorders (iPPSDs, historically named pseudohypoparathyroidism (PHP)) are primarily characterized by end-organ resistance to parathormone (PTH), which leads to hypocalcemia, hyperphosphatemia and elevated PTH levels. The extent to which bone is responsive to PTH in these patients remains controversial. Until now, variable bone phenotypes have been associated to different subtypes of iPPSDs and increased concentrations of bone turnover markers (BTMs) are described. Persistently elevated PTH levels may cause bone abnormalities similar to what observed in hyperparathyroidism (osteitis fibrosa and rickets). Moreover, data about bone mineral density (BMD) are sparse and report both normal, increased or decreased values. Aim of the present study is to characterize bone metabolism in a cohort of iPPSD patients. We collected data about BMD, vertebral morphometry and BTMs to describe bone abnormalities, aiming to investigate whether there is a relationship with PTH levels or iPPSD subtype. We enrolled 21 patients (62% females, mean age 39.6±11.3 years) diagnosed with iPPSDs and regularly followed-up at our Centre. Six patients were diagnosed with iPPSD2/PHP1A (28.6%), 13 patients with iPPSD3/PHP1B (61.8%), 1 patient with iPPSD4/Acrodysostosis type 1 and 1 patient had no detected mutations. In our cohort PTH levels show significant positive correlation with both CTX and bone alkaline phosphatase (bALP) levels (CTX: $r=0.482$, $P=0.02$; bALP: r=0.508, $P=0.02$). Bone turnover markers were not significantly different between iPPSD2/PHP1A and iPPSD3/PHP1B patients. As for BMD values, mean lumbar, femoral neck and total hip scores were 1.083± 0.18, 0.856±0.18 and 0.968±0.18 g/cm^2 respectively, with no significant difference between iPPSD2/PHP1A and iPPSD3/PHP1B patients. One patient (5%) was diagnosed with osteoporosis and one patient with osteopenia according to Z and T-scores respectively, as expected for age and sex. Fractures were described in 2 patients with pre-existing comorbidities. As for vertebral morphometry, we described rickets-like signs in 39% (7/18) of patients, with no difference among various iPPSD subtypes. It is worth report one patient affected by iPPSD3/PHP1B, who presented PTH > 1000 pg/ml at diagnosis with concomitant cystic bone lesions (compatible with brown tumors/osteitis fibrosa cystica) at multiple sites. In conclusion, our study confirms previous reported data about bone metabolism and phenotypes in iPPSDs. According to BTMs and skeletal remodeling, bone seems to be responsive to PTH in both iPPSD2/PHP1A and iPPSD3/PHP1B. Although these are preliminary data that we are expanding through comparative studies, they could have clinical impact on management, suggesting to control PTH levels on optimal range to avoid negative impact on bone.

Clustering of clinical and biochemical data for defining primary hyperparathyroidism 'phenotypes' and predicting parathyroid imaging results

Karolina Kucharczyk[1], Anna Drynda[1], Jacek Podlewski[2], Malgorzata Trofimiuk-Muldner[3] & Alicja Hubalewska-Dydejczyk[3]
[1]Jagiellonian University Medical College, Students' Scientific Group at the Department of Endocrinology, Krakow, Poland; [2]Dover Fueling Solutions, Krakow, Poland; [3]Jagiellonian University Medical College, Department of Endocrinology, Krakow, Poland

Introduction
Primary hyperparathyroidism (PHPT) is a prevalent endocrinopathy typically identified through biochemical testing. PHPT is characterized by hypercalcemia accompanied by increased or inappropriately normal plasma parathyroid hormone (PTH) concentrations. Preoperative imaging is conducted when surgery is indicated to pinpoint parathyroid adenomas. MIBI scintigraphy is highly specific and sensitive in diagnosing PHPT, with a higher adenoma detection rate demonstrated for patients with larger lesions or higher blood calcium concentrations. The study aimed to investigate the relationship between the results of biochemical tests and clinical manifestations (PHPT 'phenotype') and the rate of positive results of parathyroid [99mTc]Tc-Sestamibi scintigraphy.
Materials and methods
This was a retrospective study of patients suspected of PHPT who underwent parathyroid [99mTc]Tc-Sestamibi SPECT/CT scintigraphy between 2010 and 2022. Patients' cluster analysis was conducted based on PTH, serum calcium (Ca), and phosphate (Pi) concentrations to find distinct patterns in these parameters. Furthermore, we compared the distributions of additional patients' attributes, including gender, lesion size, serum vitamin D, ALP concentrations, urinary calcium, urolithiasis prevalence, as well as parathyroid scintigraphy results.
Results
Five hundred and thirteen patients were divided into 5 clusters using different algorithms. Finally, clusters from K-means methods were selected based on statistical metrics and expert interpretation. Those were organized in ascending order of positive scintigraphy results, with Cluster 5 reaching a 79.5% positivity rate and median values of PTH – 315.5 pmol/l, Ca – 2.96 mmol/l, and Pi – 0.7 mmol/l. As the proportion of positive imaging outcomes declined, median PTH and calcium concentrations decreased while phosphate concentrations increased. In Cluster 1, with 30% of positive imaging results, medians were as follows: PTH – 79.06 pmol/l, Ca – 2.55 mmol/l and Pi – 1.1 mmol/l. A comparative analysis of various clinical and biochemical parameters revealed statistically significant differences between clusters. Patients from Clusters with a higher frequency of positive scintigraphy were significantly more likely to be males, vitamin D deficient, with higher ALP concentrations, diagnosed with urolithiasis, and harbouring larger lesions.
Conclusions
PHPT 'phenotypes' correlated with disease severity are evidently linked to parathyroid scintigraphy detection rate. Therefore, it is crucial to know that false-negative imaging is more likely in PHPT patients with minor deviations in laboratory tests. Judicious assessment of biochemical and clinical features may limit the number of redundant parathyroid scintigraphies and, in consequence, reduce healthcare costs and unnecessary radiation exposure.

Mild hyponatremia is not associated with degradation of trabecular bone microarchitecture despite bone mass loss

Fabio Bioletto, Michela Sibilla, Alessandro Maria Berton, Nunzia Prencipe, Emanuele Varaldo, Federica Maiorino, Daniela Cuboni, Alessia Pusterla, Valentina Gasco, Silvia Grottoli, Ezio Ghigo, Emanuela Arvat, Massimo Procopio & Marco Barale
University of Turin, Department of Medical Sciences, Turin, Italy

Context
Hyponatremia is associated with an increased risk of osteoporosis and fractures, and in recent years increasing evidence is accumulating in favor of a likely causal relationship between hyponatremia and bone loss. In rat models, the induction of hyponatremia enhances osteoclast activation and bone catabolism. In humans, the correction of hyponatremia by tolvaptan or SGLT2-inhibitors has a favorable effect on bone turnover markers, possibly due to an interplay both with osteoblast and osteoclast activation. The impact of hyponatremia on non-invasive indices of bone quality, however, is unknown.
Objective
To evaluate whether trabecular bone microarchitecture, assessed non-invasively by trabecular bone score (TBS), is altered in patients with hyponatremia.
Methods
We conducted a cross-sectional analysis of the 2005–2008 cycles of the National Health and Nutrition Examination Survey (NHANES), in which TBS measurement was performed. The main outcome measures were TBS values and bone mineral density (BMD) T-scores at the lumbar spine, total hip and femoral neck.
Results
A total of 4204 subjects aged 50 years or older were included (4041 normonatremic, 163 hyponatremic). The mean serum sodium value in hyponatremic patients was 132.6±2.1 mmol/l, with sodium levels in the range of mild hyponatremia (130–134 mmol/l) in 90.8% of cases. Univariate analyses did not show any difference in TBS between patients with and without hyponatremia (1.308±0.145 vs 1.311±0.141, $P=0.806$). Hyponatremic subjects had lower BMD T-score at total hip (−0.70±1.46 vs −0.13±1.32, $P<0.001$) and femoral neck (−1.11±1.26 vs −0.72±1.14, $P=0.004$), while no difference was observed at lumbar spine (−0.27±1.63 vs −0.31±1.51, $P=0.772$). After adjustment for relevant confounders (i.e.: age, sex, ethnicity, smoking, body mass index, 25-hydroxyvitaminD, diabetes, chronic kidney disease, use of loop, thiazide or potassium-sparing diuretics, history of chronic glucocorticoid treatment), hyponatremia was confirmed as an independent predictor of lower BMD T-score at the total hip ($\beta=-0.20$, 95%CI:[−0.39,−0.02], $P=0.029$), while the significance was lost at the femoral neck ($P=0.308$). The lack of association between hyponatremia and lumbar spine BMD ($P=0.236$) or TBS ($P=0.346$) was confirmed.

Conclusions
This study confirms that hyponatremia is associated with a reduced bone density, particularly at the total hip. On the other hand, no significant impact on trabecular bone microarchitecture, evaluated by TBS, was found. The lack of prospective data does not allow to assess the prognostic role of these parameters as predictors of incident fractures, but the available evidence may suggest, differently from other forms of secondary osteoporosis, a possible limited added value of TBS in this setting.

The clinical presentation of primary hyperparathyroidism: effects of obesity and vitamin D deficiency

Vit Zikan[1,2], Jan Hrdlicka[3], Judita Klímová[4], Václav Hána Jr[1], Monika Wagnerova[5], Petr Libánský[6], Dana Michalska[1], Renata Vlasakova[1] & Ivan Raska Jr[1]
[1]General University Hospital in Prague, Department of Internal Medicine 3, Prague, Czech Republic; [2]General University Hospital, Internal Medicine 3, Prague, Czech Republic; [3]General University Hospital in Prague, Department of Radiology, Prague, Czech Republic; [4]Military University Hospital in Prague, Department of Internal Medicine, Prague, Czech Republic; [5]General University Hospital in Prague, Department of Radiology and Institute of Nuclear Medicine, Prague, Czech Republic; [6]Motol University Hospital in Prague, Department of Surgery III, Prague, Czech Republic

Our understanding of modifiable risk factors for developing primary hyperparathyroidism (PHPT) may support interventions to prevent the development of the disease or reduce its severity and deepen our insights into its pathogenesis. Obesity has been associated with elevated serum parathyroid hormone (PTH) in the general population and may also alter the clinical presentation in patients with PHPT.
Objectives
The objectives of the study were to compare the clinical, radiological and biochemical presentation of obese vs nonobese PHPT patients and to assess the impact of obesity and vitamin D deficiency on the presentation of PHPT.
Methods
Calcium metabolism and bone turnover markers (BTMs) S-CTX and PINP were analysed. Bone mineral density (BMD) and body composition was assessed by dual-energy X-ray absorptiometry (DXA). Clinical fractures were assessed from medical records.
Results
One hundred forty-four PHPT patients (79% postmenopausal women) were included in this analysis. Sixty-three percent of patients fulfilled the criteria for asymptomatic PHPT (84 patients with classic PHPT and 11 patients were normocalcemic, NHPT). Obesity was diagnosed in 64% of NHPT patients and in 44% of PHPT. The obese patients showed higher BMD in total and femoral neck and a lower rate of osteoporosis (41.8% vs 60.7%); however higher prevalence of clinical vertebral fractures was observed in obese women (9% vs 3.6%). Regarding the BTMs, it was found to be significantly lower values in women with obesity ($P < 0.05$); however, the comparison of those with severe deficient (<25 nmol/l; 18.8%) vs replete (≥ 75 nmol/l; 15%) 25OHD demonstrated more severe PHPT as reflected by significantly higher PTH, Ca and BTMs. Conclusions: In PHPT and NHPT patients, obesity is a protective factor for hip BMD; however, our findings of higher number of vertebral fractures in obese women suggest that BMD does not adequately assess the risk for vertebral fractures. Severe vitamin D deficiency may increase PTH and bone loss.

The impact of diabetes mellitus on morbidity and mortality in patients with covid-19 pneumonia. retrospective study

Elona Xhardo Hysenbelli[1,1], Bledar Hysenbelli[2], Sofiela Telo[3] & Dorina Ylli[4]
[1]Sushn, Internal Medicine, Tirana, Albania; [2]Qsut, Emergency Care Department, Tirana, Albania; [3]Sushn, Epidemiologu and Statistics, Tirana, Albania; [4]Qsut, Endocrinology, Tirana, Albania

Background
The relationship between diabetes and COVID-19 is known to be bidirectional. Diabetes Mellitus (DM) and hyperglycemia are important risk factors for poor outcomes in hospitalized patients with coronavirus disease 2019 (COVID-19) pneumonia.
Objective
This study aimed to evaluate the impact of glycemic control pre- and after admission, on outcomes of hospitalised patients with COVID-19 pneumonia.
Methods
A total of 400 hospitalized patients with confirmed COVID-19-pneumonia during the interval 2020-2021 in e tertiary Hospital Center in Albania were included in the present study. Diabetic patients were classified in two groups, new onset and pre-existing diabetes. The outcomes were compared with non-DM patients with COVID-19 pneumonia. At the same time we analysed how mean glucose during the hospitalization period could influence final outcomes regarding in-hospital case fatality and in-hospital adverse events.
Results
Overall, 400 hospitalizations with confirmed COVID-19 pneumonia were documented. COVID-19 patients with DM demonstrated an aggravated comorbidity profile, with a higher Charlson comorbidity index. Risk for acute respiratory distress syndrome (96% CI: 1.57–1.64), $P<0.001$), non-invasive ventilation (95% CI: 1.43–1.57), $P<0.001$ and mechanical ventilation (95% CI: 1.39–1.48), $P<0.001$ were increased in DM patients. DM was an independent risk factor for in-hospital complications like major cardiac events, acute kidney failure, and in-hospital mortality (OR: 1.24 (95% CI: 1.25–1.31), $P<0.001$) Severe hyperglycemia (mean blood glucose $>$ 250 mg/dl) on second day of hospitalization was associated with high mortality compared with patients with mean blood glucose around 140 mg/dl. In-hospital hypoglycemia events (blood glucose $<$ 70 mg/dl) was also associated with increased mortality.
Conclusion
In patients with COVID-19-pneumonia, DM is a important risk factor for adverse events and fatality. Severe hyperglycemia and hypoglycemia events after admission were both strong predictors of poor outcomes. Diabetics patients with COVID-19 are a vulnerable group that requires intense medical care and need to be strictly monitored during hospitalization.

Objective
For women with polycystic ovary syndrome (PCOS) weight gain and obesity exacerbate insulin resistance and increase the risk of type 2 diabetes and cardiometabolic diseases. The PCOS Phenotype in Unselected Populations (P-PUP) study includes individual participant data (IPD) from eleven well characterised, multiethnic and unselected populations globally. The aim of this study was to assess risk of obesity in women with and without PCOS according to ethnicity and age.

Methods
The dataset consisted of 9,930 unselected women, aged 15 to 60 years from Italy, Turkey, China, Iran, South Korea, United States of America, Russia and Nigeria. The women were categorized into those with PCOS (10.7%) and without PCOS (89.3%) according to Rotterdam criteria or National Institutes of Health Criteria (NIH). Multiple logistic regression was used to estimate odd ratios (ORs) with 95% confidence intervals (CI) for obesity (BMI >30 kg/m^2) comparing women with and without PCOS, adjusting for age and ethnicity. We performed sub-analyses according to ethnicity and age.
Results
Obesity was more common in women with PCOS (17.9%), compared to women without PCOS (14.4%) (aOR 1.6, 95% CI 1.3-1.9). We observed significant differences in the prevalence of obesity according to ethnic groups, being lowest for Asian (3.8%), followed by Middle Eastern (24.1%), Caucasian (29.1%) and Black women (33.8%). After adjusting for age, compared to Asian women with PCOS, the odds for obesity were higher for Middle Eastern women (aOR 6.3, 95% CI 3.6-11.9), Caucasians (aOR 9.5, 95% CI 4.8-18.9) and Black women (aOR 10.3, 95% CI 5.0-21.5) with PCOS. The risk for obesity in women with PCOS increased with age, being 14.5% for women aged 15-39 years and 48.6% for women aged 40-60 years (aOR 4.0, 95% CI 2.6-6.2).
Conclusion
In a large, unselected, multiethnic population obesity was more common in women with PCOS compared to women without PCOS. We observed significant differences in obesity by ethnicity, with Asian women with PCOS having the lowest odds and Middle Eastern, Caucasian and Black women all having higher odds for obesity. Compared to younger individuals with PCOS, those aged 40 to 60 years had a 4-fold risk for obesity.

Demographics and baseline characteristics of patients with charcot foot: a multi-center cohort analysis

Edward Jude[1], Christos Siafarikas[2], Robert Bem[3], Javier LaFontaine[4], Marie-France Kong[5], Tsvetalina Tankova[6], Pappachan Joseph[7], Ashu Rastogi[8] & Nicolaas Tentolouris[2]
[1]Tameside and Glossop Integrated Care NHS Foundation Trust, Ashton Under Lyne, United Kingdom; [2]National and Kapodistrian University of Athens, Athens, Greece; [3]Institute of Clinical and Experimental Medicine, Czech Republic; [4]utrgv school of podiatric medicine, San Antonio, United States; [5]leicester general hospita; l, leicester, United Kingdom; [6]medical universty of sofia, sofia, Bulgaria; [7]lancashire teaching hospitals, Preston, United Kingdom; [8]Postgraduate institute of Medical Education and Research, Chandigarh, India

Aims
Charcot foot (CF) is a rare complication of T2DM, progressively leads to bone deformities of the lower extremities. The aim of this study was to record baseline characteristics of patients with CF.
Patients and methods
A multicenter retrospective cohort study ($n=774$), including all patients diagnosed with CF from eight Diabetic Foot Clinics in 6 countries between 01/01/1996 and 31/12/2022, was performed. Data regarding duration and complications of DM, anthropometric, clinical and laboratory parameters were obtained from the medical records.
Results
Mean age of patients was 56.5 ± 10.7 years and the mean age at CF diagnosis was 54.5 ± 11.7 years, 70.5% were men. T2DM was more prevalent (83.2%), the mean duration of DM at diagnosis was 17.3 years and median glycated hemoglobin was 8% (Interquartile range-IQR 6.8-9.3%) at diagnosis of CF. Regarding anthropometric features, mean height, weight and body mass index (BMI) were 169.40 ± 16.5 cm, 84.4 ± 21.0 kg, 28.97 ± 7.8 kg/m^2, respectively. Most of the patients had hypertension (74.5%), quarter of them were active or ex-smokers (25.2%) or alcohol users (23.3) and previous medical history comprised of peripheral artery disease (19.7%), coronary artery disease (17.5%) or stroke (5.4%). Neuropathy was the most prevalent (89%) amongst the microvascular complications followed by retinopathy (60%) and nephropathy (45%). A foot ulcer was present in about half of the patients (48.5%) while CF was equally distributed between feet (right foot 49%-left foot 44%-bilateral 6.5%) and majority of them were in midfoot (65%), forefoot 18%, hindfoot 13.9% and multiple joint involvement (2.6%). Patients with type 1DM in comparison with those with T2DM were diagnosed with CF at younger age (46.9 ± 11.0 vs 57.9 ± 10.2 years, $P<0.001$), had lower BMI (26.6 ± 6.0 vs 29.5 ± 8.0 kg/m^2, $P=0.001$) and longer diabetes duration [median (IQ): 29.0 (21.0-38.0) vs 14.0 (8.0-20.0) years, $P<0.001$]. No differences were found between T1D and T2DM in HbA1c. No significant gender differences were found in terms of age at CF diagnosis, BMI or HbA1c; however, the duration of DM at CF diagnosis was lower in men vs women 15.0 (1.0-22.0) vs 17.0 (10.0-25.0) years, $P=0.037$].
Conclusion
This is the largest cohort of patients with CF globally. CF is predominant in males, occurs in people with long-standing DM, is often accompanied by microvascular complications, half of patients have foot ulcers at CF diagnosis, affects equally both feet, and the more frequent location is in the midfoot. Further studies are needed to look at outcomes and mortality.

Screening for gestational diabetes in the first trimester: the impact of fasting blood glucose in maternal and foetal health

Ana Carreira[1], Sofia Lopes[1], Kristina Hundarova[2], Antonio Lobo[2], Maria Céu Almeida[2], Luísa Ruas[1], Sandra Paiva[1], Miguel Melo[1] & Isabel Paiva[1]
[1]Hospitais da Universidade de Coimbra, Unidade Local de Saú de de Coimbra, Endocrinology, Diabetes and Metabolism, Coimbra, Portugal; [2]Hospitais da Universidade de Coimbra, Unidade Local de Saú de de Coimbra, Obstetrics, Coimbra, Portugal

Introduction
Screening for gestational diabetes (GD) in the first trimester using fasting plasma glucose (FPG) ≥92 mg/dl is routinely performed in several countries. However, evidence on the benefits and harms of early universal screening, as well as the optimal cut-off of FPG, is conflicting. This results in lack of standardised screening and treatment approaches for GD worldwide.
Aims
o compare the use of pharmacological treatment and pregnancy outcomes in GD diagnosed in the first and second trimesters, as well as between different levels of FPG in the first trimester.
Materials and methods
Retrospective cohort study of singleton pregnancies with GD that were followed in a tertiary centre (2016-2020). Cases of first-trimester-diagnosed GD were divided in 3 groups according to their FPG level (G1: 92-94 mg/dl, G2: 95-100 mg/dl, G3: >100 mg/dl). All women received guidance on lifestyle behavior changes. Neonatal morbidity included respiratory distress syndrome, hypoglycaemia and/or hyperbilirubinaemia.
Results
1498 pregnancies were analysed, with mean maternal age of 34.0 ± 5.4 years and pregestational BMI of 27.1 ± 5.9 kg/m^2 48.8% diagnosed in the first trimester. Compared to second-trimester, first-trimester GD showed a greater need for pharmacological treatment (43.0% vs 26.4%, $P<0,001$) and earlier start of insulin treatment (19.7 ± 7.1 vs 30.9 ± 3.1 weeks, $P<0.001$); with no differences in pregnancy outcomes. FPG in the first-trimester-diagnosed GD was 92-94 mg/dl in 46.0%, 95-100 mg/dl in 36.8% and >100 mg/dl in 17.2%. Pregestational BMI was superior in G3 (28.5 ± 6.8 vs 26.8 ± 6.0 kg/m^2, $P=0.007$). Adjusting for BMI, the risk of neonatal morbidity was reduced by 39.2% in G1 (CI: 0.39-0.92) and the risk of preterm birth was 2.0 times higher in G3 (CI: 1.1-3.7), compared to the remaining. There were no differences on the risk of large or small for gestational age, macrosomia or caesarean delivery between groups. The need for pharmacological treatment was inferior in G1 ($P=0.002$), and increased progressively across groups (36.9% $<$ 40.9% $<$ 63.5%). In multivariate analysis, the odd for requiring pharmacological treatment increased 6.0% per 1 mg/dl of FPG (CI: 1.02-1.10), 7.9% per year of maternal age (CI: 1.03-1.13) and 11.9% per 1 kg/m^2 of BMI (CI: 1.08-1.16), and was 80.6% higher in women with previous GD (CI: 1.07-3.06). Pharmacological treatment showed no association with pregnancy outcomes.
Conclusion
Screening in the first trimester was essential for the early diagnosis and treatment of a large proportion of GD. Women diagnosed by FPG of 92-94 mg/dl showed a lower risk of neonatal morbidity and a lesser need for pharmacological intervention, but suffered no evident harm from ongoing monitoring and treatment.

Overweight and obesity in survivors of childhood cancer

Miriam Helin[1], Inna Zaslavsky-Paltiel[2], Michal Ben Ami[1,3], Eve Stern[1,3], Liat Lerner[4] & Dalit Modan[1,3]
[1]Tel Aviv University, Faculty of Medicine, Tel Aviv, Israel; [2]Chaim Sheba Medical Center, Gertner Institute for epidemiology and health policy resaerch, Ramat Gan, Israel; [3]The Edmond and Lily Safra Children' s Hospital, Chaim Sheba Medical Center, Pediatric Endocrinology and Diabates, Ramat Gan, Israel; [4]Faculty of Medicine, Tel Aviv University, School of Public Health

Background
Multiple studies demonstrated increased incidence of obesity, as well as associated morbidity, such as the metabolic syndrome and cardiovascular disease, in childhood cancer survivors (CCS). Still, data regarding the rates and the timeline of obesity as well as of specific risk factors are inconsistent.
Aim
To evaluate the rate of overweight and obesity in CCS, to characterize longitudinal changes in weight status, and to identify predictors of obesity in this population.
Methods
A retrospective cohort study, comprising of all patients followed at the endocrine late effects of childhood cancer clinic between 1.1.2000 –31.12.2020, diagnosed between the ages of 0-18 years, with follow-up of at least one year following completion of anti-cancer treatment. Pertinent data were abstracted from the patients' medical charts.
Results
The final study cohort included 820 CCS (males:473, 57.7%). The mean age at the time of oncological diagnosis was 7.1 ± 5.1 years, with a median follow-up of 5.5 years from diagnosis. At their last clinic visit, 15.6% of survivors were overweight and 11.1% of them were obese. Compared to the general population, we observed higher rates of overweight and obesity in CCS males aged 2-6 years (33% vs 14%, $P<0.001$), in males aged 6-12 years (38% vs 19%, $P<0.001$) and in females aged 6-12 years (35% vs 21%, $P<0.001$). Multivariate analysis identified weight status at the time of diagnosis ($P<0.001$), and endocrine dysfunctions (OR = 1.46, 95%CI 1.08-1.98, $P=0.01$), as independent predictors of overweight and obesity. The highest rates of overweight and obesity were observed 3-5 years after diagnosis (OR = 1.3, 95% CI 1.11-1.53, $P=0.001$). Diagnosis between the ages 10-14 years, was associated with lower odds of overweight and obesity at the end of follow up compared to diagnosis at an age younger than three years (OR 0.51, 95% CI 0.32-0.83, $P<0.01$). There was no association between weight status at the last visit and gender or type of oncological disease. There was a significant increase in BMI-SDS up to 5 years after diagnosis (0.067 ± 0.033, $P=0.04$), followed by a decrease in BMI-SDS with a later follow up of 5-10 years (-0.11 ± 0.037, $P=0.002$), and more than 10 years after diagnosis (-0.25 ± 0.055, $P<0.001$).
Conclusion
Weight status at diagnosis, endocrine deficiencies, and length of follow-up were identified as predictors of overweight and obesity in CCS. Our results may help in identifying at-risk patients and in designing appropriate targeted interventions that might decrease obesity and related morbidity in CCS.

Post-lifestyle modification program changes in betatrophin and FGF21 levels among arab adolescents with varying levels of adiposity

Mona Alenazi[1], Shaun Sabico[1] & Nasser Al-Daghri[1]
[1]King Saud university, Biochemistry, Riyadh, Saudi Arabia

Background and Aim
Betatrophin has been observed to play an important role in regulating lipid and glucose metabolism, at least in adults. FGF21 is one of the members of endocrine arm of FGF family and its actions as a glucose and lipids metabolism regulator. FGF21 is rapidly emerging as an attractive target in the treatment of metabolic syndrome and type 2 diabetes. They may serve as both risk factors and biomarkers of chronic metabolic disorders. This study aimed to investigate the changes in betatrophin and FGF21 levels in Arab adolescents with varying levels of BMI and glycemia after a 12-month lifestyle modification program.
Methods
A total of 218 children and adolescents (Male = 106, Female = 112) aged 13-17 years were included and stratified based on baseline BMI [normal ($n=45$, overweight ($n=77$ and obese ($n=96$] before undergoing a 12-month intervention program. Anthropometric and fasting blood samples were taken at baseline and after 12 months of intervention. Glycemic and lipid profiles were measured routinely. Betatrophin and FGF21 were assessed using commercially available assays.
Results
At baseline, obese adolescents had a higher betatrophin level [0.7 ng/ml (0.4–1.3), $P=0.032$]. Follow-up BMI was significantly lower in the obese ($P<0.001$) and overweight ($P=0.018$) groups. However, in obesity adolescents, betatrophin levels and BMI were significantly lower after 12-month lifestyle intervention [0.5 ng/ml (0.1–1.1), $P=0.032$; 33.1 ± 7.5), $P<0.001$ respectively] and FGF21 was significantly higher in prediabetic and obesity subjects [194.4 (103.4 - 295.4), $P=0.017$; 208.0 (115.8 - 362.0), $P=0.003$ respectively]. Follow-up lipid profile and insulin were significantly higher in all obese participants ($P<0.05$). Finally, betatrophin levels of those who achieved 5% weight loss ($n=25$) showed no significant difference after follow-up ($P=0.59$).
Conclusion
Changes significantly in FGF21 and betatrophin after lifestyle modification program. An increase in FGF21 and a decrease in betatrophin were associated with clinical characteristics related to the adrenergic and lipolytic responses to a healthy lifestyle.

A single nucleotide polymorphism in the EGF gene is associated with glycemic control in type two diabetes mellitus patients

Mahmoud Alfaqih[1], Jannat Maraqah[2] & Ebaa Ababneh[3]
[1]Arabian Gulf University, Biochemistry, Manama, Bahrain; [2]Jordan University of Science and Technology, Physiology and Biochemistry, Irbid, Jordan; [3]University of Central Florida, Burnett School of Biomedical Sciences, Orlando, United States

Background
Poor glycemic control in patients with type two diabetes mellitus (T2DM) is a strong risk risk factor for the development of complications and is associated with increased mortality. A growing body of evidence has demonstrated a role of the epidermal growth factor (EGF) in glucose homeostasis. The EGF contributes to the function, survival and proliferation of the β cells of the pancreas. The EGF also influences the action of insulin via the modulation of insulin receptor expression and downstream signaling pathways. The collective effect of these actions regulates glucose uptake, utilization and sensitivity to insulin. Given the above, it is conceivable that the EGF could also be associated with glycemic control in T2DM patients. Variations in the *EGF* gene, including single nucleotide polymorphisms (SNPs), could affect the level of the coded EGF protein. Hence, this investigation tested the association of rs4444903 SNP in the *EGF* gene, EGF protein and *EGF* mRNA levels with glycemic control.
Methods
In this case-control study, a total of 330 patients with T2DM were recruited. Cases were patients with poor glycemic control and controls were patients with good glycemic control. Blood samples were collected for DNA extraction and measurement of the EGF protein. An enzyme-linked immunosorbent assay (ELISA) was used to quantify levels of the EGF. Polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) was used to determine *EGF* rs4444903 genotype. An additional set of 42 patients per group was recruited to determine *EGF* mRNA expression in peripheral monocytes. mRNA levels were quantified using qPCR.
Results
Patients with poor glycemic control had significantly lower levels of EGF compared to controls ($P<0.05$). GA genotype of rs4444903 was significantly more frequent among the poor glycemic control group ($P<0.05$). Multivariate regression analysis confirmed this association and showed that EGF levels significantly lowered the risk of poor glycemic control (OR = 0.99, 95%CI:0.98-0.99, $P<0.001$). In this analysis, the GA genotype was associated with an increased risk of poor glycemic control (OR = 1.96, 95%CI:1.02-3.57, $P=0.04$). Cases had a markedly reduced expression of *EGF* mRNA (60% of the expression levels observed in the controls).
Conclusion
This study revealed the association between EGF genetic variation, protein and mRNA expression with glycemic control. Future studies should provide more insights into the molecular mechanism(s) of this association and the role of the EGF in the management of poor glycemic in T2DM.]

First trimester fasting glycaemia ≥ 92 mg/dl and risk of gestational diabetes in the 24-28th week ogtt

Catarina Cidade-Rodrigues[1], Vania Benido[1], Catarina Chaves[1], Bruna Silva[1], Ana Saavedra[1], Alexandra Araujo[1], Claudia Machado[1],

Catarina Pereira[1], Vania Gomes[1], Odete Figueiredo[2], Anabela Melo[2], Anabela Ferreira[2], Mariana Martinho[3], Ana Morgado[2], Margarida Almeida[1], Maria Ceu Almeida[4] & Filipe Cunha[1]
[1]Centro Hospitalar do Tamega e Sousa, Endocrinology, Portugal; [2]Centro Hospitalar do Tamega e Sousa, Gynecology and Obstetrics, Portugal; [3]Centro Hospitalar de Vila Nova de Gaia/Espinho, Endocrinology, Portugal; [4]Centro Hospitalar Universitário de Coimbra, Gynecology and Obstetrics, Portugal

Introduction
Gestational diabetes (GD) is defined as a glucose intolerance firstly recognized during pregnancy and it is the severity of hyperglycaemia which is relevant to maternal and foetal risks. The American Diabetes Association (ADA) recommends screening before 15 weeks of gestation for women at risk, using standard diagnostic criteria, and defines early abnormal glucose metabolism as fasting glucose 110-125 mg/dl or HbA1c 5.9-6.4%. However, the benefit of treating women with early pregnancy detected GD has not been well established, and one third of untreated women showed normal results when retested at 24-28 weeks.
Objectives
We aimed to study the prevalence of GD diagnosis in the 2nd trimester OGTT in women who had 1st trimester glycaemia (FTG) between 92-125 mg/dl and were not pharmacologically treated.
Materials and Methods
Retrospective study using a convenience sample of women from the Portuguese national GD registry who had a FTG between 92-125 mg/dl and had passed unnoticed until the realization of the 24-28th week OGTT and had received no pharmacological treatment. We excluded women without data on known GD risk factors. The primary endpoint was a positive 24-28th week OGTT according to the WHO diagnostic criteria. Women with GD diagnosis by the OGTT and those without GD criteria were compared. A multivariate logistic regression analysis was used to study predictors of GD by the 24-28th week OGTT: the variables included were FTG and those with known association with GD.
Results
We studied 225 women with a median age of 34 (30-37) years and median BMI of 28.3 (24.2-32.4). Forty-eight (21.3%) women had normal results in the 24-28th week OGTT. Women with abnormal OGTT results were older [34 (31-38), 32 (29-35), $P=0.02$], and had higher BMI [29.3 (24.4-33.6) kg/m^2 vs 27.4 (23.1-30.3) kg/m^2, $P=0.05$]. There were no differences between groups concerning T2D family history, previous GD, previous miscarriage, presence of chronic hypertension, or FTG levels. Women with GD in the OGTT were more likely to use insulin or metformin for the remainder of the pregnancy. In the multivariate logistic regression analysis, age $>$ 35 years and BMI(per 1 kg/m^2) associated with diagnosis of GD on the OGTT with an OR (95% CI) of 2.34 (1.04-5.31), $P=0.04$, and 1.07 (1.00-1.14), $P=0.047$, respectively, independently of FTG levels, T2D family history, or previous GD.
Conclusion
More than 20% of women with FTG between 92-125 mg/dl had a normal 24-28th week OGTT. Older age and higher BMI were associated with increased risk of abnormal OGTT.

Impact of gestational diabetes and its management on the nutritional balance and quality of life of a population of tunisian women

Chaima Arfa[1], Chaima Jemai[1], Wafa Ben Brahim[1], Mouna Djebbi[1], Achwak Mehrez[1], Yasmine Fakhfekh[1], Yosra Htira[1], Zohra Hadj Ali[1] & Faika Ben Mami[1]
[1]National Institute of Nutrition of Tunis, C

Introduction
Gestational diabetes mellitus (GDM) is the most common endocrinopathy in pregnancy. Its management is based on hygienic and dietary measures associated, if needed, with insulintherapy. Therapeutic goals must be quickly reached in order to limit complications. GDM has some therapeutic and progressive particularities which could alter the quality of life of patients. The aim of our study was to evaluate the nutritional intake of a population of women with GDM and to assess its impact on their quality of life.
Methods
This was a cross-sectional study, carried out at the research unit on diabetes and pregnancy (UR17SPO2) of department C of the national institute of nutrition of Tunis. We included 40 women with gestational diabetes, defined according to ADA 2023. The data collection was carried out using an interview, anthropometric measurements, a dietary survey, and a pre-established questionnaire assessing the impact of GDM on patients'quality of life.
Results
The mean age was 33.6$\pm$5.54 years. The average pre-gestational BMI was 27.67$\pm$4.93 kg/m^2. The average energy intake was 2019.08$\pm$330.9 kcal/d. The majority of patients (95%) had a hypoglucidic diet ($<$5 g/kg/d). 55% of Women had protein intake below recommended requirements. All the population had a hyperlipid diet ($>$1 g/kg/d). The average ratio w6/w3 was 18.64$\pm$5.83. We noted insufficient intakes of iron, iodine, calcium, zinc, vitamin D, vitamin B9 and vitamin B12. The average fiber intake was 26.54$\pm$6.15 g/d. Most women appreciated the personalized therapeutic education. Following the diet was difficult for 62.5% of patients. 87.5% made diet deviations. Family support was essential for diabetes self-management. The quality life of 77.5% of patients was affected by GDM. Thus, women do not arrive always express their emotions towards the practitioner which can lead to stress or guilt.
Conclusion
Psychological care should be proposed to patients with GDM in order to manage the psychological impact of the disease and improve the quality of life of patients.

Diabetes and covid-19: factors involved in the occurrence of complications and death: about 60 cases

Marwa Sassioui[1], Saloua Elamari[1], Soukaina Laidi[1] & Marouan Fatima[1]
[1]Cheikh Khalifa Bin Zayd Al Nahyan Hospital - University Mohamed VI of Health Sciences, Casablanca, Morocco

Introduction
Coronavirus 2019 (COVID-19) is a potentially fatal infection caused by the acute respiratory syndrome virus coronavirus-2. Diabetes is one of the most distinct comorbidities of COVID-19. Our study describes the clinical characteristics of diabetic patients with COVID-19 to identify factors predictive of the occurrence of complications and death in these patients.
Materials and methods
This was a retrospective, monocentric study that included diabetic patients with Covid-19 referred to Mohamed VI International University Hospital from January 01 to December 21, 2021. We performed a multivariate analysis to quantify risk and identify significant predictive factors for complications and death.
Results
Our study included 60 patients. The sample was 63.33% male, with a median age of 67 years. At least one complication was present in 41.67% of patients, including death in 21.7% of subjects in the series. In univariate analysis, variables that were associated with the risk of complications occurring were: male gender, overweight or obesity, heart failure, otolaryngological signs, high percentageé of lung lesions on CT scan, low glomerular filtration rate and mean daily blood glucose $>$2.5g/l; while protective factors were insulin treatment and high saturation. Only male gender (OR: 28.55; $P=0.005$), overweight and obesityé (OR: 9.48; $P=0.025$), hyperleukocytosis (OR: 8.98; $P=0.038$) and blood glucose levels in the first 4 days persisted as a predictor of the occurrence of complications and death.
Conclusion
Male diabetic patients with high BMI admitted with hyperleukocytosis and persistent high blood glucose levels during hospitalization are more unlikely to progress to more severe COVID-19 and have a poor prognosis.

Adult sitosterolemia in singapore: a case report

Mark Poh[1,2] & Abel Chen[1]
[1]Tan Tock Seng Hospital, Endocrinology, Singapore, Singapore; [2]Tan Tock Seng Hospital, Singapore

Introduction
Sitosterolemia is a rare lipid disorder characterised by excessive accumulation of phytosterols in the body. There are fewer than 110 cases worldwide, and to our knowledge, there are no reported cases of adult Sitosterolemia from South-East Asia. We report our experience in diagnosing a middle-aged Chinese lady from Singapore with Sitosterolemia.
Case Report
A 45-year-old Chinese lady was referred to the Endocrinology clinic in Oct 2022 by her General Practitioner for possible Familial Hypercholesterolemia (FH). She had first noticed tendon xanthomata on her two children (5-year old daughter; 3-year old son) and brought them for review at another pediatric institution.

Investigations for her children revealed very elevated Total Cholesterol (TC) levels (daughter 16 mmol/l; son 8 mmol/l) and Low Density Lipoprotein (LDL) levels, raising the suspicion for FH. Our patient is a non-smoker who consumes a low-fat diet and engages in weekly yoga sessions and runs. She is in a non-consanguinous marriage and does not have a family history of early cardiovascular events or deaths. The father of her 2 children does not have hyperlipidemia. She does not have tendon xanthomata or corneal arcus on examination. She does not have diabetes mellitus, hypertension, thyroid or kidney disorders. She was previously on atorvastatin 10 mg ON, which was increased to atorvastatin 20 mg ON after her first consult with our Endocrinology clinic in October 2022. However, her LDL remained elevated at 4.5 mmol/l and therapy was switched to rosuvastatin 20 mg ON in December 2022. Her LDL remained high at 4.8 mmol/l when rechecked in April 2023 despite compliance to rosuvastatin. She was counselled for and underwent genetic testing for FH. Around this time, the patient's daughter was found to have elevated plant sterol levels at another institution. We hence switched our patient to ezetimibe 10 mg ON while awaiting the results of her own genetic testing. There was a marked improvement in her LDL levels to 1.9 mmol/l 3 months after switching to ezetimibe monotherapy. Molecular genetic analysis later revealed that she was heterozygous for a variant of the ABCG5 gene c.1166G> A (p.R389H). This variant gene has been implicated in sitosterolemia in which there is a defective ATP-binding cassette transporter leading to decreased gut transport and excretion of plant sterols.

Conclusion

This case illustrates the importance of considering sitosterolemia as a differential apart from familial or polygenic hypercholesterolemia in patients with hyperlipidemia as this would greatly impact subsequent management.

Strength-endurance training and liraglutide treatment: impact on metabolic parameters in middle-aged ovariectomized female rats

Branka Šošić-Jurjević[1], Svetlana Trifunovć[1], Dragana Vlahović[1], Ivona Gizdović[1], Natasa Ristic[1], Ljiljana Marina[2] & Branko Filipović[1]
[1]Institute for biological research "Siniš Stanković " - National Institute of Republic of Serbia, University of Belgrade, Belgrade, Serbia; [2]National Centre for Infertility and Endocrinology of Gender, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Exercise training and liraglutide have been shown to be effective in promoting weight loss, improving glycemic control, and regulating blood lipid levels, especially in animal models and patients with obesity and diabetes. However, their combined effects on body composition, glucose, and lipid metabolism in healthy aging models have not been studied yet. In this study, we used apparently healthy middle-aged (16-month-old) female Wistar rats that underwent ovariectomy (Ovx) to mimic human menopause. The Ovx was performed under isoflurane anesthesia (3%) with ketoprofen analgesia (5 mg/day). Two weeks after the surgery, the Ovx rats were randomly assigned to four groups: sedentary control (SC; received 0.3 ml/day normal saline subcutaneously), liraglutide (L; received 0.3ml Saxenda ®, Novo Nordisk A/S, Denmark, at a dose of 0.186 mg/kg body mass/day subcutaneously), exercise strength-endurance training (E; ladder-climbing with 25-50% body weight load 3 times/week), and liraglutide + exercise (L+E) groups. The treatment lasted for seven weeks, with an additional two weeks of adaptation to exercise or liraglutide treatment. Compared to the sedentary control group, the L+E group showed the most significant weight loss ($P<0.05$) and reduction in relative retroperitoneal adipose tissue weight (g/100g body mass). The relative weight of the slow-twitch soleus muscle increased ($P<0.05$) in the L+E group, while the relative weight of the mixed (fast/slow)-twitch gastrocnemius muscle remained unchanged. The serum glucose area under the curve (AUC) following the intraperitoneal glucose tolerance test was lower only in the E group. Conversely, liraglutide treatment mainly contributed to the reduction of total cholesterol, triglycerides, and non-high density lipoprotein (HDL) concentrations in serum compared to exercise alone, which was similar to the effects of the combined E + L treatment. Our findings suggest that in apparently healthy middle-aged Ovx rats, the combination of liraglutide treatment and exercise had the most significant synergistic effects on weight loss, reduction of adipose tissue, soleus muscle activation and improvement in body composition. The improved lipid profiles were mainly due to liraglutide treatment, while exercise alone enhanced glycemic control, indicating their diverse impacts on metabolic parameters in this model.

The association of metabolic dysfunction-associated steatotic liver disease (masld) and metabolic syndrome with cardiovascular outcomes: a nationwide study

Sohyun Cho[1], Rosa Oh[1], Seohyun Kim[2], Ji Yoon Kim[1], You-Bin Lee[1], Sang-Man Jin[1], Kyu Yeon Hur[1], Gyuri Kim[1] & Jae Hyeon Kim[1]
[1]Samsung Medical center, Sungkyunkwan University School of Medicine, Department of Medicine, Seoul, Korea, Rep. of South; [2]Samsung Advanced Institute for Health Sciences and Technology, Sungkyunkwan University, Department of Clinical Research Design and Evaluation, Seoul, Korea, Rep. of South

Background

Metabolic Dysfunction-Associated Steatotic Liver Disease(MASLD) is considered a potential independent risk factor for cardiovascular disease(CVD) as it shares a common risk factor with CVD. We investigated the association with cardiovascular risk according to the metabolic risk factors in patients with MASLD.

Methods

This nationwide study included 1,710,144 individuals aged 40–79 years who underwent health check-ups between 2009 and 2012 in Korea. We excluded previous CVD history, those with viral hepatitis, those who died before follow-up investigation, and missing data. Participants were categorized into no steatotic liver disease(SLD), MASLD, MASLD with increased alcohol intake(MetALD), and alcohol-related liver disease(ALD) and the combination of the presence or absence of risk factor of metabolic syndrome(MetS). Hepatic steatosis was defined as the fatty liver index (FLI) $\geq$30. MASLD was defined as the presence of at least one of cardiometabolic risk factors: 1) Waist circumference $\geq$90 cm in men and $\geq$85 cm in women or body mass index$\geq$23 kg/m^2; 2) Blood pressure $\geq$130/85 mmHg or specific drug treatment; 3) Triglyceride $\geq$150 mg/dl or specific drug treatment; 4) High-density lipoprotein cholesterol $\leq$40 mg/dl for men and $\leq$50 mg/dl for women; 5) Fasting blood glucose levels $\geq$100 mg/dl or specific drug treatment. The primary outcome was a hospitalization due to CVD and CVD-related mortality. Hospitalization due to CVD was defined as the ICD-10 codes of I21-23, I50, I63. CVD-related mortality was defined as heart disease (I00-99). Cox analyses were used to analyze the association between metabolic dysfunction and MASLD and CVD.

Results

The study population consists of a total of 785.132 participants. There were 370.207 male (47.2%) and 414,529 female (52.8%). During a median 8.6 years of follow up, 46,391 (5.9%) hospitalization, 6,802 (0.9%) CVD-related mortality were detected. When no SLD/risk factor(-) were set as the reference group, in no SLD (FLI <30), the more metabolic risk factors, the higher the adjusted hazard ratio (aHR) in hospitalization and CVD-related mortality. In the FLI $\geq$30 (SLD), the hospitalization risk and CVD-related mortality was higher than the reference group. Even within the MASLD, the more metabolic risk factors, the higher the aHR, and the highest aHR in the ALD (aHR, 1.86; 95% CI,1.70–2.03) in hospitalization of CVD.

Conclusion

MASLD independently increases CVD-related outcomes, and the importance of MASLD is more emphasized when accompanied by metabolic syndrome. And both MASLD and significant alcohol consumption increased CVD-related outcome.

Biometric and metabolic changes at one-year follow-up in patients with obesity and steatotic liver disease undergoing endoscopic sleeve gastroplasty-endosleeve (apollo method)

Diego Schwarzstein[1], Lissette Batista[1], Patricia Gonçalves[1], Luis Yip[1], Leoniana Bustillos[1], Mar Bacardit[1], Cristina Colomer[1] & Josep Merlo[1]
[1]Clínica ServiDigest, Obesity Unit, Barcelona, Spain

Introduction

Metabolic dysfunction-associated steatotic liver disease (MASLD, formerly called non-alcoholic fatty liver disease, NAFLD) is a leading cause of chronic liver disease, affecting 25% adult population worlwide. Its most advanced form is the metabolic dysfunction-associated steatohepatitis, or MASH which may progress to cirrhosis. It has no approved pharmacotherapy yet, and weight reduction is an important therapeutic option. Few studies have evaluated the effect of Endoscopic Sleeve Gastroplasty (ESG) on comorbidities in patients with obesity and MASLD.

Aims

To evaluate the evolution of metabolic comorbidities, weight changes and technique's safety in patients with obesity and MASLD undergoing ESG.

Material and Methods
We performed retrospective-descriptive analysis in 32 patients with MASLD and Obesity undergoing ESG between 2016-2022. We evaluated the evolution of analytical and anthropometric parameters, and metabolic comorbidities with 1-year follow-up.
Results
72% of the patients were women, mean age 44 +/- 8.5 years. Mean baseline BMI (body mass index) was 39 +/- 5.47 kg/m^2, most of them type II obesity (57%). 11 patients (36%) had steatosis grade I, 11 (36%) grade II and 10 (28%) grade III. There were 7 patients with hypertension (HT) (28%), 2 with diabetes (8.7%), 6 with pre-diabetes (26%), 10 with dyslipidemia (47.6%) and 3 with severe Obstructive Sleep Apnoea (OSA) (17%). At 1-year follow-up, there was resolution of HT in 3 patients (*P*; 0.003), of prediabetes in all cases (*P*; 0.000), of dyslipidemia in 6 cases (*P* 0.361) and of OSA in 1 case (*P*; 0.020). We found a significant decrease in basal glycemia (*P*; 0.025), glycosylated hemoglobin (*P*; 0.046) and triglycerides (*P*; 0.013). There were significant differences in % TWL (total weight loss) mainly at month 6 of treatment: 18.7% TWL (*P*; 0.004). We observed good correlation between % TWL, age and BMI. 84% of patients completed the endocrinology/nutrition visits. There were no complications in the studied population.
Conclusions
ESG can be considered an effective and safe option in patients with obesity and MASLD, with a positive impact on excess weight and the evolution of associated metabolic comorbidities.

Cardiac changes in obese patients following bariatric surgery

David Verissimo[1], Joana Vinhais[1], Catarina Ivo[1], Pedro Daniel[2], Bruno Stuart[2], Ana Cláudia Martins[1], Joao Silva[1], Dolores Passos[1], Luis Lopes[1], J Jácome Castro[1] & Mafalda Marcelino[1]
[1]Armed Forces Hospital, Department of Endocrinology, Lisboa, Portugal; [2]Armed Forces Hospital, Department of Cardiology, Lisboa, Portugal

Introduction
Obesity is a chronic disease whose association with increased cardiovascular morbidity and mortality, including heart failure, is well established. Not only is obesity intricately connected with an increased prevalence of concurrent risk factors, such as coronary artery disease, hypertension, diabetes mellitus, and obstructive sleep apnea, but it also exerts a direct impact on myocardial structure and pump performance. Over time, prolonged obesity fosters cardiac remodeling, marked by left ventricle hypertrophy, cardiac fibrosis, and diastolic dysfunction, culminating in the progression to manifest heart failure. The intricate interplay between obesity and cardiovascular health is underscored by these structural and functional alterations in the heart. Bariatric surgery emerges as a highly effective intervention for obesity, exhibiting a remarkable remission rate of associated comorbidities, including cardiac dysfunction. Notably, gastric bypass surgery has demonstrated significant benefits in the reversal of left ventricle remodeling, preservation of both left and right ventricle function, along concomitant weight loss.
Material and methods
Prospective study comparing pre- and post-surgical echocardiograms of 38 obese patients submitted to bariatric surgery.
Results
After 21 [16-30] months, BMI, waist circumference, and fat mass percentage decreased by 31.7% ($P<0.001$), 20.9% ($P<0.001$) and 41.8%, ($P<0.001$), respectively, with remission of Diabetes *mellitus*, dyslipidemia, and obstructive sleep apnea of 82.4% ($P<0.001$), 36.1% ($P<0.001$) and 48.5%, ($P<0.001$). We observed a reduction in ventricular hypertrophy (mainly eccentric) from 36.4% to 13.2%, $P=0.004$, due to a reduction in left ventricle mass/heigh$^{2.7}$ (-13.9%, $P<0.001$), septal wall thickness (-10.9%, $P<0.001$), posterior wall thickness (-7.3%, $P=0.007$), and relative wall thicknesses (-6.5%, $P=0.017$), without a significant volumetric change. Changes in both BMI and abdominal circumference were associated with the described shifts in septal wall thickness ($r=0.415$, $P<0.001$ and 0.428, $P<0.001$), posterior wall thickness ($r=0.314$, $P=0.006$ and r=0.377, $P=0.001$), and left ventricle mass/heigh$^{2.7}$ ($r=0.336$, $P=0.003$ and r=0.309, $P=0.007$). No association was observed between fat mass percentage. There were no significant differences in left ventricle function (ejection fraction, fractional shortening, nor cardiac output). Despite an improvement in E/A of 25.4% ($P=0.005$), there was no difference in the prevalence of diastolic disfunction (31.6% vs 28.9%, $P=1.000$).
Conclusions
Weight loss following bariatric surgery had a positive effect in left ventricle remodeling, a hallmark of obesity-related cardiomyopathy.

Predicting liver fibrosis using artificial intelligence in obese patiens

Rona Penso[1,1], Natalia Perez[1], Pilar Matias[1], Antonio Torres[1], Andres Sanchez-Pernaute[1], Candela García[1], Irene Crespo[1], Lorea Herraiz[1], Maria Elena Mendoza[1] & Miguel Angel Rubio[1]
[1], Madrid, Spain

Introduction
The prevalence of hepatic steatosis in people with obesity is very high. However, what is relevant is to detect those patients with associated fibrosis. The aim of the present study was to predict by artificial intelligence (AI) using clinical-analytical parameters, the presence of liver fibrosis in the biopsy performed during bariatric surgery (BS) of patients with obesity.
Subjects and methodology
Cross-sectional study of patients with obesity undergoing BS (2010-2018) who had liver biopsy (after informed consent) during the intervention. Patients with other liver diseases were excluded. Heat MAP was used initially to filter clinical and analytical variables with more association with the Target (fibrosis), subsequently the sample was randomly divided into 2 groups, 75% to train the AI models: Gradient-boosting, LGBM and xgboost. The remaining 25% to test efficacy and reduce overfitting. Sensitivity, specificity and accuracy were calculated using the best AI model.
Results
362 patients (68.8% women), aged 47 [39-47] years, and BMI 42 [38-46] kg/m^2. Comorbidities: arterial hypertension 49.5%, Dyslipemia 46% and Type2 Diabetes (Dm^2) 42%. Biopsies: 83.5% showed steatosis, 18% some degree of fibrosis (10.7%, 3.1% and 4.3% grades 1,2 and 3 respectively). It was observed in the heat map that the variables abdominal perimeter, Hypertension, Dm^2, Insulin, daily amount of alcohol ingested, Albumin, HBA1c, HOMA-IR index, C-peptide, HDLc, GOT, GPT and GGT, are more related to fibrosis. Gradient-boosting was the model that provided the best overall results. Among the variables finally used by the model, those with the greatest weight were GOT and HDLc, followed by GGT, HbA1c, Insulin, GPT, Albumin, amount of alcohol ingested, history of Dm^2 and HOMA-IR index. In the 25% of patients reserved for the accuracy test of the best model, it was observed that only 7.1% presented fibrosis in the biopsy, and the model predicted fibrosis in 12.5%, with only 1 false negative case. Finally, a Sensitivity:0.75, specificity:0.93 and accuracy of:0.827 was achieved.
Conclusions
The Gradient-Boosting model is highly used in medical studies since it can automatically identify more complex data structures, such as nonlinearity and diverse interactions; it has allowed to predict in previous studies cardiovascular events, delirium, sepsis, among o thers. In our sample it showed excellent specificity and good accuracy, which implies that its use in the clinic practice could avoid many liver biopsies, given the few false negatives it presents. This accuracy could even be improved with further training of the model

Evaluation of the digital support tool gro health W8Buddy as part of tier 3 weight management service

Farah Abdelhameed[1], Petra Hanson[1,2], Mohammed Sahir[1], Nick Parsons[3], Arjun Panesar[4], Michaela de la Fosse[4], Charlotte Summers[4], Amit Kaura[5], Harpal Randeva[1,2] & Thomas M Barber[1,2]
[1]University Hospital Coventry & Warwickshire NHS Trust, United Kingdom; [2]Warwick Medical School, University of Warwick, United Kingdom; [3]University of Warwick, United Kingdom; [4]DDM Health, United Kingdom; [5]Imperial College London, United Kingdom

Introduction
The escalating prevalence of obesity worldwide increases the risk of chronic diseases and diminishes life expectancy with growing economic burden necessitating intervention. The existing tiered approach to weight management, particularly specialist Tier 3 services, falls short of meeting the population's needs. The emergence of digital health tools, while promising, lacks exploration in specialized NHS weight management services (WMS).
Methods
This was a service evaluation study to evaluate the effectiveness and clinical impact of the W8Buddy digital support tool as part of a specialist WMS. W8buddy was collaboratively developed September 2022 with input from patients and clinical teams. It is a personalized platform, offering users a tailored weight management plan to empower individuals or caregivers to cultivate the necessary attitudes, knowledge, and skills to self-manage their health. All patients accessing the service were offered W8buddy and everyone received standard of care regardless of whether they used the digital tool. No financial incentives were given for using W8Buddy.

Results
Complete data was available for 226 patients (118 users, 108 non-users). W8buddy users, predominantly female (80%) and Caucasian, had a mean age of 42years, while non-users averaged 48years ($P=0.01$). Co-morbidity frequencies were comparable. Users had significantly higher baseline weight (135 kg vs 123 kg, $P=0.003$) and BMI (48 kg/m^2 vs 45 kg/m^2, $P=0.009$). During follow-up (3 months for users, 6 months for non-users), 28% ($n=220/783$) activated the tool by June 2023, of which 93% ($n=205/220$) actively engaged with the platform. W8Buddy demonstrated a substantial impact on absolute weight loss (β -1.16, SE 0.40, $P=0.004$) compared to standard care alone. Time using W8Buddy was a crucial predictor of weight loss ($P=0.05$), with a 0.74 kg monthly loss compared to standard care (β -0.74, 95%CI (-1.28, -0.21), $P=0.007$). W8buddy users with type 2 diabetes (T2DM) experienced a significant HbA1c reduction (59.8 mmol/mol to 51.2 mmol/mol, $P=0.018$) compared to non-users with T2DM. Optional surveys included satisfaction with life, PHQ8, Karolinska scale, and quality of life score (EQ5D5L). W8Buddy users showed significant improvement across all psychological outcomes ($P<0.001$) during follow-up.
Conclusion
W8Buddy demonstrated significant improvements in clinical and psychological outcomes for users. These findings suggest that digital tools can complement traditional services and promote patient empowerment. Future research should explore the key beneficial aspects of the tool for users and strategies to boost activation and engagement rates. Endorsed by National Institute for Health and Care Excellence (NICE) guidelines, W8Buddy holds promise for improved weight management and glycaemic control within specialized WMS.

Advanced hybrid closed-loop therapy in adults with type 1 diabetes: outcomes in a real-world setting

Elena Pérez Galende[1], Gema Gonzalez Fernandez[1], Pablo Lozano Martínez[1], Clara Fernández Rivera[1], Marta Dolz Lopez[1], Cesar Jesus Avellaned Fabon[2] & Maria Orosia Bandres Nivela[1,2]
[1]Lozano Blesa Clinical Hospital, Endocrinology, Zaragoza, Spain; [2]Lozano Blesa Clinical Hospital, Zaragoza, Spain

Introduction
In the past few years, advances in technology applied to diabetes have significantly changed the type 1 diabetes management. However, only a minority of patients with type 1 diabetes achieves the recommended glycemic goals. Advanced Hybrid Closed-Loop (AHCL) systems, which combine continuous glucose monitoring (CGM) with a continuous subcutaneous insulin infusion (CSII) pump and a control algorithm, improve glycemic control and patient-reported outcomes, such as satisfaction.
Objectives
To evaluate the glycemic control in real life with the different AHCL systems, as well as the differences between them and the degree of patient satisfaction with the treatment.
Material and methods
A prospective observational study was carried out with adults with type 1 diabetes who started treatment with an AHCL system at our Hospital. Data on glycemic control were collected, in terms of HbA1c and CGM glucometric parameters, as well as data related to treatment satisfaction at baseline and at 6 months. In addition, glucometric parameters were also collected one month after the start of therapy.
Results
A total of 40 patients were included (27 started Minimed 780G, 6 Tandem Control-IQ and 7 DIABELOOP DBLG1 patients). They had a mean age of 39.9 ± 14.3 years, the majority were women (67.5%), with a mean duration of diabetes of 26.9 ± 12.4 years. In the total cohort, after 6 months of treatment, HbA1c was reduced from 7.26 ± 0.91% to 6.98 ± 0.76% ($P=0.002$), as well as the TIR increased from 65 (IQR 56 -71) % to 77.5 (IQR 71-85) % ($P=0.0003$). It was observed that a TIR of 75 (72-84) % was reached one month after starting treatment ($P<0.0001$). The percentage of patients who achieved optimal control after therapy increased from 17.5% to 75% ($P<0.0001$). At 6 months after the start of therapy, no significant differences in glycemic control were observed between the systems, however, Minimed 780G was the only system that improved HbA1c (from 7.35 ± 0.91 to 7.07 ± 0.84) ($P=0.03$) as well as the TIR (65 (IQR 56-71) to 79.5 (IQR 71-82.25) ($P<0.0001$). According to the DTSQ-c and DTSQ-s, the change of treatment to an AHCL system was satisfactory and there was a significant improvement in satisfaction after 6 months of therapy ($P<0.0001$), with no significant differences between the different systems.
Conclusion
After 6 months of treatment with AHCL systems, significant improvements were observed, both in glycemic results and those related to patient satisfaction, with no between-group differences.

Association of MMP-2 gene polymorphisms with diabetic retinopathy in tunisian population

Sameh Sarray[1,2], Ben Lamine Laila[3], Dallal Meriem[3], Intissar Ezzid[4] & Touhami Mahjoub[3]
[1]Arabian Gulf University, Medical Biochemistry, Manama, Bahrain; [2]Faculty of Sciences, University Tunis El Manar, Biochemistry, Tunis, Tunisia; [3]Faculty of Pharmacy of Monastir, University of Monastir, Monastir, Tunisia, Laboratory of Human Genome and Multifactorial Diseases (LR12ES07), Monastir, Tunisia; [4]Higher Institute of Biotechnology of Monastir, Monastir, Tunisia

Aims
Few studies investigated the association of genetic difference in metalloproteinase-2 (MMP-2) gene with diabetic retinopathy but with mixed outcome. The aim of the study is to investigate the association between a set of MMP-2 genetic variants and the risk of diabetic retinopathy in an Arab Tunisian population with type 2 diabetes.
Subjects and Methods
A retrospective case-control study involving 779 type 2 diabetes patients with or without diabetic retinopathy was conducted. A total of four MMP-2 SNPs (rs243865 (C/T), rs243864 (T/G), rs243866 (G/T) and rs2285053 (C/T)) were selected for this study, based on their established MAF (>5%) in Caucasians, and association with DR. Genotyping of MMP-2 variants was performed by real time PCR. Replicated blinded quality control samples were included to evaluate reproducibility of the genotyping procedure; concordance was >99%.
Results
The minor allele frequency (MAF) of the rs243864 MMP-2 variant was significantly higher among diabetic retinopathy patients. Setting homozygous wild type genotype carrier as reference, the rs243864T/G allele was associated with increased risk of diabetic retinopathy under the dominant, recessive, and additive models which persisted when key covariates were controlled for, while a reduced risk of diabetic retinopathy progression was seen after adjustment between non-proliferative and proliferative diabetic patients. Furthermore, the heterozygous genotype GT of the rs243866 variant is positively associated with the risk of proliferative diabetic retinopathy in the additive model. A limited linkage disequilibrium (LD) was revealed between the four-matrix metalloproteinase-2 variants. Four-loci haplotype analysis identified GCTC, TTTC, and GCTT haplotypes to be positively associated with the risk of diabetic retinopathy.
Conclusion
MMP-2 constitutes an at-risk locus of risk of DR, and for the first time, we found an association in an Arab Tunisian population where the MMP-2 gene variant rs243864 (–790T/G) and rs243866 (-1575G/T) are linked with the risk of DR development and progression.

Metabolic and cardio-renal benefits of SGLT2- inhibitors in diabetic patients

Ergita Nelaj[1], Julinda Feracaku[2], Kei Xhixhabesi[1] & Irida Kecaj[1]
[1]University Hospital Center, Internal Medicine, Tirana, Albania; [2]Regional Hospital of Gjirokatra " Omer Nishani", Albania

Introduction
Diabetes mellitus (DM) increases the risk of any form of cardiovascular (CVD) and renal disease. Their identification is important for a further careful monitoring and treatment in all aspects. Sodium-glucose cotransporter-2 inhibitors (SGLT2i) have been associated with a remarkable reduction of cardiovascular and renal mortality, lower hospitalization rates for heart failure and lower progression of renal damage and albuminuria. Our study aim to assess SGLT2i effects on both cardio- and renal protection in diabetic patients.
Material and Methods
Were included elderly patients (>65 years) with T2DM, divided in two groups, one group treated with iSGLT2, and the other without. Data were collected at the beginning of treatment, 3, 6, 9 and 12 months after. HbA1C, BMI, GFR and renal

parameters, uric acid, NTproBNP, echocardiography, PAS and PAD values, were evaluated in every meetings, in both groups.
Results
Included in total 298 elderly diabetic patients. At 198 of them dapagliflozin 10 mg, was initiated. After 12 months, HbA1c, weight, systolic blood pressure, NTproBNP, uric acid, albuminuria, were lower in group with dapagliflozin versus the other group without it, and estimated glomerular filtration rate was higher (75.3 –87.19mL/min/1.73m^2; $P<0.005$). Follow up in patients with SGLT2i showed a significant decrease in left ventricular end-diastolic dimension (LV-EDD) (62.86 mm to 54.85 mm; $P<0.001$) and improvement in LV-EF. The SGLT2i-induced improvements in cardiac function were more prominent in HF patients than those without HF.
Conclusion
SGLT2i (Dapagliflozin) showed metabolic benefits in patients with T2D with clinically significant reductions in HbA1c, blood pressure, weight, uric acid, and NTproBNP. Cardiovascular and renal benefits were shown, also. So, SGLT2i has a significant effect in both, cardio- and renal protection in diabetic patients.

The effect of dynamics in fasting glucose level on the risk of chronic kidney disease and ESRD: a nationwide cohort study

Haein Hwang[1], Heesung Kim[1], Seon Mee Kang[1] & Eun-Hee Cho[1]
[1]Kangwon National University Hospital, Internal Medicine, Chuncheon, Korea, Rep. of South

Background
Diabetes and renal disease are global burden with increasing prevalence, respectively. Moreover, they are closely related because diabetic nephropathy itself is well known serious complication of diabetes. However, the significance of decreasing fasting blood glucose on the risk of renal complications remains unclear. We identified the effect of chanes in fasting serum glucose level without diabetes mellitus on the renal complication in Korean adults.
Methods
We analyzed the data from retrospective cohort of Korean National Health Insurance Service-Health Screening (NHIS-HealS). In total, 267.176 Korean adults aged over 40 years measured change in serum fasting glucose level without diabetes at baseline according to the criteria of impaired and diabetic fasting glucose status: normal fasting glucose (NFG, fasting glucose: <100 mg/dl), impaired fasting glucose (IFG, fasting glucose: 100.0–125.9 mg/dl), and diabetic fasting glucose (DFG, fasting glucose: ≥ 126.0 mg/dl). ComparedCox proportional hazard regression model was used to obtain the hazards ratio (HR) with 95% confidence interval (CI) for the incidence of CKD and ESRD. Individuals, selected among national health examination participants in first in 2002–2003 and second in 2004–2005, underwent follow-up evaluations until 2019.
Results
In this report, we describe the protective effect of early glucose recovery on the risk of CKD and ESRD development. In comparison with participants with persistant DFG, participants with recovery from DFG to NFG had an decreased risk of CKD(HR [95% CI]: 0.76 [0.59-0.97], $P=0.025$) and ESRD(HR [95% CI]: 0.64 [0.39-1.07], $P=0.089$).
Conclusions
Early recovery of NFG in individuals with DFG is associated with decreased risk of development of Chronic Kidney Disease and End Stage Renal Disease.

Is type 1 diabetes a risk factor for insulin resistance in young adults?

Samir Mkaouer[1], Zeineb Rekaya[1], Yazidi Meriem[1], Kamoun Elyes[1], Khessairi Nadia[1], Oueslati Ibtissem[1], Chaker Fatma[1] & Chihaoui Melika[1]
[1]La Rabta university hospital, Endocrinology department, tunis, Tunisia

Introduction
Insulin resistance is classically a feature of type 2 diabetes mellitus (T2D). It may also develop among patients with type 1 diabetes (T1D) increasing the risk of cardiovascular mortality. Metabolic syndrome (MS) reflects a state of IR. The aim of this study was to assess the frequency of MS in a population of young adults with T1D and compare it to healthy controls.
Methods
We conducted a case control study including 68 T1D patients and 68 healthy controls matched for age, gender, and body mass index (BMI). The study subjects were young adults, aged between 18 and 45 years. Subjects with other autoimmune, inflammatory, or neoplastic diseases, as well as those with renal failure, were not included. Each patient and each control underwent a physical examination (anthropometric parameters and blood pressure) and a fasting biological sample collection for the measurement of fasting blood glucose, HbA1c, and lipid parameters. MS was diagnosed according to the International Federation of Diabetes (IDF) criteria.
Results
The study population consisted of 58 men (42.6%) and 78 women (57.4%). The mean age was 29.4$\pm$7.23 years. The mean BMI was 24.9$\pm$3.9 Kg/m^2 for T1D patients and 25.0$\pm$4.1 for controls ($P=0.823$). The median duration of diabetes was 11 years (IQR: 4.2 –17.0). The HbA1c median was 8.5% (IQR: 7.7-10.8) in patients with T1D and 5.0% (IQR: 4.9-5.1) in controls ($P<0.001$). Three T1D patients and one healthy control had hypertension ($P=0,31$). Android obesity was observed in 44.6% of the T1D patients and in 47% of the controls ($P=0,731$). Low HDLc levels were observed in 36.4% of the T1D patients and in 38.1% of the controls ($P=0.839$). High triglyceride levels were observed in 13.4% of the T1D patients and in 7.4% of the controls ($P=0,247$). MS was observed in 14 T1D patients (20.6%) and 6 controls (8.8%) ($P=0.053$).
Conclusion
The prevalence of MS in the patients with T1D in our study was similar to that found in a recent meta-analysis (19.8% [13.6-26.8%]). However, the metabolic profile of the T1D patients and controls was comparable, suggesting that T1D is not a risk factor for MS and insulin resistance in young adults.

DOI: 10.1530/endoabs.99.P66

Prevalence and predictive factors of sleep apnoea in type 2 diabetic patients

Meriem Adel[1], Rayene Ben mohamed[1], Marwa Chiboub[1], Lina Ghram[1], Hajer Kandara[1], Manel Jemel[1] & Ines Kammoun[1]
[1]National Institute of Nutrition and Food Technology, Endocrinology, Tunis

Introduction
Obstructive sleep apnoea (OSA) is common in people with type 2 diabetes mellitus (T2DM), with prevalence ranging from 20-50% and up to 85% in obese T2DM. However, OSA remains largely undiagnosed due to the high cost of testing and limited availability of sleep clinics, particularly in developing countries. The aim of this study is to determine the prevalence of type 2 diabetic patients at high risk of OSA and to identify factors associated with OSA in this population.
Methods
A cross-sectional study was conducted on 130 patients with T2DM who were hospitalized in the Endocrinology Department of the National Institute of Nutrition and Food Technology in Tunis. The inclusion criteria were patients aged 30 years or older with T2DM diagnosed for at least 2 years. The study excluded patients with known OSA, any endocrinopathy that could be the cause of OSA, acute respiratory failure, acute or chronic bronchopneumonia, or bronchopulmonary tumour pathology. Screening for OSA was conducted using the Berlin questionnaire and the ApneaLink sleep screening device.
Results
The mean age of the patients was 59.37$\pm$7.80 years, with a female predominance (63.1%). Hypertension was present in 68% of cases. The mean BMI of the patients was 30.53$\pm$5.16 kg/m^2. The mean waist circumference was 101.23$\pm$13.3 cm. Fat distribution was android in 96.34% of women and 52% of men. The mean neck circumference was 39.51$\pm$3.11 cm. The mean duration of diabetes was 12.54$\pm$7.81 years. The mean HbA1c was 11.15$\pm$1.82%. According to the Berlin questionnaire, 62.3% of the population were at high risk of OSA, and according to the Apnealink device, 61% had an AHI $\geq$ 5/h and 20% an AHI $\geq$ 15/h. The factors associated with high risk of OSA in our study were: Age ($P=0.036$), female gender ($P=0.011$) and BMI ($P=0.013$) especially android fat distribution ($P=0.03$), high fasting glucose ($P=0.046$), hypercholesterolaemia ($P=0.013$) and diabetic nephropathy ($P=0.010$). In terms of functional signs, snoring ($P=0.024$), insomnia ($P=0.048$), chronic fatigue ($P=0.011$) and memory problems ($P=0.017$) were also associated with a high risk of OSAHS. Multivariate analysis showed a positive and statistically significant association with a high risk of OSAS for: female sex ($P=0.045$), fasting plasma glucose ($P=0.038$)) and diabetic nephropathy ($P=0.012$)
Conclusion
OSA is often associated with T2DM. Systematic screening for OSA in these patients is essential, especially in the presence of android obesity and poorly controlled diabetes.

Analysis of autoimmunity to the insulin-receptor in diabetes mellitus

Thilo Samson Chillon[1], Kamil Demircan[1], Sabrina Asaad[1], Waldemar Minich[1] & Lutz Schomburg[1]
[1]Institute of Experimental Endocrinology, Charité- Universitätsmedizin Berlin

Introduction
Diabetes mellitus (DM) is a complex chronic metabolic disease characterized by elevated blood glucose levels due to insulin resistance and the failure of pancreatic beta cells to compensate. T2D and its complications have reached epidemic proportions worldwide over the past four decades [1]. A very rare condition known as Type B Insulin Resistance (TBIR) is characterized by severe insulin resistance and the presence of circulating autoantibodies (autoAb) directed against the insulin receptor (InsR). TBIR usually manifests in adulthood and is associated with a high risk of mortality. Insulin receptor autoAb are associated with higher fasting insulin levels in patients with TBIR [2]. Current methods for the diagnosis of TBIR have several limitations, most importantly they cannot be used for routine applications or for the analysis of large sample cohorts. There for it has been suggested that Type 1 Diabetes (T1D) and T2D patients with severe insulin resistance may be underdiagnosed of InsR-autoAb.
Objectivee
The pilot study aimed to determine the prevalence of InsR-autoAb in healthy controls and patients with DM.
Subjects and Methods
An in-house developed and validated fluorescence immunoprecipitation assay [2] was used to quantify InsR autoAb in sera from a small commercial cohort of ($n=443$ participants, including ($n=296$ self-reported healthy subjects, ($n=111$ T2D patients, and ($n=36$ patients with T1D.
Results
The group of T2D subjects showed an InsR autoAb prevalence of 4.5% compared to 0% in T1D and 2% in healthy subjects. In a more rigorous analysis using a stricter cut-off of BI >20, the prevalence in the T2D group is 2.7% compared to 0% in healthy subjects.
Conclusion
The pilot study supports the hypothesis that there are patients with T2D with undiagnosed InsR autoAb. None of the T1D patients showed InsR autoAb, suggesting that this is associated with acquired insulin resistance rather than insulin deficiency. This raises the question of the clinical relevance of these autoAb in the pathogenesis, which needs to be tested in sufficiently large prospective clinical trials.

The correlation between heart failure and diabetic kidney disease in individuals diagnosed with type 2 diabetes mellitus

Yanina Rebrova[1], Yana Saienko[1], Borys Mankovsky[2] & Ievgen Marushko[1]
[1]Ukrainian Children's Cardiac Center, Kyiv, Ukraine; [2]Dmitry F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine

Background
Agrowing body of evidence suggests that type 2 diabetes mellitus (T2DM) may contribute to the the development and deterioration of heart failure (HF) with either reduced or preserved ejection fraction. On the other hand, diabetic kidney disease (DKD) is associated with a high risk and worse outcomes of HF. However, the relationship between DKD and various types of HF hasn't been fully investigated. The aim of this study was to assess the association between the signs of DKD and different types of HF in patients with T2DM.
Methods
Three groups of patients with T2DM were examined. The first group included 20 patients with T2DM and no HF. (age - 62.6±10.0 years, mean diabetes duration - 3.9±2.5 years, HbA1c - 7.0±1.2%, creatinine - 99.0±19.0 μ mol/l, estimated glomerular filtration rate (eGFR) - 64.0±16.0 ml/min/1.73m^2, albumin/creatinine ratio (ACR) - 25.0±21.0 mg/g, ejection fraction (EF) - 58.0±4.0%.(data are presented as mean±SD). The second group included 15 patients with T2DM and HF with reduced EF (HFrEF). (age 66.0±7.0 years, mean diabetes duration - 4.0±2.0 years, HbA1c - 6.9±0.7%, creatinine - 122.0±26.0 μ mol/l, eGFR - 48.0±9.0 mL/min/1.73m^2, ACR - 76.0±73.0 mg/g, EF - 34.0±10.0%). The third group included 15 patients with T2DM and HF with preserved EF (HFprEF). (age - 67.0±9.0 years, mean diabetes duration - 5.0±2.0 years, HbA1c - 7.0±2.0%, creatinine - 130.0±52.0 μ mol/l, eGFR - 48.0±18.0 mL/min/1.73m^2, ACR - 115.0±110.0 mg/g, EF -55.0±3.0%). The ACR in urine and eGFR were recorded and compared among these three groups using Student's t-test.
Results
We found that the eGFR levels were significantly lower in patients with T2DM and HFprEF compared to patients without HF and patients with HFrEF (48.0±18.0; 64.0±16.0; 48.0±9.0, –respectively, $P<0.05$). Also the ACR was significantly higher in patients with T2DM and HFprEF compared to patients without HF and patients with HFrEF (115.0±110.0; 25.0±21.0; 76.0±73.0, –respectively, $P<0.05$)
Conclusion
We found that the signs of DKD were the most pronounced in the group of patients with T2DM and HFprEF, which could suggest an important role of DKD in the pathogenesis of HFpEF in patients with T2DM.

The sodium plunge: a world-record dip with a happy ending

Mohsin Mukhtar[1], Irbaz Nazir[1], Ghazanfar Rana[2] & Aftab Mirza[1]
[1]St. Luke's General Hospital, Endocrinology, Kilkenny, Ireland; [2]University Hospital Waterford, Cardiology, Waterford, Ireland

Severe or profound hyponatremia, defined by a serum sodium level below 125 mmol/l[5], presents a critical challenge with potential grave neurological consequences. We present a case of a middle-aged woman in her late 50s with a history of depression, bipolar affective disorder, chronic gastritis and hyperlipidaemia presented to the acute medical assessment unit with a five-day history of severe vomiting, profuse diarrhoea, generalized weakness and multiple falls in the last 3 day and exhibited an extraordinary serum sodium level of 94 mmol/l, which we believe to be the lowest ever recorded in reported literature[1], with a successful outcome. The underlying causes included a combination of diarrhoea, vomiting, and medication, ultimately resulting in hypovolemic hyponatremia and **SIADH**. Another intriguing aspect of this case is the lack of any neurological symptoms even at this low serum sodium level. Rapid and meticulous management was initiated, involving the cessation of the escitalopram and olanzapine, intravenous fluid replacement with isotonic saline, with a target correction of serum sodium no more than 10meq/day and frequent neurological monitoring. There was close monitoring of serum electrolytes, every 6 hours. The approach aimed to correct the electrolyte imbalance while preventing rapid sodium correction and associated complications The favourable outcome following meticulous management underscores the importance of individualized care and comprehensive understanding of the complex interactions underlying electrolyte imbalances.

Background
The genotyped Mexico City Prospective Study (MCPS) cohort enables the causal effects of adiposity on lipids to be explored in an overweight Hispanic population with scarce statin use.
Methods
MCPS participants aged 35-84 years, with baseline nuclear magnetic resonance measurements of blood lipids, and not using lipid-lowering therapy at recruitment were included. Using the Mendelian randomisation one-sample ratio method, univariable and multivariable models with genetic scores for body-mass index (BMI) and waist-hip-ratio (WHR) as instruments estimated the unadjusted and mutually-adjusted effects of BMI and WHR on six nuclear magnetic resonance spectroscopy-measured plasma lipids: total cholesterol; low-density lipoprotein cholesterol (LDL-C); high-density lipoprotein cholesterol (HDL-C); triglycerides; apolipoprotein A1; apolipoprotein B. Interactions by age, sex and diabetes were explored.
Results
Among 110,669 included participants (mean age 52 years), mean (SD) BMI and WHR were 29.0 (4.9) kg/m^2 and 0.90 (0.07), respectively. Each 5 kg/m^2 higher genetically-predicted BMI (772 SNPs, 3.0% variation) was associated with 0.19SD higher triglycerides (95% CI 0.15-0.22), 0.14SD lower HDL-C (0.11-0.18), 0.11SD lower LDL-C (0.07-0.15), 0.06SD lower apolipoprotein A1 (0.02-0.09) and 0.03SD lower apolipoprotein B (-0.01-0.07). By contrast, each 0.075 unit higher genetically-predicted WHR (398 SNPs, 0.9% variation) was associated with 0.66SD higher triglycerides (0.57-0.74), 0.29SD lower HDL-C (0.21-0.37), 0.13SD lower LDL-C (0.05-0.20), 0.04SD lower apolipoprotein A1 (-0.03-0.12) and 0.10SD higher apolipoprotein B (0.03-0.18). Overall, higher BMI was associated with 0.09SD lower total cholesterol (0.05-0.12) and WHR was associated with 0.04SD lower total cholesterol (-0.03-0.12). Adjustment of BMI for WHR (or vice versa) had little impact on the effect size estimates. Associations were similar in men and women and irrespective of history of diabetes, but for several lipid indices the associations varied significantly depending on age. In particular, associations of BMI and WHR with triglycerides were substantially stronger at younger than at older ages.
Conclusion
In Mexican adults not on lipid-lowering therapy, genetically-predicted general and particularly central adiposity are associated with substantially higher triglycerides but moderately lower cholesterol levels. Triglycerides may be a more important lipid mediator of adiposity-associated atherosclerosis in this population than cholesterol.

Metabolic and renal benefits of using sodium-glucose cotransporter type 2 inhibitors in patients with type 1 diabetes mellitus and continuous subcutaneous insulin infusion

Paloma Perez Lopez[1], Beatriz Torres Torres[1], Esther Delgado Garcia[1], Emilia Gomez Hoyos[1], Gonzalo Diaz Soto[1], Maria de la O Nieto de la Marca[1], Ana Ortolábuigues[1] & Daniel De Luis Roman[1]
[1]Hospital Clinico Universitario de Valladolid, Endocrinology and Nutrition, Valladolid, Spain

Ntroduction and Aim
The use of sodium-glucose cotransporter type 2 (SGLT-2) inhibitors has importantly improved the management of patients with type 2 diabetes mellitus. The aim of the present study was to evaluate the renal and metabolic effects after one year of SGLT-2 use in a cohort of patients with type 1 diabetes mellitus (T1D) treated with continuous subcutaneous insulin infusion (CSII).
Methods
Retrospective observational study in adult patients with T1D under treatment with CSII who started SGLT-2 in a tertiary hospital. Clinical, metabolic and glycometric parameters of Continuous Glucose Monitoring (CGM), including the Time in Tight Range (TTR) and the Glycemia Risk Index (GRI) were obtained at baseline and at 6 and 12 months of follow-up, as well as the existence of complications derived from the use of SGLT-2.
Results
18 patients were selected (55.6% female) with a mean age of 41.5 [39-48] years and 20 [11.8-29] years of T1D evolution were evaluated. Initially 22.2% met criteria for diabetic nephropathy. After 12 months of treatment, there was an increase in Time in range 70-180 mg/dl (TIR) (63.0 [53.0-74.0] vs 78.0[66.0-85.0]%; $P<0.01$) and a decrease in GRI (39.2[28.4-43.8] vs 20.0[14.2-33.2]; $P<0.05$), Time above 180 mg/dl (TAR) (31.5[20.5-39.5] vs 21.0[13.3-30.3]%; $P<0.05$) and Coefficient of Variation (CV) (34.8[32.8-38.4] vs 31.5[29.1-36.7]%; $P<0.05$), as well as a trend towards better TTR (45.0[32.5-57.5] vs 51.0[38.3-59.8]%; $P=$ns). No changes were observed in time below 70 mg/dl (TBR) (2.0[1.0-4.8] vs 2.0[1.0-2.8]%; $P=$ns) or in glycosylated hemoglobin A1c (7.3[6.6-7.8] vs 7.1[6.6-7.6]%; $P=$ns). In terms of renal parameters, at 12 months of treatment, a decrease in albuminuria (AlbU) was observed (11.5[3.8-107.9] vs 7.8[3.1-13.6]mg/l; $P<0.01$) as well as an increase in serum urea levels (34.0[27.8-36.3] vs 43.0[33.0-51.0]mg/dl, $P<0.05$], with no worsening of creatinine levels (0.9[0.8-1.0] vs 1.0[0.8-1.0]mg/dl, $P=$ns]. At 6 months follow-up, albumin-creatinine ratio (ACR) levels decreased in 2 patients with initial ACR > 300 mg/g: 1 achieved ACR less than 30 mg/dl (29.6 mg/g), and 1 less than 300 mg/dl (161 mg/g). Treatment with SGLT-2 was withdrawn in 3 patients (17.3%): 1 case due to gestational desire and 2 because of genitourinary infections. No case of ketoacidosis was documented during follow-up.
Conclusion
The use of SGLT-2 in patients with T1D under treatment with CSII led to an increase in TIR, with a significant decrease in GRI, TAR and CV, as well as improvement in renal parameters (AlbU, ACR), without the presence of serious complications during follow-up. The use of SGLT-2 may be a good therapeutic alternative in patients with T1D treated with CSII.

Vitamin b12 deficit mimics diabetic polyneuropathy in patients taking metformin

Anna Alieva[1] & Kamila Kenjaeva[2]
[1]Republican Specialized Scientific-and-Practical Medical Centre of Endocrinology, Intensive Care Unit, Tashkent, Uzbekistan; [2]Mirzo Ulug'bek shoh ko'chasi 56, Intensive Care Unit, Toshkent, Uzbekistan

Introduction
Prolonged use of Metformin is associated with the development of vitamin B12 deficiency. The aim of our study was to investigate the relationship of clinical manifestations similar to diabetic polyneuropathy with vitamin B12 levels in patients with type 2 diabetes mellitus.
Materials and methods
We examined 35 patients with type 2 diabetes taking Metformin. Mean age 55.9±11.5 years, mean diabetes duration 9.2±7.7 years. All patients were tested for diabetic polyneuropathy (DPN). The level of vitamin B12 was determined by the chemiluminescence immunoassay method.
Results
There was a trend towards a decrease in the level of vitamin B12 in persons with reduced sensitivity compared to persons with preserved sensitivity: 243.85±117.8 versus 336.66±98.3 pg/ml for pain sensitivity; 299.1±84.3 versus 326.9±121.2 pg/ml for tactile sensitivity; 297.0±175.2 versus 357.0±134.9 pg/ml for temperature sensitivity; 117.8±73.3 pg/ml for persons with vibration sensitivity from 0 to 3 points versus 522.5±188.2 pg/ml for persons with vibration sensitivity from 4 to 6 points ($P<0.05$). Also, among persons with a decrease in tendon reflexes, the level of vitamin B12 was lower (197.0±78.5 pg/ml) compared to persons with preserved reflexes (316.2±117.1 pg/ml).
Conclusion
The presence of clinical manifestations of polyneuropathy was associated with a decrease in the level of vitamin B12 in the blood in patients with type 2 diabetes mellitus taking Metformin, a significant decrease in the level of vitamin B12 was shown in patients with reduced vibration sensitivity. Patients with clinical manifestations of diabetic polyneuropathy should measure vitamin B12 levels.

Gestational diabetes: what is the evolution in the postpartum period, those on a hygienic diet, versus on insulin therapy?

Rakia Bachir Moctar[1], Bensbaa Salma[1], Nassim Essaba Haraj[1], El Aziz Siham[1] & Asma Chadli[1]

[1]CHU Ibn Rochd, Casablanca, Morocco, Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, Casablanca, Morocco

Introduction
Gestational diabetes or gestational diabetes is an increase in blood sugar levels that appears during pregnancy and disappears after delivery. It has an impact on the health of both mother and child.
Our objective
was to detect predisposing factors for remission in patients followed for gestational diabetes after delivery on a hygienic diet, versus on insulin therapy.
Patients and Methods
Our work is a case-control study including 182 patients with gestational diabetes followed at the Endocrinology-Diabetology department between January 2016 and January 2022. Diabetes is screened in the postpartum period at 6 to 8 weeks by HGPO75 g, divided into two groups: G1 (Diabetes has disappeared after pregnancy) and G2 (Diabetes has persisted after pregnancy). To do this work, we used SPSS software.
Results
The study included 182 patients, 46.18%, Diabetes disappeared after pregnancy (G1) and remained more or less on a hygienic-dietary diet with a good clinical course, G2, Diabetes persisted after pregnancy 52.12%, and are on insulin therapy. A pre-pregnancy BMI (<25 kg/m^2) of 25.4% (G1) and 29.8% (G2), P ($=0.06$). A mean post-pregnancy GAJ of 0.94 g/I(G1), 1.8 g/I(G2), a mean pregnancy weight gain of 0.27 kg/Sa(G1), 0.39 kg/Sa (G2), P(0.08), a hypertension of 12.3%(G1), 21.9% (G2), P(0.8), and a lost follow-up of 1.12%(G1), 1.1% (G2), with a good remission for patients doing physical activity, with a normal BMI and a normal HbA1C.
Discussion and Conclusion
Remissions are not uncommon in our patients, with a good balance of diabetes and good weight monitoring. It is therefore essential to screen for them and also to look for those lost to follow-up.

Effect of alcohol-induced hypoglycemia on myocardial perfusion

Nodira Alikhanova[1], Charos Musakhanova[1], Nozimakhon Nazarova[1], Feruza Takhirova[1], Lola Abboskhujaeva[1], Gulzoda Akramova[1], Munavvara Shakirova[1], Doniyor Nurmukhammedov[1], Lutfulla Usmanov[1] & Farrukh Almuradov[1]
[1]Republican Specialized Scientific and Practical Medical Center of Endocrinology Named after Academician Y.Kh. Turakulov, Diabetology, Tashkent

Background and Aims
When alcohol abuse and diabetes are combined, the consequences can be unpredictable and cause a double whammy, since both conditions cause similar pathological effects, in particular negative effects on the cardiovascular system.
Methods
The patient is 49 years old, male. Height 175 cm, weight 95 kg. BMI 31.02 kg/m^2. T2D was diagnosed 10 years ago. At the beginning of the disease, he took oral hypoglycemic drugs (can't remember their names). For 5 years, he has been taking medium- and short-acting human insulin. Poor control glycemia and bread units. BP has been increasing for 5 years and at the time of examination, he took Telmisartan 80 mg once daily. Diagnosed with type 2 diabetes mellitus in the decompensation stage. Complication: Diabetic nephropathy, CKD 1. Hypertension, stage 1 arterial hypertension. In addition to routine tests to diagnose CKD, we performed carotid-femoral sphygmography (SphygmoCor XCEL, AtCor) to assess pulse wave velocity (PWV) and Myocardial perfusion imaging using SPECT - AnyScan® SC - Mediso with technetium-99m sestamibi before and after 6-month follow-up. To evaluate summed score of perfusion during rest (SRS), computer software is used to evaluate perfusion isotope activity in each segment compared to the volume of radiopharmaceutical accumulation, set as 100%, in 17 segments of the polar map. the decrease in the accumulation of the radiopharmaceutical was translated into a point scale: 0 points - 70% and more, 1 point - 69-50%, 2 points - 49-30%, 3 points - 29-10%, 4 points - 9 and below%.
Results
Results of first laboratory examination: HbA1C - 11.2%, fasting blood sugar - 10.8 mmol/l. Instrumental examination ECG unchanged. PWV 14,70 m/s. SRS - 0 points, average perfusion indicator (API) - $84.95 \pm 7.3\%$. The patient was prescribed to take dapagliflozin 10 mg 1 tablet once daily for 6months. During the re-appointment the patient complained of general weakness. Body weight 96 kg, TVI 31.34 kg/m^2. HbA1C - 9.4%, fasting blood sugar - 13.4 mmol/l. The patient underwent re- sphygmography and SPECT examination. PWV 14,70 m/s. SRS –9 points, API - $74.0 \pm 23.2\%$. Despite the decrease in vascular stiffness according to the results of Sphygmocore, a decrease in myocardial perfusion was noted. The patient admitted that he had been abusing alcohol for the past few months and had frequent nocturnal hypoglycemia
Conclusion
Despite a decrease in vascular stiffness during treatment with dapagliflozin, a decrease in myocardial perfusion was noted due to alcohol-induced hypoglycemic conditions.

Association between low vitamin d level and depressive symptoms

Nana Kvinikadze[1], Mariam Tkeshelashvili[1], Claytan Monis[1], Nanditha Narendran Geetha[1] & Elene Pestvenidze[1]
[1]Tbilisi State Medical University, USMD program, T'bilisi, Georgia

Background
Depression has a multifaceted nature that is influenced by genetics, molecular mechanisms, and environmental stress. Vitamin D is involved in the development of depression, impacting neurotransmitters and neurological function when deficient, therefore it can be seen as a part of the discourse around depression, as well as preventing, treating and managing the same.
Aim
The aim of this study is to assess the relationship between low Vitamin D level and depressive symptoms in adult patients.
Methods
This prospective cohort study focuses on Vitamin D deficient adults. Family doctors conducted self-report surveys, covering demographics, medical history, Vitamin D levels, and the PHQ-9 questionnaire. Follow-up was done after one month using the same questionnaire. The study analyzed data using Prism, employing descriptive statistics, paired t-tests, Fisher's exact test and Pearson correlation analysis.
Results
The study involves 43 participants (4 excluded). Paired T-test revealed a significant decline ($P=0.0018$) in depression symptoms with vitamin D supplementation. By Subgroup analyses females ($P=0.0093$), age (18-25) ($P=0.0317$), unmarried ($P=0.0216$) and moderate workplace stress ($P=0.0176$) demonstrated significant decline in PHQ-9 scores with supplementation. Pearson correlation analysis between vitamin D levels and depression symptoms yielded to a nonsignificant result ($P=0.5887$). Fisher's exact test found no significant link ($P=0.4121$) between severities of vitamin D deficiency and depression symptoms.
Conclusion
This study supports Vitamin D's role in mitigating depressive symptoms. Significant declines were observed with supplementation, particularly among females, those aged 18-25, unmarried individuals, and those with moderate workplace stress. However, no link was found between severities of vitamin D deficiency and depressive symptoms. These findings suggest that vitamin D is involved in pathogenesis of depression and even though there is no direct correlation its supplementation alleviates the depressive symptoms.

The prognostic significance of antinuclear antibodies in metabolic steatopathy: a cross-sectional study

Ahmed Mohamed Nefzi[1], Bouchabou Bochra[1], El Mouldi yosr[1], Nakhli Abdelwahab[1], Hemdani Nesrine[1], Benzarti Zeineb[1], Ben Nejma Houda[1] & Ennaifer Rym[1]
[1]Hôpital Mongi Slim, Hepato-gastroenterology, Marsa, Tunisia

Introduction
The pathophysiology of metabolic steatopathy remains complex, prompting numerous inquiries to date. While the isolated presence of antinuclear antibodies (ANA) has been reported in this pathology, their prognostic relevance has not been adequately investigated. The objectives of our study were to:
- Examine the prevalence of antinuclear antibodies during metabolic steatopathy.
- Investigate the prognostic significance of ANA in metabolic steatopathy.
Patients and Methods
This was a single-center, cross-sectional, descriptive study encompassing all patients diagnosed with metabolic steatopathy from March 2021 to December 2022. Patients diagnosed with connectivitis and autoimmune hepatitis were excluded. Clinical data (age, medical history, anthropometric measurements, and blood pressure) were collected. A laboratory assessment (metabolic and hepatic profiles, viral serologies for hepatitis B and C) was conducted, along with the detection of antinuclear antibodies. Liver fibrosis evaluation employed transient elastography (Fibroscan), and cardiovascular risk assessment utilized the GLOBORISK score.
Results
The study population comprised 104 patients with a mean age of 54.51 ± 10.2 years and a gender ratio of 0.52. Histories of type 2 diabetes, hypertension, and dyslipidemia were noted in 41.3%, 44.2%, and 30.8% of patients, respectively. ANA were positive in 13.5% of patients ($n = 14$) with titers ranging from 1/80 to 1/400. No significant differences were observed in basic demographic data based on ANA positivity. Regarding biological data, thrombocytopenia was more frequently observed in ANA-positive patients (35.7% versus 5.5%) ($P = 0.038$). Liver elasticity was higher in patients with positive ANA (8.7 kPa versus 6.9 kPa), although not statistically significant ($P = 0.327$). Cardiovascular risk assessment did not show an elevated risk in ANA-positive patients ($P = 0.207$).
Conclusion
Our study suggests that ANA positivity during metabolic steatopathy is not uncommon. However, it appears to be an epiphenomenon without substantial prognostic implications. Larger studies with better-matched groups are required to confirm this hypothesis.

Testosterone replacement therapy improves metabolic parameters in obese men with testosterone deficiency: a meta-analysis and systematic review

Yaoxia Liu[1], Tao Wang[2], Yerong Yu[3] & Min Zhang[1]
[1]Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China., Geriatric Endocrinology, Chengdu, China; [2]West China Second University Hospital, Sichuan University., Key Laboratory of Birth Defects and Related Diseases of Women and Children (Sichuan University), Ministry of Education, Chengdu, China; [3]West China School of Medicine/ West China Hospital of Sichuan University., Endocrinology and Metabolism., Chengdu, China

Objective
This systematic review aimed to assess the efficacy and safety of testosterone replacement therapy (TRT) in obese men with testosterone deficiency through the analysis of randomized controlled trials (RCTs).
Materials and Methods
A comprehensive computer-based search was conducted in Cochrane Library, PubMed, Embase, Web of Science, Scopus, Open SIGLE database, China National Knowledge Infrastructure (CNKI), Wanfang Data, VIP database, and China Biology Medicine (CBM) database to identify RCTs involving obese men with testosterone deficiency treated with TRT.
Results
A total of 10 RCTs, all published in English, were included in this study, involving 665 subjects at baseline. Meta-analysis demonstrated that, compared to the control group, TRT resulted in a decrease in body mass index (BMI) by 0.57 kg/m^2 (MD = -0.57, 95% CI: -0.94 to -0.20, $P = 0.002$), a reduction in waist circumference by 2.78 cm (MD = -2.78, 95% CI: -4.86 to -0.70, $P = 0.009$), an increase in lean body mass by 1.96 kg (MD = 1.96, 95% CI: 0.30 to 3.61, $P = 0.027$), a decrease in fasting blood glucose by 0.53 mmol/l (MD = -0.88, 95% CI: -0.88 to -0.19, $P = 0.020$), a decrease in HOMA-IR by 1.89 (MD = -1.89, 95% CI: -3.11 to -0.65, $P = 0.003$), a decrease in HbA1c by 0.52% (MD = -0.52, 95% CI: -0.82 to -0.22, $P = 0.0006$), and a decrease in triglycerides by 0.22 mmol/l (MD = -0.22, 95% CI: -0.36 to -0.07, $P = 0.003$). There were no statistically significant differences in body weight, body fat mass, non-fat body mass, total cholesterol (TC), LDL cholesterol (LDL-C), and HDL cholesterol (HDL-C) between the groups. SBP and DBP did not significantly increase after TRT compared to the control group. However, TRT was associated with a statistically significant increase in hematocrit (HCT) by 3.19% (MD = 3.19, 95% CI: 2.14 to 4.24, $P < 0.00001$). The impact of TRT on PSA levels could not be conclusively determined.
Conclusion
The meta-analysis of randomized controlled trials suggests that testosterone replacement therapy in obese men with testosterone deficiency can improve metabolic parameters. TRT leads to reductions in BMI, waist circumference, and triglycerides, while increasing lean body mass and improving insulin resistance. There is no significant effect on blood pressure, but there is a risk of increased hematocrit. In clinical practice, it is recommended to carefully consider the indications for TRT and closely monitor cardiovascular risks.

Serum Oxytocin predicts body dysmorphic concerns and ketosis occurrence in patients withobesity on a VLCKD

Rebecca Rossetti[1], Rossella Tozzi[1], Davide Masi[1], Maria Ignazia Curreli[1], Sabrina Basciani[1], Maria Elena Spoltore[1], Elena Gangitano[1], Paola Nevi[1], Orietta Gandini[1], Vittoria Strinati[1], Maria Chiara Massari[1], Mikiko Watanabe[1], Stefania Mariani[1], Lucio Gnessi[1] & Carla Lubrano[1]
[1]Sapienza University of Rome, Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Roma, Italy

Introduction
Obesity is a chronic neurometabolic disorder with complex psychological aspects. Patients with obesity often suffer from eating disorders and altered body image perception and show increased plasma concentrations of oxytocin (OT).
Objective and Design
This pilot study investigates the interplay between psychological factors, OT levels, and very-low-calorie ketogenic diet (VLCKD)-induced weight loss. We collected data from patients with overweight or obesity undergoing VLCKD, assessing anthropometrics, metabolism, psychometrics, and OT levels at baseline (t0) and after 45 days of diet (t1). The psychometric analysis involved the Ritvo Autism Asperger Diagnostic Scale-Revised (RAADS-R), the Body Uneasiness Test (BUT), and the Twenty-item Toronto Alexithymia Scale (TAS 20).
Results
Forty-seven participants (28 females) were enrolled, exhibiting a mean baseline BMI of 35.88 ± 4.37 kg/m^2 and a serum OT concentration of 1163.74 ± 410.08 pg/ml at t0. Following VLCKD intervention, significant alterations in anthropometric, biochemical, and body composition parameters were evident at t1. Notably, a substantial average weight loss of -8.8 kg and a significant reduction in mean BMI to 32.76 kg/m^2 ($P < 0.001$) were observed. Additionally, a remarkable decline in OT levels to 734.35 ± 203.35 pg/ml was recorded ($P < 0.001$). Correlation analyses revealed associations between baseline OT levels and body weight ($r = 0.35$, $P < 0.05$), BMI ($r = 0.39$, $P < 0.05$), total fat mass ($r = 0.35$, $P < 0.05$), trunk fat ($r = 0.33$, $P < 0.05$), and android fat distribution ($r = 0.43$, $P < 0.05$). Psychometric evaluations unveiled pathological BUT Global Severity Index (BUT-GSI) in 39% of participants, with OT exhibiting a direct association with BUT-GSI ($r = 0.416$, $P < 0.05$). Moreover, baseline OT levels correlated with weight loss and BMI ($P < 0.005$). A linear relationship emerged between the reduction in OT levels (t0-t1) and BMI decline. Baseline OT also correlated directly with t1 plasma ketone bodies, remaining significant after adjustments ($P = 0.02$). Furthermore, the ROC curve highlighted the predictive capacity of baseline OT levels (>1034 pg/ml) for ketosis occurrence at t1, with 100% sensitivity and 60.7% specificity (AUC 0.819, $P < 0.001$). Multivariate analyses revealed the female sex was negatively associated with BUT-GSI, while OT at t0 displayed a positive correlation. OT at t1 indicated a trend but did not achieve statistical significance.
Conclusion
This investigation underscores the complex interplay among psychological parameters, circulating OT levels, and VLCKD-induced weight loss, highlighting baseline OT as a potential predictive marker for diet-induced ketosis and weight reduction in obesity.

Resting metabolic rate in children with obesity: a predictor of metabolic syndrome

Amalia Ioana Arhire[1,2], Papuc Teodora[2], Miruna Sinziana Chiper[2] & Boroghina Steluta[3,4]
[1]Kilostop Junior, Endocrinology, Diabetes and Nutrition Department, Bucharest, Romania; [2]Elias Hospital, Endocrinology, Diabetes and Nutrition Department, Bucuresti, Romania; [3]Kilostop Junior, Endocrinology, Diabetes and Nutrition Department, Bucuresti, Romania; [4]Fundeni Clinical Institute, Gastroenterology, Bucharest, Romania

Introduction
The prevalence of obesity and metabolic syndrome among children is rising alarmingly worldwide, so the need is high for an objective and easily manageable predictor, in order to control obesity's impact on health. Childhood weight gain results from an imbalance between energy expenditure and energy intake, where the intake surpasses the energy requirements, including metabolic rate and growth. Physical inactivity impacts growth and muscle formation and can lead to pediatric obesity through low resting metabolic rate. We studied the correlation between the resting metabolic rate, LDL-cholesterol and waist circumference on a group of children with obesity in order to emphasize the importance of metabolic syndrome screening, especially in children with high percentage of body fat and low resting metabolic rate.
Materials and method
We conducted a retrospective correlational study on 168 children from the southern part of Romania, who were patients in our nutrition clinic from 2020-2021, with the age median 12, BMI median 27.2 kg/m^2, obesity degree median 143%, 89 male/79 female. We used indirect calorimetry to measure the resting metabolic rate.
Results and conclusion
77 of our patients have LDL-cholesterol values over 100 mg/dl (45.83%) and 103 of them have their waist circumference over the 95th percentile (61.3%). The percentage from the predicted resting metabolic rate negatively correlates with the LDL-cholesterol values (r=-0.18, p value=0.019) and with waist circumference (r=-0.192, p value=0.013). Thus, as resting metabolic rates values decrease, waist circumference and LDL-cholesterol values increase, leading to metabolic syndrome. Recognizing the impact of resting metabolic rate on weight gain during childhood is crucial as these children are more predisposed to metabolic complications. A more intensive lifestyle intervention with focus on diet but also physical activity is needed on these patients to prevent obesity and other complications of metabolic syndrome.
Keywords: pediatric obesity, LDL-cholesterol, waist circumference, metabolic syndrome, resting metabolic rate

Sleep quality in adults with type 2 diabetes mellitus: a tunisian study

Sana Khamassi[1], Emna Bornaz[1], Haifa Abdesselem[1], Dorra Ben salem[1], Kamilia Ounaissa[1] & Chiraz Amrouche[1]
[1]National Institute of Nutrition, Outpatient Department and Functional Explorations, Tunis, Tunisia

Introduction
Diabetes mellitus, evolving as a silent epidemic, is a chronic metabolic disease associated with high morbidity and mortality among the patients. In addition to its micro and macrovascular complications as well as its impact on quality of life, evidence has shown that patients with diabetes mellitus are prone to poor sleep quality [1]. This study aims to evaluate the sleep quality (SQ) in patients with type 2 diabetes mellitus (T2DM) and to determine possible factors that may alter the SQ of these patients.
Methods
A cross-sectional study was conducted in 100 adults with T2DM. Patients' demographic and anthropometric characteristics, diabetes related complications and biological parameters were collected. SQ was evaluated using the Pittsburgh sleep quality index (PSQI) in its arabic-validated version. The total PSQI score was obtained by adding seven scores corresponding to seven subcomponents of sleep quality, ranging between 0 and 21. PSQI score >5 indicates significant sleep disturbance and categorizes the subjects as poor sleepers.
Results
Mean age was 54.45$\pm$7.13 years with female predominance (72%). Mean diabetes duration was 12.67$\pm$7.35 years, mean glycated hemoglobin was 9.69$\pm$2.02 % and mean BMI was 29.49$\pm$4.97 Kg/m^2. Half of our sample was obese (49%). Twenty two percent of patients used oral glucose-lowering drugs (OGLDs), mostly sulfonylureas (87,5%), while 78% used insulin. Within the insulin user subgroup, 67% were prescribed metformin, and 12% were on iSGLT2. Retinopathy, nephropathy and peripheral neuropathy were found, respectively in 40%, 22% and 27% of patients. Mean DN4 score was 1.82$\pm$1.65. Mean ALT and AST levels were 20.73$\pm$7.90 UI/l and 20.72$\pm$7.08 UI/l, respectively. The mean PSQI score was 7.89$\pm$3.69 with extremes ranging from 1 to 15 and 69% of our patients had poor sleep quality. Patients with poor SQ had significantly higher prevalence of mild retinopathy (87.5% vs 12.5%; P=0.049) and peripheral neuropathy (86.4% vs 13.6%; P=0.034). Additionally, a significant disturbance of sleep was higher among patients using sulfonylureas (90% vs 10%; P=0.021). Patients with poor SQ had higher DN4 score (2.06$\pm$1.74 vs 1.17$\pm$1.21; P=0.017), higher ALT levels (21.93$\pm$8.04 UI/l vs 17.70$\pm$5.94 UI/l; P=0.016) and AST levels (21.86$\pm$7.89 UI/l vs 17.96$\pm$4.61; P=0.021).
Conclusion
highlights the high occurrence of poor sleep quality among patients with type 2 diabetes mellitus (T2DM), particularly in the presence of microvascular complications. These results underscore the importance of advocating for screening this disorder in this population

Maaori and pacific-specific diabetes protective crebrf r457q variant alters glucocorticoid receptor activity

Kate Lee[1,2], Sanaz Vakili[1] & Peter Shepherd[1,2]
[1]University of Auckland, [1]Maurice Wilkins Centre

Type 2 diabetes (T2D) is a debilitating, multifactorial disease with a complex mix of genetic and environmental pathomechanisms. For this reason, effective treatment of T2D requires a varied arsenal of therapeutic strategies and indeed, it is an excellent candidate for precision medicine. Essential for this, we need a more detailed understanding of the genetic drivers and how these differ between individuals. There is an ever-intensifying global effort to identify genetic associations with diabetes and their mechanisms; however, these efforts mostly exclude indigenous populations which have been shown to have unique genetic variants and often higher rates of T2D. In New Zealand/Aotearoa we have indigenous Māori population as well as a large population of Pacific peoples and we are exploring unique variants associated with diabetes and metabolic disease with a focus on enabling precision medicine. A coding SNP (p.Arg457Gln) in the Creb3 regulatory factor (CREBRF) gene, found in ~25% of M?ori and peoples of the Pacific islands, is associated with a large increase in BMI, yet paradoxically, it is also associated with an approximately 50% reduction in the incidence of type-2 diabetes and gestational diabetes [Minster et al 2016, Krishnan et al 2020]. The mechanisms by which the variant drives diabetes protection remains unknown and CREBRF itself was only identified in 2008 [Audas et al 2008]. To date, CREBRF has been shown to regulate cAMP response element binding proteins (CREB3 and CREBL2) that are ubiquitously expressed and have roles in several key cellular processes including ER/Golgi stress and cell metabolism. CREBRF has also been shown to regulate glucocorticoid receptor (GR) signalling [Penney et al 2018, Martyn et al 2012]. We have characterised 20-month-old mice carrying the variant and show there are differences in body composition that manifest at this age and in males this is accompanied by lower myostatin levels [Lee et al 2022]. We have also shown the variant to alter GR transcriptional activity in vitro and in vivo. This includes differential responses of GR-mediated genes such as Dusp1 and Hsd11b1. Despite this, the mice show no overall changes in cortisol nor ATCH, no difference in response to dexamethasone suppression test and no difference in acute restraint test. This differential regulation of GR activity has the potential to explain diabetes protection in carriers of the variant and inform effective therapeutic approaches in non-carriers and therefore we are further exploring impacts on islet, adipose and muscle function.

Expression of pro-inflammatory cytokines and fibrinogen in human diabetic nephropathy

Maha Maqsood, Saima Sharif, Saira Rafaqat & Shagufta Naz
Lahore College for Women University, Lahore, Zoology, Lahore, Pakistan

Background
Diabetic nephropathy (DN) is a micro-chronic diabetic complication brought on by changes in metabolism and hemodynamics. Inflammatory cytokines, generally

IL-1β, IL-6 and IL-18 are linked in the development and advancement of DN. They act as pleiotropic polypeptides regulating inflammatory and immune responses through actions on cells. Fibrinogen is the liver-synthesized protein, with different functions and responses to both acute and chronic stimuli.
Aim
The aim of this research work is to find the relationship of IL-1β, IL-6, IL-18 and fibrinogen in the advancement of diabetic nephropathy.
Methods
This cross sectional study was conducted on 1152 subjects selected from different cities (Lahore, Gujranwala, Multan, Islamabad, Karachi and Gharro) of Pakistan. The enrolled subjects were categorized into control group (n=384), diabetes mellitus group (DM) (n=384) and diabetic nephropathy group (DN) (n=384). The serum concentration of IL-1β, IL-6, IL-18 and fibrinogen were determined by enzyme-linked immunosorbent assay (ELISA). The expression analysis of IL-1β, IL-6, IL-18 and fibrinogen were performed by Real Time PCR.
Results
The significant increased level of serum IL-6 (56.01 pg/ml), IL-1β (36.93 pg/ml) and decreased level of IL-18 (132.61pg/ml) and Fibrinogen (11.93 pg/ml) was observed in DN subjects as compared to control and DM subjects. The expression profile of IL-6 were increased by more than thirty three fold (n-fold = ∼ 33.3) and expression of IL-1β increased by more than eleven fold (n-fold = ∼ 11.76) in DN group. The decreased expression of IL-18 (n-fold = ∼ 1.92) and fibrinogen (n-fold = ∼ 12.03) was observed in DN group as compared to DM and control group. The uric acid, creatinine, blood sugar and GFR highly correlated with inflammatory cytokines that showed the disease severity. The predictive model by linear regression analysis concluded that age, serum creatinine, blood sugar and expression of IL-6 plays an essential role in the progression of DN. An inverse relationship between fibrinogen and blood sugar was observed in DN subjects. Differences in serum levels of IL-1β, IL-6, IL-18 and fibrinogen was observed among population of selected cities.
Conclusion
The present study implicates that among pro-inflammatory cytokines, Il-6 is an important predictor of DN progression in Pakistani population. The significant variation was observed in the expression of IL-1β, IL-6, IL-18 & fibrinogen in Lahore, Gujranwala, Multan, Islamabad, Karachi and Gharro that screen the variation in different races of Pakistan.

Cognitive disorders in elderly with type 2 diabetes

Maryam Cheikhrouhou, Kamilia Ounaissa, Abir El Amri, Nesine Dhieb, Dorra Ben Salem, Emna Bornaz, Haifa Abdesslem, Chiraz Amrouche
National Nutrition Institute, Department of Nutritional Diseases D, Tunisia

Introduction
Cognitive disorders are common in the elderly population. Diabetes accelerates cognitive deterioration in this population. We aimed to estimate the frequency of cognitive disorders in elderly diabetics ubjects.
Methods
This was a cross-sectional study including200 elderly diabetic patients. Cognitive function was assessed using the Mini Mental State Examination (MMSE) score. Participants having a score below 26 were considered cognitively impaired.
Results
Median HbA1C was 8.66%. The median MMSE score was 26 (IIQ= [23-27]). A score <26 was recorded in 28.5% of patients. We noted that cognitive impairment was more frequent in women ($p<0.001$) and that it increased with age (p=0.034). thus, cognitive disorders were found in 22.1% of patients aged between 70 and 75, 53.3% of patients aged between 75 and 80, and 44.4% of patients aged over 80. Patients with cognitive impairment, hadmore frequently a poor glycemic control (70.2% vs 51.1% $p<0.001$) and a higher frequency of mild and sever hypoglycemia (43.9% vs 27.3% p=0.023), than those without cognitive disorders.
Conclusion
Cognitive disorders are common among older diabetics. Systematic screening and optimization of treatment are essential in these patients.

Mauriac syndrome in adolescents: A clinical entity that still exists

Marwa Sassioui, Saloua ELAMARI, Soukaina LAIDI & Marouan Fatima
Cheikh khalifa bin zayd al nahyan Hospital - University Mohamed VI of health sciences, casablanca , Morocco

Introduction
Mauriac syndrome is a rare pathology characterized by the presence in an unbalanced type 1 diabetic (T1DM) of delayed stature-weight and puberty, and hepatomegaly with disturbance of the liver balance. We report a case of Mauriac syndrome in a young diabetic to recall the syndrom, as well as the diagnostic criteria.
Medical observation
This was a 17-year-old patient, type 1 diabetic since the age of 2, with recurrent ketoacidosis. Admitted to the endocrinology department post ketoacidosis. On clinical examination, abdominal distension was noted, with a liver arrow greater than 12 cm. Height 136 cm (-4 DS) and weight 30 kg. The pubertal stage according to Tanner's classification was P2G2. Biology revealed poorly balanced diabetes (HbA1c 12%) and moderate cytolysis. Viral serologies and immunological work-up were negative; thyroid work-up was normal. Abdominal ultrasound showed hepatomegaly (hepatic arrow FH: 17cm) homogeneous and hyperechoic. Liver biopsy concluded glycogenic overload.
Conclusion
Mauriac syndrome was first described by Mauriac in 1930, in children with type 1 diabetes mellitus presenting with stunted growth and puberty, hepatomegaly and elevated transaminases. Differential diagnoses include toxic causes, viral hepatitis, Wilson's disease, autoimmune hepatitis, celiac disease and minor glycogenosis. Paraclinical investigations confirm clinical suspicion and establish the diagnosis. The gold standard is liver biopsy, to rule out autoimmune hepatitis. Balanced diabetes allows normalization of liver function and recovery of growth and puberty.

Testosterone levels in men with type 2 diabetes: impact of statins and dyslipidemia

Anis Grassa[1], Manel Jemel[1], salma salhi[1], Brahim Khalfa[1], Asma Krir[2], Ahlem Benhmid[2], Marwa Chiboub[1], Radhouane Gharbi[1] & Ines Kammoun[1]
[1]National Institute of Nutrition and Food Technologies, Zouheir Kallel, [2]Pasteur Institute of Tunis

Introduction
Hypogonadism (HG), a condition characterized by insufficient testosterone levels, is a prevalent concern in men with Type 2 Diabetes (T2D). Simultaneously, the use of statins and the presence of dyslipidemia are common aspects of the medical management of individuals with T2D. This study investigates the intricate relationship between HG, statin therapy, and dyslipidemia in men with T2D, aiming to unravel potential correlations and shed light on the complex health dynamics within this population.
Methods
This is a cross-sectional study that included 250 male patients aged 40 to 65 diagnosed with T2D, recruited from outpatient clinics. All patients underwent lipid and hormonal assessments. HG was considered in the presence of specific criteria: Total Testosterone (TT) levels below 231 ng/dL, Free Testosterone (FT) levels below 6.5 ng/dL, or Bioavailable Testosterone (BT) levels below 150 ng/dL.
Results
The median age of our cohort was 58 years, with an interquartile range of [52.7-62], spanning from 40 to 65 years. Regarding blood lipids, the average levels of total cholesterol (TC), triglycerides (TG), and high-density lipoprotein cholesterol (HDLc) were 4.14 ± 0.96 mmol/L, 1.44 ± 0.89 mmol/L, and 1.03 ± 0.22 mmol/L, respectively. Dyslipidemia was noted in 72.3% of patients, predominantly marked by hypoHDLemia (55.7%) followed by hypertriglyceridemia (27.7%). Additionally, 12.8% of patients exhibited hypercholesterolemia . Notably, 69.2% of participants were under statin therapy. Concerning TT levels, The average level was 438.8 ± 172.1 ng/dL. No significant difference was observed between the statin group (434.0 ± 158.2 ng/dL) and the non-statin group (453.6 ± 201.2 ng/dL) (p=0.414). The analysis of HG prevalence between the statin (69.7%) and non-statin groups (71.1%) did not reveal a significant difference (p=0.829).
Conclusion
These findings suggest that in the studied cohort of men with T2D, dyslipidemia and statin therapy did not significantly impact total testosterone levels or the prevalence of hypogonadism. Further research may be warranted to explore additional factors influencing hormonal health in this population.

Investigation of anti-diabetic effects of various extracts of Jatropha tanjorensis in BRIN-BD11 clonal pancreatic beta cells

Simren Kaur Heer[1], Opeolu Ojo[1,2], Ayokunle Benjamin Falana[1], Adaeze Enebuse[3], Mojisola Adie[1] & Iyiola Tella[3,4]
[1]University of Wolverhampton, Faculty of Science and Engineering, [2]IRiD Biosciences, Stoke-on-Trent, [3]Modibbo Adama University, Department of Forestry and Wildlife Management, Yola, Nigeria, [4]First Technical University, Faculty of Natural and Applied Sciences, Ibadan, Nigeria

Aim
Beneficial effects of Jatropha tanjorensis (J. tanjorensis) extracts in African traditional medicinal practices for the management of type 2 diabetes have been reported. However, mechanisms through which these extracts exert their anti-diabetic actions have not been widely studied.
Methods and materials
Effects of various aqueous extracts of root, leaf, and bark J. tanjorensis (0-1000 μg/ml) on insulin-release, cytotoxicity and cell viability were investigated using BRIN-BD11 cells. Effects of leaf extracts (100 μg/ml) on glucose-stimulated insulin secretion and changes in insulinotropic actions in the presence of known modulators as well as the absence of extracellular calcium were also assessed.
Results
J. tanjorensis extracts stimulated insulin secretion from BRIN-BD11 cells at concentrations $\geq$0.1 μg/ml for leaf (1.7-fold, $P<0.001$), 1 μg/ml for bark (2-fold, $P<0.05$) and 10 μg/ml for root (1.8-fold, $P<0.05$) extracts. These insulin-releasing effects were not associated with significant release of lactate dehydrogenase at concentrations $\leq$100 μg/ml for leaf, 100 çg/ml for bark and 100 μg/ml for root extracts. Effects of the leaf extracts were inhibited by diazoxide (51%, $P<0.01$), verapamil (29%, P0.05) and in the absence of intracellular calcium (41%, $P<0.01$). However, effects of the extract were enhanced by KCl (2.3-fold, $P<0.01$. Improved intracellular calcium concentration were observed in cells treated with the leaf extracts of J. tanjorensis (2.4-fold, P0.01).
Conclusion
The results confirm insulinotropic actions of J. tanjorensis extracts and suggest that the KATP-dependent pathway may be involved in the mechanism of action.

NGO project on status report on pediatric diabetes in developing countries

S Pal[1] & T Roy[1]
[1]SFCCP NGO, Med, meerut, India

Issues
In developing nations diagnosis of diabetes brings mental-trauma/depression in family. Focused treatment for pediatric age-group is unavailable in developing-countries. 26% of diagnosed diabetics are children's. Adequately trained physicians/Nurses in issues of pediatric-diabetes provide continuity of care, relief from depression and smooth transition from diagnosis to treatment. Qualitative collaborative relationship between these makes diabetics life bearable. Our NGO-project highlights significance of relationship between nurses and diabetic-children in community clinic setup of rural India. For Diabetes, its assumed that depression is inevitable sequel to diagnosis. Retrospective analysis of past studies shows—counselling improves QOL & attitude towards diabetes-treatment.
Aims
To describe care issues in diabetic-children's. Observe/modify nature of relationship between nurse and child. To evolve comprehensive treatment plan for patients and families.
Methods
A retrospective analysis of data base from 7 rural health-clinics. Specialized therapy/support to pediatric-age-group not available at any centre. Total 117 children's [4-13 years] diagnosed with diabetes. 23 had additional endocrine/-metabolic problems. Nursing/medical care plan analyzed. No specialized trained personal in rural/tribal India. Opinion/needs from patients families collected on feedback questionnaire. Then we trained 10 nurses & 2 physicians for handling pediatric cases [4 weeks training].
Results
out of 117, 41 discontinued Rx due to improper counseling/guidance. 3 died. Patient/family's feedback highlights: Better access to newer drugs-delivery-systems, psychosocial support, follow-up-plan. Nurses/physician be sensitized in pediatric care-issues. Main issues of concern were: [1] illness and coping with their feelings. [2] Initial impact of diagnosis and a search for solution? Expectations for future life & its quality? [3] Concerns of cost of RX [4] Availability of proper follow-up centers in rural areas of developing nations.
Conclusion
Multifaceted Relationship between physician/nurse and Diabetics children's is crucial. This relationship provides better continuity of treatment. We show concerns/difficulties while working in Asian set-up to experts/seniors at ECE congress

Real-world comparison of real-time continuous glucose monitoring and intermittently scanned continuous glucose monitoring in glycemic control among individuals with type 1 diabetes: a nationwide cohort study

Ji Yoon Kim[1], Seohyun Kim[2], Rosa Oh[1], So Hyun Cho[1] & Jae Hyeon Kim[1]
[1]Samsung Medical Center, Medicine, Seoul, Korea, Rep. of South; [2]Sungkyunkwan University, Clinical Research Design and Evaluation, Seoul, Korea, Rep. of South

Aim
There is little real-world evidence comparing the effectiveness of real-time continuous glucose monitoring (rtCGM) and intermittently-scanned continuous glucose monitoring (isCGM) in glycemic control, with a large population and long-term follow-up. This study aimed to compare the association of rtCGM and isCGM with glycemic control in individuals with type 1 diabetes (T1D) in a real-world setting.
Methods
From the Korean National Health Insurance Service Cohort (2016–2022), individuals with T1D managed by intensive insulin therapy were followed up for 2 years at 3-month intervals since the initiation of CGM. The HbA1c and coefficient of variation (CV) of rtCGM and isCGM users were compared using an independent two-sample t-test and a linear mixed model.
Results
A total of 4,333 and 6,257 individuals were included in the HbA1c and CV analyses, respectively. Overall, a significant reduction in HbA1c levels was observed after 3 months of receiving CGM, and the effect remained durable for 2 years. A greater reduction in HbA1c levels was observed with rtCGM compared to isCGM (P for between-group difference <0.05 in both children and adults). The mean HbA1c level decreased from 8.9% at baseline to 7.1% at 24 months in rtCGM users, whereas it decreased from 8.6% to 7.5% in isCGM users. The greater reduction in HbA1c with rtCGM remained significant after adjusting for the baseline characteristics of users. CV also decreased more with rtCGM than with isCGM.
Conclusion
In this large nationwide cohort study, the use of rtCGM was associated with a greater improvement in glycemic control including HbA1c reduction than the use of isCGM in individuals with T1D.

[1]Sorbonne Université, Inserm, Nutrition and Obesities: Systemic Approaches (NutriOmics) Research Unit, Paris, France; [2]Sapienza University of Rome, Experimental Medicine, Roma, Italy; [3]Université de Paris, Inserm U1016, Team ' Mucosal microbiota in chronic inflammatory diseases', Cnrs Umr 8104, Paris, France; [4]Hôpital privédes Peupliers - Ramsay Générale de Santé, Paris, France; [5]Sorbonne Université, Inserm Umrs-938, Centre de Recherche Saint-Antoine, Crsa, AP-HP, Paris, France; Paris Center for Microbiome Medicine, Fédération Hospitalo-Universitaire, Paris, France; INRAE, UMR1319 Micalis & AgroParisTech, Jouy en Josas, France

Introduction
While extensive research on the fecal microbiome (FM) has already underscored the gut microbiome's role in metabolic diseases, it is imperative to recognize its limitations in depicting the entire gastrointestinal tract. Each segment of the tract harbors unique conditions shaping microbial ecosystems, necessitating exploration

beyond the FM. The upper small intestine (USI) significantly impacts nutrient digestion and absorption, hinting at its microbiome's potential influence on the regulation of host metabolism. In a recent systematic review of the literature, we pointed out that studies on the C57BL/6 murine strain fed a high-fat diet showed a causal connection between the USI microbiome (USIM) and metabolism. However, research on individuals with obesity remains scarce and conflicting, and comparative studies between different gastrointestinal niches in patients with obesity are lacking.
Materials and Methods
This pilot study employed Shotgun Illumina sequencing to conduct metagenomic analysis of the USI, FM, and oral microbiome (OM) in both candidates for metabolic surgery ($n=15$) and healthy controls ($n=15$).
Results
USIM exhibited lower gene richness than OM and FM ($P<0.0001$). Compositionally, USIM resembled OM more than FM but exhibited significant differences from FM. Multivariate permutational analysis revealed that body composition and corpulence variables accounted for variance in USIM and its associated metabolome composition, showing a negative correlation with metagenomic richness. Comparison between groups with and without obesity within each ecosystem unveiled greater metagenomic richness in the USI of patients with obesity ($P=0.037$). This group also displayed a lower relative abundance of Proteobacteria ($P<0.001$), notably Neisseriaceae ($P<0.0001$), in the USIM.
Conclusion
Our study underscores the significance of studying the proximal gut microbiota to unravel intricate connections between gut microbiota composition and metabolic health. These insights provide a foundation for potential therapeutic interventions targeting the proximal gut microbiome in managing metabolic diseases.

The development of cardiovascular disease or cancer is correlated with higher FIB-4 in patients with T2DM

Katerina Stefanaki[1], Dimitrios Karagiannakis[2], Petrea Foteini[3], Panagiota Zacharaki[1], Alexandra Giannou[3], Olympia Michalopoulou[1], Paraskevi Kazakou[1], Theodora Psaltopoulou[1], Vasiliki Vasileiou[3] & Stavroula Paschou[1]
[1]Alexandra Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece., Endocrine Unit and Diabetes Center, Department of Clinical Therapeutics, Athens, Greece; [2]Laiko General Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, Academic Department of Gastroenterology; [3]Alexandra Hospital, Athens, Greece., Department of Endocrinology

Introduction
Metabolic dysfunction-associated steatotic liver disease (MASLD) is a common feature of type 2 diabetes mellitus (T2DM). Liver fibrosis has been associated with an increased risk of cardiovascular diseases (CVD).
Aim
To investigate whether the fibrosis 4 index (FIB-4), a non-invasive marker of liver fibrosis, is associated with CVD or cancer in patients with T2DM.
Methods
Two hundred and nine consecutive T2DM patients were retrospectively evaluated. The mean time from the diagnosis to the first visit to our diabetes center was 9.83 ± 8.6 years (median: 8.2 years; IQR: 12).
Results
One hundred and thirty-two (63.2%) patients were male and 77 (36.8%) were female. The mean age, body mass index (BMI), glycated hemoglobin (HbA1c), and FIB-4 were 64.3 ± 11 years, 30.5 ± 5.8 kg/m^2, 7.8 ± 2, and 1.15 ± 0.5, respectively. One hundred and fifty (71.8%) patients had FIB-4 <1.3, and 59 (28.2%) had FIB-4 >1.3. Patients with CVD at the first visit were significantly older compared to patients without CVD (68.9 ± 8.4 vs 62.9 ± 11.4, respectively; $P<0.001$), while they had substantially higher FIB-4 (1.26 ± 0.54 vs 1.08 ± 0.51, respectively; $P=0.007$). Patients with cancer of any type at the first visit were older (68.2 ± 9.5 vs 64.4 ± 10.9 years, $P=0.098$), having significantly higher FIB-4 (1.37 ± 0.6 vs 1.1 ± 0.5, $P=0.004$) compared to those without cancer. A significant correlation was revealed between FIB-4$>$ 1.3 and the presence of CVD (χ 2=4.92, $P=0.027$) or the presence of cancer (χ 2=7.603, $P=0.006$), respectively. In the multivariate analysis, the presence of CVD was found to be independently associated with sex (male: OR 0.261, 95% CI 0.095-0.717; $P=$ 0.009), age (OR 1.057, 95% CI 1.008- 1.108; $P=$ 0.021), and hypertension (OR 6.146, 95% CI 2.442-15.471; $P<0.001$).
Conclusion
T2DM patients who develop CVD or cancer are older with higher FIB-4. Older female patients with a history of hypertension are at a higher risk of developing CVD.

The influence of finerenone on renal function in patients with type 2 diabetes

Yanina Rebrova[1], Yana Saienko[1], Borys Mankovsky[2] & Ievgen Marushko[1]
[1]Ukrainian Children's Cardiac Center, Cardiometabolic Disease, Kyiv, Ukraine; [2]Dmitry F. Chebotarev Institute of Gerontology of the National Academy of Medical Sciences of Ukraine, Kyiv, Ukraine

Background
Chronic kidney disease develops in approximately 40% of patients with type 2 diabetes mellitus (T2DM) and significantly increases the risk of mortality and cardiovascular morbidity. Finerenone, a novel nonsteroidal mineralocorticoid receptor antagonist, has demonstrated a significant impact on renal function by reducing proteinuria and preserving glomerular filtration rate in patients with chronic kidney disease. However, the influence of finerenone on kidney function in the different patients populations requires the further investigation. Therefore, the aim of our study was to investigate the influence of treatment with finerenone on kidney function in patients with chronic kidney disease with and without T2DM.
Methods
Two groups of patients were examined. The first group included 45 patients with T2DM who were taking finerenone. Their age was 63.0 ± 6.0 years, duration of diabetes - 7.0 ± 4.0 years, HbA1c was 7.6 ± 2.2%, creatinine level -115.6 ± 3.78 μ mol/l, estimated glomerular filtration rate (eGFR) -50.95 ± 1.56 ml/min/1.73m^2, and the urinary albumin-to-creatinine ratio (UACR) -43.08 ± 10.84 mg/g % (data are presented as mean$\pm$SD). The second group consisted of 40 patients without type 2 diabetes but with chronic kidney disease (CKD) who were taking finerenone. Their age was $54,0\pm4,0$ years, HbA1c -5.1 ± 0.9%, creatinine level -84.73 ± 2.01 μ mol/l, eGFR -83.60 ± 1.86 ml/min/1.73 m^2, and UACR -25.14 ± 4.18 mg/g. To compare the effect of finerenone on eGFR and UACR, we used one-way analysis of variance (ANOVA) and Student's t-test.
Results
In patients with diabetes, the increase in eGFR under the influence of the drug does not significantly differ between groups with and without diabetes (54.41 ± 1.77 ml/min/1.73 m^2; 86.75 ± 1.69 ml/min/1.73 m^2, –respectively, $P<0.05$). The decrease in UACR under the influence of the drug does not significantly differ between groups with and without diabetes, but there is a tendency toward a more pronounced effect in patients without diabetes (42.42 ± 10.68 mg/g; 21.32 ± 4.38 mg/g,–respectively, $P<0.05$).
Conclusion
We found that finerenone positively affects kidney function in patients with and without T2M. The administration of finerenone has been associated with a decrease in urinary albumin excretion and a slowing of the progression of kidney disease, highlighting its potential as a therapeutic option for managing renal complications.

Familial partial lipodystrophy:genetic and clinical data from a greek referral center

Aikaterini Kountouri[1], Emmanouil Korakas[1], Eirini Maratou[2], Ignatios Ikonomidis[3], Konstantinos Balampanis[1], Loukia Pliouta[1], Stavros Liatis[4], Nikolaos Tentolouris[4], Panagiotis Toulas[5], Foteini Kousathana[1], Christoforos Giatzakis[6], George Dimitriadis[7] & Vaia Lambadiari[1]
[1]Attikon University Hospital, Second Department of Internal Medicine, Chaidari, Greece; [2]Attikon University Hospital, Department of Clinical Biochemistry, Chaidari, Greece; [3]Attikon University Hospital, Second Cardiology Department, Chaidari, Greece; [4]Laiko Hospital, First Department of Propaedeutic and Internal Medicine, Athens, Greece; [5]Bioiatriki Healthcare Group, Athens, Greece; [6]DNAbiolab, Cretan Center for Research and Development of Applications on Genetics and Molecular Biology, Heraklion, Greece; [7]Sector of Medicine, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Background
Familial partial lipodystrophy (FPLD) is a rare syndrome in which a patient's phenotype is not dependent merely on the specific genetic mutation, but also on a combination of other demographic, environmental and genetic factors. In this report, we present a large cohort of novel mutation in FPLD patients from a large referral center in Greece and we investigate the possible relationship between the genetic variations detected and their phenotype and the effect of metreleptin treatment in eligible FPLD patients.

Methods
This is a prospective observational study in a Greek referral center, included patients who fulfilled the clinical criteria of FPLD. A genetic analysis was conducted, which included sequence and deletion/duplication analyses of the LMNA and PPRARG genes. Anthropometric parameters and laboratory examinations were evaluated. The treatment responses of patients who received treatment with metreleptin were evaluated at 3 and 12 months.
Results
Overall, 39 patients were included in the study. The mean ± SD age was 47.59 ± 10.13 years, and 30 patients were female (76.9%). All the patients presented lipoatrophy in lower limbs, 59% in upper limbs and 66.7% in gluteal area. 97.4% displayed fat deposition in the abdomen, 46.2% in the trunk, 56.4% in the face and 35.9% in the neck. 76.9% presented acanthosis nigricans while 12.8% displayed muscular hypertrophy. Regarding the comorbidities related to lipodystrophy phenotype, 66.7% suffered from diabetes mellitus, thirty 76.9% presented dyslipidemia, 61.5% had hypertension, 56.4% had NASH or NAFLD and six 5.4% suffered from heart diseases. 33.3% of females met the criteria for PCOS. Genetic testing for did not result in any of the already known pathogenic mutations, but it revealed three likely pathogenic mutations, along with various changes in other exons and introns, especially in introns 7 and 10, whose pathogenicity and the subsequent role in the patients' phenotype remains unclear. Treatment with metreleptin in eligible FPLD patients significantly improved indices of glycemic and lipidemic control, and the benefit was sustained after 12 months.
Conclusion
We have shown the presence of mutations both in exons, which are different from the ones which already have an established association with the disease, and in introns, which might also contribute to the final amino acid products and the phenotype of the patient. The sustainable and favorable results of metreleptin treatment in FPLD patients were confirmed, and they are independent from any baseline parameters.

Obesity (OB) and type-2 diabetes (T2D) are chronic endocrine-metabolic diseases, associated to insulin-resistance (IR), that represent capital health problems. Fortunately, both pathologies are, at least, partially reversible by dietary interventions, but the potential metabolic, molecular, cellular factors and mechanisms that might be involved in the total/partial reversion of OB/IR/T2D by dietary interventions are poorly known. Thus, in this work, we aimed evaluate the impact of Mediterranean-diet (MedD) and a low-fat-diet (LFD) on the reversion of OB/IR/T2D, and the associated metabolic/cellular/molecular alterations in key tissues [e.g. visceral adipose tissue (VAT) and liver]. To that end, 8-weeks old littermate-male-mice were fed a high-fat diet [HFD; 60% fat (54.2% lard + 5.6% soybean oil)] to develop OB/IR, or a control-diet [17.4% fat (soybean oil), (n = 12] for 14-weeks. Then, HFD group mice (with OB/IR) were divided into 3 groups with different diet interventions for additional 13-weeks: i) maintained with the same HFD (n = 12); ii) shifted to MedD [35% fat: 21.7% MUFA (extra virgin olive-oil), 5.9% PUFA (4.9% corn-oil + 1% fish-oil), and 6.9% SFA (butter); (n = 18]; or, iii) shifted to a LFD [30.1% fat: 12.7% MUFA (extra virgin olive oil), 6.8% PUFA (5.7% corn-oil + 1.1% fish-oils) and 9.7% SFA (butter); (n = 18], while the control-diet group continued with the same diet for a total of 27 weeks. Before and after diet intervention, body-status (weight and composition), glucose homeostasis, indirect calorimetry, and activity as well as plasma insulin, leptin, ghrelin, and ALT were measured. Finally, alterations in the expression of inflammasome- and proliferation-related genes were measured in VAT and liver. As main results, we could observe that both MedD and LFD significantly reversed the OB/IR/metabolic-status induced by HFD (i.e. decreased body/tissue weights, body fat mass, VAT adipocytes area, liver triglyceride content, and proliferation-related genes expression in VAT and liver; improved glucose/insulin tolerance; reestablished respiratory exchange ratio, energy expenditure and activity; recovered plasma insulin/-leptin/ghrelin/ALT levels), close to the levels found in the control-diet group. Additionally, MedD/lFD reduced inflammasome-related genes expression vs HFD group in VAT. However, this inflammatory profile was only reverted in the liver of MedD, but not LFD, group vs HFD-group. All toghether, we can conclude that MedD and LFD intervention successfully reverted OB/IR/metabolic-status, but the molecular fingerprints associated to this beneficial effects at the VAT and liver are distinct.

Risk of type 2 diabetes in 99,892 nordic women with polycystic ovary syndrome and 446,055 controls: national cohort study from Denmark, Finland and Sweden

Dorte Glintborg[1,2], Meri-Maija Ollila[3], Jens-Jakob Møller[4], Paula Pesonen[3], Sofia Persson[5], Evangelia Elenis[5], Katrine Rubin[1,6], Mika Gissler[7,8,9], Marianne Andersen[1], Inger Sundström-Poromaa[5] & Terhi Piltonen[3]
[1]Odense University Hospital, Odense, Denmark; [2]University of Southern Denmark, Odense, Denmark; [3]Oulu University Hospital, Oulu, Finland; [4]Odense University Hospital, OPEN, Odense, Denmark; [5]Uppsala University Hospital, Sweden; [6]University of Southern Denmark, OPEN research unit, Odense, Denmark; [7]Helsinki, Department of Knowledge Brokers, THL Finnish Institute for Health and Welfare, Helsinki, Finland, Helsinki, Finland; [8]Region Stockholm, Academic Primary Health Care Centre, Sweden; [9]Karolinska Institute, Department of Molecular Medicine and Surgery, Sweden

Background
The risk of type 2 diabetes (T2D) in PCOS is associated with BMI, but prospective data regarding risk of T2D in PCOS are limited. We investigated prospective risk of T2D in Nordic women with PCOS compared to controls.
Methods
National register-based study in women with PCOS and age-matched controls originating from Denmark (PCOS Denmark, (n = 27,016, controls, (n = 133,994), Finland (PCOS Finland, (n = 20,467, controls, (n = 58,051), and Sweden (PCOS Sweden, (n = 52,409, controls, (n = 254,010). The main study outcome was T2D occurring after PCOS diagnosis. T2D was defined according to ICD-10 diagnosis codes and/or filled medicine prescriptions. Cox regression analyses were adjusted for BMI and length of education.
Findings
The median age at cohort entry was 28 years in PCOS Denmark, Finland and Sweden with median follow-up time (interquartile range) in women with PCOS of 8.5 (4.0; 14.8), 9.8 (5.1; 15.1), and 6.0 (2.0; 10.0) years, respectively. The crude hazard ratio (HR, 95% CI) for T2D in women with PCOS was 4.28 (3.98 –4.60) in Denmark, 3.40 (3.11 - 3.74) in Finland and 5.68 (5.20 –6.21) in Sweden. In adjusted regression analyses, BMI $\geq$ 30 vs $<$ 25 kg/m^2 was associated with 7.6- to 11.3-fold risk of T2D. In a combined meta-analysis (PCOS, (n = 99,892, controls, (n = 446,055), the crude HR for T2D in PCOS was 4.64 (3.40 –5.87) and adjusted HR 2.92 (2.32 –3.51).
Interpretation
Diagnosis of PCOS and BMI $\geq$30 kg/m^2 represented a high-risk phenotype for prospective risk of T2D across Nordic countries.

Comparison of metabolic and immunological profile of 2 types of familial partial lipodystrophy syndromes (PLIN1 and LMNA)

Dupuis Hippolyte[1], Stienne Lucie[1], Lion Georges[2], Pigny Pascal[2] & Marie-Christine Vantyghem[1,3]
[1]Hospital Center University De Lille, Endocrinology-Diabetology-Metabolism-Nutrition, Lille, France; [2]Hospital Center University De Lille, Nuclear Medicine, Lille, France; [3]Lille University Hospital, competence center for rare endocrine diseases Firendo Prisis, Lille, France

Familial Partial Lipodystrophy Syndromes (FPLD) are rare diseases characterized by partial lack of subcutaneous fat resulting in a severe metabolic

syndrome and cardiovascular complications. Besides premature cell senescence, 2 main mechanisms are involved in FPLD: impaired adipocyte differentiation and lipid droplet, corresponding to two of the main causes of FPLD: *LMNA*-related FPLD2 and *PLIN*-related FPLD4. The objective of this study was to compare the clinical, metabolic and immuno-hematological profile of these 2 types of FPLD.
Methods
The study was conducted in the frame of a prospective cohort (NCT0178428) aiming to characterize different types of fat disorders associated with a variable degree of insulin resistance from lean control subjects to obese patients and lipodystrophy syndromes in a university hospital. Clinical (sex, age), metabolic (HbA1c, fasting blood glucose and C-peptide, triglycerides, liver enzymes, leptin, CRP), % of fat mass (DEXA), intra&total abdominal fat and % of liver steatosis (MRI) were recorded. Four groups of patients (20 lean and 20 non-diabetic obese patients, 26 R482-*LMNA*-mutated patients and 8 *PLIN1*-linked FPLD patients were compared with the Mann-Whitney test, whereas correlation studies were done with the Pearson test.
Results
The 2 FPLD groups (FPLD2 and FPLD4) showed higher BMI, intraabdominal fat, HbA1c, triglycerides, ALAT, fatty liver, and eosinophils than the lean controls, but FPLD2 and FPLD4 groups only differed by a significantly lower leptin level in the FPLD4 group. Compared to lean controls, leukocytes & neutrophils were increased, and NK cells decreased, in the FPLD2 group. Basophils levels were increased in the FPLD4 group compared to lean, but also obese subjects. Basophils were the cell subtype the most often correlated positively with metabolic (HbA1c, FBG, triglycerides) and liver (ALAT, steatosis %) parameters, and negatively with the % of body fat mass and leptin levels.
Conclusion
This is the first report comparing the clinical and biological phenotype, including immune-hematological profile, of FPLD patients, especially the rare FPLD4 patients, to lean and obese control groups. Although the controverses on the pathogenicity of *PLIN1* variants, the phenotype of FPLD4 was similar to FPLD2, with however a less severe lipoatrophy as suggested by a lower leptin level. In addition, despite the small size of the groups, we found variations of NK and basophils cells, key cells involved in Th2 response, suggesting the potential interest of targeting basophil activation with treatments such as omalizumab, benlizumab, in the field of these rare orphan diseases.

Clinical outcomes of patients with diabetic foot ulcer treated with dalbavancin in the outpatient setting

Sarah Lawless[1], Elias Eltoum[1], Emily Madden[1], Avril Clancy[1], Ana Rueda[1], Carole Doherty[2], Siobhan Bacon[1] & Catherine McHugh[1]
[1]Sligo University Hospital, Department of Diabetes, Endocrinology and Metabolism, Ireland; [2]Sligo University Hospital, Department of Pharmacy, Ireland

Aims
The primary aim of this retrospective study was to examine clinical outcomes of patients with diabetic foot ulcer (DFU) and/or osteomyelitis (OM) who attended day services at Sligo University Hospital (SUH) for dalbavancin between November 2020 and August 2023. The secondary aim was to perform a cost analysis of the use of dalbavancin.
Methods
Clinical information was obtained from the Prowellness electronic patient record and laboratory results were extracted from the SUH information system.
Results
In total, data from 42 patients who received dalbavancin was collected. 37(90.2%) patients have T2DM, 9(24.3%) of which are insulin dependent, and 4(12.9%) patients carry a diagnoses of T1DM. Mean duration of diabetes is 16.1 years. Average HbA1c was 61.2 mmol/mol. We have follow up podiatry data on 34 of these patients, unfortunately, 8 patients either transferred care to another hospital or did not attend follow up clinics. 26 (76.47%) achieved remission with no active foot disease, 10 (38.5%) of these patients suffered another diabetic foot ulcer at a different site(s) post resolution. 18 of these patients have been discharged to community podiatry. Prior to the availability of dalbavancin, patients with DFU were admitted as inpatients for treatment as out-patient antimicrobial therapy (OPAT) is limited in our area. A cost analysis was performed comparing inpatient admission and outpatient treatment with dalbavancin. The average length of stay for an inpatient with diabetes in Ireland is 8+/-13 days. The Health Service Executive advised in 2019, that the cost of a hospital bed is € 878 per night. Therefore, the average cost of an admission is approximately € 7024. The current cost of a course of a complete course of dalbavancin is € 3852.
Conclusion
Patients treated with dalbavancin for DFU have had good clinical outcomes to date while avoiding inpatient admission. There is significant cost savings using this approach.

MAFLD and type 2 diabetes: is dual therapy an effective option?

Giovanni Ragozzino[1], Igea Martina Madonna[1] & Edi Mattera[2]
[1]University of Campania, Environmental Biological and Pharmaceutical Sciences and Technologies, Caserta; [2]University of Campania, Precision Medicine, Naples

Background and Aims
Metabolic dysfunction-associated fatty liver disease (MAFLD) is a diagnosis of inclusion relying on a set of metabolic risk factors and the presence of hepatic steatosisis; viscerl obesity, insulin resistance, type 2 diabetes (T2D) may often coexist in MAFLD patients. MAFLD is present in up to 80%f of T2D patients. Pioglidazone, a peroxisome proliferator-activated receptor agonist reduce hepatic/visceral fat (HVF) and improve necroinflammation in liver. Dulaglutide, a weekly glucagon-like peptide-1 (GLP-1) receptor agonist, significantly reduces liver fatty content (LFC) and improves GGT levels in NAFLD. Aim of this study was to evaluate dual treatment (pioglidazone plus dulaglutide) vs pioglidazone alone in recruited MAFLD/T2D patients.
Method
MAFLD was assessed using ultrasound-fatty liver index that allows to grade steatosis severity (US-FLI score ≥ 3) and liver fibrosis (F1-F2 staged according to the METAVIR score). Eligible patients (pioglidazone, 30 mg/die, os undergoing treatment for at least 1yr) added 1.5 mg subcutaneous dulaglutide weekly for 36 weeks. Fifty-seven MAFLD/T2D patients were studied (baseline, 3, 6 and 9 months). Plasma markers of hepatic dysfunction (ALT, AST, γ GT), cardiometabolic risk (triglycerides, total, non-HDL cholesterol, Apo-B100, Apo-B48, HbA1c, 1.5-anhydroglucitol [1,5-AG]), inflammation (hs C-reaction protein, TNF-α, IL-10/IL-6 ratio) were studied.
Results
Significant reduction in HVF ($P<0.05$) and LFC percentage ($P<0.02$), IL10/IL-6 ratio ($P<0.002$) and ALT ($P<0.05$), Apo-B100 ($P<0.001$), non-HDL cholesterol ($P<0.05$) and HbA1c ($P<0.02$) at 9 months were observed. HbA1c was inversely correlated with 1,5-AG and the factors significantly associated with advanced fibrosis were IL-10/IL-6 and 1.5-AG ($P=0.008$) (by multivariate logistic regression analysis). Only 5 patients experienced a worsening of METAVIR score/US-FLI and metabolic/inflammation biomarkers. Dual therapy were well tolerated and most events were gastrointestinal (nausea, diarrhea, vomiting, abdominal pain, decreased appetite, and fatigue) in nature.
Conclusion
Our study has several limitations. First, the sample size is relatively small. Second, the duration of drug treatment itself is longer due to the addition of drug (dulaglutide) to monotherapy (pioglitazone). Hence, it is difficult to distinguish the effect of the combination of drugs from that of long-term treatment. Notwithstanding the limitations described, it may be argued that MAFLD/T2D dual therapy (pioglidazone plus dulaglutide) showed metabolic and LFC improvement vs monotherapy (pioglidazone) group and reduction in liver stiffness, and ALT levels. Body weight gain (subcutaneous fat increase) mediated by pioglitazone monotherapy decreased following concomitant use of dulaglutide. Dual therapy might be effective for the treatment of MAFLD/T2D patients, as well as improving glycemic control and visceral obesity.

Acquired partial lipodystrophy: leptin and glucose blood levels in a pregnant patient

Martina Romanisio[1], Leonardo Bighetti[1], Tommaso Daffara[1], Carola Ciamparini[1], Davide Vimercati[1], Rosa Pitino[1], Caterina Pelosini[2], Gianluca Aimaretti[1], Marina Caputo[1,3] & Flavia Prodam[1,3]
[1]Endocrinology, Department of Translational Medicine, Università del Piemonte Orientale, Novara, Italy; [2]Chemistry and Endocrinology Laboratory, University Hospital of Pisa, Pisa, Italy; [3]Department of Health Sciences, Università del Piemonte Orientale, Novara, Italy

Lipodystrophy syndromes are a rare and heterogeneous disease characterized by loss of subcutaneous adipose tissue, deposition of fat in ectopic areas, and

consequently metabolic impairment, and its recognition is based on physical examination and clinical history. Because of the complexity of the disease, pregnancy represents a dainty and challenging event, still understudied. Here we report a case of a 28 year-old Caucasian female followed for type 2 diabetes and hypertriglyceridemia since she was 21 in the context of acquired partial lipodystrophy. Past medical history included childhood lymphocytic leukemia treated by chemo- and radiotherapy and allogeneic bone marrow transplant and subsequently she developed heart disease with left ventricular dysfunction (ejection fraction EF 45% in 2007) that was treated with beta-blocker and ACEi, and it normalized during follow-up. Diabetes mellitus wasn't adequately controlled (time in range TIR 5%, time above range TAR 95%, time below range TBR 0%, glucose management indicator GMI 11.3%) with insulin, metformin, and semaglutide; hypertriglyceridemia was discreetly controlled with PUFA and fenofibrate. In December 2021 she became unexpectedly pregnant and semaglutide, metformin, fenofibrate, and ACEi were stopped, PUFA was reduced and, after gynecological consultation, acetylsalicylic acid was added. During pregnancy Ambulatory Glucose Profile (AGP) reports improved with a TIR in the third trimester of 77%. Leptin values were periodically evaluated during pregnancy and in the early post-partum period: a progressive increase of levels was shown, with a peak in the third trimester (41.53 ng/ml), then after the delivery, there was a decline. Despite achieving good glycemic control, at 33 weeks of gestation, the patient developed acute pulmonary edema with the need for urgent cesarean delivery. The echocardiographic evaluation showed severe left ventricular diastolic dysfunction (FE 30%) that was treated with invasive ventilation (NIV), diuretic, nitroglycerin, inotropic drug, and ivabradine. No adipose tissue depots were observed at cardiac MRI. Furthermore, on suspicion of Sheehan syndrome, the patient started cortone acetate and then discontinued due to evidence of normal HPA axis function. The newborn was in good general condition except for the development of transient hypoglycemia and the finding of triple X syndrome. The management of lipodystrophies in pregnancy appears to be challenging and still poorly studied. Increased leptin values may suggest placental or fetal involvement in the metabolic improvement of the patient.

GLP-1RAs boost erectile function in men with type 2 diabetes and erectile dysfunction: results from a 1-year retrospective cohort study

Giuseppe Lisco[1], Vincenzo Triggiani[1], Emilio Jirillo[1], Edoardo Guastamacchia[1] & Vito Angelo Giagulli[1]
[1]University of Bari "Aldo Moro", Interdisciplinary Department of Medicine - Section of Internal Medicine, Geriatrics, Endocrinology and Rare Diseases, School of Medicine, Bari

Background
Glucagon-like peptide 1 receptor agonists (GLP-1RAs) are proven to boost serum testosterone levels in men with type 2 diabetes (T2D) and functional hypogonadism. Nevertheless, the therapeutic potential of this class of drugs on erectile dysfunction (ED) has yet to be entirely studied in men with T2D and functional hypogonadism.
Methods
A retrospective cohort study was conducted on 108 outpatients (60 [56, 65] years) with T2D and complaining of ED. Data were extracted from the database referring to patients with a 1-year follow-up on stable treatment with metformin alone (M, $n=45$) and GLP-1RAs as an add-on to metformin (GLP-1RA + M, $n=63$). Erectile function was assessed by the 5-item International Index of Erectile Function (IIEF5) at baseline and after 1 year of treatment. Values were compared between baseline (T0) and after 12 months of treatment (T12).
Results
ED was confirmed at baseline in all (IIEF5 score 13 to 19 points). After 12 months of treatment, glucose management was better in patients on GLP-1RAs + M (HbA1c T0: 8.3 ± 0.2 vs HbA1c T12: 7% ± 0.3%, $P<0.0001$) than in those on M (HbA1c T0: 7 ± 0.5 vs HbA1c T12: 7.3 ± 0.4, $P= 0.0007$). GLP-1RAs + M over M resulted in a significant weight loss (-5.82 ± 0.69 kg, $P<0.0001$), reduction in waist circumference (-4.99 ± 0.6 cm, $P<0.0001$), improvement in HbA1c (-0.56% ± 0.13%, $P<0.0001$), and fasting plasma glucose (-25.54 ± 3.09 mg/dl, $P<0.0001$), increase in total (+41.41 ± 6.11 ng/dl, $P<0.0001$) and free (0.44 ± 0.09 ng/dl, $P<0.0001$) testosterone levels, and gain in self-reported erectile function (IIEF5 score: +2.26 ± 0.26, $P<0.0001$). The gain in IIEF5 scores was more relevant in patients with higher baseline IIEF5 (estimated coefficient: 0.16 ± 0.08, $P= 0.045$), those having carotid stenosis (0.50 ± 0.24, $P= 0.045$), and showing weight loss from baseline (-0.08 ± 0.03, $P= 0.013$), regardless of serum testosterone. The leading determinant of the final IIEF5 score was a 1-year treatment with GLP-1RAs + M over M (2.74 ± 0.53, $P<0.0001$).
Conclusions
GLP-1RAs + M over M improved ED regardless of different background characteristics and testicular function of T2D patients and partially irrespective of therapeutic targets achieved after 12 months of treatment. Controlled trials are needed to confirm if GLP-1RAs have direct and helpful vasculature effects boosting erectile function in T2D.

Study of genetic predisposition and other pathogenetic mechanisms underlying hypogonadotropic hypogonadism in type 2 diabetes mellitus

Biagio Cangiano[1,2], Alessandro Amodeo[1], Elena Lunati[3], Valeria Vezzoli[2], Elena Galazzi[2], Luca Persani[1], Paolo Fiorina[1] & Marco Bonomi[1,2]
[1]University of Milan, Milano, Italy; [2]Italian Auxological Institute San Luca Hospital, Milano, Italy; [3]Ospedale Fatebenefratelli e Oftalmico, Milano, Italy

Background
In patients affected by type 2 diabetes mellitus (T2DM) a high prevalence of hypogonadotropic hypogonadism (HH) has been reported, even if there is no consensus on its pathogenic mechanisms. In addition to acquired causes, an individual predisposition has also been suggested. The understanding of
Purpose
The aim of this observational study is to assess: (1) the prevalence of hypogonadism in T2DM using the validated criteria from the EMAS study; (2) the correlations of hypogonadotropic hypogonadism (HH) with specific clinical features and predisposing factors; (3) the enrichment in rare pathogenic or likely pathogenic variants in HH diabetic subjects compared to the general population.
Materials and Methods
We consecutively enrolled 167 male patients affected with T2DM from (aged 18 to 85); patients with other known causes of hypogonadism were excluded. In each patient we studied the gonadal function, classifying them according to the EMAS validated criteria according to calculated free testosterone and LH levels. The age, BMI, smoking habit, the severity of diabetic disease, its treatments, complications, as well as leptin levels and HOMA-IR values were recorded, and used in a multivariate logistic analysis. 33 HH patients with T2DM were analyzed using a Target-Next Generation Sequencing (NGS), to search for rare allelic HH variants (RV). To verify the prediction of pathogenicity, we classyfied the RV according to The American College of Medical Genetics and Genomics (ACMG) guidelines. We conducted the same NGS analysis in 79 controls selected from the general population and compared the prevalences using Fisher Exact Test.
Results
The 51% of patients with T2DM showed some degree of hypogonadism: 30% had HH, and 21% showed primary hypogonadism (PH). To logistic multivariate analysis corrected for confounders, HH was correlated with leptin levels ($P=0.039$) and smoking (pack-years, $P=0.027$). No significant enrichment in rare CHH variants was found in T2DM patients with HH, as compared to the general population. However, we found 1 likely pathogenic *TBX3* variant according to ACMG criteria among the cases.
Discussion
We confirmed a high prevalence of hypogonadism in diabetes in a large cohort of patients. Genetic predisposition does not appear to be a significant cause of HH in T2DM, although some sporadic cases may occur. The presence of a rare, probably pathogenic genetic variant, and the significant and independent association of HH with leptin levels and smoking habits, seem to suggest that different mechanisms could underlie HH in T2DM

Comparison between most recent guidelines about NAFLD medical treatment

Irene Samperi[1], Marco Grasso[2], Maria Chantal Ponziani[3], Alberto Carpenito[4], Francesco Tassone[5], Carla Micaela Cuttica[6], Filippo Egalini[7], Roberta Guido[8], Morena Pisarro[9], Isabella Buffardi[9] & Anna Nelva[10]
[1]SSD of Diabetology and Metabolic Diseases- - Azienda Sanitaria Locale Novara, Novara, Italy; [2]Diabetology, Ospedale di Cittadella, Padova, Italy; [3]SSD of Diabetology and Metabolic Diseases - Azienda Sanitaria Locale Novara, Novara, Italy; [4]CAD Montoro-asl Avellino, Avellino, Italy; [5]SC Endocrinologia, Diabetologia & Metabolismo, ASO Santa Croce & Carle di Cuneo, Cuneo, Italy; [6]Unit of Endocrinology, Galliera Hospital, Genoa, Italy; [7]Endocrinology, Diabetes and Metabolism, Department of Medical Sciences, University of Turin, Turin, Italy; [8]Diabetology, ASL3 genovese, genoa, Italy; [9]Endocrinology, Rome, Italy; [10]Endocrinology, Biella, Italy

Background
Given the high prevalence of Nonalcoholic Fatty Liver Disease (NAFLD) in clinical endocrinology, diabetology, and primary care practice, international societies have addressed guidelines to drive clinicians in screening, diagnosis, and treatment for this condition.
Aim
compare the most recent guidelines to address similarities and differences and help clinicians choosing the most updated evidence. We considered Italian guidelines (2021), AACE-AASLD guideline (2022) and AASLD Practice Guidance (2023). Herein we present findings about pharmacotherapy.
Results
Italian guidelines used Methodological Manual for clinical practice guidelines developed by the Italian Istituto Superiore di Sanità, using the PICO approach. AACE guideline was conducted by a clinical practice committee that selected and graded articles. Recommendations were made on the grade for the quality of the literature and on expert opinion. AASLD didn't use a grading system therefore they present statements from experts, based on available literature, rather than recommendations. Guidelines address medication with different strengths and in a personalized approach as shown in the table.

Medication	Italian	AACE	AASLD
Vitamin E	Suggested	Consider in patients without DM	Consider
GLP1ra	Limited data	Recommended in patients with Dm^2 and biopsy NASH+ Recommended for the use of obesity and NAFLD Consider in patients with DM and a high probability of NASH	Consider Semaglutide in patients with DM and obesity
Pioglitazone	Suggested	Recommended in patients with Dm^2 and biopsy NASH+ Consider in patients with DM and a high probability of NASH	Consider in patients with DM
SGLT2i	Not suggested	No evidence	Limited data
DPP4i	Not suggested	Non recommended	Not indicated
Metformin	Not suggested	Non recommended	NA
Acarbose	NA	Non recommended	NA
Insulin	NA	Non recommended	NA
Orlistat	NA	Potential effect	NA
Naltrexone/bupropion	NA	Potential effect	NA
Ursodeoxycholic acid	Not suggested	NA	Not indicated
Obeticholic acid	Suggested (not yet approved)	NA	Limited data
Statins	NA	NA	Not indicated
Silymarin	NA	NA	Limited data, not indicated

NA: Not available

Conclusion
The prevalence of NAFLD is increasing worldwide and more efforts are being made to diagnose and treat this condition. Recently nomenclature has changed to MASLD (metabolic dysfunction-associated steatotic liver disease) to include patients with fatty liver regardless of the amount and pattern of alcohol intake with metabolic comorbidities (hypertension, dyslipidemia, overweight or high weight circumference, pre-diabetes or diabetes). Despite having no specific treatment approved for this condition several medications have been used. Guidelines underline the need to tailor the treatment based on patient comorbidities

Obesity in transition towards diabesity: anthropometric determinants and markers of tissue damage

Chiara Mele[1], Stefania Mai[2], Martina Borrini[1], Beatrice Cavigiolo[1], Marina Caputo[3], Massimo Scacchi[4], Gianluca Aimaretti[1] & Paolo Marzullo[1]
[1]University of Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [2]Istituto Auxologico Italiano, IRCCS, Laboratory of Metabolic Research, Piancavallo, Verbania, Italy; [3]University of Piemonte Orientale, Department of Health Sciences, Novara, Italy; [4]Istituto Auxologico Italiano, IRCCS, Division of General Medicine, Piancavallo, Verbania, Italy

Background
The term 'Diabesity' defines the complex relationship between obesity and type 2 diabetes mellitus (T2DM), that involves the convergent role of insulin resistance and chronic inflammation in amplifying the risk of systemic complications. To date, this link has not been fully characterized in terms of markers of tissue damage. The aim of this study was to investigate the association between the newly diagnosed glycemic alterations and the biomarkers of tissue damage through the interaction with the metabolic mileau.
Methods
This observational cohort study consecutively enrolled 656 adult subjects (M/F = 277/379, age 50.6 ± 14.9 years; BMI 47.5 ± 7.5 kg/m^2) with moderate-to-severe obesity and without a previous diagnosis of T2DM. For each patient, fasting glucose, glycated haemoglobin, and OGTT glucose and insulin levels were assessed. T2DM, impaired fasting glucose (IFG), and impaired glucose tolerance (IGT) were defined according to the ADA criteria, and analyzed in relation to metabolic, body composition and cardiorenal function parameters, intimal media thickness (IMT) and adipokines levels.
Results
The prevalence of screen-detected T2DM was 16.2% and the intermediate conditions of prediabetes, in particular IFG and IGT, were observed in 9.5% and 35.7% of cases, respectively. The waist-to-hip ratio (WHR) was found to be the most accurate anthropometric parameter in predicting the severity of glycaemic alterations ($P < 0.0001$). Among the markers of tissue damage, the most significant variations within the glycemic alteration categories concerned the estimated Glomerular Filtration Rate (eGFR) and microalbuminuria ($P < 0.01$ for both). The 2h post-OGTT glucose level was the glycaemic homeostasis index more strongly correlated with the IMT ($r = 0.21$, $P < 0.01$) and the markers of renal function and damage (eGFR: r = 0.09, $P < 0.05$; microalbuminuria: r = 0,20, $P < 0.01$), independently from sex and age. At the multivariable logistic regression analysis, age (OR = 1.03, 95%CI 1.01-1.05, $P = 0.001$), male sex (OR = 1.90, 95%CI 1.12-3.21, $P < 0.05$), C-reactive protein (OR = 1.35, 95%CI 1-05-1.74, $P < 0.05$) and adiponectin levels (OR = 0.94, 95%CI 0.88-0.99, $P < 0.05$) emerged as the main risk factor of T2DM in our cohort.
Conclusion
Our study identified the 2h post-OGTT glucose level as the most effective tool for the screening of glycemic alterations in the obese population. Moreover, we identified IMT, eGFR and microalbuminuria as the marker of tissue damage more closely associated with glycemic homeostasis in our cohort. Finally, the systemic inflammation index and adiponectin levels represent independent risk factors of screen-detected T2DM together with age and male sex.

TYG Index: a practical tool for evaluating metabolic parameters in obese individuals

Özge Başaksu[1,1], Feride Özkara[1], Rıfat Emral[1], Volkan Genç[2], Demet Çorapçıoğlu[2] & Mustafa Şahin[1]
[1]Ankara University, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara University, General Surgery, Ankara, Turkey

Background and Aim
The triglyceride glucose (TyG) index has been proposed as a marker of insulin resistance. This study aims to evaluate the utility of the TyG index in routine practice for predicting diabetes, prediabetes, and metabolic dysfunction-associated fatty liver disease (MAFLD) in obese individuals.
Methods
The study retrospectively analyzed data from obese individuals at our outpatient clinic. The study recorded patient characteristics such as age, gender, fasting plasma glucose (FPG), fasting insulin, lipid profile, HbA1c, ALT, AST, vitamin D levels, and platelet counts. Additionally, the body mass index (BMI), Homeostatic Model Assessment of Insulin Resistance (HOMA-IR), AST/Platelet Ratio Index (APRI), Fibrosis-4 Index (FIB-4), TyG Index, and TyG-BMI Index scores were calculated to establish the database.
Results
A total of 299 patients were examined in this study. The mean age of the patients was 37.53 ± 11.46 years, with 49.5% (148) female, and the mean BMI was found to be 44.16 ± 6.81 kg/m^2. The mean HbA1c values were 5.98 ± 1.02 and the mean TyG index values were 4.75 ± 0.29. Patients were divided into three groups based on their HbA1c values, namely normal, pre-diabetic, and diabetic, and were compared in terms of TyG index values. In post-hoc analysis, patients with diabetes had statistically significantly higher TyG index scores compared to both the pre-diabetic and normal groups ($P < 0.001$, $P < 0.001$, respectively). Additionally, patients with pre-diabetes had statistically significantly higher TyG index scores compared to the normal group ($P < 0.001$). According to the results of Pearson correlation analysis, the TyG index score showed a positive correlation with metabolic parameters such as APRI ($r = 0.245$, $P < 0.001$), HOMA-IR ($r = 0.306$, $P < 0.001$), LDL

($r=0.243$, $P<0.001$), and HbA1c ($r=0.475$, $P<0.001$), while it exhibited a negative correlation with HDL ($r=-0.313$, $P<0.001$). No statistically significant relationship was observed between FIB-4 index and TyG index score ($r=0.086$, $P=0.146$). In the stepwise regression analysis, with HbA1c as the dependent variable and age and TyG index as independent variables, the model revealed that TyG index score ($\beta=0.449$, $P<0.001$) and age ($\beta=0.223$, $P<0.001$) significantly predicted HbA1c levels.

Conclusion

The TyG index appears to be a practical parameter that can be used in daily practice, offering ease of use and lower cost. It seems to be a convenient method for the early assessment of the risk of diabetes development and the potential presence of MAFLD in obese individuals.

Diagnostic accuracy of FIB-4 score compared to Fibroscan assessment of liver fibrosis in overweight and obesity patients

Meliha Melin Uygur[1], Çağlayan Keklikkiran[2], Süreyya Uygur[3], Burak Gemici[4] & Oğuz Suveren[4,5]

[1]Department of Endocrinology and Metabolism Disease, School of Medicine, Recep Tayyip Erdoğan University, Rize, Turkey; [2]Recep Tayyip Erdoğan University, Department of Gastroenterology, Turkey; [3]yıldız Technical University, Department of Geomatic Engineering, Faculty of Civil Engineering, Turkey; [4]Recep Tayyip Erdoğan University, School of Medicine, Turkey; [5]Recep Tayyip Erdoğan University, Turkey

Objective

Increasing obesity rates are causing a surge in non-alcoholic fatty liver disease (NAFLD) prevalence which may progress further to non-alcoholic steatohepatitis (NASH) to cirrhosis. The utility of Fibroscan was shown in stratifying risk for significant liver disease in patients with obesity but it has a limited availability. The aim of the study was to compare the accuracy of Fibrosis-4 (FIB-4)) score to diagnose advanced fibrosis in overweight and obesity patients.

Methods

We conducted the study in 369 (145 men, 224 women) patients aged between 18-75 years old and body mass index over 25 kg/m^2 from department of endocrinology and metabolism disease and gastroenterology, School of Medicine, Recep Tayyip Erdoğan University. We performed a fibroscan assessment and collected biochemical, demographic, and clinical data. Patients were categorized as group I with mild/moderate fibrosis (F0- F2) and group II with advanced fibrosis (AF) (F3-F4) based on fibroscan liver stiffness measurement (LSM).

Results

FIB-4 score was significantly higher in group 2 than group 1 ($P<0.001$). There was no significant difference in alanine transaminase level (P:0.15) and platelet count (P:0.32) between the groups whereas gamma glutamyl transferase and aspartate transaminase levels were significantly higher in group 2 (P:0.003 andp:0.003, respectively). There was a positive correlation between FIB-4 score and LSM (r:0.416, $P<0.001$). The cutoff point of 1.04 for FIB-4 score provided 70% sensitivity and 62% specificity with an area under the curve equal to 72% ($P<0.001$).

Conclusion

FIB-4 score could predict advanced fibrosis in overweight and obesity patients particularly in settings where fibroscan assessment is limited. Based on this score, patients can be followed for progression of NAFLD, and prompt treatment modification could be implemented.

Impact of diabetes mellitus type 2 on the prognosis of metabolic steatopathy

Ahmed Mohamed Nefzi[1], Bouchabou Bochra[1], El Mouldi yosr[1], Nakhli Abdelwahab[1], Hemdani Nesrine[1], Benzarti Zeineb[1], Ben Nejma Houda[1] & Ennaifer Rym[1]

[1]Hôpital Mongi Slim, Hepato-gastroenterology, Marsa, Tunisia

Introduction

The coexistence of type 2 diabetes in patients with metabolic steatopathy is quite common due to a shared pathophysiology of the two conditions, primarily centered around insulin resistance. The objective of our study was to investigate the impact of type 2 diabetes on the prognosis of metabolic steatopathy.

Patients and Methods

This was a cross-sectional, single-center descriptive study that collected all cases of metabolic steatopathy presenting to outpatient clinics between March 2021 and December 2022. The age and various medical histories were specified. Anthropometric measurements were taken. A biological assessment, including a metabolic and hepatic profile, was conducted. Liver fibrosis was assessed using simple serum tests (APRI and FIB-4) and Transient elastography-Fibroscan. The quantification of the degree of steatosis was performed using the Controlled Attenuation Parameter (CAP) integrated into the Fibroscan device. We divided the study population into two groups: Group 1: diabetic patients and Group 2: non-diabetic patients. We compared the clinical, biological profiles, and the degree of liver fibrosis and steatosis in each of the two groups.

Results

We collected 139 patients with a mean age of 54.21 ± 10.7 years and a gender ratio of 0.52. The prevalence of type 2 diabetes was 43.2%. In terms of basic demographic data, a history of hypertension and associated dyslipidemia was significantly more common in Group 1, with p-values of 0.016 and 0.009, respectively. The average waist circumference of diabetic patients was significantly higher (105.2 cm versus 100.8 cm) ($P=0.05$). In terms of biological data, hypertransaminasemia was more frequently observed among diabetic patients ($P=0.037$), with a predominance of ASAT (42.1 versus 28.8 IU/l) ($P=0.025$). The average FIB-4 score was significantly higher in diabetic patients (0.149 versus 0.105) ($P=0.05$). Liver elasticity was higher in Group 1 (9.93 versus 5.77 kPa) ($P=0.001$). We did not observe a significant difference in terms of degree of hepatic steatosis between the two groups.

Conclusion

Type 2 diabetes accelerates the progression of hepatic fibrosis in patients with metabolic steatopathy and, therefore, worsens the prognosis for these patients.

Trajectories and associations of symptoms of mental health and well-being with insulin resistance and metabolic health in women with gestational diabetes

Ludmila Nicolazzi[1]

[1]CHUV, Department Woman-Mother-Child, Lausanne

Background

Gestational diabetes mellitus (GDM) is characterized by increased insulin resistance. There is a link between perinatal depression or anxiety and GDM. Mental health problems are associated with higher insulin resistance and could explain the underlying association between GDM and depression or anxiety symptoms. We investigated the trajectories and associations between symptoms of mental health and well-being with insulin resistance and metabolic health in women with GDM.

Methods

This study included the control group ($n=106$) of a randomized controlled trial in women with GDM that were followed-up during pregnancy and up to 1-year postpartum. We measured symptoms of mental health (Edinburgh Postnatal Depression Scale (EPDS), Anxiety subscale of the Hospital Anxiety and Depression Scale (HADS-A), well-being (The World Health Organization Well-Being Index (WHO-5)) and metabolic health, including insulin resistance variables (HOMA-insulin resistance (IR) and Matsuda Index of insulin sensitivity) as well as weight during pregnancy and in the postpartum.

Results

HOMA-IR was higher during pregnancy compared to 6-8 weeks postpartum and increased between 6-8 weeks and 1-year postpartum (all $P<0.05$). Matsuda index decreased between 6-8 weeks and 1-year postpartum ($P<0.001$). EPDS scores decreased between pregnancy and both 6-8 weeks and 1-year postpartum (all $P<0.05$). HADS-A scores did not change between pregnancy and the postpartum. WHO-5 scores improved significantly from pregnancy and both 6-8 weeks and 1-year postpartum ($P<0.001$). Correlation coefficients within outcome at the three different time points were high for metabolic measures and ranged between 0.94 to 0.96 for weight, from 0.77 to 0.89 for HOMA-IR and 0.64 for the Matsuda index (all $P<0.001$). Mental health and well-being variables were moderately correlated in all three time points. After adjustment for cofounders, Matsuda index was negatively associated with EPDS scores and positively associated to WHO-5 scores at 6-8 weeks postpartum. No other association between insulin resistance and mental health or well-being outcomes were found.

Conclusion

While insulin resistance fluctuated with values being lowest in the early postpartum and increasing thereafter, both depression and well-being scores decreased between

pregnancy and the postpartum and did not change in the postpartum period. Intraindividual variability was larger for mental health and well-being than for metabolic health outcomes at different time points, indicating a higher plasticity for mental health and well-being outcomes that could be acted upon. We found only few associations between mental health and well-being and metabolic health outcomes.

Cell cycle synchronization enhances insulin secretion in MIN6 cells

Tapabrata Pramanik[1], Prachi Verma[1] & Aditya Mittal[1]
[1]Indian Institute of Technology Delhi, Kusuma School of Biological Sciences, New Delhi, India

Type I diabetes mellitus (DM) is characterized by an autoimmune destruction of the pancreatic β-cells that leads to absolute insulin deficiency. However, T1DM individuals undergoing exogenous insulin therapy may show partial remission of endogenous insulin secretion and better insulin sensitivity, and this remission may range between few months to many years. This partial remission is known as the 'honeymoon phase,' and extending the duration of this remission has been a centre stage for medical intervention towards T1DM. Since proliferation renders pancreatic β-cells immature, we aimed to investigate whether arresting cells can possibly enhance GSIS. In other words, we wanted to check whether cell cycle synchronization can possibly be an underlying reason behind the honeymoon phase. Among various cell culture model systems used for studying glucose stimulated insulin secretion (GSIS), Mouse Insulinoma 6 (Min6) cells is a widely used mouse pancreatic β-cell line which mimics pancreatic β-cell physiology. We treated Min6 cells with nocodazole (60 ng/ml) for 16 hours to arrest them at mitotic phase. An enhanced GSIS was observed at incremental EGC's, ranging from basal (2.8 mM) to hyperglycemic (25 mM) level. The amount of secreted insulin was measured by sandwich ELISA method. The synchronization of cells was confirmed by flow cytometry. The fold change in GSIS observed for the synchronized cells was significantly higher (statistically) as compared to the non-synchronized cells. Cellular protein content as well as secreted protein content in the supernatant medium remained constant, irrespective of EGC and synchronization, as measured by Bradford method. Thus, we show that synchronization of cells or proliferative arrest can enhance GSIS and might be one of the underlying reasons behind the remission of endogenous insulin secretion in T1DM individuals, commonly known as the honeymoon phase. We propose a model at the cellular level, in which initial destruction of some β-cells results in production of new β-cells that are synchronized, thereby providing higher levels of insulin secretion from lower number of cells. Subsequently, the higher metabolic load (resulting from higher insulin secretion as shown by us earlier) experienced by lesser number of β-cells results in further cell death eventually leading to complete destruction of β-cells. To our knowledge, this is the first cellular level model that correlates well with the clinical observation of honeymoon phase in T1DM.

Evaluation of a new prototype ELISA for the detection of autoantibodies against IA2 in patients with type 1 diabetes mellitus

Skander Elleuche[1], Gia-Gia Hò[1], Alexander Kühnl[1], Malgorzata Baranowska-Dell[2], Kai Masur[3,4], Petra Augstein[5,6], Sandra Saschenbrecker[1], Christian Probst[1], Lars Komorowski[1], Kersten Dieckmann[1] & Cornelia Dähnrich[1]
[1]Institute for Experimental Immunology, affiliated to Euroimmun Medizinische Labordiagnostika AG, Lübeck, Germany; [2]Department of General, Visceral, Thoracic, and Vascular Surgery, Research Group of Predictive Diagnostics, University Medical Center Greifswald, Greifswald, Germany; [3]Leibniz Institute for Plasma Science and Technology (INP Greifswald), Greifswald, Germany; [4]Diabetes Competence Centre Karlsburg (KDK), Karlsburg, Germany; [5]Institute of Diabetes "Gerhardt Katsch", Karlsburg, Germany; [6]Department for Diabetology, Klinikum Karlsburg, Heart and Diabetes Center Karlsburg, Karlsburg, Germany

Introduction
Autoantibodies against insulinoma-associated antigen-2 (anti-IA2) are an important marker for diagnosis and prediction of new-onset type 1 diabetes mellitus (T1DM). Here we report on a new prototype Anti-IA2 ELISA with shorter total incubation time (3h15min) compared to the established EUROIMMUN Anti-IA2 ELISA (minimum 17h40min). The study evaluates the performance of the prototype assay.
Methods
The clinical performance of the prototype ELISA was evaluated using a sensitivity panel comprising sera from 32 patients with suspected T1DM and 111 patients with confirmed T1DM, and a specificity panel consisting of sera from 50 suspected cases each of connective tissue disease and celiac disease, and from 210 healthy donors. For method comparison, 32 samples from suspected T1DM cases and a subset of 100 samples from confirmed T1DM patients were additionally analyzed using the established EUROIMMUN Anti-IA2 ELISA and the Medipan CentAK anti-IA_2 M radioimmunoassay (RIA), respectively.
Results
The clinical sensitivity of the prototype ELISA amounted to 73.4% (105/143) at a specificity of 99.4% (308/310). Method comparison revealed a sensitivity of the prototype of 93.3% (28/30) referring to the established ELISA and 93.8% (61/65) referring to the RIA, while the overall agreement was 90.6% (29/32, ELISA) and 90.0% (90/100, RIA).
Conclusions
The results suggest that the new Anti-IA2 ELISA will be a valuable tool in supporting the serodiagnosis of T1DM. Reducing the processing time to a few hours minimizes the time required for laboratory testing, reinforcing the prototype's suitability to replace the established ELISA. Additionally, the new assay enables easier automation in conjunction with other ELISA with similar timelines on EUROIMMUN Analyzer I or EUROLabWorkstation ELISA.

Use of glycated albumin in transfusion-dependent β-thalassemic (TDT) patients with diabetes mellitus: preliminary results

Martina Verrienti[1], Alberto Gobbo[1], Camilla Alice Cattaneo[1], Elisa Mari[2], Olga Sofritti[2], Marcello Monesi[3], Stefano Pizzicotti[4], Filomena Longo[2], Maria Rosaria Ambrosio[1] & Maria Chiara Zatelli[1]
[1]Section of Endocrinology and Internal Medicine, Department of Medical Sciences, University of Ferrara, Ferrara, Italy; [2]Regional HUB Centre for Thalassaemia and Haemoglobinopathies, Department of Medicine, AOU S. Anna, Ferrara, Italy; [3]Primary Care Department, Diabetes Unit, Ferrara "Sant' Anna" Hospital, Ferrara, Italy; [4]Department of Translational Medicine and for Romagna, University of Ferrara, Ferrara, Italy

Background
Patients with transfusion-dependent β -thalassemia (TDT) often experience several endocrine complications, including diabetes mellitus (DM). In TDT, the reliability of glycated haemoglobin (HbA1c) assessment is compromised due to elevated erythrocytes turnover and frequent transfusions. Glycated Albumin (GA), a product of non-enzymatic albumin glycation, has been investigated as a medium-term glycaemic marker (21 days) in the general diabetic population. Since GA is not affected by erythropoiesis nor by iron imbalance, it could potentially serve as a reliable marker for diagnosing and monitoring DM in TDT.
Objective
To evaluate the use of GA assessment in a population of TDT patients with DM.
Methods
We conducted a single-centre observational study, enrolling 28 TDT adults (15F, 13M, mean age 53.7 ± 7.4 years, mean BMI 23.7 ± 3.4 Kg/m^2) with DM. Patients were tested for fasting glucose (FG), HbA1c, fructosamine, GA and iron deposit indexes (ferritin, T2* pancreas). GA measurement was performed using a standardized enzymatic quantitative method. Two hours after a standardized meal (50 g carbohydrates), post-prandial glycaemia (PPG) was assessed. Based on glycaemic control, patients were divided into groups according to FG (A $\geq$ 130 mg/dl; B $<$ 130 mg/dl) or PPG (C $\geq$ 180 mg/dl; D $<$ 180 mg/dl).
Results
GA was associated with FG (Pearson's $r=0.613$, $P<.01$), HbA1c (Pearson's $r=0.748$, $P<.001$), fructosamine (Pearson's $r=0.620$, $P<.001$), and with PPG (Pearson's $r=0.432$, $P<.05$), but not with sex, age, BMI and iron deposits. By using ROC curves we identified a GA cut-off value of 15.7% as displaying 100% sensitivity and 58% specificity to differentiate A from B patients (AUC=0.845, $P=.005$). Similarly, a GA threshold of 15.2% had 100% sensitivity and 50% specificity in discriminating C from D patients (AUC=0.769, $P=.025$).
Conclusion
To the best of our knowledge, these are the first data regarding the use of GA in diabetic TDT patients. The identified GA thresholds may help the identification of non-compensated TDT diabetic patients, taking into account the risk of false positives. Further studies, using continuous glucose monitoring to assess glycaemic control, are warranted in order to understand more about the role of GA in monitoring diabetic TDT patients.

Extracts of Vernonia amygdalina stimulated non-toxic insulin secretion from clonal pancreatic cells and improved glucose tolerance in mice with diet-induced obesity-diabetes

Ayokunle Falana[1], Simren Heer[1], Ayodele Falobi[1], Moji Adie[1], Joy Edeani[1], O Ogundepo[2] & Opeolu Ojo[1]
[1]University of Wolverhampton, Science and Engineering, Wolverhampton, United Kingdom; [2]Obafemi Awolowo University, Nigeria

[1]= School of Sciences, Faculty of Science and Engineering, University of Wolverhampton, Wolverhampton, UK
[2]= Department of Biochemistry, Obafemi Awolowo University, Ile-Ife, Nigeria
[3]= IRiD Biosciences, Wilding Road, Ball Green, Stoke-on-Trent, ST6 8BQ

Aim

Vernonia amygdalina extract is used traditionally for type 2 diabetes treatment in developing countries. Studies have reported antidiabetic properties of aqueous and methanolic extracts of *V. amygdalina* but mechanisms underlying these actions are poorly understood. This study investigates effects of *V. amygdalina* extracts on insulin secretion, cytotoxicity, cells viability, mechanism of action and intracellular calcium.

Methods

Insulin-releasing effect of *V. amygdalina* extract (0 –1000µ g/ml) were investigated using BRIN-BD11 cells. Effects of the extract (100µ g/ml) on insulin secretion at various glucose concentration, presence of established modulators of insulin secretion and in the absence of extracellular calcium were also investigated. Insulin concentrations were measured by ELISA. Effect of the plant extract on cytotoxicity and intracellular calcium concentration were also assessed. Acute *in vivo* effects of the extract were investigated using mice with diet-induced obesity-diabetes.

Results

The extract had total flavonoid and total phenolic contents of **** QE/g and **** GE/g respectively. *V. amygdalina* extract stimulated insulin secretion at concentration $\geq$0.1ug/ml in a dose-dependent manner (1.4 to 2.5-fold, $P<0.001$). The insulinotropic effects of the plant extract was not associated with cytotoxicity or impaired cell viability. Insulin-release increase with increasing glucose concentration (1.1mM to 5.6mM, 10%, $P<0.05$, and 5.6mM to 16.7mM, 13%, $P<0.05$). Actions of the extract was reduced in the presence of diazoxide (300µ M, 46%, $P<0.01$), verapamil (50nM, 34%, $P<0.01$) and in the absence of extracellular calcium (20%, $P<0.05$). Enhanced insulin secretion was observed in incubations containing KCl (30mM, 3.0-fold, $P<0.001$) and IBMX (200µ M, 1.9-fold, $P<0.01$). *V. amygdalina* extracts enhanced intracellular calcium concentration by 24% ($P<0.01$). Glucose tolerance and insulin secretion also improved by 23% ($P<0.01$) and 34% ($P<0.01$) respectively in diet-induced mice treated with the extract.

Conclusion

These results suggest that the anti-diabetic properties of *V. amygdalina* extract may involve the activation of the ATP-dependent pathway of insulin secretion. These results encourage further investigations of the anti-diabetic actions of *V. amygdalina* extracts.

New onset diabetes after transplantation (NODAT) in kidney transplant recipient in Montenegro

Danilo Radunovic[1], Snezana Vujosevic[2], Filip Tomovic[1], Vladimir Prelevic[1] & Sanja Borozan[2]
[1]Clinic for Nephrology, Clinical Centre of Montenegro, Podgorica; [2]Department of Endocrinology, Clinical Centre of Montenegro

Background and aim

Renal transplantation is considered to be the best renal replacement therapy for patients with end-stage renal disease. Posttransplant complications include NODAT, which is now considered to be determinant of loss of renal allograft, development of infections, and increased risk of morbidity and mortality. Prevalence of NODAT vary, from 2% - 53%.

Materials and methods

We examined the characteristics and risk factors for NODAT in patients with kidney transplants monitored at the Clinical Centre of Montenegro.

Results

Currently 147 patients with kidney transplants are being monitored. Of that number, 13 (8. 84%) have confirmed NODAT. The distribution by gender is 8 men (61. 5%) and 5 women (38. 5%), 8 (61. 5%) patients had obesity. The average age of patients with NODAT at the time of transplantation was 40.6 years. The average time from transplantation to the development of NODAT was 5 years. There were 7 (53. 8%) patients on calcineurin inhibitor (CIN) therapy (tacrolimus) and 6 patients (46. 2%) on ciclosporin therapy. All patients had additional corticosteroid (methylprednisolone), the dose of which was successively reduced after transplantation, while the maintenance dose was 5 mg every second day. There were 13 patients on mycophenolate mofetil (MMF) therapy. Two (15. 4%) patients are being treated with mTOR inhibitor (everolimus) developed breast cancer and were switched from CIN inhibitor to everolimus, both had steroid before transplantation due to the underlying diagnosis (SLE, sarcoidosis). One of the patients had proven BK nephropathy in the follow-up, for which therapy was corrected by reducing the dose of tacrolimus and corticosteroid, but he still developed NODAT. One patient had chronic hepatitis C infection, and developed NODAT after retransplantation with standard doses of immunosuppressants. One patient with primary diagnosis of ADPKD and biopsy-proven FSGS, developed NODAT after a second kidney transplant, another day after rituximab administration due to proven recurrence of FSGS in the transplanted kidney. One patient developed NODAT in the context of proven CMV reactivation after kidney transplantation and it is interesting that he developed an acute myocardial infarction within the same episode of CMV reactivation. NODAT was the earliest to develop after transplantation in patients who had previously received steroid therapy, elderly patients, and patients who had received ciclosporin therapy. All patients were treated with insulin.

Conclusion

The main risk factors for the development of NODAT were obesity, therapy with CIN inhibitors, and long-term use of corticosteroids before and after kidney transplantation.

Degenerative complications of diabetes type 2

Zakariaa Ilham[1,2], Saloua Elamari[2], Soukaina Laidi[2] & Marouan Fatima[2]
[1]Cheikh Khalifa Ibn Zayed Al Nahyan, Endocrinology, Casablanca, Morocco; [2]

Introduction

Diabetes is a major public health problem with a growing prevalence and heavy socio-economic impact. Its severity is closely linked to the complications it can cause, which can be prevented when detected early. The aim of this study was to assess the epidemiological and clinico-biological profile of patients with degenerative complications of type 2 diabetes in our department.

Methods

This was a prospective study that included all type 2 diabetic patients with at least one degenerative complication and who have come to our department for the first time between the months of September and November 2023. Epidemiological, clinical, and paraclinical data were collected from medical records and supplemented by patient bedside interviews.

Results

We included 101 patients; the average age was 68 years old. Two-thirds of the patients were men; hypertension and dyslipidemia were observed in 77.2%, obesity was present in 29.7%. The median duration of diabetes progression was 20 years. The average glycated hemoglobin (Hba1c) level was 9% and the mean fasting blood glucose level was 1.84 g/l. The majority of patients were on insulin therapy accounting for 52 %. Microangiopathies were found in 81.88% of patients while macroangiopathies were present in 80.2%, with a predominance of ischemic heart diseases at 56.43%. Eighty-seven percent of patients had unstructured follow-up with at least one consultation per year. There is a correlation between the age of diabetes, glycemic control and the onset of degenerative complications in type 2 diabetes.

Conclusion

Monitoring and screening for complications would help prevent degenerative effects of diabetes. The elements predisposing individuals to complications are likely still unknown and constitute a research avenue.

Rare case of hypoglycemia attributed to sildenafil in a patient with primary pulmonary hypertension

Elena Gross[1] & Romy Block[1]
[1]Northshore University, Division of Endocrinology and Metabolism, Skokie, United States

Introduction

Primary Pulmonary Hypertension (PPH) is a condition defined by atypically high blood pressure in the vessels in the lungs and heart. Due to the high blood pressure in the pulmonary system, the arteries in the lungs shrink and reduce oxygen flow

throughout the body. It is characterized by shortness of breath and chest pain, and can often be linked with heart disease, lung disease, or connective tissue disease. Patients with PPH are typically treated with Sildenafil or Tadalafil which is a phosphodiesterase inhibitor which relaxes the vessels to improve blood flow.
Case Presentation
A 55-year-old African American female with PPH presents with slurred speech, dizziness, and hypoglycemia. The patient was talking with someone on the phone and was unintelligible and EMS was called. The patient does not smoke or drink, works out with a trainer, and describes herself as a healthy eater. The patient was diagnosed with PPH in December 2022 and started treatment immediately after. She was then treated with a variety of medications including Sildenafil, Macitentan, Spironolactone, and Digoxin. The patient admits that she frequently forgets to take her mid day doses of medications Monday through Friday for the past 3 months which likely contributes to her worsening symptoms. The patient with PPH and HF was taken to the ER to rule out a stroke and was found to have hypoglycemia on arrival with a sugar of 38 mg/dl. She was treated with a dextrose solution of 25 g to improve her sugars and symptoms resolved. Her sugar dropped again in the ER and she was admitted for evaluation of an insulinoma. The workup was negative and the care team concluded that the hypoglycemia was not due to an issue with the patient's pancreas. Nutrition counseling was given including the addition of bedtime snacks of protein, fat, and carbohydrates and the avoidance of simple sugars. Her hypoglycemia improved but did not resolve. Then, Sildenafil was suspected of causing the low sugar. The medication was changed to 20 mg Tadalafil and the hypoglycemia resolved.
Discussion
There are case reports of hypoglycemia with Sildenafil in 2% of patients post trials. After being taken off the Sildenafil, the patient had improved sugars and no further hypoglycemia.
Conclusion
This case illustrates the possibility for patients to develop extreme hypoglycemia when on Sildenafil. Physicians should have a high index of suspicion for patients who have incidents of hypoglycemia on treatment.

Hepatic steatosis index as a non-invasive marker for liver steatosis in patients with endogenous cushing syndrome, Ercusyn krakow database

Mari Minasyan[1], Aleksandra Gamrat[1,2], Alicja Hubalewska-Dydejczyk[1,3], Elena Valassi[4,4] & Aleksandra Gilis-Januszewska[1,3]
[1]Kraków, Endocrinology, Oncological Endocrinology, and Nuclear Medicine Department, University Hospital, Krakow, Poland, Kraków, Poland; [2]Jagiellonian University Medical College, Doctoral School of Medical and Health Science; [3]Kraków, Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland, Kraków, Poland; [4]Barcelona, Endocrinology and Nutrition Department, Germans Trias i Pujol Hospital and Research Institute, Badalona, Spain, Barcelona, Spain

Introduction
Liver Steatosis(LS) can be one of the metabolic complications of Cushing Syndrome(CS). The data on the impact of cortisol on liver function are very limited, and there is only one study reporting a prevalence of LS of roughly 20%. Hepatic Steatosis Index (HSI) predicts LS based on ALT, AST, BMI, sex and co-existence of diabetes mellitus/impaired glucose intolerance.
Objectives
To evaluate the prevalence of LS in patients with CS at the time of diagnosis by using HSI.
Methods
We analyzed retrospectively adult patients from the ERCUSyN, Krakow database with complete HSI data available. 82 of 135 patients, aged 27-87 years, predominantly women ($n=64$), were eligible for the study. The HSI score was calculated using the following formula: $8\times$ (ALT/AST)+BMI+2(if type 2 diabetes)+2(if female). Collected data were from the baseline CS diagnosis. Patients with score 36 or above were classified as having a high probability of LS. We compared HSI results with the liver steatosis diagnosed based on abdominal ultrasonography (USG) findings, clinical and demographic factors.
Results
High HSI was observed in 81.7% patients (82.8% of females, 77.8% of males). HSI was elevated in 85%, 80% and 73% of patients with pituitary, adrenal and ectopic CS respectively. 41% of patients with elevated HSI were obese. HSI was elevated in among: 100% patients with confirmed liver steatosis on USG, 72% patients with normal USG and 78% patients who did not undergo USG. Conclusions: The prevalence of liver steatosis in active CS may be higher than previously reported. Further investigation should be undertaken to show if patients with high risk of LS based on HSI and normal liver image on USG, may benefit from liver MRI in order to confirm the diagnosis.

Analysis of the use of integrated continuous subcutaneous insulin infusion systems in pregnant women with type 1 diabetes

Sara Hami Gil[1], Celia Gallego Díaz[1], Pavle Puzigaca[1], Manuel Romero Muñoz[1] & María Victoria Cózar León[1]
[1]Hospital Universitario Nuestra Señora de Valme, Endocrinología y Nutrición, Sevilla, Spain

Introduction and objective
Treatment with integrated continuous subcutaneous insulin infusion (CSII) and continuous glucose monitoring systems (CGM) helps to improve glycaemic control in people with type 1 diabetes mellitus (DM1). There is increasing use in pregnant women, but there are no protocols for its continuation during delivery. The aim of this work is to analyse glycaemic control during pregnancy, in addition to studying obstetric and neonatal outcomes.
Methods
Descriptive study of 10 patients with DM1 treated with the Minimed 670G or 780G system during pregnancy and delivery at the AGS Sur in Seville.
Results
The mean maternal age was 37.2 ± 3 years, 25.3 ± 10 years since diagnosis, 70% of patients had diabetic retinopathy with no other associated diabetic complications. Weight gain during pregnancy was 12.2 ± 4.7 kg. We present the glucometry parameters by trimester: 9 deliveries were term (8 without complications) and 1 preterm due to pre-eclampsia. 70% of the patients (3 caesarean sections) used intrapartum therapy with ISCI + MCG in automatic mode, with blood glucose levels in range without extra insulin, no postpartum hypoglycaemia was observed; 30% discontinued treatment (2 caesarean sections and 1 complicated delivery) with high blood glucose levels during and after delivery; one of them developed ketoacidosis in the immediate postpartum period. The weight of the NBs was 3377 +/- 599 g (2 macrosomic). Apgar >7 in 90% of them, neonatal hypoglycaemia 30%, shoulder dystocia 20%, severe respiratory distress with admission to neonatal ICU 10%
Conclusion
Therapy with integrated CSII + CGM systems achieves good glycaemic control in pregnant women with type 1 DM. Maintaining this therapy during labour allowed good glycaemic control during delivery and prevented hypoglycaemia in the immediate postpartum period. Studies and protocols for the use of these treatments during labour and immediate postpartum are needed.

A cost-effectiveness analysis of inpatient continuous glucose monitoring vs capillary blood glucose

David Verissimo[1], Beatriz R Pereira[1], Joana Vinhais[1], Catarina Ivo[1], Ana Cláudia Martins[1], Joao Silva[1], Dolores Passos[1], Luis Lopes[1], J Jácome Castro[1] & Mafalda Marcelino[1]
[1]Armed Forces Hospital, Department of Endocrinology, Lisboa, Portugal

Introduction
We conducted a prospective study to compare the efficacy of continuous glucose monitoring (CGM) devices versus capillary blood glucose (CBG) in the glycemic control of inpatient type 2 diabetes on intensive insulin therapy. The use of CGM was associated with improved glycemic control, including an increased time in range (TIR) and reduced hyperglycemic events, being safe concerning hypoglycemias. The present study is the cost-effectiveness analysis associated with these results.
Aim
The primary objective was to compare the cost-effectiveness of achieving glycemic control (defined as the number of patients within TIR goals) between

Abstract p284

	Mean blood glucose (mg/dl)	GMI (%)	CV (%)	TIR (%)	TBR (%)	TAR (%)
1ª T (10-14 weeks)	131 ± 7	6.4 ± 0.2	30.5 ± 3	62.6 ± 6	1.9 ± 1	35 ± 7
2ª T (20-24 weeks)	126 ± 13	6.4 ± 0.2	29.4 ± 2	64.7 ± 5	1.5 ± 0.8	33.8 ± 5
3ª T (32-36 weeks)	124 ± 5	6.2 ± 0.1	28.8 ± 3	70.5 ± 5	1.7 ± 1	27.8 ± 5

both groups. Secondary endpoints included cost-effectiveness analyses of each of the TIR goals, for each percentual increment in TIR, for increasing the number of daily readings and for reducing inpatient glucose management costs.
Methods
Cost-effectiveness was evaluated by comparing the average cost-effectiveness ratio (ACER) between both groups and by calculating the incremental cost-effectiveness ratio (ICER). The interpretation of the ICER was based on willingness to pay threshold of 24,697.561 €/patient within TIR goal, according to Portugal's 2023 gross domestic product per capita.
Results
CGM group had a significantly higher number of patients with glycemic control (10 vs 2, $P = 0.021$), despite no difference between groups regarding most of TIR goals, with exception for 'Time above 250 < 5%' (16 vs 4, $P = 0.002$). In the ACER comparison, CGM showed lower median cost per effect for the primary outcome (11.1 vs 34.9 € /patient). As for secondary outcomes, CGM achieved lower ACER for 'Time in Range >70%' (7.8 vs 11.6 € /patient), for 'Time above 180 < 25%": 7.4 vs 9.9 € /patient, and 'Time above 250 < 5%": 6.9 vs 17.4 € /patient). Regarding ICER, CGM costed more 156 € /patient in glycemic control than CBG, considered as acceptable within the cost-effectiveness analysis plane. As for secondary outcomes, only 'hypoglycemia <4%' ICER showed a negative cost-effectiveness impact (-304 € /patient in glycemic control). The remaining were all positive and considered below the WTP threshold line.
Conclusions
There are no published data regarding the cost-effectiveness of CGM in inpatient settings. Our study suggests that the use of CGM may be more cost-effective inpatient diabetes glycemic control than CBG monitoring. CGM devices were associated with an improved glycemic control, mainly in reducing hyperglycemia, at a lower cost. Our results endorse the feasibility of incorporating these devices into the context of Portugal's national healthcare, presenting a favorable cost-effective option compared to CBG monitoring.

The clock regulator bmal1 mediates the circadian control of gc-dependent skeletal muscle catabolism by driving PI3K (P100α)-GR interaction

Mariarosaria Negri[1], Claudia Pivonello[2], Feliciana Amatrudo[1], Roberta Patalano[3], Donatella Paola Provvisiero[3], Cristina de Angelis[3], Angelica Larocca[3], Chiara Simeoli[3], Annamaria Colao[3,4] & Rosario Pivonello[3,4]
[1]Università Telematica Pegaso, Dipartimento di Scienze Umanistiche, Naples, Italy; [2]Università Federico II di Napoli, Dipartimento di Sanità Pubblica, Naples, Italy; [3]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia, Andrologia e Nutrizione, Naples, Italy; [4]Federico II University, Unesco Chair for Health Education and Sustainable Developmen, Naples, Italy

The transcriptional activator Bmal1, reaching acrophase in the morning and bathyphase in the evening, is the main regulator of circadian clock. A mutual interaction between circadian clock and glucocorticoids (GCs) has been described as well as their implication in muscle metabolism. The current *in vitro* study aims at investigating Bmal1 involvement in muscle catabolism induced by GCs circadian exposure. To this aim, mouse myocytes C2C12 were serum-shocked to synchronize clock genes oscillation. Using acrophase and bathyphase of Bmal1, hydrocortisone (HC) administrations were aligned to daytime of human cortisol peaks and nadir. During Bmal1 acrophase, myocytes were exposed to physiological concentration of 450nM and to non-physiological concentrations of 650nM and 750nM HC. During Bmal1 bathyphase, myocytes were exposed to physiological concentration of 150nM and to non-physiological concentrations of 177nM and 300nM HC. Atrogenes circadian expression was measured by RT-qPCR, while mTOR and KLF15 expression by WB. To address Bmal1 involvement in GC-induced muscle catabolism, myocytes Bmal1-knockdown (Bmal1-KD) were performed using siRNA technology and mTOR and KLF15 expression after HC exposures were compared to negative control (NC). PI3K ($P100\alpha$)-GR/IRS-1 interactions in Bmal1 bathyphase and acrophase as well as in Bmal1-KD and NC myocytes exposed to 300nM HC were monitored by co-immunoprecipitation (Co-IP). Localization of structural protein myosin and of glucocorticoid receptor (GR) were detected by immunofluorescence (IF). At Bmal1 acrophase and bathyphase, no significant change in atrogenes levels was revealed. Conversely, only at Bmal1 bathyphase, 300nM HC significantly inhibited mTORC1 (61.03%; $P=0.005$ vs 150nM) and pp70S6K (49.80%; $P=0.002$ vs 150nM) and significantly stimulated KLF15 expression (53.34%; $P=0.02$ vs 150nM). In Bmal1-KD myocytes, displaying lower Bmal1 expression than NC (65%; $P=0.02$), 300nM HC significantly decreased mTORC1 (32.62%; $P=0.02$ vs NC) and significantly increased KLF15 expression (54.20%; $P=0.02$ vs NC). Co-IP demonstrated that 300nM HC, both in bathyphase and Bmal1-KD myocytes, facilitated PI3K ($P110\alpha$)-GR interaction (93.88% and 97.36% vs acrophase and NC respectively), simultaneously reducing PI3K ($P110\alpha$)-IRS-1 (31.01% and 27.58% vs acrophase and NC respectively) interaction. IF for heavy chain myosin revealed that compared to NC, myocytes Bmal1-KD plus 150nM HC showed reduced myotubes formation and nuclear GR expression, whereas Bmal1-KD plus 300nM HC showed reduced myotubes formation, increased nuclear GR expression and myosin co-localization. These data demonstrated that Bmal1 down-regulation contributes to muscle catabolism induced by GCs triggering PI3K ($P110\alpha$)-GR interaction and inhibiting myotube formation.

Performance of a machine learning-based early warning system in hospitalized patients with diabetes mellitus

Pedro Caraballo[1], Karen Fischer[2], Parvez Rahman[2], Gyorgy Simon[3], Genevieve Melton[3], Hojjat Salehinejad[2], Bijan Borah[2] & M. Regina Castro[1]
[1]Mayo Clinic, Internal Medicine, Rochester, United States; [2]Mayo Clinic, Rochester, United States; [3]University of Minnesota, Minneapolis, United States

Introduction
Diabetes mellitus is a risk factor for micro-macrovascular complications and increases the risk of hospitalization, and adverse events. Early detection of impending deterioration can prompt interventions and prevent adverse events. Early warning systems (EWS) combined with rapid response teams can mitigate adverse events in the hospital setting. Machine learning-based EWS can use electronic health record data and automatically alert the care team with enough time for an early intervention. However, implementation of these systems can be impacted by their reliability, biases, and poor clinical adoption. Here we present our findings evaluating the performance of an EWS integrated into the EHR in patients with diabetes mellitus compared with those without diabetes.
Methods
We collected machine learning-based EWS scores for adult patients ($\geq$ 18 y-o) hospitalized on general wards. The EWS estimated the probability of an adverse event (mortality, cardiac arrest, intensive care transfer, or evaluation by rapid response team) on a scale of 0 to 100. We used three metrics to characterize and compare the distributions of the scores among patients with diabetes and without diabetes: the First Score 3 hours after admission; the Highest Score at any time during the hospitalization; and the Last Score just before an adverse event or before dismissal for those without an adverse event. Additional data was collected including age, sex, and length of stay.
Results
Among 61,151 admissions (female 51%, mean age 62(SD 18.5) years, length of stay 4.7(6.1) days) there were 15,727 (26%) patients with diabetes. Patients with diabetes had similar rate of adverse events compared to non-diabetics (11.92% vs 11.63%, $P=0.323$). However, the distributions of the First, Highest and Last Scores were higher in patients with diabetes and significantly different ($P<0.005$) when compared with non-diabetics (mean 32.5 vs 27.4, 46.3 vs 40.1 and 31.5 vs 27.2 respectively).
Conclusion
When using a machine learning-based EWS, patients with diabetes seem to have higher risk of deterioration when compared with nondiabetic. However, they seem to have the same proportion of adverse events compared to nondiabetics. These findings are reassuring of the hospital care received by patients with diabetes; despite their higher risk they are not suffering additional complications. Our study was performed in a single institution and did not investigate the specific causes or clinical interventions responsible for the findings. Additional assessment of these factors could prove to be important when planning best hospital practices for diabetic patients admitted in general wards.

Asprosin- novel player in metabolic disorders

Iveta Nedeva[1,2], Vera Karamfilova[2] & Yavor Assyov[2]
[1]Medical University of Sofia, Epidemiology and Hygiene, Sofia, Bulgaria; [2]Medical University of Sofia, Internal Medicine, Sofia, Bulgaria

Background
Asprosin, a novel glucogenic adipokine, is encoded by two exons (exon 65 and exon66) of the gene Fibrillin 1 (FBN1) and mainly synthesized and released by

white adipose tissue during fasting. Asprosin plays a complex role in the central nervous system (CNS), peripheral tissues, and organs. It is involved in appetite, glucose metabolism, insulin resistance (IR) and cell apoptosis.
Objective
The aim of the current study was to determine the levels of asprosin in subjects from the entire spectrum of the carbohydrate metabolism.
Methods
A total of 153 causcasian subjects participated in this study: group 1, healthy volunteers; group 2, obese subjects without glycemic disturbances; group 3- subjects with prediabetes and group 4, patients with newly identified type 2 diabetes
Results
Subject with body mass index ≥ 30 kg/m^2 and dysglycemia (prediabetes and diabetes) showed significantly high levels of asprosin (1.40 ng/ml [IQR = 0.98-1.94]; 1.27 ng/ml [IQR = 0.86-2.12]; 1.09 ng/ml [IQR = 0.89-1.58]) compared to the control group (0.71 ng/ml [IQR = 0.54-0.92]; $P < 0.001$). Correlation analysis showed that serum asprosin also had significant positive associations with some anthropometric parameters, liver enzymes, fasting and post load glucose and insulin, LDL and triglycerides. Furthermore, we estimated a markedly relationship between asprosin concentrations and intima media thickness of the common carotid artery as well as neuropathy disability and vibration sensitivity. The circulating asprosin levels for differentiating subjects with carbohydrate disturbances and those with obesity were determined by ROC analysis. The AUC for disturbances of the glucose metabolism was 0.672 ($P < 0.001$; 95% CI = 0.581-0.751) and for obesity AUC was 0.849 ($P < 0.001$; 95% CI = 0.785-0.919).
Conclusion
Circulatin asprosin could be used as a predictive factor for early carbohydrate disorders and might be a potential new therapeutic target for the treatment of dysglycemia and obesity. Further prospective studies are needed to confirm this observation.

Exploring the nexus of sex hormones and obesity in adult males: insights from a comprehensive clinical analysis

Yaoxia Liu[1], Tao Wang[2], Yerong Yu[3] & Min Zhang[1]
[1]Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China., Geriatric Endocrinology, Chengdu, China; [2]West China Second University Hospital, Sichuan University., Key Laboratory of Birth Defects and Related Diseases of Women and Children (Sichuan University), Ministry of Education, Chengdu, China; [3]West China School of Medicine/ West China Hospital of Sichuan University., Endocrinology and Metabolism., Chengdu, China

Background and purpose
Obese men often exhibit hypoandrogenemia. Although previous research has established obesity and metabolic-related disorders as key factors contributing to decreased androgens in males, there are rare studies to comprehensively understand the correlation between sex hormones and obesity, as well as metabolic indicators, particularly in non Caucasian populations. This study aims to comprehensively investigate the relationship between sex hormones and obesity in adult males using a large-scale clinical sample in non Caucasian populations.
Materials and Methods
Participants were screened based on inclusion and exclusion criteria, and the sex hormone indicators including sex hormone binding globulin (SHBG), total testosterone (TT), estradiol (E2), luteinizing hormone (LH), follicle stimulating hormone (FSH), free testosterone (FT), bioactive testosterone (BioT), as well as metabolic indicators including BMI, blood lipids, fasting glucose, blood uric acid were collected and analyzed.
Results
A total of 360 adult males were included. The findings showed that TT (ng/ml) exhibited a sequential decrease from the obese group, the overweight group and the normal group ($P < 0.05$). When BMI (kg/m^2) $\geq$ 28.326, a significant decrease in FT was observed (0.080 vs 0.090, $P < 0.05$), and when BMI (kg/m^2) $\geq$ 28.360, a significant decline in BioT was observed (1.85 vs 2.10, $P < 0.05$). Multivariate linear regression analysis revealed that SHBG was negatively correlated with BMI and triglycerides, and positively with age; TT was negatively correlated with BMI, blood glucose and TG; FT was negatively correlated with BMI, age, and blood glucose; BioT was negatively correlated with BMI, age, and blood glucose; E2 was positively correlated with BMI and negatively with TG. However, LH and FSH were positively correlated with age only.
Conclusion
Increased BMI and glucose levels correlated with lower androgen hormone levels including serum TT, FT and BioT, which reminds us to pay particular attention to the possibility of hypogonadism in obese men.

P290

The discourse of medical treatment for obesity: sentiment analysis of the literature

Georgios Gavriiloglou[1], Christos Savvidis[1], Efthymia Kallistrou[1], Vasiliki Tsiama[1] & Ioannis Ilias[1]
[1]Hippokration General Hospital, Department of Endocrinology, Athens, Greece

Aim
Obesity can be addressed through lifestyle interventions like modifying diet and engaging in physical activity. In cases where these measures prove ineffective, there is the option of administering medication (RxOb) or of surgical intervention. Sentiment analysis (SA) is an automated procedure employed to extract emotional information prevalent in a given body of text. Specifically, SA enables the determination of the "sentiment polarity" –whether the overall tone is positive or negative. Given the feasibility of implementing SA in medical texts (Artif Intell Med 2015; 64: 17-27), our objective was to employ SA to assess the medical literature's stance, distinct from that of the lay press, concerning RxOb.
Methods
We collected (using MeSH terms) the English language abstracts of randomized clinical trials (RCTs) on RxOb in PubMed, from 2013 to 2023. For SA, we used two, state-of-the-art artificial intelligence SA tools, to generate averaged sentiment scores for each publication. SA scores were categorized into positive (maximum +1.00), neutral (0), or negative (maximum -1.00). Statistical analysis for differences between each year's publications' SA was done with analysis of variance (ANOVA); Pearson's correlation was used to assess time trends.
Results
Seventy abstracts of RCTs were retained from an initial collection of 217 papers. The average $\pm$ SD SA was positive at 0.59 $\pm$ 0.35. The lowest SAs were noted in 2017 and the highest in 2022 ($P < 0.05$, ANOVA). A positive correlation between SA and time, specifically within the period 2017-2022, was found (r: = + 0.38, p: 0.008).
Discussion
RxOb is a dynamic and evolving field, with an expanding body of literature. SA of this literature offers a unique perspective by helping to uncover prevailing sentiments, trends, and perceptions. The application of SA to medical literature allows for the swift assessment of extensive published data collections, offering a rapid synthesis of overall findings that align with the outcomes of a conventional meta-analysis (Reg Anesth Pain Med 2022; 47: 151-154). Nevertheless, our findings are based on SA of existing literature and may not capture all relevant factors influencing sentiments. Future research could delve deeper into the underlying causes of this positive trend, such as specific breakthroughs or changing perceptions among healthcare professionals.

Endoscopic argon plasma coagulation (APC) treatment for dumping syndrome and post-bariatric hypoglucemia in patients with ROUX-EN-Y gastric bypass

Sara Mera Carreiro[1], Blanca Bernaldo Madrid[1], Clara Rodríguez Carrillo[2], Patricia Espinosa De Los Monteros[1], Laura Avila Anton[1], Noelia Sánchez-Maroto García[1], Laura Martínez Suero[2], Teresa Rueda Ortín[1], Jose Miguel Esteban López-Jamar[2] & Miguel Angel Rubio Herrera[1]
[1]Hospital Clinico Universitario San Carlos, Endocrinology, Diabetes and Nutrition, Madrid, Spain; [2]Hospital Clinico Universitario San Carlos, Digestive System and Gastroenterology, Madrid, Spain

Background
Dumping syndrome (DS) and post-bariatric hypoglycemia (PBH) are some of the most challenging problems encountered during the follow-up of bariatric surgery (BS), especially after Roux-en-y gastric bypass (yRGB). When pharmacological and dietary treatment fail to control DS and PBH, surgical revision is often the next therapeutic step. Endoscopic treatment with argon plasma coagulation (APC) may be an alternative treatment by reducing the diameter of the gastro-jejunal anastomosis and thus slowing gastric emptying.
Objectives
To evaluate the efficacy and safety of endoscopic APC treatment in patients who have undergone yRGB and developed DS and PBH.
Material and methods
Retrospective study of patients who underwent endoscopic gastro-jejunal anastomotic reduction using APC at 1.9 liters/min flow and 90 watts in our center between 2018-2022 to treat refractory DS and PBH following yRGB. Improvement of DS symptoms according to Sigstad score, reduction of PBH with disappearance of Whipple's triad and anthropometric data were evaluated.

Statistics: Descriptive analysis and comparison of means (t-Sudent or U-Mann-Whitney) was carried out, cording to the normality distribution of variables.
Results
25 consecutive patients aged 52.3±9.2 years were recruited. Pre-surgery BMI was 42.7±5.5 kg/m^2; nadir BMI was 26.6±3.8 and BMI before APC was 30.8±6.3. Dumping symptoms appeared 26 (20-84) months after BS. Most patients received dietary (fractionated food, low-GI carbohydrates) and pharmacological treatment (acarbose, iSGLT1/2, octreotide). All patients had an average of 2 APC endoscopic procedures (range 1-4), initial gastro-jejunal anastomosis diameter of 26.8±7.2 mm and final diameter after APC of 16.4±4.4 mm. Adverse events were mild and did not require hospitalization: pain ($n=3$ (12%), vomiting ($n=2$ (8%), ulcer ($n=3$ (12%), bleeding ($n=1$ (4%), stenosis ($n=3$ (12%). Symptoms improved in 100% of patients with a decrease in Sigstad score from 6.8±2.6 to 0.9±2 points and the resolution of all PBH ($P<0.0001$). 84% of patients were able to discontinue pharmacological treatment. In addition, 80% of patients had a significant weight loss (%BW) ($P<0.01$) after APC during the 2-year follow-up: 7.6±5.2% (6 months), 8.9±4.8% (12 months), 6.6±5.6% (18 months) and 5.3±5.01% (24 months).
Conclusions
Endoscopic APC is an effective, safe and reproducible procedure for the management of DS and PBH in patients with prior yRGB who are refractory to dietary and pharmacological treatment, or even as a single first-line therapy. It also contributes to weight loss after weight regain in BS.

The effect of ketogenic diet versus mediterranean diet on clinical and biochemical markers of inflammation in patients with obesity and psoriatic arthritis

Aikaterini Kountouri[1], Pelagia Katsimbri[2], Emmanouil Korakas[1], Loukia Pliouta[1], Vasileia Agapitou[1], Eirini Maratou[3], George Pavlidis[4], Ignatios Ikonomidis[4], Argyro Papathanasi[5], Sofia Malisova[6], Dionysios Vlachos[6], Evangelia Papadavid[5] & Vaia Lambadiari[1]
[1]Attikon University Hospital, Second Department of Internal Medicine, Chaidari, Greece; [2]Attikon University Hospital, Rheumatology and Clinical Immunology Unit, Fourth Department of Internal Medicine, Chaidari, Greece; [3]Attikon University Hospital, Department of Clinical Biochemistry, Chaidari, Greece; [4]Attikon University Hospital, Second Cardiology Department, Chaidari, Greece; [5]Attikon University Hospital, Second department of Dermatology and Venereology, Chaidari, Greece; [6]Independent Researcher, Athens, Greece

Background
Obesity is over-represented in patients with psoriasis (PSO) and psoriatic arthritis (PsA) and associated with higher disease activity and poorer treatment response. A substantial number of studies have highlighted the beneficial effect of weight loss in PSO and PsA disease activity. However, the data regarding the most efficacious diet pattern are scarce. The aim of our study to evaluate the effectiveness of Mediterranean diet (MD) and Ketogenic diet (KD), in patients with PSA
Methods
Sixteen patients were randomly assigned to start either with MD or KD for a period of 8 weeks. After a 6-week washout interval, the two groups were crossed over to the other type of diet for 8-week period. Disease activity was assessed using the Psoriasis Area and Severity Index (PASI) and the Disease Activity Index for Psoriatic Arthritis (DAPSA) score. Metabolic and disease parameters were evaluated at the beginning and at the end of each diet-intervention.
Results
At baseline, patients presented mean weight of 108.44 kg, mean PASI of 5.09 and a mean DAPSA of 54.02. At the end of the study, MD and KD resulted in significant reduction in weight($P=0.002$, $P<0.001$, respectively), in BMI ($P=0.006$, $P<0.001$, respectively), in waist circumference($P=0.001$, $P<0.001$, respectively), in total fat mass ($P=0.007$, $P<0.001$, respectively) and in visceral fat ($P=0.01$, $P<0.001$, respectively). After KD, patients displayed a significant reduction in PASI ($P=0.04$), DAPSA ($P=0.004$), IL-6 ($P=0.047$), IL-17 ($P=0.042$) and in IL-23 ($P=0.037$), whereas no significant differences were observed in these markers after MD ($P>0.05$), compared to baseline (table 1).
Conclusion
The 22-week MD-KD diet program in patients with PSA led to beneficial results in markers of inflammation and disease activity. KD had a more significant impact on weight loss and in parameters of disease activity. A larger number of patients and a longer follow-up period may be necessary to fully elucidate the effect of different diets on disease activity in patients with PSO and PsA.

Effectiveness of treatment with Vitamins B12 and D in patients with diabetic peripheral neuropathy by sudoscan

Tamar Maghradze[1], Eelena Shelestova[2] & Ramaz Kurashvili[2]
[1]National Centre for Diabetes Research, Endocrinology, T'bilisi, Georgia; [2]National Centre for Diabetes Research, T'bilisi, Georgia

Diabetic peripheral neuropathy (DPN) is the most common cause of neuropathy worldwide, its prevalence increases with diabetes duration (DD). About 60%-70% diabetic patients will eventually develop DPN. Vitamin B12/D (VitB12/D) deficiency is a global public health problem. Around 29.66% of diabetic patients have confirmed B12 insufficiency. Patients on Metformin have statistically lower values of B12 ($P=0.01$). Vitamin D deficiency is considered to be a contributing factor to the development of type 2 diabetes (T2DM).
Our aim was to study the effect of VitB12/D therapy in patient with T2DM and DPN.
Methods
Totally 52 patients were studied (27 males/33 females, mean age 51±5yrs, DD - 5-10 years, HbA1c at entry - 8,3±1,5%). Before initiating treatment with VitB12/D below tests were performed and following results were obtained: Vitamin B12 (150±20pg/mL [n - 200-835 pg/mL]), Vitamin D (15±25 ng/m [n - 30-100 ng/ml]); all neurological tests (10-g monofilament test, tip-term/temperature test, vibration test with the 128-Hz tuning fork, prick tests) were positive, and neurological examination with Sudoscan (a non–invasive method for the assessment of the small fiber function, Impeto Medical, France) revealed presence of mild small fiber neuropathy. Treatment with oral VitB12/D was initiated in all the patients.
Results
At month 3 post treatment initiation all tests were repeated. In 88% of patients VitB12/D levels were within the normal range; results of monofilament, tip-term/temperature test and Sudoscan examination improved in 41 patients (78,5%).
Conclusion
This study shows that 3-month treatment with VitB12/D improves condition of peripheral nerve fibers. Observations will continue.

The relationship between emotion regulation strategies, illness uncertainty and health-promoting self-care in individuals with type-2 diabetes mellitus

Merve Murat[1], Selda Celik[1], Seda Er[2] & Gulden Anataca[3]
[1]Health Sciences University, Turkey; [2]I stanbul Üniversitesi-Cerrahpaş a, Turkey; [3]Kanuni Sultan Süleyman Training and Research Hospital, Turkey

Introduction
Diabetes Mellitus is a significant metabolic condition characterized by its widespread occurrence and associated complications. Reports indicate that DM impacts 25% of the global population. The way individuals handle their existing

illnesses throughout their lifetimes is crucial in terms of uncertainty and self-care behaviors within chronic diseases such as DM. The connection between individuals' physiological parameters (HbA1c etc.) and uncertainty, as well as emotion regulation strategies, is highlighted. Examining the correlation between psychological and physiological variables in individuals with type 2 diabetes is emphasized as a pivotal aspect of disease management.
Aim
This study aims to assess how emotion regulation strategies impact physiological symptoms, illness uncertainty, and the practice of health-promoting self-care among individuals diagnosed with Type 2 DM.
Method
This is a descriptive cross-sectional study. The sample consisted of 433 patients who followed in a public hospital in Istanbul, Turkey. Data were collected using a Personal Information Form, the Cognitive Emotion Regulation Scale, the Mishel Uncertainty in Illness Scale, and the Diabetes Health Promotion Self-Care Scale.
Results
The participants, with a mean age of 52.84 ± 7.11 years, were mostly male (56.4%), married (80.8%), and university graduates (49.4%). In terms of diabetes and health characteristics, the participants had an average diabetes diagnosis duration of 4.33 ± 1.33 years, and the average HbA1c value was 8.61 ± 0.73%. Notably, 56.1% of participants received Oral Anti-Diabetic and Insulin treatment, and 37% took diabetes training for self-care. Daily living activities were successfully performed by 94.7% of participants, with only 2.5% requiring assistance. About 50.3% were uncertain about whether DM would impact their lives, and their overall health status was reported as good. Participants scored high on the Mishel Uncertainty in Illness Scale, Diabetes Health Promotion Self-Care Scale, and Cognitive Emotion Regulation Scale Subscales.
Conclusion
In conclusion, according to the study results, the interventions to strengthen people diagnosed with type-2 DM mental and physical health should be developed.

Eating disorders in obese patients with type 2 diabetes

Meriem Adel[1], Marwa Chiboub[2], Asma Zelaiti[2], Hajer Kandara[3] & Ines Kammoun[2]
[1]Tunisia, Endocrinology, Tunis, Tunisia; [2]National institute of nutrition and food technology, Endocrinology, Tunis; [3]Tunisia, Endocrinology, Tunis

Introduction
Eating disorders (ED) are more prevalent among obese individuals with type 2 diabetes than in the general population. The co-occurrence of diabetes and ED can impair metabolic control, resulting in earlier and more severe degenerative complications, as well as increased morbidity and mortality. This study aims to assess the prevalence of eating disorders in obese patients with type 2 diabetes.
Method
A cross-sectional descriptive study was conducted at the endocrinology department of the National Institute of Nutrition and Food Technology. Forty-five obese type 2 diabetic patients were recruited. Each patient was asked to complete two questionnaires, the *Bulimic Investigatory Test Edinburgh* (BITE) and *Sick, Control, One stone, Fat, Food* (SCOFF). Anthropometric measurements and dietary survey data were collected for each patient.
Results
The mean age of the population was 58.2 ± 12.5 years, with a female predominance (91.1%). The mean Body Mass Index (BMI) was 34.8 ± 5.2 kg/m^2. All participants had android obesity. Eating disorders were present in 95.6% of the population, with unspecified type in all cases and specified type (according to the SCOFF questionnaire) in 35.6% of patients. According to the BITE questionnaire, bulimia/binge eating was found in 11% of patients. The most common unspecified eating disorder was cognitive restriction (71.1%). Night eating syndrome, external eating, and snacking were observed in 56%, 62.2%, and 49% respectively. A statistically significant positive correlation was found between eating disorders and anthropometric parameters: weight ($P = 0.016$), BMI ($P = 0.004$), waist circumference ($P = 0.018$), and obesity class ($P = 0.012$). No significant association was found between eating disorders and glycemic control, except for purging disorders ($P = 0.009$). There were no significant association found between glycaemic control and ED. Among the degenerative complications of diabetes, only neuropathy was significantly associated with snacking ($P = 0.013$).
Conclusions
The prevalence of eating disorders is significant among obese type 2 diabetics, highlighting the importance of early detection and appropriate management of these disorders.

Unveiling connections: type 2 diabetes, male hypogonadism, and inflammation –insights from a clinical study

Anis Grassa[1], Manel Jemel[1], Salma Salhi[1], Asma Krir[2], Ahlem Benhmid[2], Marwa Chiboub[1], Radhouane Gharbi[1] & Ines Kammoun[1]
[1]National Institute of Nutrition and Food Technologies, Zouheir Kallel, Endocrinology, Tunis, Tunisia; [2]Pasteur Institute of Tunis, Tunisia

Introduction
The interplay between type 2 diabetes (T2D), male hypogonadism (HG), and inflammation has emerged as a fascinating area of medical research. Understanding the complex relationship among these factors is crucial for advancing our knowledge.
Methods
The study focused on 250 adult male patients with T2D recruited from outpatient clinics at the National Institute of Nutrition and Food Technology. A thorough assessment of gonadal hormones, including Sex Hormone-Binding Globulin and albumin, was conducted to calculate Free Testosterone (FT) and Bioavailable Testosterone (BT) using the Vermeulen formula [1]. Diagnostic criteria for HG included specific thresholds: Total Testosterone (TT) below 231 ng/dl, FT below 6.5 ng/dl, or BT below 150 ng/dl. Additionally, various inflammatory markers, such as CRP, IL6, and TNF-alpha, were assessed for all patients.
Results
Mean levels of TT, FT, and BT were 438.8 ± 172.1 ng/dl, 8.8 ± 2.8 ng/dl, and 194.7 ± 60.4 ng/dl, respectively. Median values (IQR) for inflammatory markers CRP, IL6, and TNF-alpha were 1.7 (0.9-3.3) mg/l, 2.5 (1.7-6.9) and 1.8 (1.0-2.5), respectively. A significant inverse correlation was found between TT and CRP ($r = -0.192$; $P = 0.010$), as well as FT ($r = -0.165$; $P = 0.031$). However, no such association was observed with BT ($P = 0.056$). The prevalence of HG was 27.2% ($n = 68$), and variations in inflammatory marker levels based on gonadal status were not statistically significant. Comparison between HG vs non-HG groups revealed median (IQR) CRP values of (2.00 mg/l vs 1.46; $P = 0.238$); IL6 values of (2.73 pg/mL vs 2.38; $P = 0.491$) and TNF-alpha values of (1.78 pg/mL vs 1.78; $P = 0.665$).
Conclusion
In conclusion, this study sheds light on the intricate relationship between DT2, male HG, and inflammation. While significant correlations were observed between testosterone levels and CRP, further research is needed to unravel the complexities of this association. Understanding these dynamics is essential for developing targeted therapeutic strategies and improving the overall care of individuals with both DT2 and male HG.

An hepatomegaly in a child with type 1 diabetes and celiac disease: what could it be?

Yasmine Fakhfekh[1], Chaima Jemai[1], Yosra Ben Hmida[1], Yosra Htira[1], Dorsaf Ben Salem[1], Takwa Moussa[1], Zohra Hadj Ali[1], Imen Hedfi[1], Olfa Lajili[1] & Faika Ben Mami[1]
[1]National institute of nutrition of Tunis, C

Introduction
Type 1 diabetes mellitus (T1DM) and celiac disease are two frequently associated autoimmune pathologies. The association with hepatomegaly raises discussion of many diagnosis.
Case presentation
We report the case of a 12-years-old T1DM girl admitted at department C of the national institute of nutrition of Tunis for diabetic ketosis. She has T1DM since 5 years, with poor glycemic control (HbA1C = 10%) and poor therapeutic adherence. On examination, she had abdominal bloating with homogeneous hepatomegaly. Height was 146 cm (less than 2nd percentile), weight 38 kg (less than 2nd percentile) and body mass index of 17.8 Kg/m^2. Tanner stage was S1P1A1. Biological investigations showed, mixed dyslipidemia, normal liver and renal functions and normal TSH. AST/ALT ratio was 1.35. FSH and LH levels were low. Ultrasound abdomen revealed hepatomegaly with a liver span of 19 cm. Based on the clinical history and investigations, Mauriac syndrome seems to be the most likely diagnosis of our patient. A holistic multidisciplinary approach, in collaboration with the child psychiatrist, was opted, in order to optimize diabetes management and to reduce hepatic metabolic overload. Further investigations was conducted to rule out differential diagnoses, especially viral and autoimmune hepatitis.

Conclusion
Poor acceptance of type 1 diabetes leads to non-compliance with insulin therapy. Then, energy metabolism becomes defective with growth retardation and pubertal delay. Glucose accumulates in the liver leading to metabolic liver disease. Liver damage could be irreversible. Therapeutic education, good doctor-patient relationship and family support constitute the main cornerstones of the management of T1DM diabetes complicated by Mauriac syndrome.

Current prevalence and patterns of hypolipidemic medication based on real-life nation-wide data on 10, 816, 286 individuals

Konstantinos Mathioudakis[1], Maria Yavropoulou[2], Maria Evangelia Koloutsou[2], Polyzois Makras[3], Evangelos Liberopoulos[4] & Konstantinos Athanasakis[5]
[1]IDIKA SA - E-Government Center for Social Security Services, Athens, Greece; [2]First Department of Propaedeutic and Internal Medicine, National and Kapodistrian University of Athens, Athens, Greece; [3]Department of Medical Research, 251 Hellenic Air Force & VA General Hospital, 3 Kanellopoulou St, 11525, Athens, Greece; [4]First Department of Propaedeutic and Internal Medicine, National and Kapodistrian University of Athens, Athens, Greece; [5]Laboratory for Health Technology Assessment (LabHTA), Department of Public Health Policy, School of Public Health, University of West Attica, Athens, 11521, Greece

Background
Hypercholesterolemia has an established causal role in the progression of atherosclerosis and development of cardiovascular disease (CVD). In studies carried out after 2002, the estimated prevalence of self-reported dyslipidemia in the Greek population ranges from 11% to 23%, whereas approximately 35% of mortality in Greece is attributed to cardiovascular disease (CVD). Relevant real-life data, however, are scarce.
Methods
In the present study we used theelectronic prescription database of the National Organization for Health Care Services Provision (IDIKA), embracing almost 100% of all prescriptions issued in Greece, to capture individuals who received hypolipidemic treatment during the year 2021.
Results
The study population consisted of 10,482,487individuals, accounting for the totalGreek population in 2021. The overall prevalence of medication-prescribed dyslipidemia accounted for the 19% of the total Greek population ($n=1,998,393$), beingslightly higher in women than in men (19.7% vs 18%, respectively) across all age groups and was gradually increased with advancing age (7% in those <50 years, to 44.5% in those aged 70 and above). Notably, 1052 individuals with medication-prescribed dyslipidemia were underage (accounting for 0.05% of the total underage population in Greece). Most common concomitant diseases were arterial hypertension (45.7%) diabetes type mellitus 2 (28.4 %), and coronary artery disease (14.4%). General practitioners(33,72%), Internists(33,69%), and Cardiologists(21,64%) prescribed the vast majority of hypolipidemic treatment. The annual cost of treatment per-patient was on average 144€ (total cost € 203,375,511)with rosuvastatin and atorvastatin being more frequently prescribed accounting for more than 80% of all prescriptions.
Conclusion
Approximately 18% of the total Greek population has been prescribed with a hypolipidemic agent during 2021. Prevention and control of dyslipidemia, as one of the most important modifiable risk factors for CVDremains a yet unmet challenge.

Effectiveness of dapagliflozin and sitagliptin fixed dose combination in indian patients with type 2 diabetes mellitus in real world settings: age stratified-analysis from a retrospective study

Ritesh Agrawala[1], Supratik Bhattacharyya[2], Prakadeesh Bharathi B[3], Vinay Kudrigikar[3], Prachi Ahire[3], Shruti Dharmadhikari[3], Chintan Khandhedia[3], Neeraj Markandeywar[3], Amey Mane[3] & Suyog Mehta[3]
[1]AMRI Hospital, Bhubaneswar; [2]SKN Diabetes and Endocrine Centre, Kolkata; [3]Sun Pharma Laboratories Ltd, Medical Affairs

Introduction and Objective
Incidence of type 2 diabetes mellitus (T2D) is rapidly increasing resulting in significant metabolic disorders and complications. Dapagliflozin and sitagliptin have complimentary mechanism of action and have shown synergistic effects in controlling blood glucose levels with advantage of low risk of hypoglycemia. Use of fixed dose combinations (FDC) is associated with improved patient compliance. This is an Age Stratified analysis of electronic medical record (EMR) based study assessing effectiveness of dapagliflozin + sitagliptin FDC in patients with T2D.
Methods
In this real-world, retrospective, observational, EMR based study, data of adult patients (age $\geq$18 years) of either gender with T2D having HbA1c $\geq$7% at baseline were included. Patients who were prescribed dapagliflozin and sitagliptin FDC in any visit other than baseline visit on EMR platform were included. Patients on insulin or other injectable antidiabetic medications were excluded. Primary endpoint was mean change in HbA1c from baseline to 3 months in patients with HbA1c $\geq$8% at baseline. This is an age stratified-analysis of primary outcome.
Results
Total 3,112 patients fulfilled selection criteria, of which 838 patients were eligible for primary analysis. Patients were stratified in following age groups - Group 1: age $\leq$ 50 years ($n=299$); Group 2: 51-60 years ($n=281$); Group 3: 61-70 years ($n=198$) and Group 4: $>$70 years ($n=60$). Mean HbA1c reduced from 9.29% at baseline to 7.98% at 3 months (change -1.31%, $P<0.001$). Significant reduction in HbA1c from baseline to 3 months was observed in all age groups - Group 1: 9.31% vs 7.90% [change -1.41%]; Group 2: 9.29% to 7.97% [-1.32%]; Group 3: 9.22% vs 8.05% [-1.17%]; Group 4: 9.49% vs 8.13% [-1.35%]. Fasting and Postprandial blood glucose (FBG and PPBG) reduced significantly in all age strata from baseline to 3 months. FBG changes - Group 1: 175.67 to 137.27 (-38.4 mg/dl; ($n=251$), Group 2: 166.83 to 136.19 (-30.64 mg/dl; ($n=236$), Group 3: 161.77 to 128.26 (–33.51 mg/dl, ($n=170$), Group 4: 155.61 to 123.66 (–31.95 mg/dl; ($n=53$). PPBG changes - Group 1: 252.19 to 200.02 (-52.17 mg/dl; ($n=205$), Group 2: 254.08 to 201.32 (–52.76 mg/dl; ($n=205$), Group 3: 240.52 to 197.63 (–42.89 mg/dl; ($n=154$), Group 4: 246.10 to 202.52 (–43.58 mg/dl; ($n=58$). $P<0.001$ for all comparisons.
Conclusion
In patients with T2D and higher HbA1c value, Dapagliflozin + Sitagliptin FDC showed significant reduction in HbA1c, FBG and PPBG across all age groups. These findings highlight utility of Dapagliflozin + Sitagliptin FDC in managing T2D irrespective of age.

Effect of prior GLP-1 RA treatment on clinical outcomes in patients with type 2 diabetes initiating treatment with tirzepatide

Mohammed Suliman[1], Adam Buckley[1], Matthew Allum[1], Nader Lessan[1], Nagi Mohammed[1], Carel le Roux[2] & Sara Suliman[1]
[1]Imperial College London Diabetes Centre, Abu Dhabi, United Arab Emirates; [2]Imperial College London, London, United Kingdom

Background
Tirzepatide is a GLP-1/GIP co-agonist treatment for type 2 diabetes. Participants in the SURPASS trials were GLP-1RA naïve, but in clinical practice many patients are switched from other GLP-1RAs.
Aims
To explore effects of prior GLP-1RA treatment on tirzepatide therapy outcomes.
Methods
Review of clinical data from an outpatient Diabetes centre. Adults with 6 months follow-up post tirzepatide initiation were included, ($n=1375$. GLP-1RA exposure was classified as 'naïve' (no GLP-1RA ever dispensed, ($n=192$), 'prior exposure' (no GLP-1RA in preceding 12 months), 'injectable semaglutide' 'oral semaglutide' or 'other injectable GLP-1RA". Linear regression analyses were adjusted for prior bariatric surgery and tirzepatide discontinuation.
Results
Mean (95%CI) adjusted change in weight was -7.0(-7.6; -6.3)kg in the naïve group, -5.2(-6.2; -4.2)kg in the prior exposure group, -5.4(-6.6; -4.1)kg in the oral semaglutide group, -4.4(-5.0; -3.9)kg in the other injectable GLP-1RA group, and -3.7(-4.1; -3.3)kg in the injectable semaglutide group at 6 months. Mean adjusted change in HbA1c was -1.22(-1.36; -1.07)% in the naïve group, -0.76(-0.96; -0.55) % in the prior exposure group, -0.79(-1.06; -0.53) in the group switched from oral semaglutide, -0.70(-0.81; -0.58) in the other GLP-1RA group, and -0.55(-0.62; -0.48)% in the injectable semaglutide group. Weight outcomes differed significantly between naïve and prior exposure ($P<0.05$), injectable semaglutide ($P<0.001$), and other injectable GLP-1RA ($P<0.001$) groups, and between the prior exposure and injectable semaglutide groups ($P<0.05$).

Conclusion
At 6 months, tirzepatide treatment resulted in significantly higher reductions in weight and HbA1c in GLP-1RA naïve patients than those switched from other GLP-1RAs. Individuals switched from injectable semaglutide had the least additional weight loss and HbA1c reduction.

Metabolic dysfunction-associated steatotic liver disease (MASLD) is the main hepatic manifestation of obesity. MASLD was recently defined as liver steatosis in the presence of at least one cardiometabolic risk factor and reduced or absent alcohol intake. MASLD prevalence is rapidly increasing, thus becoming the fastest growing aetiology of the most common primary liver cancer, hepatocellular carcinoma (HCC), and the leading cause of liver transplantation in HCC patients. Currently, there is no EMA/FDA approved drug specifically for MASLD treatment. In this scenario, neuroendocrine control regulatory systems, such as the ghrelin system, have been previously proven to be a reliable source of biomarkers and therapeutic opportunities in multiple endocrine-related cancer types (e.g., breast, prostate and pituitary tumours). Therefore, the purpose of this work was to assess the expression and possible clinical relevance of ghrelin system components (GSCs: ligands, receptors, etc.) in the MASLD-HCC progression. To achieve this, we analysed GSCs mRNA expression in 2 internal retrospective cohorts of chronic liver disease (CLD) and HCC [Retrospective-1: HCC vs non-tumoral adjacent tissue (NTAT) ($n=80$); Retrospective-2: HCC vs NTAT ($n=58$), cirrhotic ($n=33$) and healthy liver tissue ($n=5$)], 10 *in silico* cohorts [7 MASLD, 3 HCC; $n=(45\text{-}369)$], 4 diet-based mice models recapitulating MASLD-HCC progression (C57BL/6J, $n=119$) and 3 human cell lines modelling healthy liver (THLE-2) and HCC (Hep3B, SNU-387). Statistical associations with key clinical features of HCC were performed. In the HCC cell lines, the impact of GSCs administration on important tumour aggressiveness parameters was evaluated using different functional assays (proliferation, migration, colony and hepatosphere formation). Some GSCs showed a progressively increasing expression according to MASLD stage, followed by a drastic downregulation in HCC. This pattern was consistently observed through every cohort and *in vivo* and *in vitro* model, suggesting a biphasic GSCs expression regulation in CLD. Moreover, the inhibition of key GSCs in HCC was associated with several clinical features of tumoral aggressiveness such as histological differentiation, survival and recurrence rate, microvascular invasion and tumour nodule number and size. Remarkably, the *in vitro* administration of certain ligands of the GSC strongly hindered HCC cells proliferation and colony and hepatosphere formation. In contrast, healthy liver cells viability rate was not affected by these GSC ligands, suggesting a clinically safe approach. In conclusion, GSCs could be major players in the physiopathology of CLD as drivers of MASLD-derived hepatocarcinogenesis and the ghrelin system could represent a novel, yet unexplored origin of biomarkers and therapeutic options for CLD.

Characteristics of presentation and management of people with hypoglycaemia while on continuous glucose monitoring devices - pilot data from DEKODE hypoglycaemia study

Charles Page[1], Aashritha Buchipudi[1], Ahmed Iqbal[2], Amanda Ling Jie yee[1], Haaziq Sheikh[1], Lakshmi Rengarajan[3], Ninoshka Merchant[1], Pranav Viswanath Iyer[1], Rajeev Raghavan[4] & Team Dekode[3]
[1]University of Birmingham Medical School, Birmingham, United Kingdom; [2]Department of Oncology & Metabolism, University of Sheffield & Sheffield Teaching Hospitals, Sheffield, United Kingdom; [3]Institute of Applied Health Research, University of Birmingham, Birmingham, United Kingdom; [4]Wolverhampton Diabetes Endocrine Centre, New Cross Hospital, Wolverhampton, United Kingdom

Background
Continuous glucose monitoring (CGM) is an increasingly important diabetes technology that has the potential to facilitate the avoidance of low glucose values. However, there is a paucity of information on admitted patients' characteristics, management, and outcomes of those admitted with hypoglycaemia despite being on CGM.
Objective
To explore the characteristics of the patient population, precipitating factors and outcomes of people admitted with hypoglycaemia while on CGM.
Methods
This retrospective study was conducted from October 2023 to January 2024 across five hospitals in the UK. All adults aged >18 years admitted to hospitals with hypoglycaemia while on CGM from November 2022 to October 2023 were included in the study. Data on sociodemographic, precipitating factors, management, outcomes and total time spent during hypoglycaemic episodes were collected. Data was analysed on SPSS 29.0.
Results
We identified 39 episodes of hypoglycaemia, with 37 occurrences in individuals with type 1 diabetes and 2 in those with type 2 diabetes. 34 episodes occurred while the person was an inpatient in the hospital. The median (interquartile) age was 49.0 (36.0-50.0) years. Their Charlson comorbidity index was 4 (4-6). 79.5% were men. The median (interquartile) HbA1c before admission was 98.0 (60.0-98.0) mmol/mol. 79.5% were level 1, 10.3% were level 2, and 10.3% were level 3 hypoglycaemia. 48.7% of episodes were due to missed meals. Patients spent 26 (16.0- 124.0) min in hypoglycaemia during these episodes. 7.7% of people received glucagon either at home, in an ambulance, or in a hospital for hypoglycaemia. However, only 5.1% were prescribed glucagon upon discharge.
Conclusion
The majority of hypoglycaemia was due to missed meals. Despite spending a median of 26 minutes in hypoglycaemia, only a small percentage received glucagon, and a mere 5.1% were prescribed glucagon upon discharge. These findings underscore the need for enhanced education and proactive management strategies for individuals on CGM to effectively prevent and address hypoglycaemic episodes, potentially improving patient outcomes and overall diabetes care.

Acute complications in diabetic patients during the month of ramadan: about 48 cases

Zaynab Hifdi[1], Soukaina Laidi[1], Saloua Elamari[1] & Marouan Fatima[1]
[1]Cheikh Khalifa Bin Zayed Al Nahyan Hospital, Casablanca, Morocco

Introduction
Diabetes, a disease on the rise worldwide, requires patients to make constant adjustments to their lifestyle. During the month of Ramadan, diabetic patients face additional challenges. The cultural practices associated with this month modify diet, sleep and physical activity, exposing patients to an increased risk of acute complications or decompensation of chronic complications. This study aims to analyze the prevalence and mechanisms of acute metabolic, cardiovascular and renal complications in diabetics during Ramadan. It also aims to propose approaches for preventing these complications.
Material and methods
We included all patients who had cardiovascular, metabolic and renal complications during Ramadan. we compared with patients who had the same complications but outside of Ramadan.
Results
We included 48 patients who had acute complications, 70% of whom during Ramadan. The study revealed that 89% of patients were at high risk of fasting during Ramadan. During this period, 51% of patients fasted, with only 3% having medical approval. Complications were more frequent during Ramadan, with 49% cardiovascular complications, 43% metabolic complications, and 8% renal complications, compared with 78%, 22%, and 0% respectively outside Ramadan.
Conclusion
Our study highlights a significantly higher prevalence of complications in diabetics during Ramadan compared with the period outside Ramadan. The results underline the importance of fasting risk stratification, therapeutic education, pre-Ramadan medical evaluation and therapeutic adjustment to prevent these complications in diabetic patients.

Preoperative vitamin b1 levels are associated with reaching normal body mass index 1 year after bariatric surgery

Bruna Silva[1], Catarina Pereira[1], Catarina Chaves[1], Tatiana Basto[2], Catarina Gil[2], César Alvarez[2] & Filipe Cunha[1]
[1]Unidade Local de Saúde do Tâmega e Sousa, E.P.E., Endocrinology, Guilhufe, Portugal; [2]Unidade Local de Saúde do Tâmega e Sousa, E.P.E., General Surgery, Guilhufe, Portugal

Introduction
Vitamin B1 (VB1) deficiency can occur in patients with obesity and after bariatric surgery (BS). Nevertheless, pre-operative measurements of VB1 are still controversial. The relationship between serum VB1 and weight loss after BS has not been reported previously.
Objectives
To study the association between pre-operative VB1 levels and weight loss after BS.
Methods
Retrospective study of patients submitted to bariatric surgery - laparoscopic Roux-en-y gastric bypass (RyGB) or vertical gastrectomy (VG) with 1 year follow-up and a pre-operative serum VB1 measurement. The primary endpoint was reaching a body mass index (BMI) $\leq$ 25 Kg/m^2. Patients with VB1 $<$ 147 nmol/l and with VB1 $\geq$ 147 nmol/l (mean VB1 value) were compared. Multivariable logistic regression analysis models were built with variables associated with weight loss (age, sex, and type of surgery) along with additional variables added to the model one-at-a-time. The latter were those variables with different distribution between groups and with possible interference with VB1 levels and function.
Results
We analysed 98 patients. Mean VB1 levels were 147 (33) nmol/l. No patients were supplemented for VB1. Patients with VB1 levels $\geq$ 147 nmol/l had higher haemoglobin ($P=0.02$), leukocyte counts ($P=0.005$) and TSH ($P=0.05$). There were no differences observed between groups regarding age, sex, type of surgery, diabetes status, initial BMI, gamma-glutamyl transpeptidase (GGT), insulin, calcium, magnesium, zinc, folic acid, vitamin B12, albumin, or vitamin D levels. Patients with VB1 levels $\geq$ 147 nmol/l reached a BMI $\leq$25 Kg/m^2 more often 58.3% vs 36.0%, $P=0.03$, and had lower BMI at 1-year [24.2 (23.0-27.2) vs 25.8 (23.6-27.9) Kg/m^2, $P=0.06$] and higher excess BMI loss [100.9% (18.5) vs 94.5% (14.8), $P=0.06$] although not statistically significant. In the multivariate logistic regression analysis, for each 10 nmol/l increase in VB1 the OR (95% CI) for the association with the primary endpoint was 1.25 (1.07-1.46), $P=0.004$ adjusted for age, sex, and surgery type. This association was similar after additional one-at-a-time adjustments for: haemoglobin, leukocytes, calcium, magnesium, GGT, insulin, diabetes status, TSH, folic acid, vitamin B12, zinc and hepatic steatosis.
Conclusions
VB1 is associated with weight loss after BS. Per each 10 nmol/l increased the risk of reaching normal BMI 1-year after BS increased by 25%.

Polycystic ovary syndrome in type 1 diabetes mellitus: a cross-sectional study of 785 women with diabetes and 1152 controls

Sofia Toft[1], Neda Rajamand Ekberg[1], Hidaya Abdulrahim[1], Angelica Lindén Hirschberg[2] & Michael Alvarsson[1]
[1]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden; [2]Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden

Background
The prevalence of reproductive disturbances in women with Type 1 Diabetes Mellitus (T1DM) is high compared to the general population. One reason might be higher prevalence of Polycystic ovary syndrome (PCOS) in T1DM. In Sweden, with a high incidence of T1DM, the prevalence of PCOS in women with T1DM is not known. Neither is the T1DM-PCOS pathophysiology.
Aim
The aim of this cross-sectional study was to investigate the prevalence of PCOS in a Swedish T1DM population compared to population-based controls, as well as characterizing patients and controls with respect to hormonal and metabolic profile.
Method
A screening questionnaire covering medical background, gynaecological history and PCOS related symptoms was sent out to female T1DM patients of age 18-55 years in Stockholm. The questionnaire was also sent to women that were matched to the patient population by age and postal address and thus served as controls. Subjects who reported one or more symptoms related to PCOS or reported close female relatives with symptoms, were offered to participate in a clinical examination by a physician (including gynaecological examination with vaginal ultrasound, assessment of body hair by the modified Ferriman-Gallwey scale and fasting blood samples).
Results
785 women with T1DM and 1152 controls were included in the questionnaire part of the study. 40.3 % vs 29.5 % ($P<0.001$) of women with T1DM and controls, respectively, reported having at least one screening symptom. Women with T1DM reported to a greater extent oligomenorrhea (25.1 % vs 17.1 %, $P<0.001$) as well as excessive hair growth (14.9 % vs 8.7 %, $P<0.001$) compared to controls. More women with T1DM than controls reported the combination of oligomenorrhea and excessive hair growth (5.1 % vs 2.6 %, $P<0.01$). 102 women with T1DM and 97 controls were subsequently included in the clinical examination. 34.3% of women with T1DM and 22.7% of controls fulfilled the Rotterdam criteria of PCOS, OR = 1.8, ($P=0.07$). There was a higher rate of polycystic ovarian morphology in women with T1DM (45.5% vs 31.0 %, $P<0.05$) compared to controls. The rate of hyperandrogenism and oligomenorrhea was the same. When analysing PCOS positive subjects only, women with T1DM had significantly higher testosteron, SHBG, androstenedione and DHEAS compared to controls.
Conclusion
These results confirm the connection between symptoms of PCOS and T1DM, also in a Swedish population. Furthermore, in women with PCOS, hormonal deviances seem to be more pronounced in those with T1DM compared to controls.

Prognostics factors for regression from prediabetes to normoglycaemia: individual participant data meta-analysis

Najmeh Davoodian[1], Mojtaba Lotfaliany[1], Rachel Huxley[2], Crystal Lee[3], Julie Pasco[4] & Mohammadreza Mohebbi[5]
[1]IMPACT, the Institute for Mental and Physical Health and Clinical Translation, School of Medicine, Deakin University, Geelong, Australia; [2]Faculty of Health, Deakin University, Melbourne, Australia; [3]School of Population Health, Curtin University, Perth, Australia; [4]IMPACT, the Institute for Mental and Physical Health and Clinical Translation, Geelong, Australia; [5]Biostatistics Unit, Faculty of Health, Deakin University, Melbourne, Australia

Background
Prediabetes, a subclinical precursor to type 2 diabetes mellitus (T2DM) that currently affects approximately 374 million adults worldwide, is a risk factor for the development of cardiovascular disease and stroke, in addition to T2DM. Prediabetes can be reversed to normoglycemia; hence, we aimed to quantify the role of metabolic risk factors in prediabetes regression to normoglycemia.
Methods
We utilized the Obesity, Diabetes, and Cardiovascular Disease Collaboration database for our individual participant data meta-analysis. This database includes 19 prospective cohort studies involving 113,296 adults across various ethnicities and age groups. We included individuals with prediabetes with at least one follow-up in the analysis. Discrete-Time Hidden Markov Models were used to estimate hazard ratios for prognostic factors of prediabetes regression in each cohort study. These estimations were then pooled in the random-effects meta-analysis model.
Results
We included 19,255 participants with prediabetes at baseline, with a median follow-up of 9.8 years (IQR 5.8–12.3); 53% were women, with a mean age of 51 years for both sexes. Former smoking (hazard ratio 0.98, 95% CI 0.89-1.06), higher waist-to-hip ratio (0.86, 0.79-0.93), higher waist-to-height ratio (0.83, 0.75-0.92), higher value of waist circumferences (0.87, 0.71-1.06), overweight (0.88, 0.81-0.96), and obesity (0.86, 0.71-1.04), high diastolic (0.93, 0.87-0.99) and systolic (0.96, 0.91-1.01) blood pressure, low serum HDL-cholesterol (0.87, 0.81-0.92), and high serum triglycerides (0.88, 0.81-0.96) were associated with a lower likelihood of individuals with prediabetes achieving normoglycemia.
Conclusion
The role of metabolic risk factors in prediabetes regression underscores the importance of lifestyle modification in the prediabetes state, not only to reduce T2DM development but also to attain normoglycemia.

Glycemic control in patients with prediabetes acutely improves serum nlrp3 inflammasome and associated interleukins post-lifestyle modification

Hend Alfadul[1], Nasser Al-Daghri[1], Shaun Sabico[1], Malak Khattak[1] & Mario Clerici[2]
[1]Chair for Biomarkers of Chronic Diseases, King Saud University, Biochemistry, Riyadh, Saudi Arabia; [2]University of Milan, Medical-Surgery Physiopathology and Transplantation, Milano, Italy

Background
Prediabetes (PD) is a significant risk factor diabetes mellitus (DM) and as such, behavioral interventions are the primary management for PD. High blood glucose levels alter circulating NLRP3 inflammasome complex activity and correlated interleukins (ILs). There is limited data available on the activity of NLRP3 inflammasome and ILs in sera of patients with PD that may or may have not developed DM. This interventional study assessed the effects of NLRP3 inflammasome activation on DM development in PD individuals who followed a six-month behavioral intervention program.
Methods
This interventional study included 67 Saudi adults, 20 males and 47 females, (mean age = 41.9 ± 8.0 years, mean BMI = 33.15 ± 5.5 kg/m^2). Overnight-fasting serum samples were collected at baseline and at 6-month follow-up. Serum levels of NLRP3, capsase-1 and correlated ILs (IL-1α, IL-1β, IL-18, IL-33 and IL-37) were assessed using commercially available immunoassay kits at both visits.
Results
IL-1α levels significantly increased in the PD group that developed T2DM after 6 months of intervention (baseline: 0.6 (0.5–0.8), follow-up: 1.0 (0.9–1.4); $P=$ 0.046), IL-33 levels significantly decreased in the PD group that reverted to normal after 6 months of intervention (baseline: 3.2 (0.7–4.0), follow-up: 0.8 (0.6–2.1); $P<0.001$), IL-37 levels significantly decreased in the PD group that remained PD after 6 months of intervention (baseline: 4.2 (2.1–10.7), follow-up: 2.9 (2.1–2.9); $P<0.001$) and NLRP3 levels significantly decreased in the PD group that remained PD after 6 months of intervention (baseline: 0.13 (0.1–0.22), follow-up: 0.11 (0.07–0.18); $P=$ 0.01). In all participants with PD, after 6 months of intervention IL-33 levels significantly decreased (baseline: 3.2 (2.9–3.9), follow-up: 0.9 (0.6–3.0); $P=$ 0.001), IL-37 levels significantly decreased (baseline: 3.0 (2.1–8.5), follow-up: 2.9 (2.1–3.0); $P=$ 0.008) and NLRP3 levels significantly decreased (baseline: 0.1 (0.1–0.2), follow-up: 0.1 (0.1–0.2); $P=$ 0.05). Results also showed a positive overtime correlation between NLRP3 and both IL-1α ($r=$ 0.3, $P=$ 0.001) and IL-33 ($r=$ 0.03, $P=$ 0.028).
Conclusion
Glycemic control positively changed NLRP3 inflammasome complex activation post-behavioral intervention program in PD individuals and this maybe pivotal in reversing the detrimental metabolic and pro-inflammatory states.

Relationship between the levels of asprosin, interleukin-6 and adiponectin in patients with type 2 diabetes mellitus with or without chronic pancreatitis

Larysa Zhuravlyova[1], Mykyta Markevych[1] & Vladyslav Kaliuzhka[2]
[1]Kharkiv National Medical University, Department of Internal Medicine No.3 and Endocrinology, Kharkiv, Ukraine; [2]Kharkiv National Medical University, Department of Neurosurgery, Kharkiv, Ukraine

Background
Asprosin is a recently discovered hormone that plays a role in regulating glucose homeostasis and energy metabolism. It is produced in white adipose tissue and released into the bloodstream in response to fasting, stimulating the liver to produce glucose. Interleukin-6 (IL-6), a pro-inflammatory cytokine, is known to contribute to the chronic low-grade inflammation seen in obesity and type 2 diabetes mellitus (T2DM). It also plays a role in insulin resistance and impaired glucose metabolism. Adiponectin, on the other hand, is an adipokine with anti-inflammatory and insulin-sensitizing properties. Investigating the complex interactions and correlations among asprosin, IL-6, and adiponectin can deepen our understanding of the mechanisms contributing to insulin resistance and hyperglycemia in T2DM. This in turn may lead to the development of more targeted and effective therapeutic strategies for managing the condition.
Methods
A total of 75 patients (28 males and 47 females with a mean age of 54.4 ± 7.5 years) with T2DM were recruited at the Department of Endocrinology of Kharkiv Regional Hospital. Chronic pancreatitis (CP) was diagnosed in 42 T2DM patients. IL-6, adiponectin and asprosin levels in blood serum were measured in all the study subjects by enzyme-linked immunosorbent assay.
Results
Our findings revealed a significant positive correlation between asprosin and IL-6 levels in patients with T2DM, both with and without CP. Additionally, we observed a negative correlation between adiponectin levels and both asprosin and IL-6 levels in patients with T2DM, with and without CP. Patients with CP showed significantly higher asprosin levels than those without CP ($P<$0,001).
Conclusions
These results suggest that there may be a potential interplay between asprosin, IL-6, and adiponectin in the context of T2DM and CP. Further studies are needed to elucidate the exact mechanisms underlying this correlation and to explore the potential therapeutic implications of targeting these molecules in the management of T2DM with and without CP.

Combined dulaglutide-dapagliflozin treatment improves vascular dysfunction and albuminuria vs DPP4 inhibitors independently of glycaemic control

Emmanouil Korakas[1], Ignatios Ikonomidis[2], John Thymis[2], Aikaterini Kountouri[1], Loukia Pliouta[1], Konstantinos Katogiannis[2], Dimitris Benas[2], Konstantinos Balampanis[1], Vasiliki Prentza[1], Foteini Kousathana[1], Gavriela Kostelli[2], George Dimitriadis[3], Athanasios Raptis[1] & Vaia Lambadiari[1]
[1]Attikon University Hospital, Second Department of Internal Medicine, Chaidari, Greece; [2]Attikon University Hospital, Second Cardiology Department, Chaidari, Greece; [3]Sector of Medicine, Medical School, National and Kapodistrian University of Athens, Athens, Greece

Background
The association between diabetes mellitus and diabetic nephropathy with vascular and endothelial properties is well-established. In this study, we compared the effect of combined treatment with dulaglutide and dapagliflozin versus DPP-4 inhibitors on endothelial glycocalyx, arterial stiffness, myocardial function and albuminuria in patients with type 2 diabetes mellitus and albuminuria.
Methods
A total of 60 patients with type 2 diabetes mellitus and albuminuria were randomized to combined dulaglutide and dapagliflozin treatment ($n=30$) or DPP-4 inhibitors (DPP-4is, ($n=30$). We measured at baseline and 4 and 12 months posttreatment: (a) perfused boundary region of the sublingual arterial microvessels (marker of endothelial glycocalyx thickness), (b) pulse wave velocity (PWV) and central systolic blood pressure (cSBP), (c) global left ventricular longitudinal strain (GLS) (d) urine albumin-to-creatinine ratio (UACR).
Results
Twelve months posttreatment, the combination of dulaglutide and dapagliflozin showed a greater improvement in all indices compared to DPP-4is, despite a similar reduction in glycosylated hemoglobin. Specifically, dual therapy showed greater improvements vs DPP-4is in PBR (2.10 ± 0.31 to 1.93 ± 0,23 μm vs 2.11 ± 0.31 to 2.08 ± 0.28 μm, $P<0.001$), in UACR (326 ± 61 to 142 ± 47 mg/g vs 345 ± 48 to 306 ± 60 mg/g, $P<0.01$), and in PWV (11.77 ± 2.37 to 10.7 ± 2.29 m/s vs 10.64 ± 2.44 to 10.54 ± 2.84 m/s, $P<0.001$), while only dual therapy showed improvement in cSBP (130.21 ± 17.23 to 123.36 ± 18.42 mmHg). Regarding GLS, both treatments were effective, but dual therapy showed a significantly higher percentage improvement compared to DPP-4is (18.19% vs 6.01%, respectively).
Conclusions
Twelve-month treatment with dulaglutide and dapagliflozin showed a greater improvement in vascular markers an albuminuria than DPP-4is in patients with type 2 diabetes mellitus and albuminuria. Early initiation of combined therapy as add-on to metformin should be considered in these patients.

PDE4 inhibition attenuates non-alcoholic fatty liver disease by increasing vldl secretion in obese animals

Hellen da Silva[1], Maria Amélia Montenegro[1], Juliana Gebenlian[2], José Antunes Rodrigues[2,2], Francisco de Paula[1,1] & Lucila Elias[2]
[1]University of Sao Paulo, Internal Medicine, Ribeirao Preto, Brazil; [2]University of Sao Paulo, Physiology, Ribeirao Preto, Brazil

Non-alcoholic fatty liver disease (NAFLD) is characterized by the pathological increase of lipid droplets, altered fat metabolism in hepatocytes and increased inflammation. Phosphodiesterase 4 (PDE4) modulates the inflammatory responses and its inhibitor can strongly reduce TNF-α release and inflammation. Additionally, PDE4 knockout mice were shown to be resistant to diet-induced obesity (DIO). The aim of this study was to investigate the role of pharmacological PDE4 inhibition in the NAFLD phenotype in DIO. To attain this purpose, obese mice were treated with rolipram, a PDE4 inhibitor. All experimental protocols were approved by the Ethics Committee for Animal Use of the Ribeirao Preto Medical School. Male C57Bl6 mice were fed with either chow or high-fat diet (HFD; 60% fat) for 12 weeks and in the 10th week they received daily subcutaneous injections of vehicle (VEH) or rolipram (2 mg/kg). Food intake and body weight were monitored and at the end of the study inguinal, retroperitoneal and brown fat pads were collected for analysis. Rolipram decreased the absolute value and change in body weight and energy intake in the HFD group, which was associated with a decrease in epididymal and retroperitoneal fat pad weight, with no effect in the chow group. Remarkably, PDE4 inhibition decreased liver triglycerides in obese animals and this effect was associated with increased noradrenaline content. Consistent with these results, histological analysis showed that rolipram decreased lipid accumulation in hepatocytes. No changes were found in plasma cholesterol, free fatty acids or triglycerides in the rolipram group compared to vehicle. In contrast, PDE4 inhibition increased PGC1-a and PPARa expression while it decreased Elov3 and MCP-1. To verify whether this effect persists regardless of change in the body weight, we fed animals with a HFD for 3 days and assessed the *in vivo* VLDL secretion by inhibiting the lipoprotein lipase enzyme in animals that received acute rolipram injection. PDE4 inhibition increased VLDL secretion in HFD-treated animals, but not in chow animals. In addition, this was associated with increased CD36 and EPAC content in the liver. These results indicate that PDE4 appears to play a role in the pathogenesis of NAFLD and reinforce PDE4 as a potential target for the treatment of obesity-associated liver disease.

Impact of simulation via instant messaging –birmingham advance (SIMBA) on clinician's confidence to manage type 1 diabetes mellitus using technological advances in endocrinology

Pavithra Sakthivel[1], Anisah Ali[1], Sangamithra Ravi[1], Rachel Shepherd[1], Abby Radcliffe[1], Rahul Sagu[1], Harshin Pallathoor Balakrishnan[2], Sumaya Najeem[2], Neelamabraprasad Goznee[2], Vyshnavi ND[2], Tamzin Ogiliev[3], Punith Kempegowda[4,5] & Simba & Comics Team[4]
[1]University of Birmingham, College of Medical and Dental Sciences, Birmingham, United Kingdom; [2]Far Eastern Federal University, School of Medicine, Vladivostok, Russian Federation; [3]Lancaster University Medical School, Lancatser, United Kingdom; [4]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [5]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom

Introduction
Various technological advances have infiltrated modern clinical practice. This is especially true for the management of type 1 diabetes mellitus (T1DM). User-friendly and convenient smartphone applications like Dexcom and Freestyle Libre have positively contributed towards the control and monitoring of diabetes for patients across the globe. Simulation via Instant Messaging –Birmingham Advance (SIMBA) conducted a virtual training session for clinicians in managing T1DM using these systems.
Aim
To improve healthcare professionals' (HCPs) knowledge and confidence in managing patients with T1DM using technological advances.
Methods
Anonymised case transcripts were created based on real-life clinical scenarios involving the management of T1DM using Freestyle Libre and Dexcom G6. They were used to train moderators, who then virtually simulated these cases with participants via WhatsApp. Clinicians' approach to each case was scored by moderators using a modified global rating scale to consider aspects including interpretation of relevant investigations and proposing an appropriate management plan. The simulation was followed by a discussion session led by a topic expert, delving into the key learning points from each case. Participants completed pre- and post-simulation surveys. Quantitative and thematic analysis of HCPs' perspectives and experience of the session was conducted.
Results
A total of 21 HCPs participated in the session, 95.2% of whom were based in the United Kingdom. Participants' self-reported confidence in using Freestyle Libre and Dexcom G6 improved from 66.7% and 33.3% to 90.5% ($P=0.0143$) and 76.2% ($P=0.0009$), respectively, following the simulation. 95.2% of participants agreed that the simulated topics applied to their clinical practice and reported that the simulation training had a positive influence on their knowledge of patient management and care provision. HCPs also believed the session improved their professionalism (52.4%), practice-based learning (76.1%) and communication skills (23.8%). Additionally, the simulation was considered impactful on a personal and professional level by 81% and 76.2%. Thematic analysis revealed that participants were more confident in offering continuous glucose monitoring (CGM) to their patients and interpreting data produced by CGM applications. Participants also gained awareness of non-medical aspects, such as the availability of educational programmes surrounding the use of technology to empower patients with T1DM.
Conclusion
SIMBA is an evidence-based educational programme that has improved HCPs' knowledge of utilising technological advancements in the management of patients with T1DM, thereby encouraging them to offer these tools to more patients and lead to better outcomes.

Transcriptome of periadrenal and subcutaneous fat in patients with hyperaldosteronism in comparison to patients with non-functional adenomas

Ulrich Dischinger[1], Christian G Ziegler[1], Lisa Kagan[1], Simon J Kloock[1], Mugdha Srivastava[2], Nada Rayes[3], Matthias Blüher[4] & Martin Fassnacht[1]
[1]University Hospital Würzburg, Division of Endocrinology and Diabetes, Würzburg, Germany; [2]University of Würzburg, Core Unit Systems Medicine, Würzburg, Germany; [3]University Hospital Leipzig, Department of Surgery, Leipzig, Germany; [4]University Hospital Leipzig, Department of Internal Medicine, Leipzig, Germany

Background
The crosstalk between the adrenal gland and different fat depots is largely unknown. As primary hyperaldosteronism leads to an increased risk of cardiovascular disease and associated pathologies (glucose intolerance, diabetes, hyperlipidemia), elucidating the interaction between aldosterone producing adenomas (APAs) and different fat depots might help to understand causality and open new diagnostic and treatment strategies.
Methods
Subcutaneous (s.c.) and periadrenal fat was collected from patients with APA (s.c. $n=13$, periadrenal, $n=20$) and, as controls, from non-functional adenomas (NFA, s.c. $n=7$, periadrenal $n=5$). mRNA was extracted from the samples and RNA sequencing was performed. Patients' characteristics were collected.
Results
RNA sequencing revealed a high number of differentially regulated genes in s.c. fat samples of patients with APA vs NFA ($n=$ 68 up, $n=259$ down), in periadrenal samples of patients with APA vs NFA ($n=$ 16 up, $n=117$ down), and in periadrenal vs s.c. samples of patients with APA ($n=$ 1632 up, $n=826$ down). Pathway analysis revealed (amongst others):
- an upregulation of the pathways 'Cushing syndrome' (enrichment score (ES) 0.6), 'aldosterone synthesis and secretion' (ES 0.6) and 'cortisol synthesis and secretion' (ES 0.7) in APA periadrenal vs APA s.c..
- an upregulation of the pathways 'steroid hormone biosynthesis' (ES 0.5), 'Cushing syndrome' (ES 0.4) and 'cortisol synthesis and secretion' (ES 0.6) in APA periadrenal vs NFA periadrenal.
- an upregulation of the pathways 'steroid hormone biosynthesis' (ES 0.5), and a downregulation of 'cortisol synthesis and secretion' (ES -0.6) and 'aldosterone synthesis and secretion' (ES -0.5) in APA s.c. vs NFA s.c.
Conclusion
RNA sequencing revealed a high number of differentially regulated pathways and genes in s.c. and periadrenal fat depots of patients with APA in comparison to patients with NFA. The findings point towards strong paracrine effects of APAs. Detected differences in subcutaneous fat might open new diagnostic strategies for hyperaldosteronism.

Weaning timing impact on adipose tissue remodelling in mice

Damien Dufour[1], Sandra Bryne[2], Philippe Collas[1], Boccara Charlotte[2] & Nolwenn Briand[1]
[1]Institute of Basic Medical Sciences, University of Oslo, Department of Molecular Medicine, Oslo, Norway; [2]Centre for Molecular Medicine Norway, Oslo, Norway

The adipose tissue is an endocrine organ distributed over multiple depots and broadly categorised into two main subtypes: white adipose tissue which stores energy as lipids and brown adipose tissue which dissipates energy in the form of heat. Adipocytes from the white depots are able to switch from a white to a brown-like phenotype, a process called beiging. This phenomenon is stimulated by cold exposure or sympathetic nervous system activation and is associated with improved metabolic health. Weaning, defined as the switch from milk to solid diet is a crucial developmental period. In mice, pups start feeding on pellets as soon as 15 days of age and stop breastfeeding around 28 days of age. Dietary alterations or overfeeding of lactating mother have long-term effects on the metabolism of offspring in both rodents and humans. To understand how weaning affects the adipose tissue in mice, we have analysed the kinetics of adipose tissue remodelling between 21 days of age (P21) and 35 days of age (P35). We have harvested the visceral perigonadal white adipose tissue (gWAT), the subcutaneous inguinal white adipose tissue (iWAT) and the interscapular brown adipose tissue (BAT) at P21, P28 and P35. Between P21 and P35, mice are accumulating WAT while BAT mass remains constant. This process is accompanied by a decrease in the proportion of beige adipocytes, and a reduced innervation and vascularisation density. We next used a model a weaning retardation whereby after 21 days of lactation (P21), four pups from the litter are kept with the dam until P28 (delayed weaning, DW) while the rest of the pups are separated (standard weaning, SW). At P28, DW mice show a decreased body mass but with a higher proportion of fat mass compared to SW controls. Indeed, iWAT mass is increased in the DW condition. Interestingly, at P56, SW mice have higher body mass and adiposity. Finally, delayed weaning induces an increase in the cutaneous temperature of male offspring only, reaching a temperature close to that of females. These results highlight the importance of the weaning period for the development of adipose tissue. Sexually dimorphic phenotypes and the uncorrelated increase in body and fat masses upon delayed weaning suggest an involvement of sexual hormones that will be further investigated.

Implication of metabolically healthy obesity on the risk of incident pancreatic cancer: a nationwide population-based cohort study

Hye Soo Chung[1]
[1]Hallym University, Internal Medicine, Korea, Rep. of South

Background
Lately, a few studies have showed different results regarding the relationship between metabolically healthy obesity and various cancers. We investigated the impact of metabolically healthy obesity on pancreatic cancer using a nationwide population-based cohort database.
Methods
Using the Korean National Health Insurance Service–Health Screening Cohort, we enrolled 347,434 Korean adults who underwent a health examination between 2009 and 2010 and were followed until 2015. This population was divided into four groups based on metabolically healthy status and body mass index: metabolically healthy normal weight, metabolically unhealthy normal weight, metabolically healthy obese, and metabolically unhealthy obese.
Results
During a median follow-up of 6.1 years, pancreatic cancer occurred in 886 individuals. The adjusted HRs for incident pancreatic cancer were 1.52 [95% confidence interval (CI) 1.27–1.81] and 1.34 (95% CI, 1.12–1.61) for the metabolically unhealthy normal weight and metabolically unhealthy obese phenotypes compared with the metabolically healthy normal weight phenotype after adjusting for several confounding factors. However, the metabolically healthy obese phenotype did not show an elevated risk of pancreatic cancer compared with the metabolically healthy normal weight phenotype. Moreover, the HR for pancreatic cancer gradually increased with an increase in number of metabolically unhealthy components, even after adjusting for body mass index (P trend <0.001).
Conclusions
Regardless of body mass index, metabolically unhealthy phenotype demonstrated significantly increased risk of pancreatic cancer, whereas obese individuals with metabolically healthy phenotype did not.

Visceral fat lipolysis using high-dose multichannel non-ablative energy-based device: anthropometric, biochemical and imaging mri study

Jesús Rodríguez Lastra[1]
[1]UAX, Physioterapy, Madrid, Spain

Objectives
Energy-based devices (EBD) have been used as a treatment for abdominal obesity, although its effects on visceral fat are not well known.
Methods
Twenty patients with abdominal obesity were treated with EBD (10 sessions of 60 minutes, and 20 minutes with capacitive and resistive electrodes temperature 45 ° C). We analysed anthropometric changes; visceral and subcutaneous fat was quantified by magnetic resonance imaging and blood samples were taken at the beginning and end of treatment.
Results
at the end of the treatment period, patients significantly reduced waist circumference, systolic blood pressure levels and visceral and subcutaneous fat mass ($P<0.05$). In addition, leptin levels, basal insulinemia and HOMA-IR index ($P<0.05$) were also reduced. No adverse effects were reported.
Discussion
The results present a window into the possibility of reducing visceral fat with improved metabolism. The follow-up of a patient who has attended re-evaluation shows that the effects are maintained over time.
Conclusions
EBD is a safe and effective method to reduce subcutaneous and visceral fat in abdominal obesity, with the consequent improvement of the metabolic profile. This can be a novel and non-harmful tool to reduce abdominal fat. Opening a new perspective for the treatment of obesity

Background and Objective
Fixed-dose combination (FDC) of dapagliflozin + metformin + sulfonylurea with complementary mechanisms can provide effective glycaemic control, preserve beta-cell function, improved compliance without risk of weight gain, and reno-protective action in type 2 diabetes mellitus (T2DM) patients. This subgroup analysis aimed to assess efficacy and safety of triple-drug FDC versus (vs) two-drug combination in T2DM Indian patients with HbA1c 9%-11%.
Method
This subgroup analysis of phase 3, open-label, four-arm, active-controlled study (CTRI/2022/06/043249) included T2DM patients (glycated haemoglobin [HbA1c] 9%-11%) taking metformin 1000 mg 2000 mg/day and glimepiride 2 mg/day at screening). Patients received FDC of dapagliflozin + glimepiride + metformin IR tablet twice-daily (BID) (5 mg + 1 mg + 500 mg [test arm 1]/5

mg + 1 mg + 1000 mg [test arm 2]) OR co administration of glimepiride tablet + metformin IR BID (1 mg + 1 tablet of 500 mg [comparator arm 1]/1 mg + 2 tablets of 500 mg [comparator arm 2]) for 16 weeks. Post Week 16, up-titrated dose of glimepiride (2 mg) in respective treatments was provided to patients with HbA1c $\geq$ 7% in each arm. In this subgroup analysis, change from Baseline in HbA1c, fasting blood glucose (FBG) and post prandial blood glucose (PPBG) till Week 28 and safety parameters were assessed.
Results
This subgroup analysis included 251 patients (58 patients [test arm 1], 67 patients [comparator arm 1], 63 patients each in test arm 2 and comparator arm 2, respectively). Demographic and baseline characteristics were comparable across all arms. Adjusted mean (SE) reduction in HbA1c was statistically significant from Baseline to Week 16 in test arm 1 [-2.15% (0.09%)] vs comparator arm 1 [-1.42% (0.09%)] with difference of 0.73% ($P<0.0001$) and adjusted mean (SE) reduction in HbA1c was statistically significant from Baseline to Week 16 in test arm 2 [-2.06% (0.09%)] vs comparator arm 2 [1.44% (0.09%)], with difference of 0.62% ($P<0.0001$). Similarly, statistically significant reduction in HbA1c was observed at Weeks 8 and 12. Proportion of patients achieving HbA1c $<$ 7% was significantly higher in test arm 1 vs comparator arm 1 (52.7% vs 29.7%, $P=0.0106$) and in test arm 2 vs comparator arm 2 (61.9% vs 43.5%, $P=0.0398$), respectively at Week 16. Significant reduction in HbA1c, FBG and PPBG was observed from Baseline to Weeks 12, 16, and 28 in each arm. None of the patients reported serious adverse events/hypoglycaemia or required rescue medication.
Conclusion
In this subgroup analysis of patients with HbA1c 9%-11%, triple FDCs of dapagliflozin + glimepiride + metformin IR tablets showed statistically significant reduction in HbA1c from Baseline to Weeks 8, 12, 16 as compared to two-drug combination. Both treatments were well tolerated.

How does neuropathic pain affect sleep quality in adults with type 2 diabetes ?

Sana Khamassi[1], Emna Bornaz[1], Haifa Abdesselem[1], Dorra Ben salem[1], Kamilia Ounaissa[1] & Chiraz Amrouche[1]
[1]National Institute of Nutrition, Outpatient Department and Functional Explorations, Tunis, Tunisia

Introduction
Diabetic peripheral neuropathy (DPN) is one of the most common and early manifested complication in adults with type 2 diabetes leading to severe repercussions including foot ulcers, amputations and chronic pain. Furthermore painful diabetic neuropathy can also negatively impact a wide range of key human physiological processes including sleep disturbance [1]. The aim of our study was to determine the effect of neuropathic pain on sleep component.
Materials
This is a cross-sectional study conducted in 100 patients with diabetes. The DN4 questionnaire was used to identify neuropathic pain. Sleep quality was evaluated using the Pittsburgh sleep quality index (PSQI) in its arabic-validated version [2]. It consists of 19 items grouped into seven subscales: self-reported sleep quality (C1), sleep latency (C2), sleep duration (C3), habitual sleep efficiency (4), sleep disturbance (C5), use of sleep medications (C6), and daytime dysfunction (C7). Higher scores in each dimension indicate poorer quality and the sum of components provides a global PSQI score. Scores $>$5 defined poor quality sleepers.
Results
Mean age was 54.45 $\pm$ 7.13 years with a sex ratio (F/M) of 2.57. Mean diabetes duration was 12.67 $\pm$ 7.35 years. Mean BMI was 29.49 $\pm$ 4.97 Kg/m^2, 32% of our patients were overweight and 49% were obese. Mean glycated hemoglobin and mean fast blood glucose were respectively 9.69 $\pm$ 2.02 % and 11.63 $\pm$ 4.80 mmol/l. More than half of our population was insulin-dependent (79%) and only 20% reported hypoglycemia. Peripheral neuropathy was found in 27 % of our sample. Eighteen percent among these patients were treated with pregabalin. Mean DN4 score was 1.82 $\pm$ 1.65 with extremes ranging from 0 to 6. The mean PSQI score was 7.89 $\pm$ 3.69 and 69% of our patients had poor sleep quality. Poor quality sleepers had higher DN4 scores (2.06 $\pm$ 1.74 vs 1.17 $\pm$ 1.21; $P=0.017$). When analyzing sleep components, DN4 score showed correlations with sleep efficiency ($P=0.031$; r = 0.227) and sleep disturbance ($P=0.027$; r = 0.232).
Conclusion
The findings from our study validate earlier research in the literature, highlighting the impact of neuropathy on sleep quality in individuals with diabetes, further exacerbating the impact of this complication.

The association between serum cholecalciferol level and lipid profile in patients with latent autoimmune diabetes in adults

Iryna Tsaryk[1] & Nataliia Pashkovska[2]
[1]Ukraine, Department of Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine; [2]Ukraine, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Introduction
The effect of cholecalciferol on regulation of the lipid profile is one of the proposed mechanisms for the relationship between cholecalciferol deficiency and cardiovascular diseases in patients with diabetes mellitus.
The aim of the study
To evaluate the dependence between cholecalciferol status and dyslipidemia in patients with different phenotypes of latent autoimmune diabetes in adults (LADA).
Material and methods
42 patients with LADA (19 –LADA1, 23 –LADA2) and 25 practically healthy individuals were examined. Lipidogram data (total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), triglycerides (TG) and cholecalciferol status were evaluated.
Results
Cholecalciferol level was registered 2.7 times lower in LADA1 group compared to control (14.63 [13.14; 15.98] ng/ml vs 40.00 [32.17; 53.00] ng/ml) and by 38.7% in LADA2 (24.51 [17.86; 32.93] ng/ml vs 40.00 [32.17; 53.00] ng/ml) ($P<0.001$). In LADA1 patients the level of cholecalciferol was lower by 40.3% ($p < 0.01$) compared to LADA2. The level of TC was 5.32 [4.83; 6.09] mmol/l in LADA1 and 5.23 [4.60; 6.10] mmol/l in LADA2 and probably differed between LADA1/control and LADA2/control (increase by 20.9% ($P<0.001$) and 18.9%, respectively ($P<0.001$)) without intergroup difference. The level of LDL-C was the highest in LADA2: by 74.2% compared with control and twice compared with LADA1 ($P<0.001$) and was 4.46 [3.99; 4.90] mmol/l; the level of HDL-C was 1.50 [1.15; 1.92] mmol/l and 1.05 [0.92; 1.13] mmol/l in LADA1 and LADA2, respectively, and was probably 19.8% lower in LADA1 ($P<0.05$) and by 43.9% in LADA2 ($P<0.001$) compared with control group, while in LADA1 the rate was 42.9% higher compared with LADA2 ($P<0.01$). The level of TG was significantly higher in patients with LADA1 and LADA2 by 84% and 48.1%, respectively, compared with the control group ($P<0.05$ and $P<0.01$, respectively) and did not differ significantly between LADA phenotypes, in the control group it was 0.81 [0.60; 1.10] mmol/l. In patients with the LADA1 phenotype, negative correlations of medium strength were recorded between TC and C-peptide level ($r=-0.562$; $p < 0.05$); LDL-C and cholecalciferol ($r=-0.533$; $P<0.05$); TG and IA-2 ab titers ($r=-0.618$; $P<0.05$). In LADA2, direct correlations of medium strength were registered between the HDL-C and cholecalciferol level ($r=0.682$; $P<0.05$); inverse correlations of medium strength –between LDL-C indicators and IA-2 ab titers ($r=-0.500$; $p < 0.05$).
Conclusions
Level of HDL-C is lower in patients with LADA2 phenotype as well as LDL-C is two times higher compare to LADA1 group. Lipid profile depends on cholecalciferol status, which indicates the importance of its adequate supplementation in patients with LADA.

Relation of diabetic peripheral neuropathy and vitamin d deficiency

Ergita Nelaj[1], Irida Kecaj[1], Kei Xhixhabesi[1], Blerta Nikolla[1] & Margarita Gjata[1]
[1]University Hospital Center, Internal Medicine, Tirana, Albania

Introduction
Diabetic Peripheral Neuropathy (DPN) is a common complication of diabetes mellitus, which seriously affect patients' lives. Vitamin D deficiency is linked to the presence of inflammation and hyperglycemia, so it could be considered as a high risk factor for DPN. In this study we evaluated vitamin D level in diabetic patients and the association between vitamin D level and occurrence of diabetic neuropathy.

Materials and methods
Our study compressed 64 patients with type 2 diabetes mellitus, not supplemented with vitamin D, divided into 3 groups: 20 diabetic patients (10 males and 10 females) with painful DPN, 20 patients (10 males and 9 females) with painless DPN and 24 patients (10 males and 14 females) without DNP (with normal nerve conduction study).
Results
The average age of our patients was 57.04 years ± 11.05. 43.4% of patients were hypertensive; 27.8% had dyslipidemia; the mean BMI was 27.29 ± 6.24 Kg/m^2. The average duration of diabetes was 08.78 years. The mean level of 25 OH vitamin D in first group was lower than in second and third group; respectively 13.24 ± 5.19 vs 16.37 ± 6.75 ng/ml vs 19.23 ± 4.52 ng/ml. There was highly statistically significant difference between the three groups regarding vitamin D level. There is a significant negative correlation between vitamin D level and score of neuropathy where the lower vitamin D level, the higher neuropathy score ($P = 0.003$). No significance for age or duration of diabetes progression.
Conclusion
Vitamin D deficiency is common in diabetic subjects with peripheral neuropathy, mainly in the painful subtype. So, we recommended assessment of vitamin D levels in all diabetic patients as correction of vitamin D deficiency may delay the development of all subtypes DPN.

Ultrasound diagnosis of diabetic nephropathy

Rostyslav Bubnov[1,2]
[1]Zabolotny Institute of Microbiology and Virology, NAS of Ukraine, Kyiv, Ukraine; [2]Clinical hospital ' Pheophania' , Ultrasound, Kyiv, Ukraine

Background
Diabetic nephropathy (DN) is a common complication of diabetes mellitus (DM), impacting the kidneys. Ultrasound serves as a valuable tool for evaluating manifestations of metabolic syndrome and nephropathy [1-3]. This study aims to investigate the efficacy of ultrasound (US) as a predictive diagnostic tool for identifying specific variants of nephropathy in patients with DM.
Methods
Thirty individuals with diabetes (age 38-76, 18 females) requiring medication for glucose control were compared with 30 age-matched controls (equal gender distribution). All participants underwent general clinical and laboratory tests. Abdominal US with convex 2-10 MHz probes was performed, including multiparameter US of the kidneys, utilizing Doppler, shear wave elastography (SWE), and measurement of fat accumulations, including visceral fat (VF) and subcutaneous fat (SF) thickness and areas [1].
Results
The resistive index (RI) in segmental renal arteries exhibited a significant increase ($P < 0.05$) in individuals with DM (0.77 vs 0.66) and correlated with higher glucose levels, insulin usage, and a history of multiorgan complications in DM. Diabetic nephropathy manifested as thinner parenchyma, smooth contours, and mild size reduction. Multiparameter US revealed increased visceral fat and various abnormalities, with distinct patterns linked to metabolic syndrome constituents. SWE showed a moderate increase in parenchyma stiffness (6.7 kPa vs 4.6 kPa, $P < 0.05$).
Conclusion
Multiparameter ultrasound is effective in detecting and distinguishing kidney disease patterns in DM. It provides valuable information for differentiation, modifying treatment approaches, and targeted prevention. The study underscores the significance of US in assessing diabetic nephropathy, offering additional insights into its manifestations.

Risk factors and surgical outcomes of diabetic foot in patients with diabetes at larribere clinic in oran university hospital

Mohamed Samir Merad[1] & Fatiha Mohammedi[1]
[1]Oran 1 Ahmed Ben Bella Medical University, Endocrinology and Diabetology department -Larribere Clinic-University Hospital Dr Benzerdjeb, Oran, Algeria

Introduction
Lower limb amputation is associated with high morbidity and mortality. As a middle-income country, we are particularly vulnerable to diabetes-related problems. The aim of this study is to identify significant risk factors for amputations.
Materials and methods
This is a prospective descriptive study conducted from June 2020 to June 2022 on 102 patients hospitalized for diabetic foot at the Endocrinology-Diabetology Department of Oran University Hospital. The patients were divided into two categories according to the outcome: amputation or non-amputation. To identify the risk factors, we performed a bivariate analysis using SPSS 20 to compare the two groups.
Results
The study included 102 diabetes patients (50 men and 52 women) with a mean age of 63 ± 1 year. Of the 102 patients, 58 (56.9%) had undergone an amputation. Univariate analysis identified insulin therapy prior to admission (OR = 8.2, CI [1.7–40]; $P = 0.003$), dry gangrene lesion (OR = 8.6, CI [3.4–21.7]; $P = 0.000001$), and osteitis (OR = 4; CI [1.5–10.5]; $P = 0.004$) as risk variables. The study found significant associations between HbA1c levels and several complications, including retinopathy (OR = 3.5; CI [1.5-8.1]; $P = 0.004$), macroangiopathic complications (OR = 2.7 CI [1.1-6.7]; $P = 0.032$), peripheral neuropathy (OR = 3.3 CI [1.4-7.8]; $P = 0.007$), and arterial stenosis (OR = 6.6 CI [2-21]; $P = 0.001$). Independent predictive markers were male gender, prevalence of neuropathy, and hospital stay longer than 33.5 days.
Conclusion
Identifying risk factors for amputation is crucial to offering effective preventative strategies based on patient and caregiver education and early diagnosis of lesions.

Mitochondrial diabetes and m.3243A > G mutation in MTL1 gene: MIDD/MELAS syndrome

Panagiota Christou[1], Maria Christou[1], Christos Zisidis[1], Athanasios Siolos[1], Ioanna Bouba[2], Eleni Bagli[3], Andreas Katsanos[3], Ioannis Georgiou[2] & Stelios Tigas[1]
[1]University Hospital of Ioannina, Department of Endocrinology, Ioannina, Greece; [2]University of Ioannina, Laboratory of Medical Genetics, Ioannina, Greece; [3]University Hospital of Ioannina, Department of Ophthalmology, Ioannina, Greece

Introduction/Aim
MIDD (maternally inherited diabetes and deafness) and MELAS (mitochondrial encephalomyopathy, lactic acidosis, stroke-like episodes) are rare, maternally inherited, multisystem disorders caused by mitochondrial DNA mutations. We present the case of a patient with mitochondrial diabetes and discuss the diagnostic challenges.
Case presentation
A 25-year-old female patient with a 7-year history of diabetes mellitus (DM) and suboptimal glycemic control (HbA1c 7.8%) on intensive insulin therapy was evaluated in our department. She reported no history of diabetic ketoacidosis, the total insulin dose was 1.21 IU/kg/day, serum C-peptide was 1.6 ng/ml and the antibodies associated with type 1 DM were negative. Family history: one sister diagnosed with MELAS syndrome (encephalopathy, epilepsy) and mother with insulin-treated DM since the age of 24 years and deafness. Clinical examination: Height 1.55m, BMI 28 kg/m^2, bilateral sensorineural deafness, retinal lesions. Cardiac ultrasound: mild left ventricular heart hypertrophy. On the basis of the medical history and clinical features a diagnosis of probable mitochondrial diabetes was made. Genetic analysis in both the patient and her mother revealed heteroplasmy for the pathogenic variant m.3243A > G in tRNA$^{Leu\ (UUR)}$, *MT-TL1* gene.
Conclusions/Discussion
Various syndromes including MIDD, MELAS and CPEO (chronic progressive external ophthalmoplegia) are caused by the mutation m.3243A > G. Although there is a significant phenotypic overlap, DM is a common feature of all three syndromes. In these rare, maternally inherited, mitochondrial disorders, multiple systems are affected (neuromuscular, eyes, heart, pancreas), and diabetes is due to a combination of insulin secretory defect as well as insulin resistance. It is estimated that mitochondrial DM is the cause of ~1% of the total DM population and m.3234A > G is the responsible pathogenic variant in over 85% of these cases. The therapeutic

choices include insulin, incretin analogs and/or oral antidiabetic medications. Metformin is however avoided because of the risk of lactic acidosis. Although there is no curative treatment, correct diagnosis of mitochondrial diabetes is necessary for the optimal management and genetic counselling of these patients.

Advanced glycation endproducts (AGE) and severity of diabetic retinopathy association analysis in latvia

Zane Svikle[1], Dace Petersone[2], Beate Peterfelde[1,3], Julija Janceva[1,3], Renate Nagobade[1,3], Kristine Baumane[1,3], Janis Valeinis[2] & Jelizaveta Sokolovska[1]
[1]University of Latvia, Faculty of Medicine, Riga, Latvia; [2]University of Latvia, Faculty of Physics, Mathematics and Optometry, Riga, Latvia; [3]Riga East University hospital, Ophthalmology department, Riga, Latvia

Background
Diabetic retinopathy (DR) is one of the most common complication of diabetes and it has a significant impact on national and global health. Accumulation of advanced glycation endproducts (AGE) is recognized as a contributing factor in the development of diabetic complications. The evaluation of AGE has the potential to be an important biomarker in DR, reflecting the impact of prolonged high glucose levels on long-term metabolic memory.
Aim
The objective of this pilot study was to assess and compare the risk levels of AGE among patients at various stages of DR in Latvia.
Methods
In the study 72 participants with type 1 or type 2 diabetes were included. They were grouped based on the severity of their DR: "no retinopathy", "non-proliferative retinopathy", and the "proliferative retinopathy" group, which included also those who had undergone laser-photocoagulation treatment. The evaluation of AGE scores was performed noninvasively using an AGE reader from Diagnoptics, which measures tissue fluorescence. Subsequently, a formula was applied to derive continuous results without categorizing individuals into distinct AGE risk groups (AGE z-score = AGE mean–(0.024*age, years + 0.83)). Statistical analysis was conducted using Fisher's exact test, the Kruskal-Wallis test, and logistic regression models implemented in the R statistical software.
Results
Subjects in the group of 'no retinopathy' ($n = 37$) compared to 'non-proliferative retinopathy' ($n = 22$) and 'proliferative retinopathy' ($n = 13$) were statistically significantly ($P < 0.05$) with more prevalent type 2 diabetes, had shorter duration of diabetes, less diabetic neuropathy cases, higher BMI, lower HbA1c and lower AGE z-score. AGE z-score was statistically significantly ($P = 0.0019$) related to the presence and severity of DR. In 4 of these patients, it was observed that a year ago they had a higher AGE z-score. The multivariable-adjusted odds ratios of any DR across AGE quartiles were 1.00, 9.93 (95% confidence interval [CI] 2.12-64.06), 0.88 (95%CI 0.20–3.92) and 3.42 (95%CI 0.76–20.29). The employed variables included age, HbA1c, gender, type of diabetes and the duration of diabetes.
Conclusion
In this pilot study we illustrated the association between the second quartile of AGE z-score and the odds of any stage of DR. Analysis with larger sample size is planned in our study soon.

"Glycemic control and hypogonadism in men with type 2 diabetes: cross-sectional study"

Anis Grassa[1], Manel Jemel[1], Salma Salhi[1], Bel Hadj Sliman Chayma[1], Meriem Adel[1], Marwa Chiboub[1], Hager Kandara[1] & Ines Kammoun[1]
[1]National Institute of Nutrition and Food Technologies, Zouheir Kallel

Introduction
Hypogonadism (HG), a condition characterized by low levels of testosterone, is a common issue in men, particularly those with type 2 diabetes (T2D). The relationship between glycemic control and HG has been a topic of interest in recent years. In this study, we aimed to investigate the influence of glycemic control on HG.
Methods
This is a descriptive cross-sectional study involving 250 men with T2D aged 40 to 65 years, followed in outpatient consultations. All patients underwent both metabolic and hormonal assessments. Glycemic control was defined based on the criteria outlined by the American Diabetes Association (ADA) in 2022, while the diagnosis of HG was determined according to the criteria established by Vermeulen [1].
Results
The median age (IQR) of men with HG was 59 years [56-64], with a prevalence of 27.2% ($n = 68$). The mean duration of diabetes was 12.5 ± 7.4 years [Range: 1-31], more than half of the patients (62.2%) had over 10 years history of type 2 diabetes. The mean fasting glucose level was 10.9 ± 4.3 mmol/l [Range: 3.2-25.8]. The mean HbA1c was 9 ± 1.7% [Range: 5.6-14.5], and glycemic control was achieved in only 21.6% of patients. Comparatively, the mean duration of diabetes between the HG and non-HG groups was nearly identical (13.0 ± 7.3 vs 12.4 ± 7.5 years; $P = 0.594$). Additionally, the mean fasting glucose levels were comparable between the two groups, HG and non-HG (10.9 ± 4.2 vs 11.0 ± 4.4 mmol/l; $P = 0.827$). However, a significant association was found between HbA1c and the prevalence of HG ($P = 0.044$). The mean HbA1c values were 9.4 ± 1.8% and 8.9 ± 1.6% for the HG and non-HG groups, respectively. In terms of glycemic imbalance, it was more frequent in patients with HG, with percentages of 85.1% compared to 75.8% in the non-HG group, although this difference did not reach statistical significance ($P = 0.083$).
Conclusion
In conclusion, our study highlights the importance of monitoring and optimizing glycemic control, especially inT2D men, as it may play a role in the development or exacerbation of HG. Future research should thoroughly investigate the causal relationship between glycemic control and HG, considering additional factors that may contribute to this association.

Tolvaptan fortnightly can reduce hyponatraemia related inpatient admissions

Aparna Chaudhary[1], Heather Sullivan[1], Tala Balafshan[1] & Ram Prakash Narayanan[1]
[1]St Helens Hospital, Diabetes centre, St Helens, United Kingdom

Hyponatremia generally defined as a serum sodium of less than 135 mmol/l is the most common type of electrolyte imbalance found in older adults. Its mild to moderate forms can predispose patients to falls, fatigue and a general decline. Severe hyponatremia can contribute to seizures, confusion and death. We present a case of a 70-year-old lady with severe symptomatic chronic hyponatremia secondary to SIADH. She also had progressive Alzheimer's dementia, anxiety, T1DM, hypertension, a stable meningioma, rheumatoid arthritis and hypercholesterolaemia. Her medication profile did not indicate any offending drugs and she was extensively investigated with no clear cause found for her SIADH. She was being managed with modified release slow sodium chloride tablets 1200 mg QDS in community and in the past been given short courses of demeclocycline and tolvaptan. Over the year previous to the endocrine clinic consultation, it was identified that she had multiple prolonged hospital presentations and inpatient admissions with increased confusion, absence seizures and agitation which then also destabilised her type 1 diabetes management. Sodium levels ranged between 114 -120 mmol/l. Due to her low sodium levels the memory clinic was hesitant to increase her memantine dose or prescribe anxiolytics for her Alzheimer's dementia and anxiety and her mental health team suspected the hyponatraemia was contributing to her general decline. She had also begun to not tolerate the sodium chloride tablets. This resulted in a significant deterioration in her quality of life. She experienced heightened anxiety, confusion and agitation exacerbated by repeated hospital admissions. Aiming to reduce the frequency of hospital admissions the patient was trialled on Tolvaptan 7.5 mg twice a month commenced in January 2023. Tolvaptan functions as a selective vasopressin receptor antagonist at the renal collecting ducts which increases free water clearance and in turn raises serum sodium concentrations. Safety netting advise was given to the family to not administer at times of obvious dehydration. The trial proved to be a success whereby the patients' sodium levels have largely been 125 mmol/l and above, thus also allowing her memantine doses to be increased. The patient has had no further hospital admissions in over a year and her grateful family reports that the patient is much happier, and her wider health has seen an improvement.

Effect of L-arginine and agmatine on GLP-1 and PYY secretion in human NCI-H716 cells: the role of calcium sensing receptors

Sevim I Pek Acar Cömert[1], Adnan Berk Dinçsoy[2], Mehmet Özcan[3], Merve Ayan[4], Pergin Atilla[4] & Esin I leri Gürel[5]
[1]Giresun University, Faculty of Medicine, Physiology Department, Giresun, Turkey; [2]Muğla University, Faculty of Medicine, Physiology Department, Muğla, Turkey; [3]Zonguldak Bulent Ecevit University, Faculty of Medicine, Department of Medical Biochemistry, Zonguldak, Turkey; [4]Hacettepe University, Faculty of Medicine, Department of Histology and Embryology, Ankara, Turkey; [5]Hacettepe University, Faculty of Medicine, Physiology Department, Ankara, Turkey

Glucagon-like peptide-1 (GLP-1) and peptide YY (PYY) are hormones secreted from enteroendocrine L cells following a meal that play a key role in regulating insulin secretion and glucose metabolism. Enteroendocrine L cells express calcium-sensing receptors (CaSRs), which serve as a physiological nutrient sensor for the release of hormones from the gastrointestinal tract. While calcium is the primary ligand for CaSR, its activity can also be controlled by amino acids and polyamines. Therefore, in human enteroendocrine L (NCI-H716) cells, we investigated the effects of L-arginine and agmatine, a naturally occurring polyamine generated from L-arginine, on GLP-1 and Pyy secretion, along with the involvement of CaSR in this effect. To investigate the effect of agmatine and L-arginine on GLP-1 and Pyy secretion, NCI-H716 cells were exposed to different concentrations of agmatine and L-arginine (20 mM and 40 mM), and GLP-1 and Pyy levels were measured. NPS 2143 and R568, which are negative and positive allosteric modulators of calcium-sensing receptors (CaSR), respectively, were also used to study the role of CaSR in hormone release. CaSR immunoreactivity and the second messengers (Ca^{+2} and cAMP) that may mediate GLP-1 and Pyy release were also examined. Agmatine and L-arginine alone at 20 mM and 40 mM did not lead to significant GLP-1 and Pyy secretion. However, when combined with NPS 2143, there was a decrease in GLP-1 and Pyy levels. The cAMP level was decreased in the 40 mM agmatine + NPS 2143 group, while it was increased in the group treated with 40 mM agmatine + R568. Additionally, 40 mM L-arginine led to an increase in intracellular calcium concentration, while NPS 2143 reduced it. CaSR immunoreactivity was not different between groups. As a result, it was observed that GLP-1 and Pyy secretion was not induced by L-arginine or agmatine in NCI-H716 cells. Interestingly, NPS 2143 administration caused changes in hormone and cAMP/calcium levels, supporting the idea that CaSRs may be involved in GLP-1 and Pyy secretion in response to L-arginine and agmatine.

Key Words: L-arginine, Agmatine, GLP-1, Pyy, CaSR, NCI-H716 cell line, NPS 2143, R568, Ca^{+2}, cAMP.

The conjugation of tigerinin-1r with modified gastric inhibitory polypeptide enhanced its cellular uptake and metabolic actions

Opeolu Ojo[1], Ayodele Abiodun Falobi[1], Joy Nneka Edeani[1], Wendy Amy Ofosu[2], Lesley Smyth[3], Olivia Corcoran[4] & Simon Dunmore[1]
[1]Diabetes Research Group, Research Institute in Healthcare Sciences, School of Life Sciences, Wolverhampton, United Kingdom; [2]University of East London Stratford Campus, School of Health, Sport and Bioscience, London, United Kingdom; [3]University of West London, School of Biomedical Sciences, London, United Kingdom; [4]University of Wolverhampton, School of Life Sciences, Wolverhampton, United Kingdom

Aim
Previous reports indicate therapeutic potentials of tigerinin-1R, isolated from the skin secretions of *Hoplobatrachus rugulosus*, as an antidiabetic agent. Despite the report of its insulin-releasing effects, the peptide's mechanism of actions is poorly understood. This study investigates the impact of conjugation of tigerinin-1R with (dAla2)-GIP on the cellular uptake and anti-diabetic actions of the peptide.
Method
Amphipathicity, net charge and theoretical isoelectric point of the hybrid peptide were evaluated. Insulin-releasing effects of the hybrid (0 –3μ M) were investigated using BRIN-BD11. Cellular uptake, cytotoxicity and cell viability were assessed Effects of the peptide on erythrocyte haemolysis, glucose stimulated insulin-secretion, intracellular calcium concentration, membrane depolarisation, and glucose tolerance in high-fat fed mice were assessed.
Result
The conjugation of tigerinin-1R with (dAla2) GIP reduced the net charge from +1 to -1.9 and the theoretical pI reduced from 8.3 to 4.4. No significant change in amphipathicity was observed. The hybrid peptide stimulated non-toxic concentration-dependent insulin secretion at concentrations ≥10nM ($P<0.05$ to $P<0.001$). At 3μ M, the stimulatory effect of G-TGN was higher than that of tigerinin-1R (1.5-fold, $P<0.01$) and GIP (1.3-fold, $P<0.05$). The hybridization of GIP and tigerinin-1R did not affect cell viability nor cause erythrocyte haemolysis. Effects of G-TGN increased with increasing glucose concentration (1.1mM to 5.6mM, 1.3-fold, $P<0.05$ and 5.6mM to 16.7mM, 1.7-fold, $P<0.01$) and in the presence of KCl (30mM, 3.6-fold, $P<0.001$) and tolbutamide (200μ M, 2.4-fold, $P<0.01$). Verapamil (50nM, 23%, $P<0.05$), diazoxide (300μ M, 27%, $P<0.05$) and removal of extracellular calcium (19%, $P<0.05$) inhibited but not abolish the effects of G-TGN. The peptide enhanced intracellular calcium (23%, $P<0.01$) and increased membrane depolarisation (19%, $P<0.05$). Improvement in glucose tolerance in mice receiving G-TGN was higher compared with tigerinin-1R (19%, $P<0.05$) and GIP (13%, $P<0.05$). Cellular uptake of G-TGN increased by 3.6-fold compared to tigerinin-1R.
Conclusion
The conjugation of (dAla2) GIP with tigerinin-1R significantly enhanced its potential and encourages its development as a novel anti-diabetic drug.

Etiological profile and evolution of secondary diabetes due to endocrinopathies

Deus Niyongabo[1], Nassim Essabah Haraj[1], Siham El aziz[1] & Asma Chadli[1]
[1]Ibn Rochd University Hospital of Casablanca, Casablanca

Introduction
Endocrinopathies, characterized by dysfunctions in the endocrine system and its hormonal glands, emerge as a significant cause of secondary diabetes. These conditions induce complex disturbances in glucose metabolism, leading to insulin resistance or alterations in insulin production, pivotal factors in the development of secondary diabetes. This study aims to describe the etiological profiles of secondary diabetes and evaluate its evolution after treating the underlying endocrinopathies.
Patients and Methods
A retrospective study over a five-year period (2018-2023), involving 88 patients with secondary diabetes due to endocrinopathies, collected at the endocrinology department of Ibn Rochd University Hospital in Casablanca. Statistical analysis was conducted using the SPSS software.
Results
The mean age of the patients was 42.5 years ± 10.9, with a female predominance. The prevalence of diabetes was 47.7% in hypercortisolism, 36.3% in acromegaly, 11.3% in hyperthyroidism, and 4.5% in pheochromocytoma. The average duration of diabetes evolution was 5.6 years ± 3.5. Regarding glycemic control, 58% were unbalanced before treating the causal endocrinopathy, with an average HbA1C of 9.7% ± 2.4. After controlling the causal disease, glycemic control was achieved in 98.6% of patients with a transition to oral antidiabetic drugs. Degenerative assessment revealed diabetic retinopathy (12.8%), diabetic nephropathy (8.6%), and diabetic neuropathy (7.5%).
Conclusion
This study highlights the crucial importance of early recognition and treatment of endocrine disorders to prevent or effectively manage secondary diabetes. Targeted management of underlying endocrinopathies significantly improves glycemic control and reduces degenerative complications associated with secondary diabetes.

Beta-type estradiol receptor modulates hepatocyte responses to metabolic challenges

Debora Rocha[1], Eloisa Vilas-Boas[2], Camille Caldeira[1] & Alicia Kowaltowski[1]
[1]Instituto de Química, Departamento de Bioquímica, São Paulo, Brazil; [2], Faculdade de Ciências Farmacêuticas, São Paulo, Brazil

Non-selective hormonal therapy with estradiol attenuates metabolic dysfunction associated to post menopause. However, its effectiveness decreases over-time, and is associated hormone-dependent cancers development. Conversely, beta-type estradiol receptor (ERβ) activation has been showing promising outcomes in basic research, improving hepatic response to energy overload insult, in addition to presenting antitumor action. Therefore, we evaluated the ability of ERβ to promote metabolic effects on hepatocytes, focusing on mitochondrial function. AML12 cells were submitted to high glucose (20 mM) plus palmitate (200 μ M), and the effect of ERβ activation with diarilpropionitrile (0.1 or 1 nM, 24h) was evaluated through Extracellular Flux Analysis. We modulated different electron

transport chain complexes to assess basal, ATP-linked, maximal, reserve capacity, and non-mitochondrial respiration. Mitochondrial network volumes and shape were evaluated through fluorescence microscopy. The substrate commitment assay evaluated the ability of cells to shift the use of carbohydrates, lipids, or aminoacids when target points of entrance into mitochondria are inhibited sequentially. The substrate capacity assay assesses the maximal ability of cells to oxidize one type of substrate. We also checked for acute responses to adrenaline, as a physiological signal, compared outcomes, including the production of ketone bodies and lipid oxidation. Overload with palmitate plus high glucose affected basal, ATP-linked and maximal respiration, as well as reserve capacity (maximal respiration difference from basal) of mitochondria. ERβ activation treatment did not change these parameters. Mitochondrial morphology also didn't present expressive changes after treatment. These results indicate that ERβ activation doesn't overtly alter metabolic fluxes nor morphology under basal conditions. However, challenging these cells with physiological or pharmacological stimuli, the responses significatively changed. The hepatocytes present higher commitment to individual substrate oxidation, decreasing the ability to shift the source of ATP. This result was verified modulating pyruvate, glutamine, or palmitate entrance into mitochondria. The capacity to oxidize these substrates didn't change after treatment, except for pyruvate, meaning that these cells presented a decreased ability to exclusively oxidize carbohydrates. Finally, physiological responses were also different. In this assay, hepatocytes submitted to overload decreased the adrenergic response, and the treatment recovered to control levels. Basal production of ketone bodies followed the same pattern, increasing in energy overload conditions, and returning to control levels after treatment. In conclusion, ERβ activation made hepatocytes respond differently when challenged with pharmacological and physiological stimuli. Our results uncover the potential of selective ERβ modulation as an alternative to estradiol or ERA activation-based therapies for metabolic diseases.

Diabetes mellitus in patients undergoing pancreatectomy (T3cDM): preliminary data analysis

Martina Borrini[1], Chiara Mele[1], Fabio Maroso[2], Rosa Pitino[1], Davide Vimercati[1], Raffaele Romito[2], Gianluca Aimaretti[1] & Paolo Marzullo[1]
[1]University of Piemonte Orientale, Department of Translational Medicine, Novara, Italy; [2]Maggiore della Carità Hospital, Department of General Surgery, Novara, Italy

Rationale and purpose
Glucose tolerance often changes in patients with pancreatic lesions and usually worsens after distal pancreatectomy; however, factors affecting interindividual variation in progression are unclear. Our study aimed to investigate the glyco-metabolic status in a series of patients undergoing pancreatic resection for treatment of benign or malignant lesions and risk factors involved in the developing T3cDM.
Methods
We conducted an observational retrospective study on 29 patients (F = 15; age, 67.4 ± 2.2y, Charlson's Comorbidity Index, 3.7 ± 0.3) subjected to distal spleno-pancreatectomy (DP, ($n = 18$), total duodeno-pancreatectomy (PD, ($n = 10$) or radical proximal-distal modular pancreato-splenectomy (RAMPS, ($n = 1$) in our university hospital. Pre- and post-surgical variables, glyco-metabolic status and the degree of glycemic control at diagnosis and during follow-up were assessed, together with pancreas autoimmunity and C-peptide levels. In a subgroup of T3cDM patients, glucose profiles obtained by continuous monitoring devices (CGM) were compared with those of an age- and sex-matched control group with T1DM.
Results
The overall prevalence of diabetes in our series was 62% (18/29), 50% of whom (9/18) developed it before surgery. In patients subjected to DP, T3cDM prevalence was 61% (11/18). Autoimmunity was negative in all cases. In the series as a whole, patients with diabetes were younger than patients without (63.3 ± 2.6y vs 74.0 ± 3.0y, $P < 0.05$), but no other anthropometric, biochemical, surgical or clinical-pathological features were identified as risk factors for T3cDM. Among T3cDM patients, 60% were treated with basal-bolus insulin regimen while the remainders were treated with combination therapies. Analysis of glucose control over time showed mean HbA1c values of 8.59 ± 0.42%. In a subgroup of insulin-treated T3cDM patients, CGM showed a higher glucose management indicator, an estimate of HbA1c, when compared to DMT1 patients (7.71 ± 0.37% vs 6.74 ± 0.20%, $P < 0.05$). Moreover, the former displayed longer TAR (20.00 ± 6.93% vs 5.00 ± 1.96%, $P = 0.06$) and shorter TBR (4.71 ± 1.06% vs 1.00 ± 0.44%, $P < 0.01$). There were no differences in insulin dosing between the two subgroups.
Conclusions
In our series, the prevalence of T3cDM in patients who underwent DP was 50%, which coexisted with a high prevalence of pre-surgical diabetes. Lower age at pancreatic surgery emerged as the only predictor of diabetes onset. Appropriate peri-operative diabetic assessment is mandatory for all patients undergoing distal pancreatic resections, and CGM could aid physicians, patients and their care-givers in building a better insight on glycemic outcomes and complications in patients developing T3cDM.

The waist-to-height ratio represents better than body mass index the prognostic impact of obesity on metabolic steatopathy

Ahmed Mohamed Nefzi[1], Bouchabou Bochra[1], El Mouldi yosr[1], Nakhli Abdelwahab[1], Hemdani Nesrine[1], Benzarti Zeineb[1], Ben Nejma Houda[1] & Ennaifer Rym[1]
[1]Hôpital Mongi Slim, Hepato-gastroenterology, Marsa, Tunisia

Introduction
Overweight is a major prognostic factor in metabolic steatopathy. The Waist-to-Height Ratio (WHtR) has recently been introduced as a clinical marker predictive of cardiovascular complications related to obesity. The objective of our study was to evaluate the performance of this ratio in detecting complications related to metabolic steatopathy (Liver fibrosis and cardiovascular risk).
Patients and Methods
This was a prospective, cross-sectional, descriptive study including all patients with metabolic steatopathy who consulted between March 2021 and December 2022. Age, medical history, and various lifestyle habits were collected. Anthropometric measurements and blood pressure were taken. Body mass index (BMI) and the WHtR were calculated. Liver fibrosis was assessed using transient elastography (Fibroscan), with advanced liver fibrosis defined in this study as elasticity ≥ 9.7 kPa. Cardiovascular risk assessment was done using the GLOBORISK score, a validated tool for evaluating 10-year cardiovascular mortality. High cardiovascular risk was defined by a GLOBORISK score ≥ 20%.
Results
The study population included 107 patients with a mean age of 54.5 ± 10.1 years and a gender-ratio of 0.53. History of hypertension, type 2 diabetes, and dyslipidemia were noted in 44.9%, 43%, and 31.8% of patients, respectively. Smoking and alcohol use were noted in 11.2% and 8.4%, respectively. The mean BMI was 30.56 ± 5.7 kg/m^2, and the mean WHtR was 0.61 ± 0.08. Advanced liver fibrosis was found in 14% of patients. We observed a high cardiovascular risk in 35.5% of patients. The WHtR showed better performance than BMI in identifying patients at risk of advanced fibrosis, with respective areas under the ROC curve of 0.729 (95% CI 0.615 –0.843) and 0.7 (95% CI 0.577 –0.839). The cutoff for the WHtR in identifying patients at risk of advanced fibrosis was 0.6, with a sensitivity of 93% and specificity of 50%. In terms of high cardiovascular risk, the WHtR showed slightly better performance than BMI, with areas under the ROC curve of 0.65 (95% CI 0.53 –0.752) and 0.61 (95% CI 0.505 - 0.731), respectively. The cutoff for this ratio in predicting high cardiovascular risk was also 0.6, with a sensitivity of 65% and specificity of 42%.
Conclusion
The WHtR is a simple tool that better represents the impact of obesity on the prognosis of metabolic steatopathy, both in terms of liver fibrosis and cardiovascular risk.

Blood glucose and insulin level during oral glucose tolerance test as predictors for treatment efficacy in obese patients

Tzvetelina Totomirova[1] & Mila Arnaudova[2]
[1]Military Medical Academy, Clinic of Endocrinology and Metabolism, Sofia, Bulgaria; [2]VITA MBAL, Endocrinology, Sofia, Bulgaria

Background
Oral glucose tolerance test (OGTT) is usually used to determine carbohydrate metabolism abnormalities in overweight patients. Measurement of glucose and insulin level on demanded 0 and 120 minute and some additional minutes could give information for obesity treatment choice and for patients' follow-up. The aim of our study is to assess whether glucose and insulin level measurement during oral glucose tolerance test could be used as predictors for treatment efficacy in obese patients.
Materials and methods
107 patients (55 women, 52 men, mean age 44.01 ± 12.87years) with mean weight 99.07 ± 18.73 kg, mean BMI 34.86 ± 6.0 kg/sq.m and mean HbA1c

5.75 ± 0.58% underwent OGTT at the end of treatment period. Additional measurements of glucose were performed on minute 60 and 180 as well as measurement of insulin level on 0, 60th, 120th, 180th minute. HOMA-IR was calculated. Patients had received different treatment for weight management including diet and exercise instruction, metformin and GLP1 analogues for the previous six months. A correlation between glucose, insulin level on different minutes and treatment efficacy results was assessed.
Results
Basal minute glucose level shows moderate significant correlation with weight decrease (phi = 0.61, $P < 0.05$). Glucose level on first hour is presenting with more strong correlation (phi = 0.72, $P < 0.05$) and the second hour blood glucose shows not significant correlation (phi = 0.47, $P = 0.24$). Insulin on 0, 60 and 120 min is presenting with strong correlation of weight loss ($P < 0.05$). HOMA-IR index is also correlating with therapeutic answer especially in metformin receiving group but not in GLP1 analogues treated group ($P < 0.05$). No difference was found depending on age, gender, and weight of patients and with weight at the start of the study.
Conclusion
Glucose and insulin level during OGTT could be used as predictors for future therapeutic efficacy and for treatment choice in obese patient. Defining such predicting factors is useful for clinical practice and should be objective of research.

Metabolic dysfunction-associated steatotic liver disease (MASLD) in obesity: a major role for transient elastography in the screening of significant liver fibrosis

Ana Carreira[1], Tânia Carvalho[1], Bernardo Canhão[2], Miguel Melo[1], João Madaleno[2], Armando Carvalho[2], Dírcea Rodrigues[1], Adélia Simão[2] & Isabel Paiva[1]
[1]Hospitais da Universidade de Coimbra, Unidade Local de Saúde de Coimbra, Endocrinology, Diabetes and Metabolism, Coimbra, Portugal; [2]Hospitais da Universidade de Coimbra, Unidade Local de Saúde de Coimbra, Internal Medicine, Coimbra, Portugal

Introduction
Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading cause of chronic liver disease (CLD). Screening of liver fibrosis by clinical scores is recommended in people with obesity, but their accuracy is still under discussion. Vibration-controlled transient elastography (VCTE) is among the best validated imaging tools to assess liver fibrosis, and is suggested in patients with indeterminate or high-risk clinical scores.
Aims
To assess the prevalence of MASLD and significant liver fibrosis in people with obesity, to identify clinical factors associated with fibrosis and to compare the accuracy of the FIB-4 and NFS scores against VCTE.
Methods
Interim analysis from a prospective cohort study conducted on people with a history of class II-III obesity, followed in a tertiary centre. All patients without history of bariatric surgery or significant alcohol intake were invited to undergo VCTE. Patients with other causes of steatosis/CLD were excluded. VCTE fibrosis scores of ≥ F2 (≥ 7kPa) were considered as significant, ≥ F3 as advanced and F4 as cirrhosis.
Results
33 cases were analyzed, with mean age of 44.1 ± 11.3 years and BMI of 38.9 ± 6.1 kg/m^2, 69.7% female. MASLD was diagnosed in 81.8%, with significant liver fibrosis in 30.3%, advanced fibrosis in 18.2% and cirrhosis in 6.1%. Aminotransferases were elevated in 27.3%; and aminotransferase elevation was associated with significant liver fibrosis (66.7% vs 16.7%, $P = 0.010$). People with diabetes showed more advanced fibrosis (42.9% vs 11.5%, $P = 0.093$). Fibrosis in VCTE correlated with BMI ($r = 0.371$, $P = 0.033$), steatosis ($r = 0.589$, $P < 0.001$), triglyceride ($r = 0.378$, $P = 0.030$) and aminotransferase levels (alanine: r = 0.442, $P = 0.010$; aspartate: r = 0.383, $P = 0.028$). Patients with recent weight loss of ≥10% had less significant liver fibrosis (0.0% vs 38.5%, $P = 0.073$). FIB-4 and NFS showed a specificity of 91.7% and 88.2% for excluding significant fibrosis, but failed to identify any of the cases of significant fibrosis. According to FIB-4, none of the cases with significant fibrosis would have undergone VCTE, whilst according to NFS, 85.7% (53.8% of the cases with an indeterminate score) would have undergone VCTE.
Conclusion
MASLD and liver fibrosis are highly prevalent in people with obesity. Higher BMI, diabetes, elevated aminotransferase and triglyceride levels were associated with increased liver fibrosis, while weight loss of ≥ 10% showed an opposite association. NFS was superior to FIB-4 as an initial screening tool, but both had a low accuracy for identifying significant fibrosis. This suggests that VCTE may have a major role in screening people with obesity and MASLD.

Diabetes remission after bariatric surgery: a 10-years follow-up study

Inês Meira[1,2], João Menino[1,2], Juliana Gonçalves[1,2], Helena Ferreira[1,2], Ana Rita Leite[1,2], Patricia Ferreira[1], Sara Ribeiro[1,2], Telma Moreno[1,2], Diana Silva[1,2], Paula Freitas[2,3], Eduardo Lima da Costa[3], Joana Queirós[1] & CRIO .[3]
[1]São João Universitary Hospital Center, Porto, Portugal; [2]Faculdade de Medicina da Universidade do Porto - FMUP, Porto, Portugal; [3]CRIO – Centro Responsabilidade Integrada Obesidade., Porto, Portugal

Introduction
Although lifestyle measures and medical therapy are the cornerstone of type 2 diabetes (T2DM) management, achieving optimal glycemic control in T2DM patients with obesity remains challenging. There is strong and consistent evidence that bariatric surgery (BS) is an effective strategy to improve glycemia in diabetic patients and often leads to remission of T2DM in patients with obesity. The majority of the published literature supporting T2DM remission after BS has short- and medium-term follow-up. However, the durability of glycemic improvements and the potential for long-term "cure" in T2DM patients following BS remain insufficiently studied.
Aim
Determine the incidence of durable remission and relapse of T2DM rates 10 years after BS, characterize the glycemic profile of these patients after surgery, and identify factors predicting persistent remission of T2DM.
Methods
Retrospective observational study of patients with T2DM undergoing BS between 2010 and 2013. Exclusion criteria included patients undergoing gastric band surgery, those without initial and 10-year post-surgery HbA1c or fasting plasma glucose (FPG) determination, and those undergoing revisional surgery or deceased during the follow-up period. Paired t-tests, Wilcoxon signed rank and McNemar tests were used to assess the differences in the metabolic status during the follow-up, as appropriate. Logistic regression models were used to assess predictors of T2DM remission.
Results
Ninety-five patients were included, 84% of whom were women, with a mean age of 48.8 ± 9.1 years and a mean HbA1c of 7.0 ± 1.5%. Ten years after surgery, the rate of complete T2DM remission was 31%, partial remission was 15%, and late recurrence after initial remission was 24%. Patients with lower HbA1c (OR = 0.50; $P = 0.05$) and taking fewer antidiabetic drugs (OR = 0.31; $P = 0.01$) preoperatively were more likely to maintain long-term remission. The surgical technique used and the duration of T2DM did not reach statistical significance as predictors of remission in multivariate analysis. Patients with T2DM maintained reductions in FPG ($P < 0.001$), HbA1c ($P < 0.001$), number of antidiabetic drugs ($P < 0.001$), and insulin use ($P < 0.001$) ten years post-BS.
Conclusion
In conclusion, BS can induce a significant and sustainable remission and improvement of T2DM. Consistent with previous studies, our data suggests that when the main goal of surgical treatment is durable diabetes remission, earlier surgical intervention is likely to be more effective. Longer follow-up reports and prospective, randomized controlled studies are important to confirm these findings.

Body mass index is a better predictor than waist circumference to assess the risk of advanced hepatofibrosis

Szymon Suwała[1] & Roman Junik[1]
[1]Nicolaus Copernicus University, Collegium Medicum, Department of Endocrinology and Diabetology, Bydgoszcz, Poland

Introduction
Obesity is the primary element of the metabolic syndrome, wherein one of the key reasons that heightens the risk of cardiovascular problems is the presence of liver fibrosis. Invasive core needle biopsy of the liver is considered the definitive method for diagnosing hepatofibrosis, however, non-invasive fibrosis indicators like FIB-4 are becoming more commonly utilized in routine clinical settings. Obesity can be defined in various ways, with the most prevalent methods relying on the measurement of body mass index (BMI) or waist circumference (WC). The aim of the study was to assess which definition of obesity (based on BMI or WC) more effectively indicates an increased risk of liver fibrosis.
Material and methods
The authors analyzed retrospective medical data from 2100 patients who were hospitalized in endocrinology department between 2013 and 2020 in whom all

necessary factors were evaluated: weight, height (to calculate BMI), waist circumference, alanine and aspartate aminotransferases and platelet count (to calculate FIB-4 for hepatofibrosis prediction). Obesity was defined in three ways, appropriate to the Caucasian population: WC $\geq$80 cm (females) or $\geq$94 cm (males) –criterion A; WC $\geq$88 cm (females) or $\geq$ 102 cm (males) –criterion B; BMI $\geq$30 kg/m^2 –criterion C. In order to determine suitable thresholds for identifying a higher risk of advanced liver fibrosis authors used cut-offs for age-dependent FIB-4: $\geq$1.21 for patients up to 49 years of age, $\geq$1.96 for patients aged 50–59 years and $\geq$2.67 for patients aged 60–69 years. Evaluation of relative risks (RR) was employed using the Chi-squared test with comparison to patients not meeting a given criterion, each time also providing the 95% confidence interval (95%CI).
Results
Criterion A was met by 82.29% of patients, criterion B was met by 63.52% of patients, and criterion C was met by 42.90% of patients. For criteria A and B, the analysis based on WC revealed statistically insignificant values for the relative risk (P=0.283 for criterion A, P=0.588 for criterion B). Only criterion C, based on BMI, showed a statistically significant increase in relative risk, which was 63% (RR 1.63%; 95%CI: 1.26-2.10; P<0.001).
Conclusion
Body mass index seems to be a better predictor of the risk of advanced liver fibrosis depending on age - patients with obesity defined by this index should be treated as potentially exposed to this complication of the metabolic syndrome and active diagnostics should be undertaken in this direction.

Diabetes and severe obstructive sleep apnea syndrome: effect on right ventricle systolic function

Syrine Dardour[1,2], Sahar Abidi[2], Fattah Kadardar[1], Habib Bessrour[2] & Hedi Ben slima[1]
[1]Menzel Bourguiba hospital, Menzel Bourguiba, Tunisia; [2]The Military Hospital of Tunis, Tunis, Tunisia

Introduction
The interaction between diabetes and obstructive sleep apnea syndrome (OSAS) is little recognized. We hypothesized that diabetes and OSAS act synergistically to increase the risk of right ventricular systolic dysfunction and that treatment of OSAS would improve right ventricular (RV) systolic function in patients with diabetes plus OSAS.
Methods
Cross-sectional study including 100 patients with severe OSAS, 49 of whom have associated diabetes. Echocardiography was performed to study right systolic function and the effect of nocturnal continuous positive airway pressure(CPAP) ventilation in the diabetes and OSAS subgroup.
Results
We did not note any significant difference for the following ultrasound parameters: Tricuspid annular plane systolic excursion (TAPSE), Systolic Shortening Fraction, Global Longitudinal Strain of the RV. We noted a significant difference for the Systolic Wave Velocity at the lateral wall of the tricuspid annulus using Tissue Doppler Imaging (S'wave) parameter which was lower in the diabetes group (12.35 cm/s Vs 13.95 cm/s P=0.005). When OSAS is associated with diabetes, Systolic RV dysfunction was observed in 25% of the sample (64% in diabetics versus 36% in non-diabetics P=0.083). We found a marked improvement in the systolic function of the RV in patients with diabetes using CPAP (A systolic dysfunction rate of the RV at 12. 5% vs 87.5% in non-fitted P<0.001).
Conclusion
In patients with severe obstructive sleep apnea syndrome and diabetes, right ventricular dysfunction primarily involves the S'Wave parameter and CPAP improves right systolic function in diabetic patients with severe OSAS.

The dependence of anxiety and depression indicators on serum cholecalciferol level in patients with latent autoimmune diabetes in adults

Nataliia Pashkovska[1] & Iryna Tsaryk[1]
[1]Ukraine, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Introduction
Literature data showed the association between serum cholecalciferol concentration and level of anxiety and depression in patients with classical types of diabetes mellitus. However, a clear relationship between these indicators in patients with latent autoimmune diabetes in adults (LADA) has not yet been established.
The aim of the study
To evaluate the dependence between level of anxiety, depression and cholecalciferol status in patients with LADA.
Material and methods
42 patients with LADA (19 –LADA1, 23 –LADA2) and 25 practically healthy individuals were examined. In addition to general clinical research methods cholecalciferol status was evaluated. The levels of anxiety and depression were determined using the Spielberg's and Beck's questionnaires, respectively. The levels of anxiety were registered as level of situational anxiety and personal anxiety.
Results
Cholecalciferol level was registered 2.7 times lower in LADA1 group compared to control (14.63 [13.14; 15.98] ng/ml vs 40.00 [32.17; 53.00] ng/ml) and by 38.7% in LADA2 (24.51 [17.86; 32.93] ng/ml vs 40.00 [32.17; 53.00] ng/ml) (P<0.001). In LADA1 patients the level of cholecalciferol was lower by 40.3% (p< 0.01) compared to LADA2. The level of situational anxiety was 34.00 [27.75; 45.50] in LADA1 and 42.50 [23.00; 55.00] in LADA2 (higher by 25% than in patients with LADA1, P<0.05) and probably differed between LADA1/control and LADA2/control –control level 23.00 [16.00; 34.00] (decrease by 32.4% (P<0.01) and 45.9%, respectively (P<0.001)). The level of personal anxiety was higher in LADA1 group by 20.7% compared to control (29.00 [22.5; 40.25] vs 23.00 [20.00; 34.00]) (P<0.05) and did not significantly differ between LADA phenotypes. The level of depression was significantly higher in patients with LADA1 (17.00 [12.00; 22.50]) and LADA2 (12.00 [7.75; 15.00]) by 3.4 times and 2.4 times, respectively, compared with the control group (5.00 [3.00; 7.00]) (P<0.05); the difference between LADA phenotypes showed that depression level was higher by 41.7% in patients with LADA1 compared to LADA2 group (P<0.05). In patients with the LADA1 phenotype, negative correlations of medium strength were recorded between level of depression and C-peptide level (r=-0.348; p<0.05); level of depression and serum cholecalciferol indicator (r=-0.443; P<0.05). In LADA2, inverse correlations of medium strength were registered between high-density lipoprotein cholesterol indicator and level of depression (r=-0.328; p<0.05).
Conclusions
Level of anxiety and depression depends on serum cholecalciferol level (especially in LADA1 phenotype) which indicates the importance of its adequate supplementation in patients with LADA.

Sleep apnoea and degenerative complications in type 2 diabetes

Meriem Adel[1,1], Rayene Ben mohamed[1], Marwa Chiboub[1], Lina Ghram[1], Hajer Kandara[1], Manel Jemel[1] & Ines Kammoun[1]
[1]National institute of nutrition and food technology, Endocrinology, Tunis

Introduction
Obstructive sleep apnoea (OSA) is notably prevalent in individuals with type 2 diabetes (T2D). This syndrome not only elevates cardiovascular risk but is also implicated in the advancement and exacerbation of microangiopathy. The objective of our study was to evaluate the prevalence of diabetic complications in patients with type 2 diabetes who have OSA.
Method
A cross-sectional study was conducted on 130 patients with DT2 who were hospitalized in the Endocrinology Department of the National Institute of Nutrition and Food Technology in Tunis. The inclusion criteria were patients aged 30 years or older with type 2 diabetes diagnosed for at least 2 years. The study excluded patients with known OSA, any endocrinopathy that could be the cause of OSA, acute respiratory failure, acute or chronic bronchopneumonia, or bronchopulmonary tumour pathology. Screening for OSA was conducted using the Berlin questionnaire and the ApneaLink sleep screening device.
Results
The mean age of the patients was 59.37$\pm$7.80 years, with a sex ratio of 0.58. Hypertension, hypercholesterolaemia and hypertriglyceridaemia were present in 68%, 69.2% and 33.8% of the cases respectively. The mean Body Mass Index was 30.53$\pm$5.16 kg/m^2. The mean duration of diabetes was 12.54$\pm$7.81 years. The mean HbA1c was 11.15$\pm$1.82%. Among our patients, 18.5% were smokers with a mean of 35.79 pack-years, and 8.5% were occasional alcohol drinkers. A total of 76.9% had at least one diabetic microangiopathy. Diabetic retinopathy was present in 54.47% of patients: mild in 26.78%, moderate in 5.35% and

proliferative in 36.6%. Nephropathy was present in 30.8% of patients. Diabetic neuropathy occurred in 58.8% of cases. Macroangiopathic complications was found in 36,9% of patients: Coronary insufficiency, Stroke and arteritis of the lower limbs occurred in 15.3%, 5.3% and 26.9% respectively. Sixty-two-point three percent of patients were at high risk of OSA according to the Berlin score. The OSA was mild in 41%, moderate in 15% and severe in 5% of cases. A statistically positive association was found between diabetic nephropathy and high risk of OSA, which persisted after multivariate analysis. However, no association was found between macroangiopathies and high OSA risk.
Conclusion
OSA is associated with complications related to T2D. There is moderate evidence suggesting a connection between OSA and Chronic Kidney Disease (CKD) in patients with Type 2 T2D. Robust prospective studies with extended follow-up periods are crucial to investigate the potential correlation between OSA and T2D complications.

DOI: 10.1530/endoabs.99.P493

Diabetic ketoacidosis - severe case, in a type 1 diabetes patient, with chronic diarrhea and mental disorders -case report

Ema Lumi[1], Tomi Punmira[2], Qirjako Gjino[3], Vlefta Bejko[4] & Agron Ylli[5]
[4]Regional Hospital, Korce, Albania, Endocrinologist, Head of Internal Unit, Korce, Albania; [2]Regional Hospital, Korce, Albania, Anesthesiology & Reanimation, Korce, Albania; [3]Regional Hospital, Korce, Albania, Gastroenterologist, Internal Unit., Korce, Albania; [4]Regional Hospital, Korce, Albania, Head of Emergency Department, Korce, Albania; [5]University Hospital Center "Mother Teresa", Prof. Dr. Endocrinologist, Head of Endocrinology Department., Tirana, Albania

Introduction
Diabetic ketoacidosis(DKA) is a serious acute complication of Diabetes mellitus that can be life - threatening. DKA is most common among people with type 1 diabetes. It is usually presented with hyperglicemia, ketoacidosis and presence of ketone bodies in the urine. Chronic diarrhea(CD) is defined as three or more loose stools daily for at least four weeks. There are many possible causes of chronic diarrhea. The most common causes are: Crohn disease & Ulcerative colitis (inflamatory diseases of gastrointestinal tract), malabsorption, endocrine diseases as hyperthyroidism, diabetic autonomic neuropathy, etc.
Case report
A 40-years old male was presented in emergency in serious condition, with tachycardia, shortness of breath, nausea and vomiting, diarrhea, fever, polyuria and polydipsia, etc. Medical history: Type 1 diabetes from 10 years, medical disorders treated with clonazepam and chronic diarrhea in the last year. He hadn't take insulin for 3 days consequently. Labs: glycemia = 1757 mg/dl, urea = 117, kreatinine = 1.92, Ph = 6.74, BE= -33, Na^+=106, K^+= 8.5, CL^-=73, Troponin = neg, leukocytes = 21200 with left deviation of formula, ketone bodies in urine=50 mg/dl, INR = 1.45, hypoalbuminemia, etc. Treatment: intensive tratment with iv insuline, intensive rehydration with normal saline, sodium bicarbonate, sc enoxaparinë, iv Ampicillin, omeprazol, human albumin, elektrolites, vitamines, etc. 24-hours later all clinic and biochemical markers were normalized. Check up for the etiology of CD: TSH, FT3, FT4 in normal range, HbA1c=11%, normal thyroid and abdominal ultrasound, calprotectin fecal test = 245 mg/kg (>100 highly positive), fecal fats-positive, fecal ascarids-positive, elastic fibres-negative. Normal in Colonoscopy. Probably diabetic autonomic neuropathy diarrhea or Irritable bowl syndrome. After 9days he was discharged from the hospital in good condition with medications: insuline basal-bolus, probiotics, rifaximin 200 mg, and clonazepam. Follow up in 6 months: colonoscopy.
Conclusion
Regular treatment of Diabetes mellitus, especially type 1 diabetes, is very important. Missed doses of insuline can lead to complications like DKA. Comorbidity of diabetes and chronic diarrhea is fairly common. Diabetic patient have 2-4 fold probability to have CD than normal people. Patient with mental disorders are more prone to gastrointestinal problems.
Key words: Diabetic Ketoacidosis (DKA), Chronic Diarrhea (CD), Mental disorders.

Comparative analysis of economic burden between cardiovascular and renal complications in hospitalized tunisian patients with type 2 diabetes: a retrospective study

Souhir Maalej[1], Fatma Mnif[1], Siddiqa Soomauroo[1], Abdel Mouhaymen Missaoui[1], Nadia Charfi[1], Faten Hadjkacem[1], Mouna Elleuch[1], Mohamed Abid[1] & Nabila Rekik[1]
[1]Hedi Chaker University Hospital, Endocrinology, Sfax

Background
Diabetes mellitus poses a global chronic health challenge, with Tunisia experiencing a concerning surge in type 2 diabetes (T2D) prevalence. Cardiovascular and renal complications are prominent and severe consequences associated with T2D. Evaluating the costs related to managing these complications is crucial to enhance care quality, optimize resource utilization, and ultimately reduce the growing economic and social burden of this chronic disease.
Materials and Methods
A retrospective descriptive study was conducted to collect data on diabetic patients with chronic cardiovascular and renal complications. The study included patients hospitalized in the Endocrinology Department of Hedi Chaker University Hospital in Sfax from January 1 to December 31, 2022. We assessed the cost of managing cardiovascular and renal complications in our hospitalized patients.
Results
The study involved 114 patients, with a sex ratio of 1.28. The average age at hospitalization was 65.38 ± 10.17 years. The average hospitalization duration in our population was 7.2 ± 4.5 days, with a minimum stay of 2 days and a maximum stay of 26 days. The hospitalization of 37 patients with cardiovascular complications alone was the most expensive, reaching 144,955.60 TND, equivalent to 46,017.65 USD, representing 56.6% of all expenses. The average cost per patient was 3,917.72 TND, or 1,243.72 USD. The 53 patients with both cardiovascular and renal complications ranked second in terms of costs, with expenditures totaling 97,548.38 TND, equivalent to 30,967.74 USD, accounting for 38.1% of the overall cost. The average cost per patient in this group was 1,840.54 TND, or 584.30 USD. Finally, the management of 24 patients with only renal complications was less costly, representing only 5.3% of total expenses, or 13,592.19 TND, equivalent to 4,314.98 USD. The average cost per patient in this group was 566.34 TND, or 179.80 USD. The table details the expenses of various analyzed elements based on the categories of complications.
Conclusion
The comprehensive cost analysis of managing cardiovascular and renal complications in diabetic patients reveals significant economic implications. Optimizing healthcare strategies is imperative to alleviate the financial burden and enhance patient outcomes.

Assessment of overactive bladder syndrome symptoms (OABSS) score following the start of sodium-glucose co-transporter-2 inhibitors in individuals with type-2 diabetes mellitus

Derya sema yaman kalender[1], Ümit Çavdar[1], Mehmet Sercan Ertürk[1] & Barış Önder Pamuk[1]
[1]Katip Çelebi University School Of Medicine, Atatürk Training And Research Hospital, Department of Endocrinology and Metabolism, Izmir, Turkey

Background
In addition to glucose-lowering effects, Sodium-Glucose Cotransporter-2 Inhibitors (SGLT2i) are the preferred treatment of choice in patients with heart failure due to their diuretic effects through glucosuria and natriuresis. However, there is limited data about urinary symptoms associated with SGLT2i use.
Objectives
Low urinary tract symptoms such as increased urinary frequency, urgency, or incontinence due to SGLT2i use are not described in many studies. We aimed to show whether SGLT2i use is associated with low urinary symptoms.

Abstract P495

Cost (TND)	Accommodation	Glycemic monitoring	Cardiovascular investigations	Radiological investigations	Biological investigations	Medical treatment	Total (%)
Cardiovascular complications	8260,00	491,83	119160,00	6853,60	8202,40	1987,77	144955,60 (56,6%)
Renal complications	5600,00	301,85	482,40	1620,40	4888,00	699,55	13592,19 (5,3%)
Cardiovascular and renal complications	14840,00	829,10	58712,80	6609,20	14446,40	2110,88	97548,38 (38,1%)
Total (%)	28700,00 (11,21%)	1622,78 (0,63%)	178355,20 (69,65%)	15083,20 (5,89%)	27536,80 (10,75%)	4798,20 (1,87%)	256096,18 (100%)

Methods
Fifty-four patients (22 male, 32 female) with type-2 diabetes mellitus (DM), over 18 years of age, without urinary infection, chronic kidney disease, or organic lower urinary tract disease were included in the study. Initially, all patients were screened for low urinary tract symptoms with the OABS-8 questionnaire before SGLT2i treatment. Whether an overactive bladder was detected or not, all patients were asked to fill out the questionnaire again at the first and third months of the treatment. Changes in symptom scores were investigated in terms of association with SGLT2i use. HbA1C, fasting blood glucose, body mass index, and blood pressure values were also evaluated.
Results
All patients' mean OABS-8 total score was 10.10 ± 5.03, significantly decreasing after SGLT2i administration. 17 out of 54 patients were with OABSS before the SGLT2i treatment. Mean total scores at baseline were 15.41 ± 4.0 and 7.1 ± 2.35 in patients with OABSS ($n = 17$) and patients without OABSS ($n = 37$), respectively. The total score of patients without OABSS was significantly decreased in the first and third months of the treatment. On the other hand, 17 patients who had OABSS showed a significant reduction in their total score in the first month but not in the third month (Table-1).

Table 1: Mean values and changes of OABSS scores in all groups

	Baseline	1st Month	3rd Month	P value
Total (n:54)	10.10 ± 5.03	8.89 ± 6.55	10.00 ± 8.26	0.002
Without OABSS (n:37)	7.1 ± 2.35	6.9 ± 6.18	6.6 ± 5.46	0.012
With OABSS (n:17)	15.41 ± 4.0	12.41 ± 5.78	16 ± 9.06	0.047

Conclusion
Although there are concerns about increased low urinary tract symptoms associated with the diüretic effects of SGLT-2 inhibitors, our study did not show an increase in OABSS scores.

Western-style diet in the presence of elevated circulating testosterone induces adipocyte hypertrophy and t-cell dysfunction in rhesus macaques

Benjamin Burwitz[1], Sofiya yusova[1], Jacob Robino[1], Diana Takahashi[1], Addie Luo[1], Ov Slayden[1], Cecily Bishop[1], Jon Hennebold[1], Charles Roberts[1] & Oleg Varlamov[1]
[1]The Oregon National Primate Research Center, Beaverton, United States

Hyperandrogenemia (elevated testosterone, T) and metabolic dysfunction are hallmarks of polycystic ovary syndrome (PCOS), which can have varying degrees of ovulatory dysfunction. Adipocyte hypertrophy, induced by obesity and hyperandrogenemia, has been suggested to contribute to the systemic low-grade inflammation thought to be one of the drivers leading to reproductive dysfunction in women with PCOS. However, whether hyperandrogenemia and adipocyte hypertrophy per se induce a proinflammatory response is unknown. Therefore, the primary objective of this study was to focus on the metabolic and immunological effects of WSD and mild hyperandrogenemia on the systemic and tissue-resident proinflammatory milieu using a nonhuman primate (NHP) model. To test whether T + WSD disrupts the immune milieu that may affect normal egg implantation and other relevant reproductive processes, we conducted immune cell profiling during the mid-luteal phase, the interval during the menstrual cycle when the uterine endometrium is permissive for embryo implantation. Individual treatments (i.e., T or WSD alone) were not included in this study because we previously determined that combined treatment led to earlier and more severe metabolic and reproductive impairments, including increased numbers of arrested antral follicles and reduced fertility. Immune cells residing in visceral omental white adipose tissue (OM-WAT), corpus luteum and the contralateral ovary, endometrium, lymph nodes, bone marrow, and peripheral blood mononuclear cells were characterized by flow cytometry during the luteal phase of the reproductive cycle. Following one year of treatment, T + WSD animals became more insulin-resistant and exhibited increased body fat and adipocyte hypertrophy compared to controls. T + WSD treatment did not induce macrophage polarization towards a proinflammatory phenotype in the tissues examined. While the major T-lymphoid cell subsets were not significantly affected by T + WSD treatment, we observed a significant reduction in the frequency of effector memory CD8 + T-cells (Tem) in OM-WAT, but not in other tissues. Notably, OM-WAT Tem frequencies were negatively correlated with insulin resistance as assessed by Homeostatic Model Assessment for Insulin Resistance (HOMA-IR). Collectively, our data show that short-term T + WSD treatment induces weight gain, insulin resistance, and adipocyte hypertrophy, but does not have a significant effect on systemic and tissue-resident proinflammatory markers, suggesting that adipocyte hypertrophy and mild hyperandrogenemia alone are not sufficient to induce a proinflammatory response. Additionally, hyperandrogenemia may induce immune tolerance in T-cells. Dysregulation of T-cell function can lead to immune-related complications that may affect implantation and early pregnancy outcomes.

The BRAF K601E mutation in thyroid tumors: One alteration with a dual clinical significance

Elisabetta Macerola, Paola Vignali, Rebecca Sparavelli, Marcello Poma, Agnese Proietti, Liborio Torregrossa, Ferruccio Santini, Rossella Elisei, Gabriele Materazzi, Fulvio Basolo & Clara Ugolini
University of Pisa, Pisa, Italy

Background
BRAF^{K601E} mutation is a class 2 oncogenic *BRAF* mutation which causes constitutive activation of MAPK pathway functioning as RAS-independent activated dimers. In thyroid cancer, the *BRAF*^{K601E} is more rare than the *BRAF*^{V600E}, and it has been mostly associated to clinically indolent follicular architecture neoplasms. This is a mono-institutional study aimed at evaluating the frequency and clinical role of *BRAF*^{K601E} mutation, either when it is identified in indeterminate thyroid nodules or in thyroid cancer.
Methods
The institutional database was searched for thyroid nodules and tumors positive for the *BRAF*^{K601E} between 2019 and 2023. Mutational screening was performed by real-time PCR in nodules with indeterminate cytology (fine-needle aspiration material) and by NGS in thyroid cancer (tumor tissue).
Results
In 5-year time interval of molecular diagnostics activity, the K601E mutation was detected in 20 out of 1173 cases (1.7%). Specifically, it was identified in 17 out of 824 indeterminate nodules (2.1%) and in 3 out of 349 carcinomas (0.9%). In thyroid cytology, nodules with K601E mutation were TIR 3A ($n = 11$) or TIR 3B ($n = 6$), according to the Italian system. Patients with K601E-positive nodules were younger (mean age 37 years ± 10.8) compared to those with non-K601E nodules in the same time period (mean age 49.9 years ± 15.2), while nodule size appeared similar in mutated (mean 2.5 cm ± 0.8) and non-mutated (mean 2.4 ± 13.4) cases. On histology, K601E positive nodules were benign tumors (follicular adenoma, $n = 1$), low-risk neoplasms (NIFTP, $n = 3$) or malignant neoplasms (minimally invasive encapsulated follicular variant PTC, $n = 10$; solid subtype PTC, $n = 2$; classic PTC, $n = 1$). None of the malignant neoplasms showed extrathyroidal extension, nor lymphovascular invasion; two tumors had central neck lymph node metastases (N1a). The three advanced thyroid *BRAF*^{K601E}-positive carcinomas showed aggressive histology (two widely invasive follicular thyroid carcinoma; one anaplastic thyroid carcinoma). Patients age was 65, 65 and 74 years, respectively. Two patients with follicular carcinoma experienced disease recurrence, and in one of them histological transformation to poorly differentiated thyroid carcinoma was identified on biopsy.
Conclusions
The *BRAF*^{K601E} mutation is rare in thyroid nodules and cancer, where it can have a dual clinical significance. In indeterminate cytology, it is mostly found in young adults, and it is predictive of malignant neoplasms with no aggressive phenotypic features. However, it can be found also in aggressive thyroid tumor types, including anaplastic thyroid cancer. Therefore, the *BRAF*^{K601E} mutation role in thyroid pathology should not be underestimated.

Effectiveness of temozolomide treatment in SDHx mutant and wildtype metastatic pheochromocytoma and paraganglioma – results of a European restrospective multicentre study

Hanna Remde[1], Julien Hadoux[2], Joakim Crona[3], Rossella Libe[4], Eugénie Lim[5], Guido Di Dalmazi[6], Emanuela Arvat[7], Magalie Haissaguerre[8], Letizia Canu[9], Gregory Kaltsas[10], Peter Igaz[11], Henri Timmers[12], Svenja Noelting[13], Marcus Quinkler[14], Timo Deutschbein[15], Martin Fassnacht[1] & Kroiss Matthias[16]
[1]University Hospital Würzburg, Würzburg, Germany; [2]Institut Gustave Roussy, Villejuif, France; [3]University of Uppsala, Uppsala, Sweden; [4]Hôpital Cochin-Port Royal, Paris, France; [5]St. Bartholomew's Hospital, London, UK; [6]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [7]University of Turin, Torino, Italy; [8]Bordeaux University, Bordeaux, France; [9]University of Florence, Firenze, Italy; [10]National and Kapodistrian University of Athens, Athens, Greece; [11]Semmelweis University, Budapest, Hungary; [12]Radboud University Medical Centre, Nijmegen, Netherlands; [13]University Hospital Zürich, Zürich, Switzerland; [14]Endokrinologie in Charlottenburg, Berlin, Germany; [15]Medicover MVZ Oldenburg, Oldenburg, Germany; [16]LMU University Hospital, München, Germany

Background
Pheochromocytomas and paragangliomas (mPPGL) are rare neuroendocrine tumors. Therapeutic options in advanced and irresectable mPPGL are limited. Two small retrospective studies demonstrated the effectiveness of temozolomide

in patients with mPPGL and suggested that patients with mutation in the succinate dehydrogenase B (SDHB) gene might benefit more than SDHB wildtype cases.
Aim
To re-evaluate safety and effectiveness of temozolomide in a larger cohort of patients with mPPGL and identify predictors of clinical response.
Methods
Data from patients with mPPGL who had received treatment with temozolomide were collected in an international retrospective setting at 15 reference centres in Europe. The objective response rate (ORR) and non-progression rate (NPR) were the primary outcome measures. The association of SDHB mutation status in and treatment response was assessed using Fisher's exact test.
Results
Radiological outcome assessment was available for 67 (94.3%) of 71 patients included into the study at data cut-off. Best response was partial response (PR) in 18 patients and stable disease (SD) in 29. The ORR was 27% and the NPR 70%. Germline SDHB mutation was available for 56 patients including 24 (43%) patients with an SDHB mutation and 32 (57%) patients with SDHB wildtype. Objective treatment response was observed in both groups but was significantly more frequent in patients with SDHB mutation (41.6% vs 12.5%, $P=0.027$). Accordingly, non-progression rate was higher in patients with SDHB mutation compared to those with SDHB wildtype (83% vs 56%, $P=0.044$).
Conclusion
Treatment with temozolomide in mPPGL can be effective in both patients with SDHB mutation and those with SDHB wildtype. However, objective response rates and non-progression rates are higher in patients carrying an SDHB mutation.

Introduction
The role of mitotane as an adjuvant therapy for adrenocortical carcinoma (ACC) remains a contentious topic due to the scarcity of robust randomized clinical trials, attributed to the low incidence of this neoplasm. Despite this, the prognosis following surgery for localized tumors is generally poor, leading to varied clinical practices.
Methods
This study utilized patient data from the ICARO registry of the GETHY group and SEEN, with disease-free survival (DFS) and overall survival (OS) as endpoints. A Cox multivariable model was employed, considering factors such as tumor size, Ki67 index, age, T stage, nodal involvement, venous invasion, radiotherapy, and adjuvant mitotane usage.
Results
The ICARO database included 357 patients treated between 1983 and 2023 across 34 centers. Among these, 223 patients had localized, non-metastatic tumors at diagnosis and underwent surgery after a median of 41 days from diagnosis. Open surgery was performed in 142 (64%) cases, with laparoscopic procedures in the remainder. R0 resection was achieved in 162 (73%) cases. Of the 223 patients with follow-up data, 138 (62%) were female, aged between 20 and 88 years, with a median age of 50 years. Functional symptoms were present in 85 (38%) patients, with Cushing's syndrome in 51 of these. Radiotherapy was administered in 27 (12%) cases, and 111 (49.7%) patients received adjuvant mitotane therapy for a median of 23 months. Mitotane levels were monitored in 93/111 patients, starting at 2 g/day. At the time of analysis, the median DFS was 28 months (95% CI, 20.8–61.3), and the median OS was 86.1 months (95% CI, 54.6–152). After adjusting for confounding factors, there is insufficient evidence to reject the null hypothesis of no effect of mitotane on DFS (Hazard Ratio [HR] 0.67, 95% CI, 0.42–1.05), or on OS (HR 0.58, 95% CI, 0.32–1.02). However, factors such as tumor size (T), nodal involvement (N), age, Ki67 index, and venous invasion were associated with recurrence and death. The effect was clearly time-variant (Schoenfeld test = 0.008), with a crossing of the Kaplan-Meier curves at 24 months.
Conclusion
In post-operative ACC cases, current evidence on adjuvant mitotane's efficacy is not definitive. However, if effective, its impact seems time-limited, likely reaching its peak within two years under conventional usage patterns. This suggests a potential requirement for prolonged maintenance therapy, emphasizing the need for in-depth research into its long-term outcomes.

Clinical impact and genetic alterations in the DAXX gene in patients with neuroendocrine tumors of the gastroenteropancreatic system and the lung

Darko Katalinic[1], Lars Toetome[2], Ivan Aleric[1], Ivana Skrlec[3], Jasminka Talapko[3] & Aleksandar Vcev[1]
[1]Faculty of Dental Medicine and Health and Faculty of Medicine, University of Osijek; [2]Center for Cancer Medicine, Oslo, Norway; [3]Faculty of Dental Medicine and Health, University of Osijek

Introduction
Neuroendocrine tumors (NETs) comprise a unique heterogeneous group of malignant growths that range from benign and multi-focal to highly malignant and metastatic. They are characterized by well-differentiated morphologic features and the ability to secrete neuropeptides, resulting in characteristic clinical syndromes. However, they are often diagnosed from the metastases of an unknown primary tumor. Therefore, high-quality genetic and immunohistochemical markers are needed to confirm the diagnosis. Here we conduct integrated genome and immunohistochemistry analysis (IHC) of the *DAXX* (death domain-associated protein) gene as well as analysis of disease-free survival (DFS) and overall survival (OS) in patients diagnosed with NETs.
Material and methods
The study consisted of 65 patients with NETs. During the study period, 36 patients were diagnosed with neuroendocrine tumors of the lung (L-NETs) and 29 patients with neuroendocrine tumors of the gastroenteropancreatic system (GEP-NETs). Tumor-DNA was isolated from fresh-frozen tumor tissue. The IHC analysis was conducted according to the standard histopathological protocol. The real-time PCR was performed for the *DAXX* gene.
Results
A total of 24 patients (36.9%) were found with mutations in the *DAXX* gene. The cumulative number of mutations detected in NETs >3 cm was significantly higher ($P<0.001$) in comparison to NETs <3 cm. We also found that mutations of the *DAXX* gene were strongly associated with increased features of malignancy including lymphovascular invasion and higher tumor grade. All patients with the mutated *DAXX* gene had a shorter DFS ($P<0.002$) and OS ($P<0.003$).
Conclusion
Our study identified a significant relation between the genomic profile of the *DAXX* gene and DFS as well as the OS in patients diagnosed with L-NETs and GEP-NETs. The *DAXX* molecular alterations influence the malignant potential of L-NETs and GEP-NETs and can predict the malignant progression. Therefore, they could be considered as a possible prognostic stratification tool.

How well does 'real world' management of Immune check point inhibitor induced hypophysits (ICI-Hp) reflect the European Society of Endocrinology (ESE) 2023 clinical practice guidelines (CPG)?: Experience from a single tertiary care centre

Shani Apsara Dilrukshi Mathara Diddhenipothage[1], Jacqui Warden[2], Katie Herbert[2], Riccardo Poli[1], Nicholas Coupe[2], Miranda Payne[2], Jeremy W Tomlinson[1] & Helen Turner[1]
[1]Oxford Centre for Diabetes, Endocrinology, and Metabolism, Endocrinology, Oxford, UK; [2]Department of Oncology, Churchill Hospital, Oxford, UK

Introduction
Hypophysitis (Hp) is a serious adverse effect (AE) of Immune check-point inhibitor (ICI) therapy in malignancy. We evaluated 6 yeas of clinical expereince with ICI against the recent ESE CPG 2023 which provides practical guidance on the management of this condition based on up-to-date evidence.
Methods
A quality improvement project (QIP) included all patients with ICI-Hp ($n=17$) referred to a dedicated Endocrine-ICI clinic (January 2017-November 2023), to determine presentation, management, and outcomes.
Results
There were 50% males, median age 63 y (IQR 51,73)] and symptom onset occurred 12 w (IQR 9,15) of ICI therapy, after the 3rd (IQR 3,4) cycle; underlying malignancy: metastatic melanoma (76%), renal cell carcinoma (12%) and mesothelioma (12%). All received Ipilimumab (Ipi), alone (5.8%) or in combination with Nivolumab (82%). Fatigue (76%), headache (71%) and nausea (65%) were common symptoms; 12% were asymptomatic. Hyponatremia 41%. All had acute secondary hypocortisolism (SHC) (random morning cortisol <100 nmol/l in 82%, <50 nmol/l in 53%). Acute secondary hypothyroidism (SHT) and hypogonadism (SHG) were reported in 35%. Low prolactin (PRL) (<110 mIU/l) 30%; elevated PRL (446-1119) 18%. Enlarged pituitary was the commonest (75%) pituitary imaging abnormality ($n=16$, performed ≤ 12 w), followed by thickened stalk (31%), supra-sellar extension (12%), mild optic-chiasm compression ($n=1$, biopsy: lymphocytic Hp). Specific management of Hp varied; IV methylprednisolone (MPP) 1 mg/kg per day ($n=4$) (indication severe headache), oral prednisolone 30–40 mg/d ($n=6$), oral dexamethasone 10 mg/d ($n=1$), and hydrocortisone (HC) 40 mg/d for 48 h ($n=4$). Symptomatic Hp recovery occurred in all; (33% within 48 h) and scan abnormalities [at 15 w (IQR 13, 22), $n=14$). One patient developed acute psychosis with high-dose MPP. Long term, all received standard HC (20 mg/d) replacement and age/weight-based levothyroxine in persistent SHT. None required sex hormone replacement. In those evaluated for pituitary recovery; There was no recovery in SHC ($n=10$), whilst recovery of SHT and SHG was reported in 43% [at 5 w (IQR 4,10)] and 67% [at 10 w (IQR 8,13)] respectively. Lack of cancer progression was noted in 65% [2.5 y (IQR 2, 6)]. Treatment with high dose GCs was not associated with cancer progression ($P=1.00$), or all-cause mortality ($P=0.515$).
Conclusions
Despite antedating ESE CPG, our practice is aligned with current guidance. GC dose (not strictly aligned with CPG) chosen for symptom severity had no effect on disease course. SHC following ICI-HP was irreversible, however recovery of SHT and SHG should be actively sought on long term follow up.

Risk of differentiated thyroid cancer among Danish women with polycystic ovary syndrome

Sarah Sørensen[1], Clarissa Frandsen[1], Thomas Maltesen[1], Christian Munk[1], Ulla Feldt-Rasmussen[2,3], Allan Jensen[1] & Susanne Kjær[1,4]
[4]Danish Cancer Society, Copenhagen, Denmark; [2]Rigshospitalet, Department of Endocrinology and Metabolism, København, Denmark; [3]Institute of Clinical Medicine, Faculty of Health and Clinical Sciences, Copenhagen University, Copenhagen, Denmark; [4]Department of Gynecology, Rigshospitalet, Denmark

Background
Gender disparity and age pattern in the incidence of thyroid cancer indicate a link between hormonal- and reproductive factors and risk of thyroid cancer. Thus, polycystic ovary syndrome (PCOS) may be a plausible risk factor for this malignancy.
Aim
In this nationwide cohort study, we investigated the association between PCOS and the risk of differentiated and papillary thyroid cancer.
Methods
We included all Danish women born during 1962–1996 ($n=990\,990$). PCOS- and cancer diagnoses, covariates, migration, and vital status were obtained from following Danish, nationwide health- and population registers: The Danish Civil Registration System, the Danish Cancer Register, the Danish National Patient Register, The Danish National Prescription Register, the Danish Medical Birth register, and educational registers at Statistics Denmark. We used the unique, personal identification number assigned to all Danish citizens at birth or immigration, which is used as key identifier all over in the Danish society to link individual level data from the above-mentioned registers. Cox-proportional hazard models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CI) for differentiated thyroid cancer overall and separately for papillary thyroid cancer according to diagnosis of and time since diagnosis of PCOS.
Results
The study cohort comprised 990 850 women. At baseline, 5584 women were diagnosed with PCOS (0.6%). At baseline, Obesity, diabetes type II, use of hormonal contraception, and previous diagnosis of benign thyroid disease were more frequent in women with PCOS, than in women without PCOS. Highest obtained level of education and parity status were similar between the two groups. During follow-up (16 975 570.8 years), we identified 980 women with differentiated thyroid cancer, fifteen of whom were previously diagnosed with PCOS. We found a tendency towards an increased rate of differentiated thyroid cancer in women with PCOS (HR = 1.52, 95% CI: 0.91–2.53). The association was strongest in the first 10 years after the PCOS diagnosis (HR = 3.81, 95% CI: 1.90–7.65). None of the women were diagnosed with differentiated thyroid cancer within the first three years following PCOS. Results were similar for papillary thyroid cancer.
Conclusions
We found a tendency towards an increased rate of differentiated and papillary thyroid cancer in women with PCOS, which was strongest the first 10 years after PCOS and potentially related to prior benign thyroid disease. Even this large study was limited by few exposed cases and therefore a relatively low statistical power.

Cervico-mediastinal hematoma: Atypical presentation of parathyroid carcinoma associated to hashimoto thyroiditis

Martina Cicia[1], Giampaolo Papi[2], Alfredo Scillitani[3], Stefania Corrado[4], Pietro Locantore[1] & Alfredo Pontecorvi[1]
[1]Fondazione Policlinico Universitario A. Gemelli, Endocrinology and Diabetology, Rome, Italy; [2]Azienda USL Modena, Endocrinology Unit, Modena, Italy; [3]Casa del Sollievo della Sofferenza in San Giovanni Rotondo, Endocrinology Unit, Foggia, Italy; [4]University of Modena and Reggio Emilia, Pathology Unit, Modena, Italy

Introduction
Parathyroid carcinoma (PC) accounts for $<1\%$ of all forms of primary hyperparathyroidism. PC is characterized by very high serum PTH and calcium levels and presents with osteopenia/osteoporosis, nephrolithiasis, asthenia, neuropsychiatric symptoms. Here, we report the unusual presentation of a PC.
Case presentation
A 48-year-old woman was referred to our Center for the sudden appearance of a large painful hematoma in the cervico-mediastinal area. Neck US showed a solid, markedly hypoechoic lesion ($40\times80\times55$ mm), extending from the right thyroid lobe to the mediastinum, associated to blood leakage in the right perithyroid area. The thyroid displayed a diffusely hypoechoic structure, without nodules. Lab tests showed: TSH 2.1 mIU/ml, Calcitonin <1 pg/ml, PTH 460 pg/ml, Calcium 14 mg/dl, Calcium ion 2.1 mmol/l, Calciuria 535 mg/24 h, Phosphorus 2.5 mg/dl, Creatinine 0.65 mg/dl, 25-OH vitamin D 10 ng/ml, CEA 2 ng/ml. Femoral-lumbar DXA detected osteopenia and renal US showed a stone within the left kidney. Neck CT demonstrated a huge mass extending from the right thyroid lobe up to the right upper bronchus and displacing the esophagus and the trachea controlaterally.
Treatment
The patient was rehydrated, treated with furosemide, cholecalciferol and bisphosphonate and submitted to right lower parathyroidectomy + right hemithyroidectomy + lymphadenectomy of the right VI cervical level. Histological examination was diagnostic for non-angio-nor neuro-invasive PC associated to lymphocytic thyroiditis; all removed lymph nodes were benign.
Outcome and follow-up
The post-operative course was regular. The patient was discharged with calcitriol and calcium carbonate therapy, then suspended. The search for mutation of the CDC73 gene was negative. The 30-day follow-up included blood tests showing normal PTH and calcium concentrations and subclinical hypothyroidism with

TSH elevated at 18 mcIU/ml Neck US did not detect residual neoplasm and 99mTc-MIBI parathyroid scan was negative. Levothyroxine therapy 50 µg/day was undertaken. Eight years after diagnosis, the patient is in good general condition, with no clinical, biochemical or imaging evidence of disease persistence/recurrence.
Conclusions
We have described the unique case of a PC presenting with pain and hematoma in either the anterior neck and the mediastinum, associated with autoimmune thyroiditis. Although parathyroid hemorrhage is a rare event, it should always be suspected when a painful swelling suddenly appears in the neck region in a hypercalcemic patient. Given the high prevalence of HT in the general population, we believe that the association between PC and autoimmune thyroiditis in our patient should be considered casual.

Do immune checkpoint inhibitor-related endocrinopathies affect survival rates in cancer patients? Presentation of two case reports

Daria Sazonova[1], Nikita Kutakov[2], Alexander Lutsenko[1], Elena Przhiyalkovskaya[1] & Ekaterina Troshina[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Clinical Hospital 'Lapino' of the 'Mother and Child' Group of companies, Moscow region, Russian Federation

Background
Immune checkpoint Inhibitors (ICIs) have revolutionized the treatment of vast array of cancers. Despite their efficacy, ICIs can cause various side effects related to the mechanism of action. Immune-related endocrine events (irEEs) are one of the most common immune-related adverse events (irAEs), accounting for 8.1% of all cases. We report two patients with durable responses to ICIs and concurrent serious irEEs.
Case 1
A 58-year-old woman with metastatic non-small cell lung cancer has been receiving nivolumab for 13 months after 4 previous lines of systemic therapy were ineffective. The patient developed primary hypothyroidism after 14 weeks of ICIs (TSH 82 mIU/l, FT4 0.67 pmol/l) and levothyroxine 100 µg/d was prescribed. After 4 weeks, she noted an episode of hypotension (90/60 mmHg), general weakness, nausea and vomiting. Lab tests showed low morning cortisol 2.8 nmol/l, Na 135 mmol/l with high ACTH 827 pg/ml, renin 184 µIU/ml, K 5.1 mmol/l. Primary adrenal insufficiency was diagnosed and all symptoms resolved after hydrocortisone 25 mg/d and fludrocortisone 0.1 mg/d treatment. To date, the patient has received 26 nivolumab infusions 240 mg/2weeks, with complete metabolic response according to 18F-FDG PET/CT.
Case 2
A 55-year-old woman with localized cutaneous melanoma, which was surgically resected and 6 months later recurred with jugular lymph nodes and liver metastases. Combination ICIs therapy was initiated (nivolumab + ipilimumab), then switching to nivolumab, which she has been receiving for 13 months. Within 4 weeks after ICIs were initiated, she noticed frequent episodes of hypoglycemia (up to 3.0 mmol/l), severe weakness, hypotension (80/60 mmHg), nausea and vomiting. Lab tests showed low morning cortisol 6.4 nmol/l, ACTH 2.1 pg/ml, renin 2.78 µIU/ml, Na 124 mmol/l, C-peptide 0.83 ng/ml, insulin 1 µU/ml, TSH 0.12 µIU/ml, FT4 8.98 pmol/l with normal-range K4.27 mmol/l. Central hypothyroidism and adrenal insufficiency were diagnosed. MRI scan identified empty sella. Symptoms of ICI-induced hypophysitis resolved after initiation of hydrocortisone 20 mg/d and levothyroxine 75 µg/d. The patient has received 26 nivolumab infusions 240 mg/2 weeks. Last 18F-FDG PET/CT confirmed complete metabolic response.
Conclusion
Increased overall survival and progression-free survival have been reported in cancer patients with ieEEs. However, causes of this correlation remain unknown, which warrants further research. Our cases demonstrate the importance of vigilant monitoring of endocrinopathies among cancer patients receiving ICIs in order to diagnose life-threatening complications in time.

Increased calcitonin level in cases with multinodular goitre and ectopic Cushing syndrome – diagnostic challenges

Mihaela Vlad[1,2], Balas Melania[1], Iuliana Gavanescu[3], Golu Ioana[1], daniela-georgiana amzar[1], Memu Eustatiu[4] & Baderca Flavia[5]
[1]'Victor Babeş' University of Medicine and Pharmacy, 2nd Internal Medicine, Timişoara, Romania; [2]"Victor Babeş" University of Medicine and Pharmacy, Center for Molecular Research in Nephrology and Vascular Disease, Timişoara, Romania; [3]Timiş County Emergency Clinical Hospital, Timişoara, Romania; [4]Emergency City Hospital, Thoracic Surgery, Timişoara, Romania; [5]Victor Babeş University of Medicine and Pharmacy, Microscopic Morphology – Histology, Timişoara, Romania

Introduction
Calcitonin is produced by parafollicular C cells of the thyroid, increased values being considered the hallmark for the medullary thyroid carcinoma (MTC). We discussed two challenging cases with high calcitonin, multinodular goitre and ACTH-dependent paraneoplastic Cushing syndrome.
Case 1
A 45-year-old female patient was admitted into our clinic due to severe fatigue, central obesity, proximal muscle atrophy, round face, buffalo hump, dorsal kyphosis due to osteoporotic vertebral fractures, high blood pressure. Laboratory evaluation revealed high morning and midnight serum cortisol, with no suppression on low-dose dexamethasone suppression test and high plasma ACTH (65.7 pg/ml), indicating an ACTH-dependent Cushing' syndrome. Pituitary magnetic resonance imaging (MRI) didn't reveal any pituitary adenoma. On thyroid ultrasound a mixed hypoechoic nodule of 6/6/8 mm in the right lobe was detected and increased calcitonin level (79.6 pg/ml). A MTC with ectopic paraneoplastic secretion of ACTH was suspected. The Calcitonin-stimulation test with Omeprazole was done, with no stimulation for Calcitonin. More extensive imaging exploration revealed a well-defined lung nodule of 10 mm. The tumor was removed and the pathology report confirmed a carcinoid tumor, stage pT1bN0M0, with Ki-67 index of 2%, and positive immunostaining for ACTH, calcitonin, chromogranin and synaptophysin. After surgery, ACTH, cortisol and calcitonin levels decreased significantly (5.4 pg/ml, 2.42 ng/dl and <2 pg/ml).
Case 2
A 44-year-old hypertensive women was admitted with typical Cushing's syndrome features and amenorrhea for 5 years. Hypercortisolism was confirmed (increased basal and nocturnal serum cortisol, unsuppressed after 1 mg dexamethasone, high ACTH levels-253 pg/ml), increased chromogranin A (2980 ng/l, NR 27–94), hyperglycemia, severe hypokalemia. The imagistic investigations showed no pathological pituitary, pulmonary and abdominal lesions. Pelvic CT and MRI confirmed an ovarian tumoral mass of 15 cm. As the patient presented 2 highly suspicious left thyroid nodules and increased calcitonin (291 pg/ml), MTC with ectopic ACTH-secretion was considered, but the pathology revealed papillary thyroid cancer. After the removal of ovarian tumor, the values of ACTH, cortisol, calcitonin, and chromogranin A decreased significantly.
Discussions
In both cases, the absence of a clear ACTH source imposed the extensive hormonal and imagistic exploration. Calcitonin determination was included in the work-up flow due to the presence of thyroid nodules. The outcome of both cases underline that the high values for calcitonin don't indicate a MTC, always.
Conclusion
When calcitonin level is elevated, but thyroid evaluation is not clear suggestive for a medullary thyroid carcinoma, an extrathyroidal neuroendocrine tumor should be taking into account for differential diagnosis.

Spontaneous and treatment-related changes in calcitonin doubling rate of medullary thyroid cancer. Long-term experience in a patient with multiple endocrine neoplasia type 2B

Judit Tőke[1], Zsuzsánna Réti[2], Miklós Garami[3], Ildiko Kalina[4], Gergely Kiss[1], Zoltán Sápi[5], Ádám Gy. Tabák[1,6,7] & Miklos Toth[1]
[1]Semmelweis University, Department of Internal Medicine and Oncology, Budapest, Hungary; [2]George Emil Palade University of Medicine, Pharmacy, Science, and Technology of Targu Mures, Targu Mures, Romania; [3]Semmelweis University, Pediatric Center, Budapest, Hungary; [4]Semmelweis University, Medical Imaging Centre, Budapest, Hungary; [5]Semmelweis University, Department of Pathology and Experimental Cancer Research, Budapest, Hungary; [6]Semmelweis University, Department of Public Health, Budapest, Hungary; [7]University College London, UCL Brain Sciences, London, UK

Introduction
Medullary thyroid carcinoma (MTC) in multiple endocrine neoplasia type 2B (MEN2B) syndrome is associated with RET mutation. Patients harbouring de

novo mutations are usually diagnosed in more advanced stages of the disease. We present the case of a young female patient with MEN2B diagnosed with stage IV medullary thyroid carcinoma at the age of 10 years.
Aim
Characterizing the efficacy of the different sequences of therapies and disease progression by calculating calcitonin doubling rates based on serial calcitonin measurements.
Methods
Different phases of spontaneous tumor development, the efficacy of surgical interventions and individual drug treatment intervals were analyzed with calcitonin doubling rates (Ct-DR).
Results
De novo mutation involving the Met918Thr in exon 16 of the RET proto-oncogene confirmed the genetic background of the disease in our patient. In 2006-2015, she underwent four operations. We found a less steep increase in log-transformed calcitonin levels after the first compared to subsequent operations. A significant drop in serum calcitonin after a pheochromocytoma removal was suggestive of calcitonin secretion, confirmed by subsequent immunohistochemical analysis. After suffering multiple surgical interventions for local and regional recurrence, the disease still progressed, leading to metastatic disease in the fifth year after diagnosis. The patient underwent five different types of TKI treatment (sunitinib, vandetanib, cabozantinib, lenvatinib, and selpercatinib), with different responses and multiple adverse effects. Three of the five TKIs resulted in an immediate drop of serum calcitonin followed by significantly less steep increases than untreated periods for vandetanib and selpercatinib. Even after the initial drop in calcitonin, we found a continuously decreasing calcitonin trajectory for selpercatinib. Sunitinib and cabozantinib had to be discontinued due to severe side effects. Vandetanib was used for the longest time, slowing the progression of the disease, and causing tolarable adverse events. The best treatment response, as reflected by negative Ct-DR and lack of side effects, was observed with selpercatinib, granting a stable disease and improving quality of life after 17 years from diagnosis.
Conclusion
Our case illustrates the long-term survival of a young MEN-2B patient diagnosed with advanced medullary thyroid carcinoma. The case presents how the effectiveness of different treatment modalities can be approached using log-transformed calcitonin levels.

Targeting focal adhesion kinase (FAK) and spleen tyrosine kinase (SYK) in gastrointestinal neuroendocrine tumors: Unveiling mechanisms and anti-proliferative effects

Lara Toffoli, Francesca D'Este, Marilyn Dainotto, Angeliki Ditsiou & Teresa Gagliano
University of Udine, Department of Medicine (DMED), Udine, Italy

Gastrointestinal neuroendocrine tumors (GI-NETs) present a challenging and diverse landscape, necessitating effective treatment strategies. Despite advancements, the demand for targeted therapies, particularly for advanced or metastatic cases, persists. Enhancing outcomes in GI-NETs management is crucial, emphasizing the need for ongoing research and development. In our laboratory, we conducted a multitarget compound screening, identifying FAK (BI-0319) and SYK (BI1002494) kinase inhibitors for their anti-proliferative effects on GI-NETs cell lines. SYK and FAK are pivotal in focal adhesions, influencing cell adhesion and migration. SYK, classically associated with immune responses, also impacts focal adhesions, influencing cell movement. FAK, a central adhesion complex component, activates during cell-ECM interactions, governing cell behaviour. Their interplay highlights the intricate relationship between immune signalling (SYK) and adhesion dynamics (FAK), contributing to a comprehensive understanding of cellular processes. Our objective was to characterize the mechanisms of action of FAK and SYK inhibitors in GI-NETs cell lines.
Methods
Using the Small intestine NET cell line GOT1 and colorectal cancer NET cell line COLO320DM as models, cells were cultivated in both 2D and 3D. Cell viability was assessed using crystal violet and cell-titer glo assays. Apoptosis was measured using the 3/7 caspase assay. Protein expression was detected by western blot and immunofluorescence. Gene expression was determined using QPCR.
Results
Both cell lines exhibited high levels of SYK and FAK. The IC50 of FAK (BI-0319) and SYK (BI1002494) was determined in both 2D and 3D. Apoptosis activation using the caspase 3/7 assay revealed limited engagement. Growth curve and real-time time-lapse analyses showed both compounds had significant anti-proliferative effects, delaying cell proliferation, and eventually leading to cell death.
Conclusion
FAK (BI-0319) and SYK (BI1002494) serve as valuable tools to understand the roles of SYK and FAK in GI-NETs biology. Further studies are warranted to investigate their roles in controlling the cell cycle and microtubule formation.

Metastatic paragangliomas – real world data in a single tertiary center

Foteini Thanasoula[1], Sofia Vlachou[2], Evanthia Kassi[3], Anna Angelousi[1] & Gregory Kaltsas[2]
[1]1st Dpt of Internal Medicine, Unit of Endocrinology, National and Kapodistrian University of Athens, Laikon Hospital, Greece; [2]1st Dpt Department of Propaedeutic and Internal Medicine, Unit of Endocrinology, National and Kapodistrian University of Athens, Laikon Hospital, Greece; [3]Department of Biochemistry,1st Dpt Department of Propaedeutic and Internal Medicine, Unit of Endocrinology, National and Kapodistrian University of Athens, Greece

Background
Paragangliomas(PGLs) and pheochromocytomas (PHEOs) are rare extra-adrenal neuroendocrine tumors of the sympathetic and parasympathetic nervous system. Metastatic status is defined by the abnormal presence of non-chromaffin tissue in extra adrenal organs. The incidence of metastases rises up to 10–17% and may appear even 10 years after the initial diagnosis.
Methods
We retrospectively analysed medical files of patients followed in a tertiary hospital (Center of excellence of rare adrenal diseases). Therapeutic modalities as well as mortality and progression status were recorded.
Results
Twenty seven patients diagnosed with metastatic PHEOs/PGL were included (mean $\pm$ s.d. age in years: 39 ± 15.6). Six patients presented with synchronous metastases and 21 patients developed metastases within a median time of 7 years of follow-up. The 60% of PHEOs and 40% of PGLs were functional. Genetic analysis was performed in 59% of the total included patients ($n = 2/12$ patients with PHEOs and $n = 7/15$ with PGLs) and was found positive in 9 patients (56%) (2 with SDHA, 1 with SDHB,5 with SDHD and 1 with EPAS1 mutation). Median PASS was 7 (min–max:1–9) for PHEOs and GAPP was 6 (min–max:4–7) for PGLs. Median Ki-67% index levels was 5 (min–max:-1–70). Median progression-free survival (PFS) for metastatic disease was 5.9 years (min:0.48-max:15.25) within a median follow-up time of 7 years. Local recurrence was treated either with radiotherapy in 6/27 patients or with second surgery in 10/27 patients, while 2 of them underwent also a third operation. In total, 12 patients were treated with chemotherapy (Cyclophospamide – vincristine -dacarbazine (CVD) or temozolomide) as first line treatment after surgery, $n = 6$ with molecular targeted treatment (MTT) including sunitinib/ cabozatinib /pazopanib as second line and $n = 6$ patients were treated with radiopeptides (PRRTS) or $n = 4$ treated with MIBG analogues. The estimated median PFS was 5,39 months (min:3,02-max:55) for chemotherapy, 6.96 (min:2.76-max:55.68) for MTT, 7.9 (min:6.6-max:180) for radiopeptides and 36.6 (min:16.2-max:124.2) for MIBG therapy. Four patients were lost during follow-up. The observed mortality rate was 21%.
Conclusions
Metastatic PHEOs/PGLs are rare adrenal entities and their management remains challenging requiring a multidisciplinary decision. In most cases metastases occur many years after the initial diagnosis and often they require multiples lines of treatment. In our study, radiopeptides showed the longer PFS comparing with the other systematic treatments.

Incidentaloma on Ga-68-DOTANOC PET; prevalence and clinical significance

Carlien De Herdt[1], Naert Laura[2], Stroobants Sigrid[2] & De Block Christophe[1]
[1]Antwerp University Hospital, Endocrinology, diabetology and metabolism, Edegem, Belgium; [2]Antwerp University Hospital, Nuclear Medicine, Edegem, Belgium

Introduction
Over the past years Ga-68-DOTANOC PET/CT is increasingly performed, which may lead to an increase in encountering incidentaloma. In 2022, a systematic review was published about incidentaloma on Ga-68-DOTANOC/DOTATE,

describing a prevalence of 4.5% and a relatively high rate of malignancy (13%). However, it was estimated that the overall prevalence was underestimated and the frequency of malignancy overestimated because of publication bias.
Methodology
The result of Ga-68-DOTANOC PET/CT's performed in adults between 2017 and 2022 in the Antwerp University Hospital were retrospectively screened for incidentaloma (= an increased, non-physiological uptake of the isotope, not related to the indication for imaging).
Results
1240 Ga-68-DOTANOC PET/CT's were performed in 804 subjects. In total, 127 incidentaloma were diagnosed in 115 subjects with a mean age of 64 ± 13 years and F/M ratio of 68/47. The most frequently reported locations of incidentaloma were the thyroid ($n=24$), brain ($n=23$) and prostate ($n=21$), followed by the spleen ($n=18$), breast ($n=12$), stomach ($n=8$), uterus ($n=4$), liver ($n=2$), pancreas ($n=2$), esophagus ($n=2$), kidney ($n=2$), ovarium ($n=1$) and mediastinum ($n=1$). In 33 (26%) incidentaloma no further investigations were performed. Rate of malignancy was 5% (3 breast cancers, 2 renal cell carcinomas and 1 prostate cancer). Increased isotope uptake in the brain, thyroid, prostate and spleen were most frequently caused by meningioma ($n=15$), benign nodules ($n=4$), benign prostate hypertrophy ($n=8$) and accessory spleen ($n=16$), respectively.
Conclusion
This is the largest single-center study describing the prevalence and etiology of Ga-68-DOTANOC incidentaloma to date. Evaluating the images of 804 subjects a prevalence of 16% was found which is higher than the prevalence of 4.5% earlier described in the systematic review of Bentestuen *et al*. The difference can be explained by the inclusion of accessory spleen in our study and the systematic review including studies focusing on incidentaloma in one specific organ. Incidentaloma were most frequently encountered in the thyroid (19%), followed by the brain (18%) and prostate (17%). The rate of malignancy in this study was 5%, which is lower than the rate of 13% described in the systematic review, possibly secondary to the inclusion of case reports with the tendency to publish the exceptional. No thyroid cancer was diagnosed in this study, however 67% of the thyroid incidentaloma did not underwent an ultrasound. With this abstract we want to stimulate other centers to publish their frequency of incidentaloma on Ga-68-DOTANOC PET/CT which may help in interpretation.

Comparison of existing guidelines on the perceived endocrine symptoms of breast cancer patients – preliminary results

Trine Lund-Jacobsen[1], Valdemar Mendez[1], Rasmus Jansen[1], Djordje Marina[1], Simone Marstrand[1], Kristian Buch-Larsen[1], Gabriella Martino[2] & Peter Schwarz[1]
[1]Copenhagen University Hospital, Rigshospitalet, Department of Endocrinolgogy and Metabolism, Copenhagen; [2]University of Messina, Department of Clinical and Experimental Medicine, Messina, Italy

Background
Through the decades, aromatase inhibitor maintenance therapy for patients with postmenopausal non-metastatic estrogen receptor-positive breast cancer has improved significantly. This study focuses on the patient's further breast cancer course and clarifies the extensive symptom burden that the endocrinologist should be aware of.
Aim
The study aims to gain insight into a potential gap between the endocrine symptoms outlined in guidelines versus the symptoms that the clinicians register in the medical records after the patients have expressed the symptoms at the consultations and in semi-structured interviews.
Methods
A Mixed-Method study. Symptoms were classified according to the National Cancer Institute (NIH) and clustered according to the European Organization for Research and Treatment of Cancer (EORTC) Quality of Life C30 (QLQ-C30) questionnaire (EORTC QLQ C30) and new domains (menopausal, body alteration, gastrointestinal, eye-, skin-, mouth- and sex-related). Patients with early breast cancer in follow-up treated with aromatase inhibitors (letrozole, exemestane or anastrozole) were included. Symptom registration was compared with the European Medicines Agency (EMA), the Food and Drug Administration (FDA), international and national guidelines for the standard evidence-based clinical practice: oncological (American Society of Clinical Oncology (ASCO), European Society for Medical Oncology (ESMO), Danish Breast Cancer Group (DBCG) and Danish Multidisciplinary Cancer Group (DMCG)) and endocrine societies (Endocrine Society, European Society of Endocrinology (ESE) and Danish Endocrine Society (DES)).
Results
Patients for the medical record audit were included over a recruitment period of 3 months ($n=23$). Single symptoms were identified by the NIH definition ($n=235$). Patients included in the semi-structured interviews ($n=19$). Single symptoms were identified by the NIH definition ($n=321$). Several symptoms identified in the medical records and interviews were also registered in the guidelines but described with different frequencies e.g., dry mouth. The breast cancer population and their symptoms were, however, not mentioned at all in best-practice endocrine guidelines and very few in some of the best-practice oncology guidelines.
Conclusion
Our results indicate that symptoms either are not outlined in the best practice guidelines or do not embrace the total patient-experienced symptoms as outlined by the physicians and patients with breast cancer. There seems to be a discrepancy between the frequency of various symptoms. Four domains: role functioning, social functioning, Global Health status/QOL, and sex-related symptoms found in medical record audits and patient interviews were exclusively absent from the guidelines. There is a need to implement the most frequent symptoms in national as well as international guidelines.

The lived experience of people with adrenocortical carcinoma

Phillip Yeoh, Wladzia Czuber-Douchan & Jackie Sturt
King's College London, Florence Nightingale Faculty of Nursing, Midwifery and Palliative Care, London, UK

Background
Adrenocortical carcinoma (ACC) is a rare and aggressive cancer of adrenal glands with an incidence worldwide around 0.7–2 cases per million per year in adult populations. The median age at diagnosis is 56 years old, with women and white Caucasians being more frequently affected. Overall median survival rate can be as low as 17 months with 5-year survival rate around 31.2%. Our systematic review identified the lack of qualitative study on the experiences of ACC. Consequently, an explorative approach using interpretative phenomenology couple with Van Manen hermeneutic methodology was used to explore the meanings of living with ACC. I have 24 years of immersion in looking after people living with ACC. This methodology allows me to use my experience, knowledge, and skills to make sense of people's experiences.
Aims
The study aims to investigate the lived experience of people diagnosed with ACC. The study objectives are: i) to understanding meaning and impact of ACC on physical, emotional, mental and psychological on people's wellbeing; ii) to understand how they manage their condition; iii) to find out their sources of help and support of living with ACC.
Method
Twenty-one participants living with ACC were purposively recruited and individually interviewed online using semi-structured questions. They were recruited from ACC support groups from US, Canada, UK, EU, Africa and Australia. The interviews were transcribed and analysed using thematic analysis. Five key main themes that emerged are: existential conundrums, inadequate care & support, life is like a roller coaster, anchoring ways for survival, living, and moving on. Lived time, lived space, lived body, and lived relation (van Manen 1997, 2014) will be used to gain insight into participants' experiences and inform future supports and interventions needed. Theory on survivorship by Mullan (1985) and Bowen Family System Theory (Kerr & Brown, 1988) were used to guide interview process to find the impact and meaning of ACC on people's lives. What the work means to the research area: The aim to improve understanding on the people with this condition so that further studies can be undertaken to improve the experiences and care pathways for them.

Endocrine autoimmunity during immunotherapy for cancer – a snapshot from an Oncologic Institute in Romania

Elena Lazar[1], Ioana Andreescu[2], Ana Lazar[3], Simona Coniac[3] & Corin Badiu[2,3]
[1]Institute of Oncology, Bucharest, Endocrinology, Bucharest; [2]National Institute of Endocrinology, Endocrinology IV, Bucuresti; [3]Carol Davila University of Medicine and Pharmacy, Bucharest

Background
In the last decade, immunotherapy proved to be the frontline in the fight against cancer in a rocketing area of cancer types. Boosting the body's inherent immune system, a new set of toxicities raised, labeled as immune-related adverse events (irAEs). Endocrine disorders, particularly thyroid dysfunctions, are by far the most frequent irAEs during immune checkpoint inhibitors (ICIs) therapy. New research data explored their predictive impact in cancer patients' overall survival. An in-depth endocrinological specific study was performed to evaluate endocrine irAEs caused by ICIs.
Methods
This is a retrospective analysis of endocrine irAEs from a cohort of cancer patients (mainly lung cancer and malignant melanoma) treated with ICIs in the Oncology Institute 'Prof. Dr. Alexandru Trestioreanu', Bucharest, Romania, from 1 October 2022 to 31 December 2023. The Institute endocrinologist assessed, followed and subsequently treated all the occurring endocrinopathies during immunotherapy. Endocrine irAEs were evaluated according to current medical practice based on routine clinical, biological and imaging criteria.
Results
Of 22 cancer patients that developed endocrine irAEs, we identified 5 cases of hypophysitis, 18 cases of thyroid disorder, 1 case of primary adrenal insufficiency, with one or more endocrine glands being affected. The anterior pituitary disorder involving several hormonal axes such as, thyroid, adrenal and gonadotropic deficiencies were common, with no proof of growth hormone deficit or hypoprolactinemia.
Conclusions
The expected increasing number of both malignancies and ICIs-treated cancer patients in the future exposes the endocrinologist face to face to a new area of pathology. Diagnosing and managing endocrine irAEs requires a collaborative effort between the oncologist and the endocrinologist to promote a better quality of life and a higher survival rate for cancer patients.

An apparently non-functional retroperitoneal SDHB-related paraganglioma

Ximena Carolina Vivas Vaca, Manuel Miguel Delgado Gómez, Ana Herrero Ruiz, Álvaro Valverde Márquez, Adriana Sofía Sánchez Velasco & María Teresa Mories Álvarez
Salamanca Health Care Complex, Endocrinology and Nutrition, Salamanca, Spain

Introduction
Paragangliomas (PGLs) are rare neuroendocrine tumors that arise from sympathetic or parasympathetic extra-adrenal paraganglia. PGLs have an extremely variable clinical presentation, depending on the localization, tumor size, catecholamine production, compressive symptoms, etc. Germline mutations in PGLs are associated in 30-35% of patients. Mutation in genes encoding the subunits of succinate dehydrogenase (SDH) leads to an increased risk of metastasis, specially SDHB mutation (35-75%). SDHB-related PGLs may be asymptomatic due to low tumoral catecholamine secretion or dopaminergic phenotype.
Case presentation
We report a case of 43-year-old man with no medical history or family history of interest, referred to our department for preoperative study. The patient presented a 4.1×5.2 cm retroperitoneal mass detected on CT scan for pain in the right groin. PGL was the first diagnosis suspicion. Laboratory tests showed 24-hour urinary excretion of normetanephrine, metanephrine and serum chromogranin A concentration within reference range. The patient underwent ^{123}I-MIBG scintigraphy with SPECT/CT that did not detect any functional lesion. Genetic testing was positive for heterozygous mutation in c.565Y>C p.(Cys189Arg) of the SDHB gen (there are 3 familial cases described). Laparotomy resection of the retroperitoneal mass was performed. Postoperative histopathological examination confirmed an extra-adrenal PGL of 4.5 cm. Lymph nodes were negative for malignant cells. During the follow-up, the patient remained well for 4 years (laboratory analysis and control CT were normal). Due to persistent pain in the right groin, laboratory tests and full body scan were carried out before the scheduled date. Surprisingly, significant elevation in 24-h urinary fractionated metanephrines [634μg/24-h (reference range <76 μg/24-h)] and 24-h urinary fractionated normetanephrine [3064 μg/24-h (reference range <444 μg/24-h)] were observed; 3-metoxitiramine and chromogranin were within the normal range. Control CT scan revealed a recurrent retroperitoneal tumor of 3.2×4.7 cm and two new masses (3.3×3.5 cm aortocaval and 1.4×1.9 cm duodenal). SPECT/TC with somatostatin analogue showed pathological accumulation in the described lesions. After alpha blockage with doxazosin, resection of the masses was performed and histopathological examination confirmed to be metastatic PGL. ^{68}Ga-DO TATATE PET/CT was carried out in order to consider metabolic therapy, which revealed increased uptake on the residual tumor post operatively.
Conclusions
– The clinical evolution observed in our patient, from non-functional to functional PGL and from localized to metastatic disease, shows us the unpredictable evolution of Cys189Arg mutation of the SDHB gen-related PGL.
– Our case demonstrates the importance of a rigorous follow-up of patients with SDHB-related PGL due to high metastatic potential.

Dual targeting Boolean logic gate CAR-T cells for selective tumor antigen encounter exert potent antitumor efficacy in advanced adrenocortical carcinoma

Marc Philipp Schauer[1,2], Andrea Stabile[2], Laura-Sophie Landwehr[1], Barbara Altieri[1], Martin Fassnacht[1,3], Justus Weber[2] & Michael Hudecek[2]
[1]University Hospital Würzburg, Department of Internal Medicine I, Division of Endocrinology & Diabetes, Würzburg, Germany; [2]University Hospital Würzburg, Department of Internal Medicine II, Center for Cellular Immunotherapy, Würzburg, Germany; [3]Comprehensive Cancer Center Mainfranken, University of Würzburg, Würzburg, Germany

Adrenocortical carcinoma (ACC) is a rare and aggressive endocrine malignancy that produces glucocorticoids in 60% of cases causing clinically relevant hypercortisolism. Since, we observed in another study, that shaping these immunosuppressive and life-threatining properties with corticosteroid inhibitors not only led to a glucocorticoid receptor-related downregulation of ROR1 but also to the upregulation of another promising membrane bound oncogenic antigen* (AG), we sought to investigate the role of a dual targeting approach using bispecific CAR-T cells in ACC. We initially evaluated AG-expression in a representative cohort of ACC samples ($n=62$) using qRT-PCR and immunohistochemistry (IHC) and show that the AG is sufficiently and homogenously overexpressed in human ACC tissues ($P<0.001$). Moreover, it is strongly associated with a poor median overal survival ($Chi^2=6.207$, $P=0.013$) and disease progression ($Chi^2=5.485$, $P=0.019$). We further demonstrate high levels of AG-expression in four different ACC cell lines using qRT-PCR and qFACS-analysis. To evaluate the interplay between ROR1 and AG we used Duolink technology, RNA-Nanostring nCounter sequencing, qRT-PCR and IHC. While observing a strong downregulation of ROR1 after corticosteroid inhibitor treatment on the one hand, we demonstrate a strong increase of AG-expression after different doses of metyrapone (21-fold change, $P=0.003$) and ketoconazole (35-fold change, $P<0.001$) on the other (values are shown for NCI-H295R cell line, respectively). Next, we used non-viral sleeping beauty transposons and CRISPR/Cas9 to generate different mono- and bispecific CAR-T cells targeting ROR1 and AG and evaluated their antitumor functionality *in vitro*. We observed potent antitumor efficacy, cytokine release and proliferation upon antigen contact of all different CAR-T cell modifications. To maintain T cell functionality, to prevent CAR-T cell tonic signalling and to reduce on-target off-tumor toxicities (OTOT) by aiming two antigens, we also attempted to apply Boolean logic gating to our CAR-T cells to prevent toxicity in healthy tissues that express very low levels of one of our two antigens. We exploited the approach of a new way of CAR engineering using co-opted intracellular proximal T cell signalling molecules that can be repurposed into surface receptors demonstrating no OTOTs of CAR-T cell function in single antigen positive tissue *in vitro*. Our preliminary data demonstrate an interplay between two CAR-T cell targets which can be used for a combined treatment approach with steroid inhibitors. We also show Boolean logic gating as novel and potentially safer approach of CAR-T cell engineering in advanced ACC. *The investigated antigen will be kept confidential because of patent law reasons.

Alteration in the molecular components of machinery that regulate gene expression mechanisms and genomic stability in thyroid cancer and their association with tumour behaviour and/or clinical features

Andrea Martínez Vara[1,2], Francisco Porcel Pastrana[1,2,3,4], Isidoro Di-Caro[1,2,3], André Sarmento-Cabral[1,2,3,4], Rafael Sánchez Sánchez[2,3], Ana Romero Lluch[5], Pilar Santisteban[6], Elena Navarro González[5], María A Gávez Moreno[1,2,3], Raúl M Luque[1,2,3,4] & Antonio J Martínez Fuentes[1,2,3,4]
[1]Maimónides Institute for Biomedical Research of Córdoba (IMIBIC), Córdoba, Spain; [2]Universidad de Córdoba, Biología Celular, Fisiología e

Inmunología, Córdoba, Spain; [3]Reina Sofía University Hospital (HURS), Córdoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Córdoba, Spain; [5]Servicio de Endocrinología y Nutrición, Hospital Virgen del Rocío, Sevilla, Spain; [6]Instituto de Investigaciones Biomédicas "Alberto Sols", Consejo Superior de Investigaciones Científicas; Universidad Autónoma de Madrid (CSIC-UAM) and Centro de Investigación Biomédica en Red de Cáncer (CIBERONC), Instituto de Salud Carlos III (ISCIII), Madrid, Spain

Emerging evidence indicates that the cellular machineries controlling gene expression mechanisms and genomic stability are altered in several endocrine-related cancers (ERCs), leading to some oncogenic events associated with tumour progression/aggressiveness. However, whether this phenomenon also occurs in thyroid cancer has not been yet explored. Therefore, this study was focused on: 1) investigating the potential alteration in the levels of components of the molecular machineries that control either RNA metabolism [Splicing machinerie, RNA-Exosome complex, Non-sense Mediated Decay (NMD)] or genomic stability (shelterin-telomerase) in clinically well-characterized human papillary and medullary thyroid cancer samples compared to its adjacent non-tumour tissue; and, 2) whether these alterations might be associated with relevant clinical parameters. Results revealed a clear dysregulation of several components of these machineries in papillary and medullary thyroid cancer samples, wherein the expression of specific components was associated with key clinical parameters. Based on these results, we explored different functional (e.g. proliferation, migration, and tumour-spheres and colonies formation) and mechanistic (gene expression/signalling pathways) assays in human thyroid cancer cell models (TCP1 and Cal62). In general, these *in vitro*studies revealed that different molecular components of splicing, RNA-exosome, NSMD and telomerase machineries significantly modulated cell aggressiveness features in thyroid cancer cells. Moreover, we targeted the key splicing-factor-3B-subunit-1 component (SF3B1; a core component of the splicing machinery) with the specific inhibitor pladienolide B as well as with a specific siRNA to carry out the silencing of SF3B1 expression. Results revealed that both pladienolide-B treatment and the silencing of SF3B1 significantly decreased different aggressiveness parameters (proliferation, migration, tumour-spheres and colonies formation) in thyroid cancer cells, thus confirming the critical role of SF3B1 and consequently, of the splicing machinery, in thyroid pathophysiology. Altogether, our data demonstrate a drastic dysregulation of the key components of the molecular machineries controlling gene expression mechanisms and genomic stability (particularly splicing) in papillary and medullary thyroid cancer samples that might be associated to the tumorigenesis of this ERC. In particular, the genetic and/or pharmacological inhibition of SF3B1 may represent a promising novel therapeutic strategy worth to be explored through randomized controlled trials that could improve the outcome of patients affected by clinically aggressive thyroid cancer.

Clinical characteristics and survival of patients with functional pancreatic neuroendocrine tumors

Bojana Popovic, Sanja Ognjanovic, Dusan Ilic, Valentina Elezovic Kovacevic, Milica Opalic Palibrk, Lena Radic, Katarina Krstic, Marijan Micev & Djuro P Macut
University Clinical Centre of Serbia, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Beograd, Serbia

Aim
Functional neuroendocrine tumors (NETs) represent a specific diagnostic and therapeutic challenge, since hormonal clinical syndrome can severely complicate clinical picture and affect treatment. Our aim was to analyze characteristics and survival of functional pancreatic NETs.
Materials and methods
We retrospectively analyzed data from 272 patients with pancreatic NETs treated at our department from the year 2005 till 2023. The patients underwent standard radiological, pathohistological and hormonal evaluation. All tumors were graded according to current ENETS guidelines. Disease stage was defined according to the ENETS/AJCC TNM staging system. Differences between continuous variables were analyzed by non-parametric tests and differences between frequencies by χ^2-test. Overall survival was analyzed by Kaplan–Meier method, and differences by Cox-regression analysis. Statistical analysis was performed by SPSS software.
Results
Functional tumors were diagnosed in 61 patients (22.4%): 24 insulinomas (8.7%), 11 serotoninomas (18%), 8 gastrinomas (13.1%), 6 patients with ectopic Cushing's syndrome (9.8%), 3 patients PTHrP secretion (4.9%), 2 glucagonomas (3.3%), and 1 VIP-oma (1.6%), while the remaining 6 patients had combinations of 2 or more aforementioned hormonal hypersecretions. Majority of functional NETs were well differentiated (NET G1 29.5%, NET G2 41.0%, NET G3 13.1%, NEC G3 1.6%, MiNEN 1.6%), and better differentiated compared to nonfunctional NETs ($P=0.018$). Functional tumors were significantly smaller ($P<0.05$), more related to MEN1 syndrome ($P=0.005$), and with lower disease stage than nonfunctional ($P=0.011$). Median overall survival of functional NETs was 104.0 months (95%CI 100.2–206.8). This was not different to nonfunctional tumors ($P=0.259$), except that NET G3 functional NETs had a tendency towards shorter survival. There was significant difference in survival within a group of functional NETs ($P<0.05$), with patients with insulinomas having the longest, and patients with ectopic Cushing's syndrome having the shortest survival. Patients with insulinomas had significantly longer survival when compared to nonfunctional NETs overall ($P=0.013$), but this was due to insulinomas being exclusively grade G1 and G2 (55.6% and 44.4% respectively), and of lower stage (SI and SII 73.7%). When G1 and G2 insulinomas were compared to respective nonfunctional tumors, there was no significant difference in survival ($P=0.326$ and $P=0.909$ respectively). On the other hand, patients with ectopic Cushing's syndrome had significantly shorter survival compared to nonfunctional NETs irrespectively of grade or stage ($P=0.008$ and $P=0.007$ respectively).
Conclusion
Almost one quarter of patients with pancreatic NETs have a recognizable hormonal syndrome. Despite some more favorable features compared to nonfunctional tumors, certain hormonal profiles independently affect survival.

Basal calcitonin and calcium gluconate test in suspect medullary thyroid carcinoma: Are we expecting too much from stimulated calcitonin?

Renato Diana[1], Erika Grossrubatscher[2], Renato Cesare Cozzi[2], Paolo Dalino Ciaramella[2] & Iacopo Chiodini[1,2]
[1]University of Milan, Department of Biotechnology and Translational Medicine, Milan, Italy; [2]Ospedale Niguarda Ca' Granda, Endocrinology Unit, Milan, Italy

Introduction
Basal calcitonin (bCT) and calcium-stimulated calcitonin (sCT) levels are useful in the management of Medullary Thyroid Cancer (MTC). Nowadays several bCT/sCT cut-offs have been proposed but univocally accepted values are still lacking. We identified gender-specific CT cut-offs in a series of patients who performed calcium gluconate test at our Centre.
Methods
Our study includes a total of 35 patients (12 males and 23 females) with thyroid nodules and biochemical suspect of MTC that performed calcium gluconate test from 2017 to 2023 and underwent total thyroidectomy according to available sCT cut-off reported in literature (until 2020 in males bCT 68 pg/ml, sCT 544; in females bCT 26, sCT 79; since 2021 in males bCT 34, sCT 466; in females, bCT 30, sCT 79). Patients with RET gene mutation were excluded. We compared bCT and sCT levels with histological results in order to define best internal cut-offs to predict diagnosis of MTC.
Results
The best cut-offs of bCT and sCT for the diagnosis of MTC were: >29.6 pg/ml (Sensitivity, Sn 85.7%, Specificity, Sp 100%, Diagnostic accuracy, DA 91.6%, $P<0.0001$) and >1242 pg/ml (Sn 57.1%, Sp 100%, DA 75%, $P=0.12$) in males; >14.6 pg/ml (Sn 100%, Sp 90%, DA 95.6%; $P<0.0001$) and >442 pg/ml (Sn 61.5%, Sp 90%, DA 73.9%, $P=0.08$) in female. According to these cut-off values, bCT was able to identify MTC in 100% of females and 85.7% of males (one male case of MTC with both negative bCT and sCT underwent total thyroidectomy for symptomatic goitre). With bCT we didn't have false positive cases in males and we had one false positive case in females. Conversely, sCT showed an inadequate diagnostic accuracy and a non-negligible risk of misdiagnosis. If we had applied only sCT cut-offs in order to decide for surgery, we would have had missed 7 patients with MTC (2 males, 5 females). Indeed, these patients had positive bCT and negative sCT and underwent thyroidectomy according to available sCT cut-off at the time of surgery.
Conclusions
In our series bCT had higher diagnostic accuracy than sCT for diagnosis of sporadic MTCs. Stimulated test seems to provide no diagnostic improvement as compared to bCT and, given its low sensitivity, it may lead to miss some MTCs cases that could be correctly identified by bCT.

Cell cycle regulation in parathyroid adenomas and multiglandular parathyroid disease: Similarities, differences and heterogeneity

Romans Uljanovs, Boriss Strumfs & Ilze Strumfa
Riga Stradins University, Department of Pathology, Riga, Latvia

Background
Primary hyperparathyroidism represents the third most common endocrine pathology. Recently, the morphological classification of underlying parathyroid lesions underwent significant alterations: the former primary parathyroid hyperplasia was reclassified as multiglandular parathyroid disease (MPD), a term that is in line with clonality studies and surgeons' needs; and the entity of atypical parathyroid tumour was separated from adenoma. Although the diagnostics of hyperparathyroidism is largely dependent on laboratory and radiological findings, pathological investigation of surgically removed glands can help to verify the diagnosis, to reach it in difficult cases and to assess the pathogenesis.
Aim
The **aim** of our study was to evaluate expression of cell cycle and apoptosis-related proteins in parathyroid adenoma and MPD in comparison to unequivocal parathyroid carcinoma and normal/atrophic glands.
Materials and methods
Expression of Ki-67, p21, p27, cyclin D1 and Bcl-2 were detected by immunohistochemistry and quantified (%) in adenomas (102) and MPD (27), compared to carcinoma (5) and normal glands (45). Descriptive statistics, Kruskal–Wallis test with Bonferroni correction and Mann–Whitney test were applied.
Results
The mean fraction of Ki-67 was 1.6% in adenomas and 1.0% in MPG, contrasting with 0.4% in normal glands and 5.8% in carcinoma; the highest values were in parallel: 3.4% vs 2.8% vs 1.0% vs 11.8%. p21 protein showed the highest expression in MPD (mean 15.7%; highest 29.8%), followed by adenoma (12.8%; 23.7%), carcinoma (7.6%; 15.6%) and normal glands (3.1%; 3.8%). Cyclin D1 levels in MPD (24.5%; 42.5%) exceeded the expression in adenoma (21.0%; 22.8%) although the levels were highest in carcinoma (31.5%; 41.8%) and low in normal tissues. Loss of p27 was significant only in carcinomas (59.0%), contrasting with 92.8% in adenomas, 94.3% in MPD and 97.9% in normal tissues. Similarly, loss of BCL2 was notable in carcinoma (28.2%), compared to adenoma (66.7%), MPD (61.3%) and normal glands (75.6%). Notably, nuclear markers showed remarkable heterogeneity by dense clusters of positive cells. Across all groups, significant differences were disclosed regarding the mean and highest fraction of Ki-67 (both $P<0.001$), p21 (both $P<0.001$), cyclin D1 ($P=0.02$) and p27-expressing cells ($P=0.010$). In contrast, adenomas, compared to MPD, featured higher proliferation but lower cyclin D1 levels; these groups did not differ by p27 and Bcl2.
Conclusion
The immunophenotype shows enhanced proliferation along with regulatory similarities between adenoma and multiglandular parathyroid disease, indicating pathogenetic links. Expression of cell cycle-related proteins in hyperfunctioning parathyroid tissues shows remarkable heterogeneity by dense clustering of positive cells, suggesting paracrine signalling mechanisms.

Long-acting starch (Glycosade(R)): An effective treatment for insulinoma-induced hypoglycemia – A case report

Karen Andrea Castillo Arias, Diego Duminy, Mireia Mora, Clara Viñals, Felicia A Hanzu, AIDA OROIS & Adriana Pane
Hospital Clínic Barcelona, Barcelona, Spain

Introduction
Insulinoma is a rare, generally benign neuroendocrine tumor, primarily manifesting as hypoglycemia in non-diabetic patients. Although surgery is the gold standard treatment for insulinoma, managing hypoglycemia becomes challenging in cases where surgery is not feasible. This challenge arises due to significant side effects that often limit the use of most drugs and therapeutic alternatives.
Case report
A 90-year-old non-diabetic man was admitted to our hospital for study due to unexplained recurrent symptomatic hypoglycemia. After excluding common causes of outpatient hypoglycemia, a post-fasting blood test revealed endogenous hyperinsulinism with blood glucose at 2.4 mmol/l, insulin at 9.6 µIU/ml (66.6 pmol/l, elevated), proinsulin at 14.6 pmol/l (elevated), and C-peptide at 2.31 ng/ml (0.76 nmol/l, elevated). Anti-insulin antibodies were negative, and urinary sulfonylurea determination was also negative. An abdominal CT scan identified a 15-mm solid nodular lesion in the tail of the pancreas. A gallium-68-tetraxetane Tyr3-octreotate PET-CT scan indicated that the mass had a maximum normalized uptake value of 19.22 and expressed somatostatin receptors 2 and 5, confirming the diagnosis of insulinoma. Due to the patient's high surgical risk, conservative medical management was chosen. Upon admission, intravenous dextrose treatment was initiated. After confirming the suspicion of insulinoma, low doses of diazoxide were attempted. However, due to the development of symptoms such as heart failure, lower limb edema, and hyponatremia upon increasing the diazoxide dose, a dietary approach took priority. The use of modified corn starch in fractionated doses, guided by continuous glucose monitoring, was introduced.
Discussion
There is limited evidence supporting the use of glycosade to treat hypoglycemia in insulinoma. Glycosade, a modified corn starch with slower absorption than normal corn starch, is employed in patients with glycogenosis to prolong the time between meals. Given its absorption profile, ease of administration, minimal short-term side effects, and relatively low cost, we consider it a valuable dietary alternative for controlling hypoglycemia. This is especially relevant today, as continuous glucose monitoring allows for a more accurate estimation of each patient's hypoglycemia pattern. This approach proves particularly applicable in patients who are inoperable, frail, and at high risk of adverse effects from traditional medical therapies.

The intrinsically disordered activation function 1 of Progesterone receptor is involved in the dynamics of the receptor complex

Pheck Khee Lau[1], Shi Hao Lee[1], Chew Leng Lim[1], Qian Yee Woo[1], Amanda Woo[1] & Valerie Lin[1,2]
[1]School of Biological Sciences, Nanyang Technological University, Singapore, Singapore; [2]Nanyang Technological University, School of Biological Sciences,, Singapore, Singapore

Progesterone receptor (PgR) is critically involved in the development of the mammary gland and the uterus in response to progesterone. It is also implicated in cancer development of these organs. An in depth understanding of how it works is pivotal for developing therapeutic interventions. PgR is a member of the nuclear receptor superfamily of transcription factors with conserved domain structures. Its transcription activity is mainly mediated by the activation function 1 (AF1) in the disordered N terminal domain (NTD) and the highly structured activation function 2 (AF2) in the ligand binding domain (LBD). It is established that AF2 forms coregulator binding interface upon ligand binding. But little is known about how AF1 works. We identified 3 critical AF1 residues K464, K481 and R492 that can be monomethylated. Mutations of these three residues to phenylalanine (KKR/FFF) largely abolished PR activity in reporter gene assay but increased AF1 interactions with coactivator SRC1 and AF2. We further determined the effect of AF1 mutations on PR regulation of cell growth, adhesion and global gene expression in MCF-7 cells stably expressing the Wt PRB or the AF1 mutant. It was found that KKR/FFF mutations significantly impaired the effect of PR on cell proliferation and cell spreading. RNA-Seq analysis revealed that the KKR/FFF mutation considerably impaired PR regulated gene expression in 40% of the genes, which included most of the well characterized PR target genes. Importantly, the impaired gene regulation by KKR/FFFF mutant is not associated with a reduced enhancer/promoter occupancy. Considering stronger interactions of AF1-KKR/FFF with AF2 and coactivator SRC1, our data lend support to the tripartite relationship among AF1, AF2 and coregulators, in which AF1 plays a key role in modulating dynamics of PgR transcription complex.

Introduction
Survival rates for ovarian cancer remain distressingly low. Despite established prognostic factors, the need for identifying modifiable parameters to influence survival outcomes is imperative. Overweight and obesity, prevalent conditions, have been implicated in cancer development and potentially poor survival. However, conflicting data on the association of Body Mass Index (BMI) with Progression-Free Survival (PFS) and Overall Survival (OS) in ovarian cancer patients necessitate further exploration.
Aim
This study aims to investigate the prognostic role of BMI before chemotherapy in women with ovarian cancer, specifically focusing on PFS and OS.
Patients and methods
A retrospective analysis encompassed 1136 patients diagnosed with ovarian carcinomas between 1995 and 2018. Patients were categorized based on BMI at presentation, and a comprehensive examination of clinicopathological, treatment, and survival data was conducted.
Results
In the patient population, normal weight patients (BMI < 25 kg/m^2) demonstrated a median PFS of 12.8 months (95% CI 11.7–13.9 months), while overweight/-obese patients (BMI ≥ 25 kg/m^2) exhibited a significantly longer median PFS of 14.9 months (95% CI 13.6–16.4 months, $P=0.006$). No statistically significant difference was noted in median OS between the two BMI groups. Subgroup analysis for different histological subtypes revealed a statistically significant benefit for overweight and obese patients with serous and endometrioid histology (mPFS 12.9 months, 95% CI 11.7–14.0 vs 15.6 months, 95% CI 13.9–17.3, $P=0.012$ and 14.6 months 95% CI 13.7–15.5 vs 25.6 months, 95% CI 9.5–41.7, $P=0.031$, respectively). Additionally, BMI ≥ 25 kg/m^2 demonstrated a significant advantage in advanced-stage disease.
Conclusions
The study underscores the intricate association between BMI and ovarian cancer prognosis. While PFS demonstrated a significant difference between BMI groups, OS did not exhibit such disparity.

Cystic mediastinal lesions as presenting manifestation of papillary thyroid cancer

Eleana Zisimopoulou, Maria Boudina, george christantoniou, Chrysanthi Zouli, Mariana Stamati, aimilia fotiadou, chrysanthi balodimou & Alexandra Chrisoulidou
Theagenio Cancer Hospital, Endocrinology, Thessaloniki, Greece

Background
Distant metastasis, as the initial manifestation of papillary thyroid cancer (PTC), is uncommon. Here, we present two unusual cases of large cystic mediastinal lesions, with histology indicative of metastasis from PTC as first diagnosis.
Case presentation
We present two male patients, aged 46 and 50 years old, who were referred to our department. The first patient, complained of persistent cough and underwent a thorax CT which revealed a large 10 cm cystic mass. Due to compressive symptoms, he underwent surgical excision of the cystic mass. The histopathology revealed neoplastic cells in the lining of the cyst, with positive immunohistochemistry for TTF-1 and PAX-8. Additionally, two lymph nodes were found in the surrounding fat tissue, constituted of cells of epithelial origin, positive in thyroglobulin (Tg), TTF-1 and PAX-8. The second patient presented with similar symptoms (persistent cough, shortness of breath in minimal exercise) and underwent a thorax CT. A large cystic mass of 8.2 cm was revealed in the mediastinum, which was surgically removed. The histopathology identified a cyst with peripheral lymphocytes and the presence of two neoplastic lesions in the surrounding fat tissue, consisting of epithelial cells with papillary architecture and positive immunochemistry in Tg and TTF-1. The work-up that followed included imaging of the thyroid by ultrasound, identification of suspicious lesions and total thyroidectomy. In the first case, a 6.7 cm PTC of tall cell variant was revealed. In the second case, the histopathology indicated a multifocal PTC metastatic to cervical lymph nodes. They both received a therapeutic dose of radioidine ablation (100 mCi). Imaging, six months after the diagnosis, did not reveal any further metastases. At present, nearly a year after operation, both patients receive thyroxine suppression therapy and are on close monitoring including measurement of thyroglobulin levels, thyroid ultrasound and thorax CT imaging.
Conclusions
In the literature, mediastinal lesions related to thyroid cancer are uncommon. However, thyroid cancer may present with extracervical manifestations such as mediastinal lesions, which probably represent the cystic degeneration of mediastinal lymph nodes. Therefore, thyroid cancer may be a part of the differential diagnosis of cystic mediastinal lesions.

Immunohistochemical profiling of HIF-2α and SSTR2 with the tumor microenvironment in metastatic pheochromocytoma and paraganglioma

Masaki Uchihara[1,2], Akiyo Tanabe[1], Yuki Kojima[2], Tatsunori Shimoi[2], Akiko Maeshima[2], Kotaro Umamoto[1], Eijiro Nakamura[2], Akihiko Shimomura[1], Chikako Shimizu[1], Kan Yonemori[2] & Hiroshi Kajio[1]
[1]National Center for Global Health and Medicine; [2]National Cancer Center Hospital

Introduction
Metastatic pheochromocytomas and paragangliomas (PPGLs) are rare endocrine malignancies with limited effective treatment options. Immunotherapy, a breakthrough in oncology, is effective in some cases of PPGLs; however, the response rate remains limited. Therefore, one strategy to improve immunotherapy is combining drugs with different action mechanisms and target resistance. The association between the tumor microenvironment (TME), including tumor-associated macrophages (TAMs) with hypoxia-induced factor-2α (HIF-2α) and somatostatin receptor 2 (SSTR2) in PPGLs, is critical for optimizing combination therapeutic strategies with immunotherapy, remains largely unexplored.
Methods
We analyzed the expression of HIF-2α, SSTR2A, and TME components, including tumor-infiltrating lymphocytes (CD4 and CD8), TAMs (CD68 and CD163), and PD-L1, using immunohistochemistry in patients with PPGLs. We also evaluated the association between these biomarkers, the prognosis, and the response to systemic chemotherapy.
Results
Among 45 patients with PPGLs, HIF2α and SSTR2A were positively expressed in 14 (31.1%) and 21 (46.7%) patients, respectively. Positive correlations were observed between CD4, CD8, CD68, and CD163 levels. A negative correlation was found between the CD163/CD68 ratio (an indicator of M2 polarization TAMs) and SSTR2A expression ($r=-0.385$, $P=0.006$), with a stronger correlation in metastatic cases ($r=-0.535$, $P=0.009$). HIF-2α expression positively correlated with PD-L1 IHS ($r=-0.348$, $P=0.013$). The co-expression of PD-L1 (IHS > 10) and HIF-2α was found in seven patients (15.6%). In light of the negative correlation between SSTR2A and the CD163/CD68 ratio, our analysis assessed the time of tumor progression across the four groups based on these parameters. All 11 patients in the low CD163/CD68 ratio and the negative expression of the SSTR2A group showed no progression or detection of metastasis. No association was observed between HIF-2α positivity, CD163/CD68 ratio, and response to CVD chemotherapy.
Conclusion
We found a negative association between M2 polarization TAMs and SSTR2A expression in PPGLs. We also observed a relationship between high PD-L1 expression and increased HIF-2α expression. Our data provides the potential of combination therapy with immunotherapy and peptide receptor radionuclide therapy or HIF-2α inhibitors as a treatment option in selected PPGL populations.

The impact of primary tumor site on clinical manifestation and prognosis of ectopic Cushing's syndrome (ECS). Do pulmonary neuroendocrine tumors stand out?

Aleksandra Gamrat[1,2], Mari Minasyan[1], Maria Aleksandra Komisarz-Calik[1], Ewelina Rzepka[1], Joanna Paleń-Tytko[1], Marta Opalinska[1], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]

[1]Jagiellonian University Medical College, Chair and Department of Endocrinology, Kraków, Poland; [2]Jagiellonian University Medical College, Doctoral School of Medical and Health Science

Introduction
Ectopic Cushing's syndrome (ECS) is a rare disease with limited and error-prone published data on the epidemiology, clinical presentation and diagnosis of ECS.
Objectives
This study aims to examine the clinical course of patients with ECS in relation to the primary tumor localization.
Methods
Thirty-five consecutive ECS patients at a tertiary clinical center were analyzed. The clinical, biochemical (including CRH/desmopressin tests/BIPSS in selected cases) and imaging (CT/MRI, somatostatin receptor imaging, and FDG PET/CT) assessment were performed. Three patients with SCLC were excluded from further analysis.
Results
The primary lesion was identified in 28/32 patients. Neuroendocrine tumor (NET) constituted 47% of all ECS (60% gastroenteropancreatic (GEP-NETs), 40% thoracic (1 thymic and 5 pulmonary carcinoids (PC)). The median follow-up was 12 months, in the PCs was significantly higher compared to the GEP-NETs (54 vs 11 months). There were 18 deaths (56.25%). In patients with PC, 1 patient died due to pulmonary embolism, while in the GEP-NETs 8(89%) patients died due to disease progression. In patients with disseminated disease 1 patient underwent chemotherapy, 4 were treated surgically, 4 with PPRT. 5/6 of PCs underwent radical surgical treatment, all were treated with steroidogenesis inhibitors. There was a significant difference in the mean age at diagnosis between women and men ($F=64.25$ vs $M=51.06$ years, $P=0.02$). The dominant clinical feature for the entire group were muscle weakness (78.13%) and edema (62.5%). Typical changes in appearance characteristic of Cushing's syndrome occurred in 6(16%) of patients, in 4/5 PC. PCs comparing to other ECSs showed more frequently striae (80% vs 14.81%, $P=0.003$), fat tissue redistribution (80% vs 51.85%, $P=0.10$). No PC experienced weight loss, observed in 11(47.4%) others ECSs ($P=0.05$). The median nocturnal serum cortisol was higher in patients with NETs compared to other ECSs (61 vs 25.5 μg/dl, $P=0,058$). In the GEP-NETs, the median concentration of both morning cortisol (71 vs 42 μg/dl, $P=0.02$) and midnight cortisol (64 vs 25.5 μg/dl. $P=0.008$) was higher than in other ECSs. In PCs, there was a strong correlation between the midnight serum cortisol and the severity of hypocalcemia (Spearman's coefficient -0.90, $P<0.05$), which was not present in GEP-NETs.
Conclusion
The clinical picture of ECS is highly variable. PCs tend to display more prevalent classic symptoms of CS and notably extended survival times compared to other ECSs. Further studies are needed to understand the natural history of ECS and to improve the diagnosis and treatment outcomes of this rare disease.

Once-daily oral paltusotine in the treatment of patients with carcinoid syndrome: interim results from a phase 2, randomized, parallel-group study

Aman Chauhan[1], Amr Mohamed[2], Keith Usiskin[3], Cosina Mui[3], Joseph Dillon[4], Xiaolin Fan[3], Shagufta Shaheen[5], Juan Manuel O'Connor[6], Simron Singh[7], Hjalmar Lagast[3] & Alan Krasner[3]
[1]University of Kentucky Healthcare, Lexington, USA; [2]University Hospital, Case Western Reserve University, Cleveland, USA; [3]Crinetics Pharmaceuticals, San Diego, USA; [4]University of Iowa, Carver College of Medicine, Iowa City, USA; [5]Stanford Medicine, Stanford, USA; [6]Instituto Alexander Fleming, Buenos Aires, Argentina; [7]Sunnybrook Health Sciences Center, Toronto, Canada

Background
Carcinoid syndrome (CS), the most common functional neuroendocrine tumor (NET) syndrome, is characterized by watery diarrhea or cutaneous flushing. While somatostatin receptor ligand (SRL) depot injections are mainstay treatments for CS, discomfort with injections and inadequate symptom relief at labeled doses are seen with many patients. Paltusotine is an investigational once-daily, oral, selective SST2 agonist in development for the treatment of acromegaly and CS. In patients with acromegaly, paltusotine has been shown to maintain IGF-I control at levels similar to those for injected depot SRLs.
Methods
This ongoing open-label, multicenter study examines the safety, tolerability, pharmacokinetics, and exploratory efficacy of paltusotine in the treatment of patients with CS. Eligible patients had documented, well-differentiated, grade I or II NETs with CS. Patients who were actively symptomatic (average of ≥ 4 BMs per day or >2 flushing episodes per day in ≥ 2 days over a 2-week period) and naïve to SRL therapy, or patients with symptom control on SRLs and demonstrated symptom worsening after SRL washout, were randomly assigned to receive 40 mg or 80 mg of once-daily oral paltusotine for 8 weeks. Safety assessments included adverse event (AE) monitoring, clinical laboratory tests, physical examinations, vital signs, and electrocardiograms. Exploratory efficacy was assessed using a daily electronic symptom diary.
Results
This interim analysis includes 16 patients who received paltusotine and had been in the study long enough to complete the randomized treatment period. Mean age was 61 years; 56% of patients were female. Six patients were naïve to SRL therapy and 10 were previously controlled on SRLs. Four patients met the entry criteria for flushing only, 6 for BM only, and 6 for both. One patient discontinued prior to the end of randomized treatment. At Week 8, mean reduction from baseline in daily BM frequency was -1.3 and in daily flushing frequency was -2.2. Mean decrease in daily frequency of urgent BM episodes was -0.6; mean decrease in flushing severity (worst flushing score, rated on a scale from 0 to 10) was -2.9. Four patients had their paltusotine dose increased during the randomized treatment period. There were no serious AEs considered related to study treatment and no AEs leading to discontinuation. No new safety signals were identified.
Conclusions
Interim data from this phase 2 study suggest that oral paltusotine controls the symptoms of CS and is well tolerated.

Early detection of recurrence and progress using serum steroid profiling by LC–MS/MS in patients with adrenocortical carcinoma

Otilia Kimpel[1], Barbara Altieri[1], Ulrich Dischinger[1], Carmina Fuss[1], Max Kurlbaum[1,2] & Martin Fassnacht[1,3]
[1]University Hospital, University of Würzburg, Germany, Division of Endocrinology and Diabetes, Dept. of Medicine,, Würzburg, Germany; [2]Core Unit Clinical Mass Spectrometry, Central Laboratory, University Hospital Würzburg, Germany; [3]Comprehensive Cancer Center Mainfranken, University of Würzburg, Germany

Background
Serum liquid chromatography–tandem mass spectrometry (LC–MS/MS) steroid profiling is used for the diagnosis of adrenocortical carcinoma (ACC). Guidelines recommend endocrine work-up in addition to radiological imaging for follow-up in ACC, but data on this topic are scarce.
Aim
To retrospectively investigate an earlier detection of a recurrent or progressive disease by using endocrine follow-up with LC–MS/MS measurements in comparison to radiological imaging.
Methods
Patients were included in this retrospective study if pre-therapeutic hormone values, regular tumour evaluation by imaging, steroid measurements by LC–MS/MS, and details on therapies were available. The utility of steroid profiles in detecting recurrence or disease progression was assessed, whereby 'endocrine progress' was defined by elevation of at least 3 of 13 analysed hormones.
Results
Patients were divided in two cohorts. Cohort A included 47 patients after R0 resection, of whom 15 experienced recurrence and 32 did not. In cohort B, 52 patients with advanced disease (including 7 patients of cohort A with recurrence) could be evaluated on 74 visits when progressive disease was documented. In 20 of 89 cases with documented recurrence and disease progression, 'endocrine progress' was detectable prior radiological progress. In these cases, recurrence/-progression was detected in median 32 days earlier by steroid measurement than by imaging, with 11-deoxycortisol and testosterone being the most sensitive markers. In 25/89 cases, no steroid hormones were elevated although a recurrence or a progressive disease was confirmed by radiologic imaging, whereas the remaining 44/89 cases did either have only 1–2 elevated steroids or the altered hormone pattern was only detected at the time, when the progress was also documented by imaging. In only 5/89 patients (5.6%) with recurrent or progressive disease an 'endocrine progress' (defined by at least 3 elevated steroids) was falsely diagnosed. Finally, patients with an early detection of a recurrence or a progression were compared to patients without reliable elevated steroid hormones. We saw a significant difference in the documented tumour mass in patients with or without an early detection (11.4 cm vs 7.4 cm; $P=0.039$). Mitotane could have an influence on steroid elevation since one third of patients without a clear steroid elevation had a mitotane plasma level above 14 mg/l, whereas this was only the case in 10% with an earlier 'endocrine progress' ($P=0.034$).

Conclusion
In conclusion, steroid profiling by LC–MS/MS is of value in detecting recurrent/progressive disease in ACC especially in patients with significant tumour volume.

Catching the silent culprits: Prospective TERT promoter mutation screening for minimally invasive follicular and oncocytic thyroid carcinoma in clinical practice

L Samuel Hellgren[1,2], Adam Stenman[3,4], Catharina Larsson[1,2], Jan Zedenius[3,4] & C Christofer Juhlin[1,2]
[1]Karolinska Institutet, Department of Oncology-Pathology, Stockholm, Sweden; [2]Karolinska University Hospital, Department of Pathology and Cancer Diagnostics, Stockholm, Sweden; [3]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden; [4]Karolinska University Hospital, Department of Breast, Endocrine Tumors, and Sarcoma, Stockholm, Sweden

De-escalation of thyroid cancer treatment is crucial to prevent over-treatment of indolent disease. However, it also underscores the importance of identifying potential clinically aggressive cases that require completion lobectomy and adjuvant radioiodine therapy. *TERT* promoter mutations are molecular events closely associated to high-risk thyroid tumors with poor outcome, and may serve as markers for cases at risk of dissemination. In various international guidelines, minimally invasive follicular thyroid carcinoma and oncocytic thyroid carcinoma (miFTC/miOTC) measuring less than 2 cm (pT1a/1b) are classified as low-risk lesions. The Swedish national guidelines recommend no additional treatment beyond diagnostic lobectomy for these patients. Our study aimed to explore the association between size-based risk assessment and *TERT* promoter mutations. Between 2019 and 2023, 77 miFTCs/miOTCs diagnosed at our department underwent digital droplet PCR analysis of tumor DNA targeting *TERT* promoter mutational hotspots C228T and C250T. Histopathological, immunohistochemical and clinical variables were collected at the end of the study (January 2024). In total, *TERT* promoter mutations were found in 8 out of 77 cases (10.4%), 6 miFTCs, and 2 miOTCs. Mutated cases were pT2 ($n=2$) and pT3a ($n=6$), but no mutations were found among the pT1a/b tumors ($n=11$). Mutated tumors displayed an average size of 55.6 mm (range 37–100 mm), significantly larger than wildtype tumors with an average size of 38.2 mm (range 9–130 mm) (*P*-value: 0.014). There were no significant differences between patients with mutated or wildtype tumors regarding patient sex, age at surgery or the Ki-67 proliferation index. In conclusion, *TERT* promoter mutations in miFTC/miOTC are associated with larger tumor size. Clinical routine sequencing of pT1a/b miFTCs and miOTCs may not be beneficial. The current strategy of releasing small, low-risk lesions as outpatients without additional treatment is supported by our molecular risk stratification, indicating that *TERT* promoter mutational sequencing in clinical routine could be reserved for larger tumors.

Clinical features and outcome in patients with functional head and neck paragangliomas: French national cohort and literature review

Iuliia Pinigina[1], Philippe Ceruse[1], Philippe Herman[2], Cardot Catherine[3], Magalie Haissaguerre[4], Erika Cornu[5], Laurence Amar[6], Marie Batisse-Lignier[7], Laurence Chardon[1], Sara Barraud[8], Loic Feuvret[1], Marc Janier[1], Lasolle Hélène[1], Francoise Borson-Chazot[1] & Abeillon Juliette[1]
[1]Hospices Civils de Lyon – HCL, Lyon, France; [2]Lariboisière Hospital AP-HP, Paris, France; [3]Hospital Center University De Lille, Lille, France; [4]Hospital Center University De Bordeaux, Bordeaux, France; [5]Médipôle Lyon-Villeurbanne, Villeurbanne, France; [6]European Hospital Georges Pompidou, Paris, France; [7]Jean Perrin Center, Clermont-Ferrand, France; [8]Hospital Robert Debré, Reims, France

Objectives
Management of functional head and neck paragangliomas (HNPGLf) presents a substantial challenge due to their rarity, the lack of standardized treatment protocols, their complex neurovascular anatomical location, and the cardiovascular risks associated with catecholamine (CA) hypersecretion. This study aimed to describe the clinical characteristics of HNPGLf and their treatment outcomes.
Methods
We retrospectively analyzed a cohort of HNPGLf patients treated at seven French EURACAN-COMETE centers from 2000 to 2023. The secretory nature was defined by CA-methylated metabolites (MM) exceeding 3 times the upper limit of normal. In addition, a comprehensive literature review was conducted.
Results
The French cohort included 20 patients (70% female, median age: 39.5 years). HNPGLf were vagal ($n=10$), jugulo-tympanic ($n=10$), and carotid ($n=3$), with a median largest dimension of 43 mm (range: 23–80), secreting noradrenaline and/or dopamine. Diagnoses were established based on tumor syndrome ($n=15$), signs of CA hypersecretion ($n=1$), germline SDHD mutation ($n=1$), and incidental findings ($n=1$). Eight out of 19 tested patients had SDHx mutations. Treatment modalities included surgery ($n=8$), external beam radiation therapy (EBRT) ($n=5$), radiosurgery ($n=1$), proton therapy (PT) ($n=1$), and ^{177}Lu-DOTATATE ($n=2$). The median post-therapeutic follow-up was 39.7 months (range: 4.1 – 176.9). There were 3 cases of morphological progression, but no metastasis. 70.6% of patients showed significant secretory improvement, with 7 patients normalizing MM levels (all had surgery), and 5 showing partial biochemical response (EBRT $n=2$, radiosurgery $n=1$, PT $n=1$, ^{177}Lu-DOTATATE $n=1$). Neurological complications occurred in 64.7% cases, primarily after surgery. The Literature cohort comprised 17 patients with demographic characteristics, clinical presentations, and tumor features similar to the French cohort. However, the proportion of females was lower (35.5%), and the secretory profile was unspecified in 41.2% of cases because total metanephrine levels were used for diagnosis. Three out of 4 tested patients had SDHx mutations. Outcomes and complications were comparable to that observed in the French cohort, except for a shorter median post-treatment follow-up (9.5 months).
Conclusion
This study presents, to the best of our knowledge, the largest reported HNPGLf cohort to date. Surgical, radiotherapeutic and radiometabolic interventions achieved tumor and secretory control in 70.6% of cases. Longer-term studies are warranted to identify the best therapeutic strategy.

Ovarian neuroendocrine tumor metastases can induce estrogen production in postmenopausal patients

Merijn Mulders, M F van Velthuysen, Eva Maria Roes, Leo Hofland, Wouter W de Herder & Hans Hofland
Erasmus MC, Rotterdam, Netherlands

Background
Neuroendocrine tumors (NET) are malignant neoplasms that can be associated with specific hormonal syndromes. We describe a novel syndrome of postmenopausal vaginal bleeding and ovarian estradiol overproduction due to ovarian NET localizations.
Methods
A clinical workup was performed for 2 index patients with ovarian metastases of small bowel neuroendocrine tumors and symptoms of postmenopausal vaginal bleeding. Ovarian tissue was collected after oophorectomy, cultured ex vivo and incubated with anti-hormonal and antitumoral drugs. Electronic medical records were screened for postmenopausal patients with ovarian NET localizations and similar symptoms that presented in our center between 1991 and 2023.
Results
In the index patients, clinically significant ovarian estrogen production was demonstrated by a combination of ovarian vein sampling and normalization of circulating estrogen levels after oophorectomy. *Ex vivo* and *in vivo* endocrine tests were unable to identify a paracrine mechanism of ovarian estradiol over-production by NET cells, although a link with gonadotrophins was observed in one case. A retrospective analysis revealed that 21% (14/66) of postmenopausal patients with an ovarian NET localization reported symptoms of vaginal blood loss. Estradiol and gonadotrophin levels were available in 7 of these patients and were compatible with aberrant estradiol production in postmenopausal women.
Conclusions
Together, these findings support the presence of a novel NET-associated hormonal syndrome, which is presumably caused by paracrine effects of infiltrating NET cells on ovarian steroidogenesis.

Presurgical lactate dehydrogenase (LDH) levels: A risk factor for disease progression in operated adrenocortical carcinomas

Ana Carreira, Joana Guiomar, Diana Festas, Diana Catarino, Dírcea Rodrigues, Carolina Moreno, Miguel Melo & Isabel Paiva
Hospitais da Universidade de Coimbra, Unidade Local de Saúde de Coimbra, Endocrinology, Diabetes and Metabolism, Coimbra, Portugal

Introduction
Adrenocortical carcinoma (ACC) is a rare malignancy with high recurrence and poor prognosis. Lactate dehydrogenase (LDH) is an enzyme of the glycolytic pathway that is associated with tumour progression in several cancers. To date, evidence on the prognostic value of LDH in ACC is limited.
Aims
To assess the impact of LDH in disease-free survival (DFS) in operated ACC.
Materials and methods
Retrospective cohort study of patients with ACC that were followed in a tertiary centre from 1991 to 2023. Cases where adrenalectomy was not performed were excluded. Elevation of baseline (presurgical) LDH was defined according to the laboratory cut-off ($\geq$ 247 U/L). The prognostic value of clinical, biochemical and histopathological variables was assessed by the analysis of Kaplan–Meier curves and Cox proportional hazard regression. A cut-off of LDH was obtained from the analysis of ROC curves.
Results
A total of 33 cases were analysed; 75.8% female, mean age at diagnosis of 49.9 $\pm$ 12.7 years, 62.1% functioning tumours, ENSAT stages II in 57.6%, III in 27.3% and IV in 15.2%. Resection was R0 in 69.7%, R1 in 18.2%, R2 in 6.1% and indeterminate in 6.1%. Baseline LDH ranged from 159 to 1848 U/L, with a median of 382.0 (IQR 271.0–621.0). Adjuvant mitotane was performed in 78.1%, chemotherapy in 25.0% and radiotherapy in 28.6%. Disease progression (RECIST 3) occurred in 66.7%; 43.3% with local recurrence and 64.5% with metastasis. Median DFS was 1.0 year, and overall survival 3.9 years (0.0-11.6). Functioning tumours (HR 3.77, CI 1.34–10.63, $P=0.012$), ENSAT stages III-IV (HR 3.49, CI 1.48–8.27, $P=0.004$), mitotic grade of >20/50HPF (HR 4.47, CI 1.50–13.30, $P=0.007$) and elevated baseline LDH (HR 7.84, CI 1.04–59.32, $P=0.046$) showed lower DFS. Each increase of 100 U/L in LDH predicted an increase of 10.2% on the risk of disease progression (CI 1.01–1.20, $P=0.028$). LDH was significantly higher in functioning tumours, with a median of 524.0 U/L (IQR 299.0–663.0) vs 242.5 U/L (IQR 173.8–493.8), $P=0.036$, and showed a correlation with urinary free cortisol (UFC) ($r=0.540$, $P=0.006$) and with tumour size ($r=0.473$, $P=0.013$). Elevated LDH, unlike functioning tumours or UFC, was associated with the development of metastases after diagnosis (80.0% vs 20%, $P=0.023$). Baseline LDH $\geq$ 266.5 U/L predicted disease progression with 95% sensitivity and 71.4% specificity (AUC 90.0%, $P=0.002$).
Conclusions
Baseline LDH levels were associated with disease progression and poor prognosis in operated ACC. LDH levels may help guiding therapeutic decisions in ACC, along with the other well-established prognostic factors.

Advanced ACC stage: Therapeutic approach and biological findings

Alessandra Cossa[1], Sara Pagotto[2], Silvia Perconti[2], Elisa Taschin[3], Elena Sofia Scialis[2], Simone De Fabritiis[2], Maria Elena Aloini[4], Diana Liberata Esposito[2], Iolanda Matarazzo[5], Fabio Verginelli[2], Lavinia Vittoria Lotti[6], Francesca Schiavi[3], Renato Mariani Costantini[2] & Antonio Stigliano[4]
[1]Surgery, Rome; [2]Center for Advanced Studies and Technology, Chieti; [3]Familial Cancer Clinical and Oncoendocrinology, Veneto Institute of Oncology, Padua; [4]Endocrinology, Clinical and Molecular Medicine, Rome; [5]Radiology, Surgical and Medical Sciences and Translational Medicine, Rome; [6]Sapienza University of Rome, Experimental Medicine, Rome

Adrenocortical carcinoma (ACC) is a rare and aggressive cancer most frequent in middle-aged females. Management is challenging and debulking surgery has been advocated to improve survival and quality of life in advanced disease. We report a remarkable case in a 60-year-old female without individual or familial risk factors who, despite good performance status, presented with a 10.3 $\times$ 5.5 $\times$ 9.0 cm right adrenal mass, liver metastases, inferior vena cava thrombosis, hypercortisolism, and hyperandrogenism. The patient underwent debulking surgery with adrenalectomy, intracaval thrombectomy and liver metastasectomies. Pathology and immunohistochemistry confirmed high-grade ACC with hepatic metastases and neoplastic inferior vena cava thrombosis, mENS@T stage pIVa (pT4, pN2, pM1). Transmission electron microscopy revealed that both the primary and the metastatic tumor were a mosaic of two cell morphotypes with differential affinity for osmium tetroxide. The most abundant corresponded to large electron-lucent cells, the other (<30%) to thinner electron-dense cells with cytoplasmic filopodia, the latter characteristics reportedly associated to oxidative stress. Both morphotypes showed mitochondrial hypertrophy and hyperplasia, accompanied, particularly in dark cells, by mitochondrial swelling and cristae degradation, known to be linked to respiratory dysfunction. Genetically, the primary and the metastatic samples demonstrated microsatellite-stable phenotype. No alterations in 81 cancer-related genes, including *TP53*, *MEN1* and *PRKAR1A*, three major ACC-related genes, were detected at germline level, while a pathogenic *TP53* c.843C>A p.(Asp281Glu) transversion was detected with strikingly conserved 27% variant allele frequency in both primary and metastatic DNA. Despite adjuvant mitotane, CT scans at one month showed multiple hepatic and bilateral pulmonary metastases with pleural and mediastinal involvement, consistent with rapid deterioration of the hormonal and clinical picture. Death ensued 40 days after surgery. This case challenges the utility of debulking surgery in advanced ACC. Furthermore, its ultrastructural and genetic features suggest that mitochondrial dysfunction and adaptive cooperation between tumor cells differing in *TP53* status and morphotype might contribute to biological aggressiveness.

Growth differentiation factor 15 (GDF-15) is induced by mitotane in adrenocortical carcinoma and associated with poor prognosis and impaired responsiveness to immunotherapy

Isabel Weigand[1], Alexandra Triebig[1], Maier Tanja[1], Tanja Anderlik[2], Hanna Remde[2], Laura-Sophie Landwehr[2], Otilia Kimpel[2], Miriam Reuter[2], Jochen Schreiner[1], Florian Wedekink[3], Eva Hoster[4], Paul Schwarzlmueller[1], Martin Reincke[1], Jörg Wischhusen[3], Martin Fassnacht[5] & Kroiss Matthias[1]
[1]LMU University Hospital, Department of Internal Medicine IV, Germany; [2]University Hospital Würzburg, Department of Internal Medicine I, Germany; [3]University Hospital Würzburg, Department of Obstetrics and Gynecology, Germany; [4]Ludwig-Maximilians-University, Institute for Medical Informatics, Biometry and Epidemiology, Germany; [5]University Hospital Würzburg, Department of Internal Medicine I, Germany

Background
Treatment of adrenocortical carcinoma (ACC) is unsatisfactory in advanced stages. Oral mitotane remains a mainstay of treatment. Response rates of ACC to immune checkpoint inhibition (ICI) are disappointing and markers of response have not been identified. Tumoural infiltration with cells of the adaptive immune system is sparse in ACC tissue. Growth/differentiation factor 15 (GDF-15) is a cytokine that has been described to impair tumoral immune infiltration and is explored as a treatment target. We previously found GDF-15 to be induced in ACC cells upon mitotane treatment.
Aim
To assess the value of serum GDF-15 for the diagnosis of ACC, as a predictor of prognosis and serum marker of response to ICI.
Methods
Clinical data from patient records were retrieved. GDF-15 was measured in serum samples. 151 patients had ACC (99 prior, 52 during mitotane) and 42 patients benign adrenal tumors (ACA). Serum GDF-15 was analyzed in a second cohort of 27 ACC patients, including 11 responders, who received ICI. mRNA expression of GDF-15 and genes related to immune response was quantified in 58 ACC tumour samples.
Results
Serum GDF-15 did not differ significantly between patients with ACC and ACA. In 40 paired specimens from patients with active ACC, serum GDF-15 increased from 0.6 $\pm$ 2.2 ng/ml prior mitotane to 2.3 $\pm$ 3.9 ng/ml after mitotane initiation ($P<0.0001$). Plasma mitotane significantly correlated with serum GDF-15 (Spearman $r=0.58$). In ACC patients, serum GDF-15 below the median of 0.81 before and 2.17 ng/ml after mitotane was associated with significantly longer patient survival compared to GDF-15 above the median. After adjustment for ENSAT stage and Ki-67 index, this association remained statistically significant with hazard ratios of 2.3 (95% CI 1.14–4.81, $P=0.021$) and 2.9 (95% CI 1.28–6.82, $P=0.01$), respectively. GDF-15 levels in responders to ICI were significantly lower than in non-responders ($P=0.039$) and patients with serum GDF-15 below the median (4.4 ng/ml) showed a trend towards longer progression-free survival with ICI. Expression of pro-inflammatory immune-related genes was lower in ACC tissue with GDF-15 expression above the median.
Conclusion
Mitotane induces GDF-15 secretion and is associated with poor overall survival and impaired response to ICI. Hence, GDF-15 may serve as a serum marker of disease

and response to ICI in ACC. GDF-15 may contribute to sparse tumoural infiltration with immune cells in ACC.

Primary hyperparathyroidism due to parathyroid cancer or atypical adenoma. a third-level spanish hospital experience

Carolina Sánchez Malo[1], Roberto Carlos Romo Remigio[1], María Dolores Martín Salvago[2], María ..[1], Rodolfo González Sendra[3] & Maria Carmen Rosa Garrido[4]

[1]Hospital of Jaen, Endocrinology and Nutrition, Jaén, Spain; [2]Hospital of Jaen, Anatomic Pathology, Jaén, Spain; [3]Hospital of Jaen, General Surgery, Jaén, Spain; [4]Hospital of Jaen, Unit of Investigation, Jaén, Spain

Parathyroid carcinoma (PC) is very rare and difficult to differentiate from atypical parathyroid adenoma (AA). *En-bloc* surgical resection is recommended, but most cases are diagnosed after non-radical surgery, and it is recommended to expand it. Given the rarity of the cases, the difficulty in the histological diagnosis (HD) and the unpredictability of the evolution, we analyzed our experience with PC and AA.

Material and methods

We conducted a retrospective analysis of 20 patients whom received surgery for primary hyperparathyroidism (PHP) from 2000 to 2022 with an HD of PC and AA. We collected data from age, sex, ultrasound data, parathyroid scintigraphy, clinical signs, pre- and post-surgery tests (PTH, calcium, phosphorus, and vitamin D), type of surgery, persistence of disease, and survival. Statistical analysis was done using SPSS®.

Results

Of our 20 patients, 11 were men and 9 women. HD of PC 12 and AA in 8. Age 61 years (28–77). We found no differences between PC or AA in pre-surgery, ultrasound, scintigraphy, clinical data, type of surgery (5 en bloc and 15 parathyroidectomies) laboratory parameters, tumor size, Ki67 or survival. We found differences in biochemical parameters before and after surgery with no differences according to AP or type of surgery. All patients are still alive. We have not expanded surgery in any case of PC diagnosed after parathyroidectomy.

Conclusions

We did not find clinical, biochemical or imaging characteristics that guide the diagnosis of PC or AA pre-surgery. The clinical and analytical evolution of PHP after surgery is independent of the HD in cases of AA and PC in our setting. Parathyroidectomy achieved the same survival as en bloc surgery.

SRSF6 modulates histone-chaperone HIRA splicing to orchestrate androgen and E2F signalling in prostate cancer

Antonio J Montero-Hidalgo[1,2,3,4], Juan Manuel Jiménez Vacas[1,2,3,4,5], Enrique Gómez-Gómez[1,3,6], Ricardo Blázquez-Encinas[1,2,3,4], Rafael Sánchez-Sánchez[1,3,7], Antonio Jesús Martínez-Fuentes[1,2,3,4], Eduardo Eyras[8,9], Justo P Castaño[1,2,3,4], Adam Sharp[5,10], David Olmos[11], Manuel D Gahete[1,2,3,4] & Raul M Luque[1,2,3,4]

[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC); [2]University of Cordoba, Department of Cell Biology, Physiology and Immunology; [3]Reina Sofia University Hospital (HURS); [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn); [5]Institute of Cancer Research; [6]Reina Sofia University Hospital (HURS), Urology service; [7]Reina Sofia University Hospital (HURS), Anatomical Pathology service; [8]The John Curtin School of Medical Research; [9]EMBL Australia Partner Laboratory Network at the Australian National University; [10]Royal Marsden NHS Foundation Trust; [11]Hospital Universitario 12 de Octubre, Department of Medical Oncology

Prostate cancer (PCa) is one of the most common endocrine-related cancers (ERCs) among men worldwide. The aggressiveness of this tumor pathology is highly influenced by different endocrine-related factors, highlighting the crucial role of androgens. Therefore, the main therapeutic approach for PCa patients is based on the pharmacological blockade of androgen-signaling. However, some patients become unresponsive and develop a highly lethal castration-resistant disease, pointing out the urgent need for effective therapeutic strategies. In this regard, the splicing process dysregulation has been considered as a cancer hallmark, but the role of certain splicing-factors remains unknown in different ERCs. Therefore, we aimed to characterize the levels and functional role of SRSF6 in PCa. To that end, we analyzed the SRSF6 levels (copy-number/mRNA/protein) across eight well-characterized PCa cohorts and the Hi-Myc transgenic model. Furthermore, we evaluated the functional response of different normal-like (RWPE-1) and PCa-derived (LNCaP/22Rv1/DU145/PC-3) cell-lines and xenograft models in response to the genetic modulation (overexpression/silencing) of SRSF6. Finally, we performed RNA-Seq together with different bioinformatic analyses to explore the molecular mechanisms underlying the functional effects upon SRSF6 modulation in PCa cells. We found that SRSF6 was upregulated in human and mouse PCa tissues, and its levels were associated with relevant clinical parameters of PCa aggressiveness (e.g. Gleason-score, presence of metastasis at diagnosis, etc.). Additionally, the SRSF6 overexpression increased, while its silencing decreased different functional parameters of tumor aggressiveness *in vitro* (i.e., proliferation, migration, colonies and tumorsphere formation) and *in vivo* (i.e., tumor growth, mitosis). Mechanistically, we demonstrated that SRSF6 regulates the splicing pattern of the histone-chaperone *HIRA*, consequently affecting the activity of the H3.3 histone variant in PCa cells [being also corroborated in breast cancer (BCa) cells] and disrupting pivotal oncogenic pathways [androgen-signaling and E2 Promoter Binding Factor (E2F) activity] in PCa cells. Altogether, our results unveiled new conceptual and functional avenues in PCa, with potential therapeutic implications, by demonstrating that SRSF6 is overexpressed and associated with the aggressiveness of PCa by regulating, among other key oncogenic pathways, AR- and E2F-activity, through the modulation of HIRA splicing. This critical mechanism, also observed in BCa, suggests that SRSF6 is a key player not only in PCa, but also in other ERCs. Therefore, these findings present a unique opportunity for further therapeutic research and clinical exploration of targeting SRSF6 in PCa/advanced-stage PCa, BCa, and, potentially, further ERC types.

Adrenal tumors in children and adolescents in Sweden: A diagnosis related groups-based analysis from 2005–2019

Eleni Terezaki[1,2], Jan Calissendorff[1,3], Buster Mannheimer[4], Jonatan Lindh[5] & Henrik Falhammar[1,3]

[1]Karolinska University Hospital, Endocrinology, Stockholm, Sweden; [2]Karolinska University Hospital, Centre for Inherited Metabolic Diseases, Stockholm, Sweden; [3]Karolinska Institutet, Molecular Medicine and Surgery, Stockholm, Sweden; [4]Karolinska Institutet, Clinical Science and Education Södersjukhuset, Stockholm, Sweden; [5]Karolinska University Hospital, Laboratory Medicine, Division of Clinical Pharmacology, Stockholm, Sweden

Adrenal tumors (ATs) are uncommon in children and adolescents. The aim of this nation-wide retrospective registry-based cohort study was to characterise the various ATs in this population and demonstrate their differences from ATs in adults. All patients under the age of 21 in Sweden with verified adrenal lesions according to ICD-codes between 2005 and 2019 were identified in linked nation-wide registries. Out of the total 232 patients, 121 (52.2%) were boys, with boy predominance preserved even in benign ATs. Mean age was 8.7 ± 7.9 years. Malignant ATs were found in 57% of patients, while 34% of patients had benign ATs with mean age at diagnosis of 4.4 and 14.5 years respectively. The most prevalent diagnosis was neuroblastoma (37.0%), followed by benign adenoma (29.7%) – of which 10% hormonally active, pheochromocytoma (8.6%) and adrenocortical carcinoma (7.3%). Hormone related prodromal symptoms were detected in 16% of patients. Endocrine commorbidities were observed in 46.6% of cases with the most common being hypertension (28%) and adrenal insufficiency (17.7%). In contrast to adults, 13 out of 20 cohort patients with pheochromocytoma had a concurent genetic syndrome and 9 out of 20 had another concomitant tumor, 7 of which were endocrine tumors. Patients were primarily treated and operated at tertiary hospital in 72.4% and 98.9% of cases respectively. 47.8% of individuals received chemotherapy and 42.2% were operated. The most common post-operative complication was adrenal insufficiency (23.5%), and was more prevalent in adrenocortical carcinomas (56.3%) and hormone-producing benign adenomas (57.1%). Unexpectedly 40% of patients with pheochromocytoma and 11.1% of benign adenomas without overt hormonal production were in need of corticosteroid replacement post-operatively. Mortality rate was 19,4%, rising to 33.3% in patients with malignant ATs and 100% within 2 years for the 5 patients with adrenal metastasis. In conclusion, ATs

were found to be rare in children and adolescents in Sweden. Hormone producing or malignant ATs were the most common diagnoses with the latter having a poor prognosis.

P509

Variants of genes that reduce the function of the progesterone receptor, vitamin D receptor, and 1α-hydroxylase enzyme are associated with an earlier onset of breast cancer

Alisa Dymova[1], Tatyana Shkeleva[2], Svetlana Kalinchenko[3], Marina Zhilenko[4] & Svetlana Samoylova[5]
[1]Moscow, Gynecology department, Moscow, Russian Federation; [2], Moscow; [3]Peoples' Friendship University of Russia - RUDN University, Clinic prof. Kalinchenko, Moscow, Russian Federation; [4], gynecology department, Moscow, Russian Federation; [5]First Moscow State Medical University, Department of Oncology, Radiotherapy and Plastic Surgery, Russian Federation

Background
Previous studies have investigated the association between genetic variability in the progesterone receptor gene and various hormonally-related conditions, such as breast cancer (BC), endometrial and ovarian cancers. Vitamin D deficiency can also lead to oncological conditions, including BC. Progesterone and Vitamin D induce their hormonal effects on target cells by binding the active form of the hormone to its receptors. Therefore, any genetic variations that may cause the dissociation of progesterone and vitamin D receptors, as well as a reduction in the synthesis of the active hormone form, may lead to increased susceptibility to BC. Notably, earlier studies did not take into account the morphological characteristics of tumors and the influence of molecular-genetic features on the age of disease manifestation.
Objective
This study aimed to assess the association between functional-reducing variants in the PGR, VDR, and CYP27B1 genes with the risk of hormone-dependent breast cancer (HBC) and the age of disease manifestation.
Methods
A retrospective case-control study was conducted, involving 87 women aged 40–72 years. Of these, 42 women had a diagnosis of HBC, and 45 women had no history of HBC in their personal or familial medical records. Genotyping was performed using SNP genotyping methods through direct sequencing. Functional-reducing variants in the progesterone receptor gene PGR c.1486G>T; p.Val660Leu, vitamin D receptor BsmI Polymorphism IVS10+283G>A, and 1α-hydroxylase enzyme g.57764205A>G; c.1137-29T>C were investigated.
Results
A significantly higher frequency of the minor allele of PGR (45% vs 16%), VDR (29% vs 17%), and the functional-reducing allele of the CYP27B1 enzyme (43% vs 12%) was observed among patients with HBC compared to the control group, confirming the association of these genetic variants with the risk of developing HBC. A significant association of PGR and VDR genotypes with HBC was observed in younger patients up to 55 years old. In older patients, the frequency of PGR and VDR variants decreased and approached the control group, indicating the contribution of other factors to the pathogenesis of the disease after the age of 55.
Conclusions
This report confirms the contribution of PGR, VDR, and CYP27B1 gene variants to the etiology of BC. The low sensitivity of PGR and VDR receptors is associated with earlier forms of HBC. Genotyping of vitamin D receptors (VDR), the activity of the 1-α-hydroxylase enzyme (CYP27B1), and progesterone receptors (PGR) in the future will enable the development of a screening strategy for identifying women at risk of developing HBC.

Systematic review of thyroid hormone patterns observed after exposure to endocrine disruptors in humans

Isabel Forner[1], Asma Baig[1] & Andreas Kortenkamp[1]
[1]Brunel University London, Uxbridge, United Kingdom

The Hypothalamic Pituitary Thyroid (HPT) axis is well-known as a classic endocrine negative feedback loop: increased levels of thyroxine (T4) in the blood are associated with a reduction of thyroid stimulating hormone (TSH) production and vice versa. However, the HPT axis is sensitive to alterations by a number of endocrine-disrupting chemicals (EDCs). Exposure to specific EDCs can deregulate the negative feedback loop and alter the TH/TSH levels. The intrinsic mechanisms for such deregulations are still unclear. Our aim is to investigate the different TH/TSH patterns associated with EDC exposures in different population groups. Therefore, we conducted an extensive systematic literature search of peer-reviewed epidemiological studies. Based on our eligibility criteria, we selected studies where the authors included TH/TSH measurements in pregnant women, workers or the general population, and the levels of the target chemicals were characterised in the corresponding human sample. We retrieved more than 25,000 studies, of which 532 were further assessed. Cross-sectional, case-control and cohort studies were the predominant study designs. A large range of chemicals were included with the predominance of heavy metals, per- and polyfluoroalkyl substances, bisphenols, phthalates, pesticides, polybrominated and polychlorinated compounds. Our results showed that the idealized view of the HPT axis is not supported by the evidence when EDCs are involved. Some EDCs induced reductions or increments of T4 and/or T3 levels but the expected TSH increase or decrease did not materialise. Similarly, changes in TSH levels did not induce alterations in T4 and/or T3. The mechanisms by which various EDCs disrupt the HPT axis and induce such patterns have not yet been fully identified. For this reason, the complexity of the EDC mode of action needs to be considered in order to identify chemicals that are potentially damaging to human health. Urinary iodine concentration and markers of thyroid activity in pregnant faroese women

Herborg Líggjasardóttir Johannesen[1], Stig Andersen[2], Stine Linding Andersen[3], Maria Skaalum Petersen[4] & Anna Sofía Veyhe[5]
[1]National Hospital of the Faroe Islands, Endocinology and internal medicine, Tórshavn, Faroe Islands; [2]Aalborg University Hospital South, Arctic Health Research Centre, Aalborg, Denmark; [3]Aalborg University Hospital South, Clinical Biochemistry, Aalborg, Denmark; [4]National Hospital of the Faroe Islands, Department of Research, Tórshavn, Faroe Islands; [5]University of the Faroe Islands, Health Science, Tórshavn, Faroe Islands

Introduction
Mild iodine deficiency in the Faroe Islands raises a concern for pregnant women. Iodine is essential for thyroid hormone synthesis, making it crucial for thyroid function during pregnancy and foetal growth. World Health Organization (WHO) classifies iodine intake in pregnant women as insufficient if the median urinary iodine concentration (UIC) is below 150 µg/l. We investigated how UIC relates to thyroglobulin (Tg) and thyroid-stimulating hormone (TSH) in serum as markers of thyroid activity.
Method
This was a cross-sectional study with longitudinal aspects in the Faroe Islands. We recruited 645 Faroese pregnant women early in the second trimester from June 2020 to April 2022 for blood and spot urine samples. UIC was measured in spot urine using the Sandell-Kolthoff reaction modified according to Wilson and van Zyl. TG measurements were conducted in 143 randomly selected participants. Serum Tg and TSH were measured using immunoassays (BRAHMS and Alinity I; Abbott).
Results
Overall, the median UIC was 110 µg/l and the median TSH was 1.23 mIU/l. There were 32 participants with UIC <50 µg/l, for whom we also had corresponding Tg values. For the entire group, 61 participants had UIC <50 µg/l regardless of Tg presence. Serum Tg levels were higher in the group with UIC <50 µg/l ($n=32$) compared to those with UIC from 50-100 µg/l or above. On the other hand, neither serum Tg nor TSH differed between groups of pregnant women with UIC of 50-99 vs 100-149 vs 150-299 µg/l, but TSH was slightly lower with UIC <50 µg/l (median 1.09 mIU/l ($n=61$)) and higher with UIC >300 µg/l (median 1.51 mIU/l ($n=42$)).
Conclusion
Among pregnant women in the Faroe Islands, TSH was similar between groups of pregnant women with UIC in the range from 50-300 µg/l. Similarly, serum Tg was raised only in the group with UIC below 50 µg/l. Results suggest that the lower limit of UIC recommended by WHO in pregnancy may be too strict when evaluated according to markers of thyroid activity.

Exploring a new avenue of disseminating peer-reviewed information on thyroid and PCOS conditions

Maiar Elhariry[1], Kashish Malhotra[2], Punith Kempegowda[3] & Kashish Goyal[4]
[1]University of Birmingham, College of Medical and Dental Sciences; [2]University of Birmingham Medical School, Institute of Applied Health Research; [3]University Hospitals Birmingham NHS Foundation Trust, Queen Elizabeth Hospital; [4]Delhi Heart Institute and Multispeciality Hospital

Background
In the current digital age, social media brought information to our fingertips but also facilitated the spread of misinformation. The exponential growth of short video platforms shows potential for formulating evidence-based techniques to ensure the dissemination of accurate information without bias.
Objectives
1. To create and disseminate peer-reviewed short videos about PCOS and Thyroid conditions. 2. To explore content creators' experience, video outreach and audience engagement on social media.
Methods
This project was run from December 2022 to May 2023 in collaboration with British Thyroid Foundation and PCOS Vitality. Scripts based on the most searched topics in PCOS and thyroid conditions were created and reviewed by experts and patients to ensure scientific accuracy and acceptability. Once finalised, we invited medical students to create videos using the scripts. The videos were reviewed, edited to fit the requirements, and posted on TikTok, Instagram, youTube, and Twitter. Video engagement across social media over two months was analysed. Content creators were invited to a semi-structured virtual interview to explore their experiences and motivation to participate. Two independent authors coded the interview transcripts using Nvivo 12.0 to identify themes using thematic inductive analysis.
Results
Over 2 months, the videos received 718 likes, 120 shares, and 54686 views for 20 videos -19458 on TikTok, 12944 on Instagram, 2606 on youTube, and 19678 on Twitter. There was an increase in followers across all platforms - from an 89% increase on TikTok to a 5% increase on Twitter. Analysis of participant experience yielded 4 main themes: Views on social media, advice when using social media, reasons for participating, and thoughts on this project. Regarding views on social media, content creators highlighted the advantages of social media, including 'large outreach' (12 references), 'convenience' (10 references), and 'accessibility to opportunities' in fields of interest (7 references). The most common themes about advice were awareness of 'audience's demographics' (9 references), 'sharing on more than one platform' (5 references), and 'collaborating with organisations' (3 references). Content creators mentioned that 'non-restricting participation criteria', 'convenience' (8 references) and 'ability to record from home with a pre-written script' (6 references) made it easier to participate.
Conclusions
Disseminating peer-reviewed information is a great way of harnessing the power of social media to increase awareness, tackle misinformation, and provide a channel for the public/patients to receive evidence-based information. Medical students have untapped potential to be content creators working with relevant authorities and patient support groups.

The short-term effect of apparent temperature on the hydration marker plasma sodium

Anna Franzén[1], Mats Pihlsgård[1], Ulf Ekelund[2,3], Simon Timpka[1,4] & Sofia Enhörning[1,5]
[1]Lund University, Department of Clinical Sciences, Malmö, Sweden; [2]Lund University, Department of Clinical Sciences, Lund, Sweden; [3]Skåne University Hospital, Emergency Medicine, Lund, Sweden; [4]Skåne University Hospital, Department of Obstetrics and Gynecology, Malmö, Sweden; [5]Skåne University Hospital, Department of Internal Medicine, Malmö, Sweden

Introduction
A recent study suggests that copeptin, a surrogate measure of the hormone vasopressin and a known risk marker of cardiometabolic disease and decreased hydration, is non-linearly related to outdoor temperature with increased levels in both hot and cold temperatures. The same u-shaped relationship has been suggested between outdoor temperature and other hydration markers. In this study, we investigated the effect of apparent outdoor temperature on plasma sodium, the main contributor to increased plasma osmolality and vasopressin secretion.
Method
Data on plasma sodium from all adult patients visiting one of eight emergency departments ($n = 331,311$) in 2017- 2018 in the southernmost region in Sweden (approximately 1.3 million inhabitants) were used. To investigate the association between apparent outdoor temperature (mean value the day of blood sampling) and plasma sodium, a cubic spline regression model with knots at the 25th, 50th, 75th and 90th temperature percentile was used. To investigate the relationship between apparent temperature and odds of hypo- and hypernatremia (P-Sodium <135 mmol/l and >145 mmol/l, respectively) among patients, a logistic regression model with the same knots was used. All of the analyses were adjusted for age, sex, day of the week, glucose, potassium and eGFR in a first model and ambulance arrival, hospital admission and current medication (diuretics, renin-angiotensin blocking agents, selective serotonin reuptake inhibitors and antidiabetics) on top of model one in a second model.
Results
Plasma sodium among patients was significantly and non-linearly associated with apparent temperature ($P < 0.001$ for both). The highest plasma sodium concentration was observed at -0.2 degrees C mean outdoor temperature. The associations between apparent temperature and hyper- and hyponatremia, respectively, were significant and non-linear ($P < 0.001$ for all). The odds of hyponatremia decreased with around 15% at mean temperatures between 0 to 10 degrees C, and increased at temperatures below -5 and above 19 degrees C. Hypernatremia increased with around 15% at temperatures around 0 degrees C and at temperatures above 20 degrees C.
Conclusion
Among patients seeking acute care, plasma sodium is related to outdoor temperature and reaches its highest concentration during cold temperatures. Our results indicate that hypohydration is more common during winter and could help explain the winter peak in copeptin concentration observed in previous studies. Given the pleiotropic hormonal effects of vasopressin, moderately increased water intake to lower vasopressin might mitigate adverse health effects of outdoor temperatures.

Real-life exposure to toxic metals: impact on thyroid gland function and male reproductive system in rats

Đurica Marić[1], Katarina Baralić[1], Dragana Vukelić[1], Ivan Milošević[2], Anja Nikolić[2], Danijela Đukić-Ćosić[1], Zorica Bulat[1] & Aleksandra Buha[1]
[1]University of Belgrade - Faculty of Pharmacy, Department of Toxicology 'Akademik Danilo Soldatović', Belgrade, Serbia; [2]University of Belgrade - Faculty of Veterinary Medicine, Department of Histology and Embryology, Belgrade, Serbia

Toxic metals can disrupt the endocrine system, harming the thyroid and male reproductive function, as indicated by epidemiological and experimental studies. A human biomonitoring study in Serbia determined the levels of toxic metals (Cd, Pb, As, Hg, Cr, and Ni) in the blood to identify real life scenario of exposure. On the basis of the metal measured levels, the doses for the oral 90 days treatment of male Wistar rats were calculated. The experiment included a control group and treatment groups that received doses reflecting the lower confidence limit of the Benchmark dose for effects on hormone levels (M1), median concentrations (M2) and 95th percentiles concentration of each metal (M3). Serum levels of the hormones TSH, fT4, fT3, T4, T3, testosterone, FSH and LH were determined. A histological analysis of the thyroid gland tissue was performed, while the redox status parameters (IMA, MDA, SH groups, GSH and SOD) were determined in the testicular tissue. Additionally, SPINA-GT and SPINA-GD were calculated with the SPINA Thyr software. In group M2 there was a statistically significant decrease in TSH levels and an increase in fT4 levels, while in group M3 a decrease in fT3 levels was observed. The levels of T4 and T3 remained relatively stable in all groups, although a decreasing trend of T3 in M3 and an increasing trend of T4 in M2 were observed. A significant decrease in SPINA-GD in all treated groups indicates a decreased activity of peripheral deiodinases, while the secretory activity of the gland was not significantly changed in any of the treated groups. Histological analysis of the thyroid tissue showed changes in all treated groups, despite the fact that in some of the treated groups no changes were observed in the levels of TSH and thyroid hormones, which can be explained by the activation of compensatory mechanisms. The analysis of reproductive hormones in the serum showed that only in the group that was exposed to the highest doses of the tested metals (M3), there was a significant decrease in the level of LH. In the M1 group, group treated with the lowest doses of metals, a decrease in the levels SH groups, GSH, and SOD was observed. This outcome may be a consequence of depletion of antioxidant protection reserves. It can be concluded that environmentally relevant doses of metals mixtures can affect the function and structure of the thyroid gland and the male reproductive system.

The influence of environmental and behavioral factors on male infertility associated hormones

Dinu Draganescu Daniela[1], Adrian Albulescu[2], Suzana Vladoiu[1], Fudulu Alina[2], Anca Botezatu[2], Ples Adriana[2], Iancu Iulia Virginia[2], Cristina Stancu[1], Andrei Muresan[1], Oana-Monica Popa[1], Luminita Udrea[1], Ioana Adina Rugescu[2], Dinu Draganescu Daria[1], Ruxandra Dumitrescu[2] & Corin Badiu[1,3]
[1]National Institute of Endocrinology; [2]Stefan S Nicolau Institute of Virology; [3]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucuresti

Male infertility arises as a global public health in the context of the dramatic decrease in birth rates. However, the underlying causes of male infertility remain unknown in many cases. An increasing number of studies suggest that environmental and behavioral factors (smoking, drinking, etc) may affect the hormone levels and other pathways involved in male fertility. The aim of this study was to investigate the influence of various environmental factors and hormonal profiles in a cohort of idiopathic infertile men. This study included 33 blood and seminal samples from patients with idiopathic infertility and 21 from the control group. Infertile group (age between 20-55 years old) inclusion criteria were: modified seminal parameters, failure to achieve pregnancy after at least one year of trying, while the exclusion criteria was: known causes for infertility. The patients filled out a standardized questionnaire designed to gather information regarding their age, smoking and drinking habits, radio frequency (RF) exposure/day, medical history, and place of residence. The percentage of smoking patients was 18.18% in infertile group, respectively 28.57% in control group, while regarding alcohol behavior, 18.18% of infertile patients reported consuming alcohol, and 19,04% in control group. The hormonal profile varies depending on a couple of behavioral/environmental factors. Estradiol levels were slightly decreased in the control group with less than 4 hours of RF exposure/day, while the infertile group displayed an opposite image, with higher levels in the case of more than 4 hours/day RF exposure. Estradiol also displayed a significant increase in the patients who consume alcoholic beverages, regardless of their fertility status ($P=0.0292$). Free testosterone also varies between drinkers and non-drinkers, regardless of their fertility status as well ($P=0.0233$). Testosterone levels also displayed variation between infertile RF exposure groups, with increased levels in the >4 hours/day group ($P=0.0276$). The same trend was observed in the case of free testosterone ($P=0.0029$). Other factors that impacts testosterone levels are smoking behavior, with a significant increase in the case of smokers ($P=0.0233$), and drinking behavior, with an increase in the case of alcohol consumption ($P=0.0398$) The landscape of male infertility should take into account environmental and behavioral factors. This preliminary study showed an important role of these factors in modifying hormone expression levels, especially testosterone, which ultimately may affect the quality of the reproductive function.

Assessment of 24h ambulatory blood pressure in women with sheehan syndrome: prevalence of hypertension and disruption of the circadian blood pressure rhythm

Salma Salhi[1], Ibtissem Oueslati[1], Elyes Kamoun[1], Anis Grassa[1], Meriem Mabrouk[1], Fatma Chaker[1], Meriem Yazidi[1] & Melika Chihaoui[1]
[1]La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Patients with Sheehan's syndrome (SS) may experience alterations in blood pressure (BP) regulation, possibly due to hormones deficiencies and hormone replacement treatment. The aim of the present study was to assess the 24h ambulatory BP in women with Sheehan syndrome.
Methods
This was a monocentric cross-sectional study involving 50 women with complete anterior hypopituitarism secondary to SS and 50 age and body-mass index (BMI) matched control women. All participants underwent clinical examination, laboratory tests, and BP measurement using ambulatory 24h-monitoring.
Results
The mean age was 62.2 $\pm$ 9.4 years in patients vs 60.6 $\pm$ 8.4 years in controls ($P=0.385$). The prevalence of hypertension before the study was 30% in patients with SS and 6% in controls ($P=0.002$). Newly diagnosed hypertension was established in 48% of patients and 58% of controls. The overall prevalence of hypertension was 78% in patients and 64% in controls ($P=0.123$). Altered nycthemeral variations in BP was observed in patients, who had more frequent non-dipper or riser profile than controls ($P<0.001$). Additionally, they had significantly higher frequency of nocturnal hypertension (38% vs 3%; $P=0.002$). SS was positively associated with a non-dipper/riser BP profile (Odds Ratio (OR) $=4.09$; 95%-confidence interval (CI): 1.58-10.55, $P=0.003$). Factors associated with hypertension in patients included age >50 years (OR$=14.25$, 95%-CI: 1.30-155.22, $P=0.029$), duration of SS $>$ 20 years (OR$=6.8$, 95%-CI: 0.96-47.3; $P=0.034$), BMI $\geq$ 26 kg/m^2 (OR$=12.19$, 95%-CI: 2.56-57.93, $P<0.001$), waist circumference $\geq$ 100 cm (OR$=6.78$, 95%-CI: 1.51-30.39, $P=0.007$), waist circumference/height ratio $\geq$ 0.62 (OR$=14.66$, 95%-CI:3.00-71.67, $P<0.001$), and visceral fatty area $\geq$ 150 cm^2 (OR$=6$, 95%-CI: 1.20-30.01, $P=0.022$). Hypertensive patients had a significantly higher cumulative dose of hydrocortisone compared to non-hypertensive patients (439.1 ± 227 vs 315.9 ± 193, $P=0.006$). Thirteen percent of hypertensive patients were on a daily hydrocortisone dose >20 mg, while all non-hypertensive patients were on 15 to 20 mg/day.
Conclusion
Our results showed a high prevalence of hypertension in women with SS and a higher disruption of the circadian BP rhythm in patients than in controls. Age, disease duration, BMI, visceral adiposity, and cumulative hydrocortisone dose were associated with hypertension.

Establishing BMI-Related thresholds for the 1 mg dexamethasone suppression test: a retrospective analysis

Claudio Urbani[1], Davide Corleo[1], Caterina Venturi[1], Giulia Marconcini[1], Fausto Bogazzi[2], Isabella Lupi[1], Ferruccio Santini[2] & Luca Manetti[1]
[1]Azienda Ospedaliero Universitaria Pisana, Endocrinology I Unit, Pisa, Italy; [2]University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy

Background
Cushing Syndrome (CS) is associated with metabolic disturbances, including obesity. The 1 mg Dexamethasone Suppression Test (1mgDST) is widely used to assess cortisol regulation in suspected CS patients. However, its interpretation may require adjustments based on individual factors, such as body mass index (BMI), due to obesity's influence on cortisol metabolism. The literature offers differing cutoff values for obese patients. This study aimed to establish BMI-related cutoffs for the 1 mgDST.
Methods
This is a historical-prospective study focused on 1,694 subjects who underwent the 1 mgDST between January 2014 and November 2021. Among them, 1,000 consecutive overweight or obese individuals were included, alongside 100 healthy-weight controls. Exclusion criteria included hypercortisolism, medications affecting dexamethasone metabolism, recent steroid or estrogen use, adrenal masses, and alcohol abuse. Data collection included anthropometric measurements, clinical features indicative of hypercortisolism, medication history, and 1 mgDST results. Waist circumference and waist-to-hip ratio were collected for obese. Body Surface Area (BSA) and BMI were calculated. BMI subgroups were established: healthy weight, overweight, and different obesity classes. Patients failing to suppress cortisol (cortisol $>$ 1.8 mg/dl) underwent a second-level assessment involving 0800 hours ACTH sampling, Low-Dose Dexamethasone Suppression Test, and urinary free cortisol tests. Statistical analysis involved group comparisons test, correlation analysis tests, and multivariate logistic regression, and Receiver Operating Characteristic (ROC) curve analysis.
Results
Among the study group, 71 patients did not achieve cortisol suppression after the 1 mgDST. Among them, 39 were excluded from a CS diagnosis based on the second-level evaluation, while 32 were lost to follow-up or declined further assessment. Overweight (n°$=96$) and obese (n°$=772$) individuals differed from healthy-weight controls, being older and having more males. Cortisol values after 1 mgDST were significantly lower in overweight/obese patients (median 0.6 vs 0.7 mg/dl; $P=0.002$). Correlation analyses showed positive associations between cortisol values and age, BMI, BSA, waist circumference, and waist-to-hip ratio, while gender negatively influenced cortisol levels. Multivariate logistic regression highlighted age's positive independent association with cortisol levels ($r=0.012$; $P<0.0001$). ROC curve analysis in overweight/obese patients revealed an optimal cortisol cutoff of 2.1 mg/dl. This threshold remained valid across obesity classes.
Conclusion
This study contributes to establishing BMI-related thresholds for the 1 mgDST, enhancing its diagnostic accuracy in overweight/obese patients. The optimal cortisol cutoff of 2.1 mg/dl proved reliable across various obesity classes, aiding in distinguishing CS from other conditions. Also, age-related variations in test results were observed. Further prospective studies with larger cohorts are required to validate and refine these thresholds.

Prevalence of hypopituitarism in adults treated with intensity-modulated radiotherapy for primary, non-pituitary, brain tumours

Darran Mc Donald[1,2], Niamh McDermott[1], Maria Tomkins[1,2], Liam O'Connell[3], Clare Faul[2,3], David Fitzpatrick[3], Chris Thompson[1,2], Michael O'Reilly[1,2] & Mark Sherlock[1,2]
[1]Beaumont Hospital, Department of Endocrinology, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, Department of Medicine, Dublin, Ireland; [3]St Luke's Radiation Oncology Network, Dublin, Ireland

Background
Improved survival rates from brain tumours have resulted in patients living longer with the effects of radiotherapy. Advances in conventional fractionated radiotherapy, such as intensity-modulated radiotherapy (IMRT), enable radiation to be delivered more precisely while partially sparing surrounding structures including the hypothalamic-pituitary axis. Despite these advances, the precise risk of hypopituitarism associated with IMRT in survivors of adult-onset non-pituitary primary brain tumours remains poorly understood.
Methods
A retrospective cohort study was conducted among patients referred to the endocrinology service in Beaumont Hospital, Ireland's National Centre for the Management of Brain Tumours. Patients with adult-onset primary brain tumours treated with IMRT between 2011 and 2022 were included. Endocrine surveillance typically consisted of annual baseline pituitary assessments and either a synacthen (SST) or insulin tolerance/glucagon stimulation test based on whether patients were candidates for growth hormone (GH) replacement.
Results
The study included 69 patients (26 women) with a median age of 38.0 (IQR 30.0-46.2) years at radiotherapy completion. Gliomas were the most common neoplasm ($n=38$), followed by meningiomas ($n=17$), pinealomas ($n=6$), medulloblastomas ($n=5$) and 'other' brain tumours ($n=3$). Median total delivered radiotherapy dose was 54 (IQR 54-60) Gray. The prevalence of hypopituitarism was 26/69 (38%) after a median of 50 (IQR 29-76) months follow up. Thirty-nine patients had baseline pituitary function testing and an SST while 30 patients had baseline pituitary function testing and dynamic GH assessment. Nineteen of the thirty patients (63.3%) who underwent dynamic GH assessments had GH deficiency. All these patients had normal IGF-1 levels at the time of diagnosis. The risk of adrenocorticotrophic hormone (ACTH), gonadotropin, and thyroid stimulating hormone (TSH) deficiency was 17/69 (24.6%), 10/69 (14.5%) and 6/69 (8.7%), respectively. Five patients out of 69 (7.2%) developed panhypopituitarism. Fifty-two percent (36/69) of patients exhibited hyperprolactinaemia at their most recent assessment. Spearman's rank identified significant positive correlations between time interval following radiotherapy and the risk of developing any hormone deficiency ($r_s=0.27$, $P=0.03$), gonadotropin ($r_s=0.37$, $P=0.002$), TSH ($r_s=0.26$, $P=0.03$) but not GH or ACTH deficiency.
Conclusion
This study demonstrated a high prevalence of hypopituitarism in adult-onset non-pituitary brain tumour survivors treated with IMRT. Almost two-fifths developed hypopituitarism at a median of 50 months follow up. The evolution of hypopituitarism occurred in a time-dependent fashion. Long-term systematic endocrine surveillance is crucial to enable timely diagnosis and treatment of hormone deficits, with the aim of optimising quality of life and preventing hypopituitarism-related complications in this patient cohort.

Increment in KI-67 proliferation indices over time is associated with worse survival outcomes in small-intestinal neuroendocrine tumours

Kosmas Daskalakis[1,2], Marina Tsoli[3], Göran Wallin[2], Angelika Kogut[4], Rajaventhan Srirajaskanthan[5], Christopher Harlow[5], Georgios Giovos[6], Martin Weickert[6], Beata Kos Kudla[7] & Gregory Kaltsas[3]
[1]General Hospital of Athens Korgialeneio - Benakeio Hellenic Red Cross, Athina, Greece; [2]Örebro University, Department of Surgery, Faculty of Medicine and Health, Örebro, Sweden; [3]National and Kapodistrian University of Athens, Endocrine Oncology Unit, 1st Department of Propaedeutic Internal Medicine, Laiko Hospital, Athens, Greece; [4]Medical University of Silesia, Department of Endocrinology and Neuroendocrine Neoplasms, Department of Endocrinology and Pathophysiology, Katowice, Poland; [5]King's College Hospital, London; [6]University Hospital Coventry & Warwickshire, Coventry; [7]Medical University of Silesia, Department of Endocrinology and Neuroendocrine Neoplasms, Department of Endocrinology and Pathophysiology, Katowice

Introduction
A change in the biological behaviour of Small-Intestinal Neuroendocrine Tumours (SiNETs), as reflected by an increase in the Ki-67 proliferation index may occur over time. The purpose of this study was to evaluate longitudinal changes in Ki-67 indices of SiNETs and assess the impact of these in overall survival (OS).
Patients and methods
We screened 551 patients with SI-NETs diagnosed from 1993, through 2021, identified using the SI-NET databases from five European referral centres. Only patients with well-differentiated tumours and available baseline tumour samples, as well as follow-up re-biopsies were included. Pathology reports were reviewed with regard to tumour histopathology and Ki-67 indices. To avoid immortal time bias, baseline for survival estimates was defined as the date of re-biopsy.
Results
We included 47 patients. Median Ki-67 index at SI-NET diagnosis was 2% (range 0.5-15%). Twenty-seven patients had grade 1 (G1) tumours (57.4%), and 20 G2 (42.6%). Mean time to re-biopsy was 48.8 months (SD: +/-162.5). At re-biopsy, the median change in Ki-67 index (absolute value; follow-up minus time of diagnosis) was 1% (range -10 to +38%). An increase in Ki-67 occurred in 20 patients (42.6%); in 11 patients the change in Ki-67 resulted in progression to higher tumour grade. The patients with an increment in Ki-67 $\geq$ 1%, with or without grade progression had a median OS of 46 months compared to 53.7 months in patients with stable or decreasing Ki-67 (hazard ratio 3.26, 95% CI: 1.11-9.58, $P=0.031$).
Conclusion
Increment in Ki-67 indices over time was observed in approximately 40% of SiNETs included in this study and was linked with worse survival outcomes. Further studies on molecular pathways with sequential biopsies at disease progression are necessary to shed light on the mechanisms that render a neoplasm more aggressive during the disease course.

Infectious complications during cushing's disease: about 51 cases

Bassiratou Hamza Maliki[1], Nassim Essabah Haraj[1], Siham El Aziz[1] & Asma Chadli[1]
[1]CHU Ibn Rochd - Casablanca, Morocco, Casablanca, Morocco

Introduction
Infections are very frequent in Cushing's disease with impact on quality of life.
Objective
The aim of our study is to describe infectious manifestations in Cushing's disease
Material and methods
Retrospective study of 51 patients diagnosed for Cushing's disease followed at the Ibn Rochd CHU Endocrinology from Casablanca from 2012 to 2023. Infectious complications were detected either at diagnosis or during monitoring. The statistical analysis was done by the SPSS version 25 software.
Results
We included 51 patients including 45 women and 6 men, the average age of patients was 36.20 years (17-69). The average seniority of the disease was 2.5 years. The average Clu was 657 mg/24 hours (116.8 - 2196). To pituitary MRI: macroadenoma in 27 patients, microadenoma in 21 patients and normal in 5 patients. The infectious complications found are: mycoses of large folds 66.67%($n=$ 34), intertrigo interdes macerated 72.55%($n=$ 37), cystitis 39.21%($n=$ 20), acute pyelonephritis 17.65%($n=$ 9), infection Pulmonary 27.45% ($n=$ 14), dental abscesses 11.76% ($n=$ 6), erysipelas of the leg 25.49% ($n=$ 13), candidosal vulvovaginitis 64.70% ($n=$ 33), esophageal candidiasis in 3 patients, 2 patients are complicated by post -operative meningitis of surgery by transphenoidal route. All our patients have healing with antibiotic and/or antifungal treatment and the management of Cushing's disease.
Conclusion
Infectious complications are frequent in Cushing's disease, hence the interest of early screening and adequate management in order to improve the quality of life in its patients.

Diagnostic value of a 3% hypertonic saline infusion test in differential diagnosis between adh deficiency and primary polydipsia

Nino Katamadze[1], Ekaterina Pigarova[1], Olga Rebrova[1] & Larisa Dzeranova[1]
[1]Endocrinology Research Centre

Aim
To assess the diagnostic value of a 3% hypertonic saline infusion test in comparison with a set of clinical and laboratory data (including a water deprivation test and MRI data) for the purpose of differential diagnosis between ADH deficiency and primary polydipsia (PP).
Materials and Methods
An interventional comparative study included 90 patients with confirmed polyuria-polydipsia syndrome. In order to assess the diagnostic characteristics, all subjects underwent sequential tests with osmotic stimulation: a 3% hypertonic saline infusion test and a water deprivation test.
Results
The study analyzed data from 90 patients who had underwent both osmotic stimulation tests. Based on the results of an analysis of the clinical, anamnestic, laboratory and instrumental data (MRI) and the results of a water deprivation test, a final diagnosis of ADH deficiency was made in 48 (53%) patients and 42 (47%) patients were diagnosed with PP. A diagnostic accuracy of the 3% hypertonic saline infusion test were calculated: sensitivity 98% (95% CI: 89%; 100%); specificity 98% (95% CI: 87%; 100%. Adverse events were studied: chills occurred significantly more often (31% vs 12%, $P<0.003$) during the 3% hypertonic saline infusion test, other signs of dehydration (dizziness, fog before the eyes, headache), and an increase in Na level >155 mmol/l were observed at equally frequency during both tests. The duration of the water deprivation test was 7 times higher than that of the 3% hypertonic saline infusion test (11 [11; 16] hours vs 1,5 [2; 2,5], p <0.001).
Conclusion
The 3% hypertonic saline infusion test has a high overall diagnostic accuracy (98%; 95% CI 92% to 100%) if compared to the set of clinical, laboratory and instrumental data of patients (including a water deprivation test). The advantage of the 3% hypertonic saline infusion test is its short duration and, as a consequence, better tolerability and compliance, while no significant differences in the occurrence of adverse events during the tests were noted.

Circulating levels of mir-375 in cushing's disease patients and evaluation of its role in the regulation of sstr2 expression in murine pituitary corticotroph tumor cell model

Claudia Pivonello[1], Roberta Patalano[2], Tatiana Montò[2], Mariarosaria Negri[3], Feliciana Amatrudo[3], Donatella Provvisiero[2], Chiara Simeoli[2], Nicola Di Paola[2], Angelica Larocca[2], Erminio Crescenzo[2], Annamaria Colao[2,4] & Rosario Pivonello[2,4]
[1]Università Federico II di Napoli, Dipartimento di Sanità Pubblica, Naples, Italy; [2]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Diabetologia. Andrologia e Nutrizione, Naples, Italy; [3]Università Telematica Pegaso, Dipartimento di Scienze Umanistiche, Naples, Italy; [4]Università Federico II di Napoli, UNESCO Chair for Health Education and Sustainable Development, Naples, Italy

In vitro studies suggest that glucocorticoids (GC) long-term exposure down-regulates SSTR2 but not SSTR5 expression in human and mouse ACTH-secreting tumor cells (AtT20), limiting the efficacy of octreotide (OCT), a somatostatin-receptor ligand with high affinity for SSTR2, in the treatment of Cushing's disease (CD). In AtT20, dexamethasone treatment increased miR-375 expression, whose analysis revealed a seed-sequence for SSTR2, supporting the hypothesis that excessive GC exposure can lead to epigenetic SSTR2 downregulation. The current study aims to evaluate miR-375 levels in CD patients and miR-375 impact on SSTR2 expression in AtT20/D16 cell model. Circulating and tissue miR-375 expression was evaluated by RT-qPCR in 21 CD patients and 19 healthy subjects; and in 6 human corticotroph pituitary tumors and 2 normal pituitaries, and in AtT20/D16 and somatotroph GH3 cell lines, respectively. SSTR2 protein expression and cellular localization were evaluated by western blot (WB) and immunofluorescence (IF) following miR-375 inhibition in AtT20/D16 in presence or not of OCT. Proliferation assay and flow cytometry were assessed to investigate the impact of miR-375 regulation on 72h of OCT at 10^{-8}M and 10^{-7}M treatment in AtT20/D16. Circulating miR-375 expression was higher in CD patients ($P<0.0001$) compared to healthy subjects, as well as tissue levels in human corticotroph pituitary tumors than in normal pituitaries. AtT20/D16 and GH3 cells exhibited an inverse pattern of expression, with low levels of SSTR2 messengers and high levels of miR-375 in AtT20/D16 and an opposite expression pattern in GH3 cells. miR-375 inhibition significantly increased membranous SSTR2 protein expression, evaluated by WB and IF, in AtT20/D16 ($P=0.0310$ and $P=0.0154$, respectively) compared to untreated cells. Receptor internalization, induced by 20 min of OCT10^{-7}M treatment, appeared stronger when OCT10^{-7}M was combined with miR-375 inhibitor. OCT10^{-7}M but not 10^{-8}M decreased cell proliferation (6.8%, $P=0.011$) compared to control. This effect was potentiated by miR-375 inhibition (miR-375inh+OCT10^{-8}M 9,0%, $P=0.023$ and miR-375inh+OCT10^{-7}M 10.1%, $P=0.0001$, vs control; miR-375inh+OCT10^{-8}M 8.5% $P=0.0058$ vs OCT10^{-8}M). Interestingly, miR-375 inhibition alone and in combination with OCT tend to increase the percentage of cells in early (miR-375inh 32.5%; miR-375inh+OCT10^{-8}M 25.7%; miR-375inh+OCT10^{-7}M 31.8%) and late apoptosis (miR-375inh 4.2%; miR-375inh+OCT10^{-8}M 4.9%; miR-375inh+OCT10^{-7}M 4.0%) compared to control (22.6% and 4.0%) and OCT alone (OCT10^{-8}M 31.8% and 3.2%; OCT10^{-7}M 27.8% and 2.5%) respectively, by inducing PARP, Caspase3 and ERK1/2 phosphorylation. Concluding, these data suggested that SSTR2 protein expression can be epigenetically downregulated by GC-induced increase of miR-375 expression at least partially and negatively influencing OCT action in corticotroph pituitary tumors.

Soluble α-klotho protein, nesfatin-1 and IGFBP-3 concentrations in the biochemical diagnosis and monitoring treatment effects in patients with acromegaly

Magdalena Ostrowska[1], Wojciech Zgliczyński[1] & Piotr Glinicki[1,2]
[1]Department of Endocrinology, Centre of Postgraduate Medical Education, Warsaw, Poland; [2]EndoLab Laboratory, Centre of Postgraduate Medical Education, Warsaw, Poland

Introduction
Active acromegaly is diagnosed based on clinical symptoms and biochemical tests, such as elevated GH concentration, IGF-1 concentration above the reference range for sex and age. However, due to certain limitations associated with IGF-1 measurements, alternative biomarkers are being sought that may be useful at various stages of the diagnostic and therapeutic process.
Purpose
Evaluation of the usefulness of serum soluble α-klotho protein, nesfatin-1 and IGFBP-3 determination in the biochemical diagnosis and treatment monitoring in patients with acromegaly.
Materials and Methods
The concentrations of soluble α-klotho protein, nesfatin-1 and IGFBP-3 were determined in patients at the time of acromegaly diagnosis, as well as after 3 and 12 months following the removal of the pituitary adenoma. The examined biomarkers were measured in 35 patients at the time of diagnosis and in 25 patients after 3 and 12 months post-surgery. Measurements of soluble α-klotho protein and nesfatin-1 were conducted using the ELISA immunoassay, while IGFBP-3 was determined using the isotopic method (RIA immunoassay).
Results
The concentration of soluble α-klotho protein was higher ($P=0.0001$) at the time of disease diagnosis compared to the control group. However, no difference was observed in the soluble α-klotho protein concentration at 3 and 12 months after surgery in the study group ($P=0.214$) vs the control group ($P=0.407$). The concentration of soluble α-klotho protein was lower ($P=0.0001$) 3 months after surgery than at the time of disease diagnosis. No difference was observed in the concentration of soluble α-klotho protein at 3 and 12 months after surgery ($P=0.802$). The IGFBP-3 concentration was lower ($P=0.0001$) at 3 and 12 months after surgery than at the time of disease diagnosis ($P=0.0001$). No differences were observed in the IGFBP-3 concentration at 3 and 12 months after surgery ($P=0.122$).
Conclusion
Determination of concentrations of the biomarkers tested: soluble α-klotho protein and IGFBP-3, may be useful in the diagnosis of patients with acromegaly. The concentration of nesfatin-1 did not show discriminatory properties in patients with acromegaly.

Utilization of MRI in the work-up of mild hyperprolactinemia

Jared Galloway[1], Maria Flynn[2], Jennifer Mann[3], Sana Ghaznavi[1], John Lysack[4], David Campbell[1] & Kirstie Lithgow[1]
[1]University of Calgary, Cumming School of Medicine, Division of Endocrinology, Canada; [2]University of Calgary, Cumming School of Medicine, Division of Internal Medicine; [3]University of Calgary, Cumming School of Medicine, Division of Neurosurgery; [4]University of Calgary, Cumming School of Medicine, Division of Radiology

Background
Hyperprolactinemia is a biochemical finding with a broad differential diagnosis and is commonly measured during the work up for amenorrhea, galactorrhea, or hypogonadism. Diagnostic workup of hyperprolactinemia should be performed in a stepwise fashion to avoid incorrect diagnoses and/or unnecessary investigations. As mild hyperprolactinemia (i.e. <100 mg/l) can be physiologic or spurious, repeating the prolactin level is a crucial step in the initial workup. Unnecessary or premature imaging can lead to incidental findings which generate further investigations and surveillance, causing undue burden on patients and the healthcare system. Our primary objective was to quantify the frequency and proportion of MRI sella ordered for isolated mild hyperprolactinemia when not confirmed by repeat measurement. Our secondary objective was to assess the frequency and type of incidental findings resulting from inappropriate or premature neuroimaging.
Methods
A retrospective chart review was performed between 2012 and 2022 in the province of Alberta, Canada. Potentially eligible cases were identified by a data analyst from Alberta Health Services. Inclusion criteria were 1) patients >18 years of age; 2) elevated serum prolactin <100 mg/l; 3) MRI sella performed following the detection of hyperprolactinemia. Cases with neuroimaging performed for alternative indications were excluded. We classified ordering of MRIs as 'appropriate' or 'inappropriate' based on the clinical indication and the presence or absence of repeat prolactin measurement.
Results
Initial screening identified 3,768 cases. Of these, 1,967 (52%) had two or more prolactin measurements prior to the MRI while 1,801 (48%) had a single prolactin measurement. In 823/1801 cases (46%) the indication for imaging was categorized as appropriate on the basis of clinical suspicion of pituitary or hypothalamic disease (e.g.: amenorrhea, mass effect symptoms). For the remaining cases ($n=978$), the ordering of neuroimaging was categorized as inappropriate. Of the MRIs performed for these cases, 61% ($n=592$) reported normal findings and 39% ($n=386$) reported one or more abnormal findings. The abnormal findings were as follows: 21% ($n=201$) reported a microadenoma, 2% ($n=21$) reported a macroadenoma, and 17% ($n=164$) reported other incidental findings (e.g.: white matter changes, cysts).
Conclusion
In 26% ($n=978$) of mild hyperprolactinemia cases, neuroimaging was performed prematurely without repeating a prolactin measurement or without an appropriate indication. Furthermore, these scans generated a large number of incidental findings which require additional investigation and follow-up. We plan to apply our results to future systems level quality improvement initiatives.

Obesity in survivors of childhood-onset craniopharyngioma – impact of parental body mass index at craniopharyngioma diagnosis?

Julia Beckhaus[1,2], Maria Eveslage[3], Brigitte Bison[4], Carsten Friedrich[1] & Hermann Müller[1]
[1]Carl von Ossietzky Universität Oldenburg School VI - School of Medicine and Health Sciences, Department of Pediatrics and Pediatric Hematology/Oncology, Klinikum Oldenburg AöR, Oldenburg, Germany; [2]Carl von Ossietzky Universität Oldenburg School IV - School of Medicine and Health Sciences, Divison of Epidemiology and Biometry, Oldenburg, Germany; [3]Institute of Biostatistics and Clinical Research, University of Münster, Münster, Germany; [4]University of Augsburg, Faculty of Medicine, Diagnostic and Interventional Neuroradiology, Augsburg, Germany

Background
It is well known that both genetic backgroup and lifestyle influence the development of 'general' obesity. However, the role of parental body mass index (BMI) on the development of obesity in long-term survivors of childhood-onset craniopharyngioma (CP) is not well understood. This study aimed to analyze the correlation of patients' BMI at diagnosis, and last visit and parental BMI at CP diagnosis and further explored potential risk factors for obesity in CP patients.
Patients and methods
291 CP patients and their parents recruited in the German KRANIOPHARYNGEOM studies were included. Correlations between patient's BMI SDS at CP diagnosis and last visit and parental BMI at CP diagnosis were analyzed. The associations between hypothalamic damage, maternal/paternal BMI and CP patients' obesity at last visit were analyzed by multivariable logistic regression.
Results
After a median follow-up of 9.38 years, 52% of CP patients developed obesity (BMI >3SDS). Patient's BMI SDS at last visit was moderately correlated with BMI-SDS at CP diagnosis ($r=0.48$, 95%-CI 0.38-0.58, $P<0.001$), and also with maternal BMI at diagnosis ($r=0.28$, 95%-CI 0.17-0.38, $P<0.001$) and paternal BMI at diagnosis ($r=0.3$, 95% CI-0.19-0.41, $P<0.001$). Hypothalamic involvement (HI) and surgical hypothalamic lesions (HL) of posterior hypothalamic structures (grade II) were independent risk factors for obesity. With increasing maternal or paternal BMI, the probabilty of developing obesity as a patient with CP increased. However, the contributing role of parental BMI to the pathogenesis of obesity was small compared to the impact of HL.
Conclusion
We conclude that besides HL, parental disposition for obesity is associated with the development of obesity in patients after CP. Hypothalamus-sparing treatment strategies are most effective in prevention of hypothalamic obesity. Our results indicate that also the family situation could have an influence on the development of obesity after CP and might be a therapeutic target.

Background
Acromegaly is a rare endocrine disorder characterised by excess growth hormone (GH) and insulin-like growth factor 1 (IGF-1) that is associated with significant morbidity and impaired quality of life (QoL). Standard-of-care (SoC) treatments for acromegaly typically require healthcare provider administration, pose a substantial treatment burden, and leave scope for improved disease control. CAM2029, an octreotide subcutaneous depot with ~5x higher bioavailability than octreotide long-acting release (LAR), is designed for once-monthly self-administration as a ready-to-use syringe or injection pen. Here, we report findings from the pivotal trial of CAM2029 in patients with acromegaly.
Methods
In this Phase 3, multinational, randomised, double-blind, placebo-controlled trial (NCT04076462), patients on stable SoC treatment (octreotide LAR or lanreotide Autogel) who had IGF-1 $\leq$1x upper limit of normal (ULN) at screening were randomised 2:1 to once-monthly CAM2029 20 mg or placebo for 24 weeks. The primary endpoint was the proportion of patients with IGF-1 $\leq$ULN (mean of week 22/24 measurements). The key secondary endpoint was the proportion of patients with both IGF-1 $\leq$ULN (week 22/24 mean) and mean GH <2.5 µg/l (week 24). Patient-reported outcomes (PROs) were compared at baseline and week 24.
Results
Seventy-two patients were randomised to CAM2029 ($n=48$) or placebo ($n=24$). A significantly greater proportion of CAM2029 vs placebo recipients achieved the primary (IGF-1 response: 72.2% vs 37.5%; $P=0.0018$) and key secondary endpoints (IGF-1 and GH response: 70.0% vs 37.5%; $P=0.0035$). These results were supported by all sensitivity and supportive analyses. Median time to loss of response (IGF-1 $>$ULN) was 8.4 weeks in the placebo arm and was not reached in the CAM2029 arm. Mean IGF-1 remained below ULN throughout the study for patients receiving CAM2029 but not for patients receiving placebo. PROs showed improved QoL, treatment convenience, and patient satisfaction for CAM2029 vs baseline SoC, with numerically greater improvements vs placebo. CAM2029 was well tolerated with a comparable safety profile to SoC; no new or unexpected safety signals were observed. One treatment-related serious adverse event (cholecystitis) occurred in the placebo arm, and 5 patients discontinued treatment due to injection site erythema/induration (CAM2029: $n=3$; placebo: $n=1$) or migraine (CAM2029: $n=1$).

Conclusion
CAM2029 provided robust biochemical control of acromegaly superior to placebo, substantially improved PROs vs baseline SoC and placebo, and had a safety profile consistent with SoC. These findings support CAM2029 as a potential therapeutic alternative to SoC acromegaly treatments that addresses unmet patient needs.

Metabolic syndrome in women with sheehan syndrome: prevalence and associated factors

Salma Salhi[1], Ibtissem Oueslati[1], Emna Talbi[2], Anis Grassa[1], Arige Abid[1], Meriem Yazid[1], Moncef Feki[2] & Melika Chihaoui[1]
[1]La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia; [2]La Rabta University Hospital, Laboratory of Biochemistry, Tunis, Tunisia

Introduction
Sheehan's syndrome (SS) is characterized by a deficiency in pituitary hormone secretion. It is now being closely inspected for its implication in the onset of metabolic syndrome (MS). The aims of this study were to determine the prevalence of MS and assess its associated factors in women with SS.
Methods
We carried out a cross-sectional study involving 50 patients diagnosed with SS and 50 controls, matched for age and body-mass index (BMI). Waist circumference measurement, 24-hour ambulatory blood pressure monitoring, and laboratory tests were performed in all participants. MS was defined according to the IDF-2009 criteria.
Results
The average age was 62.2 $\pm$ 9.4 years in patients and 60.6 $\pm$ 8.4 years in controls ($P=0.385$). The mean BMI was 29.6 $\pm$ 6,0 kg/m^2 in patients vs 30.0 $\pm$ 5.0 kg/m^2 in controls ($P=0$, 741). Waist circumference was significantly higher in patients (101.3 $\pm$ 10.2 cm) than in controls (95.7 $\pm$ 10.5 cm) ($P=0.007$). It was $\geq$ 80 cm in 98% of patients and in 86% of controls ($P=0.027$). The prevalence of MS was 64% in patients and 40% in controls ($P=0.016$). Among these patients, 87% of women with SS and 100% of the CG had three to four MS criteria. The coexistence of all five MS criteria was observed only in patients (13%). SS was positively associated with MS (Odds Ratio=2.66,: 1.18-5.98, $P=0.016$). In women with SS, age, diagnostic delay, disease duration, GH levels, FT4 levels, daily dose of levothyroxine, daily and cumulative dose of hydrocortisone, and estroprogestative therapy were not associated with MS.
Conclusion
These results emphasize the need for monitoring and managing components of MS in individuals with SS. Clinicians should develop targeted interventions that can effectively mitigate the risk of MS and its associated complications in this specific population.

2-[18F]FDG PET imaging biomarkers for clinical and metabolic assessment in ectopic cushing syndrome. increased spleen FDG uptake as a helpful parameter to predict the presence of metastases - a pilot study

Ewelina Rzepka[1], Joanna Kokoszka[2], Marta Opalinska[1], Katarzyna Sitarz[3], Anna Grochowska[4], Anna Sowa-Staszczak[1], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]
[1]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland; [2]Endocrinology, Oncologic Endocrinology, Nuclear Medicine and Internal Diseases Department, University Hospital in Krakow, Poland; [3]University Hospital in Krakow, Poland; [4]Department of Radiology, University Hospital in Krakow, Poland

Introduction
2-[18F]FDG PET/CT, commonly used for neoplastic lesions detection, also allows assessment of the severity of the inflammatory processes. Moreover, glucose uptake in spleen and bone marrow may be a useful biomarker of systemic inflammation. Patients with Cushing syndrome demonstrate many metabolic changes involving muscles and fat tissue. Some mechanisms are known, but their relationship to glucose metabolism is not well investigated. Our study aimed to correlate glucose metabolism with the use of 2-[18F]FDG PET/CT in skeletal muscle, adipose tissue, bone marrow and spleen with clinical and metabolic parameters in patients with EAS.
Materials and Methods
Analysis of 2-[18F]FDG PET/CT scans in 13 consecutive patients with EAS in comparison to healthy age, BMI and sex-matched control group was performed. On unenhanced CT scans the body composition on cross-sectional computed tomography images at the L3 level - skeletal muscle area (SMA), skeletal muscle index (SMI), visceral fat area (VFA), visceral fat index (VFI), subcutaneous fat area (SFA), subcutaneous fat index (SFI), intermuscular adipose tissue (IMAT) were assessed. Additionally, cross-sectional area (CSA) and mean attenuation (MA) of each psoas muscle at the L4 level were measured. In 2-[18F]FDG-PET scans, glucose uptake of each psoas (at the L4 vertebra) and femoris muscle (SUV max, SUV peak and SUV mean, target to background ratio [TBR]), as well as glucose uptake of subcutaneous (SAT) and visceral fat (VAT) (SUV max, SUV peak and SUV mean) were analysed. Spleen and bone marrow glucose metabolism (SUV mean, SUV max, spleen to liver ratio [SLR], bone marrow to liver ratio [BLR]) were also evaluated. The results were correlated with clinical and hormonal markers of the disease.
Results
We observed significant positive correlation between presence of metastases and spleen SUV max and SUV mean ($P=0.03$, $P=0.03$). Significant negative correlations between morning cortisol level, midnight cortisol level, cortisol after 1 mg of dexamethasone and VAT SUV peak were seen ($P=0.049$, $P=0.029$, $P=0.017$, respectively). Midnight cortisol level was negatively correlated with SAT SUV peak and SUV max ($P=0.048$, $P=0.032$, respectively).
Conclusion
Increased spleen FDG uptake, considered to be a surrogate marker of cancer-related inflammation, could be helpful to predict the presence of metastases in EAS. Negative correlation between cortisol levels and glucose metabolism parameters in fat could reflect the dominant role of insulin resistance in adipocytes, abnormal perfusion and vascular function in adipose tissue of EAS patients.

Obesity-Related pseudo-cushing syndrome and pituitary incidentaloma: a case study

Vittoria Strinati[1], Gabriele Veroi[1], Davide Masi[1], Paola Nevi[1], Valentina Ventimiglia[1], Mikiko Watanabe[1], Stefania Mariani[1], Lucio Gnessi[1] & Carla Lubrano[1]
[1]Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Sapienza University of Rome, Rome, Italy

Introduction
The diagnosis of Cushing's syndrome (CS) can be challenging for endocrinologists due to its multifaceted presentation. Accurate differentiation between Pseudo-Cushing syndrome (PCS) and true CS is crucial as their treatment approaches and outcomes vary significantly.
Case Report
A 43-year-old male patient with grade III obesity (BMI: 49.9 kg/m^2) presented to our Endocrinology outpatient clinic with a complex medical history including hypertension, impaired fasting glycemia, Basedow disease and recent hypogonadism. The patient reported a rapid and substantial weight gain of approximately 60 kg within 5 months during the Covid-19 pandemic. Physical examination revealed a 'cushingoid' appearance with facial plethora, central obesity, *striae rubrae*, and retronucal adipose tissue deposition. The patient underwent initial investigations for endogenous hypercortisolism, including overnight 1 mg dexamethasone suppression test (DST), urinary-free cortisol test, ACTH test. However, the results did not fully meet the diagnostic criteria for endogenous hypercortisolism. Therefore, an oral 2-mg 48-h low-dose dexamethasone suppression test (LDDST) was performed, revealing a lack of suppression of serum cortisol level and thus confirming the diagnosis of endogenous hypercortisolism. To investigate the possibility of Cushing Disease (CD), a 3 Tesla dynamic contrast-enhanced magnetic resonance imaging (MRI) was performed, revealing an area of delayed enhancement in the left half of the gland, measuring approximately 4 mm, and suggestive of microadenoma. Despite this finding, the possibility of PCS could not be ruled out, as the patient reported emotional distress and depressed mood despite denying alcohol consumption. The patient underwent a combined LDDST-CRH test. The basal cortisol level before CRH infusion was 30.5 nmol/l, and the cortisol level 15 minutes after CRH infusion was 35.7 nmol/l ($<$39 nmol/l). Although the result was not definitive, it indicated the possible presence of PCS and, therefore a 'wait and see' approach was adopted. The patient was started on a low-calorie diet and received medical treatment to manage comorbidities. A follow-up biochemical assessment was conducted after 3 months, which confirmed the diagnosis of PCS with concomitant non-functioning pituitary microadenoma. The patient exhibited remarkable compliance with the recommended diet, leading to a substantial weight loss of 25 kg. Additionally, diabetes and hypertension appeared well-controlled.

Conclusion
Differential diagnosis between CD and PCS is complex and may require multiple tests over time. The possibility of pituitary incidentalomas on MRI should always be considered. In cases where there is uncertainty regarding the diagnosis, a follow-up evaluation of the patient at 3-6 months, both clinically and biochemically, can be useful.

The value of digital quantification of somatostatin receptor subtypes 2 and 5 immunostaining in GH-secreting pituitary tumors

Claudia Campana[1,2], Jessica Amarù[1], Angelo Milioto[1], Federica Nista[1], Peter M. van Koetsveld[2], Anand Iyer[2], Marica Arvigo[1], Diego Ferone[1,3], Leo J. Hofland[2] & Federico Gatto[3]
[1]University of Genova, Endocrinology Unit, Department of Internal Medicine and Medical Specialties, School of Medical and Pharmaceutical Sciences, Genoa, Italy; [2]Erasmus Medical Center, Department of Internal Medicine, Division of Endocrinology, Rotterdam, Netherlands; [3]IRCCS Ospedale Policlinico San Martino, Endocrinology Unit, Genoa, Italy

Introduction
Immunohistochemistry (IHC) of somatostatin receptor subtype 2 (SST_2) is a predictive factor for first-generation somatostatin receptor ligand (fg-SRL) response in acromegaly patients. A semi-quantitative immunoreactivity score, IRS, has been proposed as the gold-standard to evaluate SST_2 IHC expression. Recently, our group developed a quantitative method to determine SST_2 expression using an open-source digital image analysis (DIA). We aimed to validate the DIA on both SST_2 and SST_5 in a new cohort of GH-secreting pituitary tumors. We then correlated fg-SRL response with SST expression, evaluated with both IRS and DIA methods.
Material and Methods
SST_2 and SST_5 expression was assessed in paraffin-embedded tissues from 42 GH-secreting pituitary tumors, using both IRS and DIA. The DIA software calculates the staining intensity (intensity/area) and the percentage of positive cells (%PC-DIA) based on four representative images. The IRS was independently performed by two researchers. Correlations were performed evaluating the 'total' receptor expression (IRS vs intensity/area) and the %PC (%PC-IRS vs %PC-DIA). GH and IGF-1 data were collected at baseline after surgery and following 6-month fg-SRL treatment.
Results
Mean SST_2 IRS was 6.41 ± 3.35, mean DIA intensity/area was 0.17 ± 0.14, and mean %PC-DIA was 63.42 ± 29.67%. As concerns SST_5, mean IRS was 4.66 ± 3.26, mean DIA intensity/area was 0.07 ± 0.09, and mean %PC-DIA was 38.27 ± 38.84%. A good correlation was observed between DIA and IRS for 'total' receptor expression (rho = 0.924 and rho = 0.872, for SST_2 and SST_5, respectively), as well as for the %PC (rho = 0.649 and rho = 0.748, all $P < 0.0001$). Twenty-four out of 42 patients (57%) were treated with fg-SRLs after surgery. A significant positive correlation was observed between GH decrease and SST_2 expression, quantified with DIA (intensity/area: rho = 0.707, %PC: rho = 0.625, $P < 0.005$) and total IRS (rho = 0.655, $P = 0.017$), but not with the %PC-IRS (rho = 0.356, $P = 0.123$). Similarly, a significant positive correlation was observed between IGF-1 xULN decrease and SST_2 expression for both DIA parameters and total IRS (rho ranging from 0.517 to 0.617, $P < 0.05$), but not for %PC-IRS (rho = 0.235, $P = 0.334$). No correlation was observed between GH, IGF-1 xULN decrease and SST_5 expression.
Conclusion
The DIA is a reliable quantification method to assess both SST_2 and SST_5 expression. SST_2, but not SST_5, expression correlated with GH and IGF-1 decrease following fg-SRL treatment. This correlation was statistically significant using both IRS and DIA when 'total' SST_2 expression was assessed. The %PC correlated with treatment response only when evaluated using the DIA, thus showing the superiority of this quantitative method.

Cell lineage specific differences in clinical behavior of clinically non-functioning pituitary adenomas according to the 2017 WHO classification – a systematic review and meta-analysis

Loren van der Hoeven[1,2,3], Tessa Slagboom[2,4], Arjan Malekzadeh[5], Jantien Hoogmoed[3,6], Madeleine Drent[2,3,4], Eleonora Aronica[7], Dirk Jan Stenvers[1,2,3,4] & Alberto Pereira[1,2,3]
[1]Amsterdam UMC, Location University of Amsterdam, Department of Endocrinology and Metabolism, Amsterdam, Netherlands; [2]Amsterdam Gastroenterology Endocrinology and Metabolism, Amsterdam, Netherlands; [3]Endo-ERN European Reference Network on Rare Endocrine Conditions; [4]Amsterdam UMC, Location Vrije Universiteit, Department of Endocrinology and Metabolism, Amsterdam, Netherlands; [5]Amsterdam UMC, Location University of Amsterdam, Medical Library, Amsterdam, Netherlands; [6]Amsterdam UMC, Location University of Amsterdam, Department of Neurosurgery, Amsterdam, Netherlands; [7]Amsterdam UMC, Location University of Amsterdam, Department of Neuropathology, Amsterdam, Netherlands

Background
In 2017, the World Health Organization (WHO) adjusted the histopathological classification of pituitary adenomas (PAs) by including pituitary cell lineage specific transcription factors (TFs), elucidating a continuous spectrum between true null cell (NCA), silent, clinically silent, and functioning adenomas. The definitions of non-functioning (silent) gonadotroph, corticotroph, somatolactotroph and thyrotroph adenomas were previously reserved for immunohistochemically hormone positive (IHC hormone+) PAs, but have been expanded to also include PAs with positive immunohistochemistry of the corresponding cell lineage specific TF (SF-1+, TPIT+ or Pit-1+) despite negative IHC of the anterior pituitary hormones (TF+/hormone- PAs). On the other hand, the definition of NCA has been narrowed to adenomas that are IHC negative both for anterior pituitary hormones and TFs. It is, however, not clear, if, and to what extent, the novel histopathological classification translates into differences in clinical behavior in clinically non-functioning pituitary adenomas.
Objectives
To systematically review potential cell lineage specific differences in the prevalence of cavernous sinus invasion in clinically non-functioning PAs.
Methods
The conduct and reporting of this systematic review and meta-analysis were in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA-statement). A comprehensive literature search in Medline, Embase and CENTRAL was performed on July 11th 2023. Cohort and cross-sectional studies were only included if the WHO 2017 histopathological classification of at least one transcription factor was applied using immunohistochemistry, and at least one clinical outcome related to invasion was reported.
Results
A total of 26 articles were included for the outcome of invasion, including a total of 2253 participants. Invasion of the cavernous sinus occurred more often in NCAs and TPIT+ non-functioning PAs compared to SF-1+ (prevalence ratio (PR) 1.60 [95% CI 1.29 – 1.97], and 1.43 [95% CI 1.22 – 1.69]). Invasion of the cavernous sinus also occurred more often in NCAs compared to PIT-1+ (PR 1.44 [95% CI 1.03 – 2.02]). There were no differences in cavernous sinus invasion between PIT-1+ compared to SF-1+, NCA compared to TPIT+ and TPIT+ compared to PIT-1+, although a trend was observed for TPIT+ being more often invasive compared to PIT-1+ (PR 1.51 [95% CI 0.88 – 2.59]).
Conclusion
The 2017 WHO classification enables to identify histopathological subgroups of clinically non-functioning PAs with distinct clinical behavior in terms of cavernous sinus invasion, with NCAs and TPIT+ PAs being more often invasive in the cavernous sinus compared to SF-1+ non-functioning PAs.

Proton beam radiotherapy for treatment of functional pituitary adenomas

Dana Erickson[1,1], Herndon Justine[2], Nadia Laack[1] & William Breen[1]
[1]Mayo Clinic, Rochester, United States; [2]Mayo Clinic, Endocrinology, Rochester, United States

Background
Proton beam therapy (PBT) provides high doses of radiation to the targeted tissues while minimizing exposure to surrounding structures. Although rarely used in patients with functional pituitary adenomas (FPA) it might be nessesary in certain clinical situations. There is paucity of data regarding short- and long-term endocrinologic outcomes.
Objectives
In patients undergoing PBT, determine rate of remission of FPA(normal hormonal values off medical suppressive therapy [MST]), control of FPA (reduction in MST and remission) and rate of hypopituitarism.

Methods
Review of prospectively set up database of adults from tertiary referral center with FPA 2015. Baseline data included demographics, tumor pathology, prior history of surgery/radiation, MST, hormonal data and incidence of pituitary insufficiencies (PI). Biochemical hormonal data, change in MST, remission of functional excess, and incidence of new PI was abstracted at 6 months, and 1, 2, 3, 4, 5 years, and up to two additional time points up to 2023. Statistical analysis includes descriptive statistics presented as number (%) and median [IQR].
Results
Twelve patients with FPA of total 40 pathologies of pituitary origin underwent PBT. Median age of patients was 43.9 years old [30.8, 56.4], median follow-up was 24 months [12, 60]. Median PBT Gy was 52.2 [50.4, 54], in median of 28 fractions. Tumors included GH-secreting in 6 (50.0%), followed by two (16.7%) ACTH-secreting, two (16.7%) PRL-secreting, one (8.3%) TSH-secreting, and one (8.3%) plurihormonal. All patients had prior surgeries (range 1-4), 3 (25%) had previous photon radiation. Eleven (91.7%) were uncontrolled despite 9 (75%) being treated with MST. The 3 (25%) patients who were not on MST had increase in size of their tumor prompting PBT. At least one PI was observed at baseline in 9 patients (75%), secondary hypogonadism most common (7, 58.3%). At 6 months remission occured in 2 (16.7%). At the end of follow-up, 3 (25%; 2 GH-secreting and 1 ACTH-secreting) had achieved remission, 2 (16.7%, 1 GH-secreting and the TSH-secreting) were controlled, with MST reduced, 4 (33.3%) were controlled but MST not reduced, and persistent hyperfunction was observed in 3 (25.0%). Only one patient (16.7%) without PI at baseline developed adrenal insufficiency at 3-years post-treatment.
Conclusion
PBT is a reasonable consideration for treatment of selected FPA for control or reduction of MST need with little newly developed PI, recognizing the already high initial prevalence of PI in this cohort a still limited follow-up.

Hyponatremia after COVID-19 is frequent in the first year and increases re-admissions

Betina Biagetti[1,2], Adrian Sanchez-Moltavá[1,3], Albert Puig-Perez[1,2], Isabel Campos-Varela[1,4], Florencia Pilia[1,5], Emilie Anderssen-Nordahl[1,6], Didac González-Sans[1,7], Marta Miarons[1,8] & Rafael Simo Canonge[1,2]
[1]Vall d'Hebron University Hospital, Barcelona, Spain; [2], Endocrinology; [3], Infectious Diseases Department; [4], Liver Unit; [5], Pneumology Department; [6], Clinical Pharmacology; [7], Systemic Autoimmune Diseases Unit; [8], Pharmacy Department

Background
Hyponatremia has been related to worse outcomes from COVID-19 infection during hospital admission. However, little is known about the incidence and prevalence of hyponatremia after discharge and the associated risk factors.
Methods
Prospective observational 24-month follow-up study of patients admitted at a tertiary hospital during the first COVID-19 wave. Kaplan-Meier curves and Cox proportional hazard models were used to assess the main variables in predicting hyponatremia on follow-up (HyPO-FU).
Results
A total of 161 out of 683 (24.4%) developed HyPO-FU. The group with HyPO-FU comprised of more men [(62.3%) vs (49.2%); $P<0.01$], older [65.6 $\pm$18.2 vs 60.3$\pm$17.0; $P<0.01$], had more comorbidities such as diabetes, hypertension, heart failure and renal failure ($P<0.01$), hyponatremia on admission [(46.1%) vs (28.5%) $P=0.01$], and were more frequently re-admitted [(16.2%) vs (3.8%); $P<0.01$) compared to patients without HyPO-FU. The mean rate of HyPO-FU was higher in the first year 23.6 per 100 individuals per year. After a stepwise Cox regression analysis, the independent risk factors of developing HyPO-FU were diabetes [OR: 2.12, IC: 95% (1.48-3.04)], hypertension [OR: 2.18, IC: 95% (1.53-3.12)], heart failure [OR: 3.34, IC: 95% (1.72-6.48)] and previous invasive ventilation support requirement [OR: 2.38, IC: 95% (1.63-3.50)].
Conclusion
HyPO-FU was frequent in the first year after COVID-19 infection, and the risk was higher in older men with comorbidities, increasing rehospitalisation. The independent associated risk factors were diabetes, hypertension, heart failure and the requirement of invasive ventilation support. Further studies aimed at evaluating the beneficial effects of correcting hyponatremia in these patients are warranted.

Management of carcinoid heart disease in neuroendocrine tumor patients: a retrospective study

Ignacio Jiménez Hernando[1], Laura González Fernández[1], Rogelio García Centeno[4], Marta Pérez Noguero[1], Mónica Gómez-Gordo Hernanz[1], Gloria Collado González[1], Isabel Losada Gata[1], Alberto García Piorno[1] & Olga González Albarrán[1]
[1]Gregorio Marañón General University Hospital, Endocrinology and Nutrition, Madrid, Spain

Introduction
Approximately 20% of neuroendocrine tumor (NET) patients experience carcinoid syndrome (CS), primarily associated with metastatic ileal NETs. CS manifests with symptoms such as diarrhea, flushes, and cardiac complications. Carcinoid heart disease (CHD) is a negative prognostic factor in NETs. However, the considerable variability in reported diagnoses and treatment approaches in the literature creates uncertainty about optimal management in this specific population.
Methods
A cross-sectional, single-center retrospective study was designed. Patients with CS followed during 2023 in our hospital were included, focusing on those with associated carcinoid heart disease. Epidemiological, clinical, biochemical, therapeutic, and evolutionary variables were recorded.
Results
Fifteen patients (9 females and 6 males) with a mean age of 65 years (45-77 years) were included. The primary tumor location was intestinal (jejuno-ileal) in 14 cases, with only 1 pancreatic case. Tumor grade was G2 in 60%, G1 in 33.3%, and G3 in 6.7%. Diarrhea was present in 80% of cases, and flushing in 60%. Biochemically, the mean chromogranin A (CgA) was 356 units (range 3.2 - 3515), and mean 5-hydroxyindoleacetic acid (5HIAA) was 77 mg/24h (range 12.4 - 437). Regarding CHD, this comorbidity was present in 20% of patients (3/15). The time from oncologic diagnosis to carcinoid heart disease diagnosis was less than 4 months (1-120 days). Two patients underwent cardiac surgery (one with a biological prosthesis and the other with a mechanical prosthesis). After surgery, their dyspnea improved according to NyHA from II-III to I-II, respectively. One patient underwent a second surgery and died due to complications. All three patients were being treated with somatostatin analogues. Only the patient with the mildest heart disease (NyHA I) received PRRT treatment. There were no statistically significant differences in CgA and 5HIAA values at diagnosis between patients with and without CHD.
Conclusions
Significant variability exists in the treatment approaches for patients with carcinoid heart disease, and mortality after valve replacement remains high. Chromogranin A and 5HIAA were not predictive markers for CHD presence in our CS population.

Approaching the reality of restoring GH secretion and growth with the investigative oral growth hormone secretagogue (GHS) LUM-201 in moderate pediatric growth hormone deficiency (PGHD)

Peter Clayton[1], Fernando Cassorla[2], OraGrowtH210 Trial Group[3], OraGrowtH212 Trial Group[3], Michael Johnson[4], Aleksandra Bruchey[3], Christopher Smith[3], Erik Brincks[3], Pisit ' Duke' Pitukcheewanot[3], John McKew[3] & Michael Thorner[3]
[1]University of Manchester, Division of Developmental Biology & Medicine; Paediatric Endocrinology, Manchester, United Kingdom; [2]University of Chile, Institute of Maternal and Child Research, Santiago, Chile; [3]Lumos Pharma, Inc., Austin, TX, United States; [4]University of VA Health System, Keswick, VA, United States

Over 40 years ago, the first enkephalin analogs that stimulated growth hormone (GH) release were synthesized in 1984, leading to the development of GHRP-6. In 1995, Merck developed a potent non-peptide orally active long-acting growth hormone GHS, ibutamoren, and cloned the GHS receptor in 1996, which led to ghrelin being identified as its natural ligand in 1999. These discoveries uncovered a new physiological pathway for GH regulation linking the GI tract and the hypothalamic-pituitary axis (HPA). In 1998, the first oral ibutamoren (now known as LUM-201) clinical trial in PGHD included pre-pubertal children with a broad spectrum of PGHD, resulting in positive growth responses coming from those with an intact HPA. Later, it was understood the best candidates for this investigative oral treatment were pre-pubertal children (those with standard stimulation testing peak GH between ≥ 3 <10 ng/ml) that respond positively to the LUM-201 Predictive Enrichment Marker (PEM) test. PEM+ responders have basal serum IGF-1 >30 ng/ml and a peak serum GH ≥ 5 ng/ml after administering a single dose of 0.8 mg/kg LUM-201. Oral once-daily LUM-201

has been studied in two phase 2 trials in PEM+ PGHD focusing on safety and effectiveness. The OraGrowthH212 trial has evaluated GH pulse profiles at baseline and after 6 months of LUM-201 at 1.6 and 3.2 mg/kg/day, while the OraGrowthH210 trial has investigated dose responses using 0.8, 1.6, and 3.2 mg/kg/d vs rhGH comparator arm. The OraGrowthH212 trial demonstrated a 62% increase in GH secretion and an 80% increase in IGF-1 concentration after 6 months of LUM-201, enhancing annualized height velocity (AHV) by 60%, which remained steady at 12 months. In the OraGrowthH210 trial, the 1.6 mg/kg/d dose achieved the highest AHV over 6 months (8.2 cm/yr), maintained at 12 months (8.0 cm/yr), comparable to historical responses in moderate PGHD and within the targeted 2 cm/yr margin of the rhGH comparator arm. Notably, LUM-201 achieved the reported growth rates with GH secretion at approximately one-fifth of the amount absorbed from daily rhGH injection. Both studies reported a favorable investigational safety profile. Oral LUM-201 allows the restoration of normal pulsatile endogenous GH secretion to support similar growth to that achieved with daily pharmacological rhGH while maintaining normal feedback mechanisms. This innovative approach to treating PGHD will remove the burden of frequent injections with an oral therapy that achieves physiological GH profiles and therefore meets the core objectives of all endocrine therapies, namely to restore normal hormonal homeostasis.

Adipsic diabetes insipidus - a rare complication of craniopharyngiomas

Alexandru Florescu[1,2], Irina Puscasu[1], Viviana Popa[1], Adina Nicolaica[1], Andra Berigoi[1], Mihaela Florea[1], Stefana Bilha[1,2] & Cristina Preda[1,2]
[1]Saint Spiridon County Hospital, Endocrinology, Iaşi, Romania; [2]Universitatea de Medicină şi Farmacie 'Grigore T. Popa' din Iaşi, Endocrinology, Iaşi, Romania

Introduction
Craniopharyngiomas are rare tumors which are typically located in the sellar and suprasellar region. They can be solid or mixed, cystic-epithelial. Treatment options include surgery, radiation or intracystic therapy. Adipsic diabetes insipidus is a rare, life-threatening disease which can sometimes be associated with craniopharyngioma, either because of tumor mass effect, or as a postprocedure complication. Ultimately, this can cause severe hypernatremia, so long term management requires a careful interplay between low dose vasopressin analog treatment and fluids.
Case report
We present the case of a 32-year-old patient, operated at 10 years for craniopharyngioma, relapsed and re-operated (a total of 5 interventions), complicated with hydrocephalus (for which a ventriculo-peritoneal shunt was inserted), panhypopituitarism (in substitution treatment with LT4, cortison acetate and testosterone), central diabetes insipidus (in treatment with vasopressin analogues) and hypothalamic syndrome (hyperphagia, somnolence, hyperhidrosis, adipsia, hyperthermia). The last cerebral MRI (2021) describes post-operative continuity defects and altered structure of the sellar region and floor of the anterior cerebral fossa, and possible remaining pituitary tissue of 9/3 mm. In october 2023, he presents for reevaluation, accusing: sleepiness, night vision disorders, hyperphagia, adipsia, pain in the lower limbs, generalized muscle weaknes and adipsia. Clinical exam revealead a BP of 109/65mmHg, a HR of 110bpm, and a BMI = 40.16 kg/m^2, and a 24 hour urine ouput of 500 mL/day of hyperchromic, cloudy urine. Biochemical evaluation revealead hypernatremia (160 mmol/l), and hormonal evaluation revelead euthyroid status under LT4 substitution, normal cortisol (under 25mg cortison acetate/daily) and low testosterone levels (limited treatment compliance). Considering the severe hypernatremia, caused by adipsia and aggravated by diabetes insipidus, oral and parenteral fluid repletion was initiated and the dose of vasopressin analogues was considerably reduced, with subsequent normalization of serum sodium to 145 mmol/l, and a urine output of 2500mL/day (urine density 1000). Upon discharge, lower dose vasopressing analogue therapy was continued, and a minimum of 2L fluid intake was recommended.
Conclusion
Adipsic diabetes insipidus is a rare, life-threatening condition, which causes severe hypernatremia through intracellular dehydration, but also extracellular hyperhydration. The mainstay of therapy is a delicate balance between vasopressin analogue treatment and fluid intake; and an individual approach must be selected in the management of these patients. Finally, even with appropriate medical treatment, adipsic diabetes insipidus remains a hard to manage condition, so patient and family education regarding fluid intake as well as frequent, careful assessment of clinical and biochimical status is of utmost importance.

Cushing's syndrome: normalization of cortisol is just the beginning

Gretchen Jordan[1] & Leslie Edwin[1]
[1]Cushing's Support and Research Foundation, Lilburn, United States

Introduction
Cushing's Syndrome is caused by elevated levels of cortisol and is characterized by dozens of non-specific physical, metabolic, and neuropsychological symptoms. The extent of damage a patient will face is directly related to time to diagnosis, experience of the doctors and surgeon, and the support and education they receive after surgery. The spectrum of long-term needs faced by patients who have been exposed to prolonged elevated cortisol are not well represented in the literature and not well understood by most doctors.
Method
In 2023, a committee of patient advocates built a quality of life survey with over 150 questions using examples from two previous patient-created studies. This survey was translated into Spanish and French, then shared amongst multiple global support communities. SurveyMonkey was used for layout and response collection.
Results
The survey received 438 responses from 38 countries. Though the majority of respondents were from the United States, the unprecedented collaborative efforts of international patient organizations was reflected in the volume of responses and added depth to the data. **Cushing's is overwhelming** – Over 90% of respondents said they were negatively impacted by the complexity of symptoms and that it is almost impossible to fully understand the diagnosis in the beginning. **Delay in diagnosis equates to worse long-term prognosis –** It took more than 10 years for a full quarter of respondents to get an accurate diagnosis. **Mental health support is vital** – It was nearly unanimous that mental health support should be part of a patient treatment package (99.3%) and that therapy can be helpful even when a patient has good coping skills (95.7%); a need to process trauma after Cushing's was expressed by 92% of participants. **Peer support can be priceless** – 98% agree that it is beneficial to share experiences with other patients, and 94% said that a 'peer sister' or 'peer brother' to guide a patient along the way would be helpful. **The devastating reality** – Almost three quarters of patients reported that grief has been constantly present throughout the journey and they were not prepared for what life was like after surgery, and concern is nearly unanimous about life-shortening cardiovascular damage and changes to the brain.
Conclusion
For a rare disease like Cushing's, it is imperative to partner with an advocacy group that can help provide crucial missing data that paints a bigger picture of the patient experience and ultimately leads to faster and better treatment.

Longterm-outcomes in patients with cushing's disease vs non-functioning pituitary adenoma after pituitary surgery: an active-comparator cohort study

Roxana Wimmer[1], Sara Germann[1], Rahel Laager[1], Beat Müller[1], Philipp Schütz[1], Nina Kaegi-Braun[1] & Alexander Kutz[1]
[1]Aarau, University Department of Medicine, Clinic for Endocrinology, Diabetology, and Metabolism, Kantonsspital Aarau, Aarau, Switzerland and Medical Faculty of the University of Basel, Basel, Switzerland, Aarau, Switzerland

Objective
There is increasing evidence that multisystem morbidity in patients with Cushing's disease (CD) is only partially reversible following treatment. We investigated complications from multiple organs in hospitalized patients with CD compared to patients with non-functioning pituitary adenoma (NFPA) after pituitary surgery.
Design
Population-based retrospective cohort study using data from the Swiss Federal Statistical Office between January 2012 and December 2020.
Methods
Through 1:5 propensity score matching, we compared hospitalized patients undergoing pituitary surgery for CD or NFPA, addressing demographic differences. The primary composite endpoint included all-cause mortality, major adverse cardiovascular events (i.e., myocardial infarction, unstable angina, heart failure, cardiac arrest, ischemic stroke), hospitalization for psychiatric disorders, sepsis, severe thromboembolic events, and fractures in need of hospitalization. Secondary endpoints comprised individual components of the primary endpoint and reintervention due to disease persistence or recurrence.
Results
After matching, 113 CD patients (mean age 45 years [SD, 15], 74.3% female) and 390 with NFPA (47 years [SD, 15], 69% female) were included and followed for a median of 54.2 months (IQR 1, 116) after surgery. CD presence was associated

with a higher incidence rate of the primary endpoint (43.2 vs 16.4 events per 1,000 person-years, HR 2.55; 95% CI 1.44 to 4.52). CD patients also showed significantly increased hospitalization rates for psychiatric disorders (HR 4.53; 95% CI 2.06 to 9.99) and sepsis (HR 4.41; 95% CI 1.18 to 16.44).
Conclusion
Even after pituitary surgery, CD patients faced a higher hazard of complications, especially psychiatric hospitalization and sepsis.

Neuropsychological profile in acromegaly: cross sectional analysis and preliminary prospective long-term study

Alessandra Mangone[1,2], Giorgia Abete Fornara[3], Elisa Sala[2], Giulia Carosi[2], Giulia Del Sindaco[1,2], Arianna Cremaschi[2], Roberta Mungari[2], Veronica Lotito[1,2], Giulio Bertani[3], Marco Locatelli[3], Emanuele Ferrante[2] & Giovanna Mantovani[1,2]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Neurosurgery Unit, Milan, Italy

Background
Psychopathological distress is a significant burden in acromegaly, mostly in terms of depression and anxiety. Patients are also reported to experience an impairment in cognitive performance, yet literature is highly heterogeneous.
M&M
We conducted a cross-sectional study recruiting 44 acromegalic patients (59% females, 29.5% with active disease, 70.5% controlled/in remission) referring to our tertiary center between 2011 and 2023 and 40 healthy controls matched for sex, age, and educational level. We explored the psychological status through Beck-Depression-Inventory-II (BDI) and State-Trait-Anxiety-Inventory X1 and X2 (STAI X1-X2) and 12 standardized tests exploring different neuropsychological areas (short- and long-term verbal and visuo-spatial memory, selective attention, attentional shifting, verbal fluencies, inhibitory functions, constructional praxis, deductive reasoning and perseverative behavior). Moreover, we performed a prospective analysis of a subgroup of 9 patients recruited at diagnosis and followed-up for 10 years. Both functions were assessed at four time-points: T1) before surgery; T2) 3 days post-operatively; T3) 12 months after and T4) 10 years after surgery.
Results
In cross-sectional study, 10 patients (22.7%) reported a pathological score indicative of depression at BDI, 50% of whom with active disease ($P=0.13$). Focusing on anxiety, 6 male patients (33.5%) scored pathologically at STAI-X1 and no female; 66% of them with active disease ($P=0.05$). Mean results of STAI-X2 indicated a slight overall trait anxiety (52.22 ± 17.96), with 7 patients (38.9%) reporting a pathological score (6 females); most of them (71%) with active disease ($P=0.017$). We indeed found an association between IGF-1 levels and STAI-X1 and STAI-X2 ($P=0.010$ and $P=0.008$, respectively) and between age and STAI-X1 and STAI-X2 ($P=0.046$ and 0.042, respectively). Considering cognitive function, mean results of both patients and controls resulted within the respective ranges of normality, yet the number of patients scoring pathologically was significantly higher vs controls, showing a deterioration in all domains explored except for constructional apraxia. No differences were found among pathological results and disease status or pituitary deficits, except for auditory learning (RAVLT-Immediate) and long-term verbal memory and (RAVLT-long-term), with hypopituitaric patients performing worse ($P=0.01$ and $P=0.01$ respectively). IGF-1 levels positively correlated only with the results of Corsi test indagating short term visuospatial memory ($P=0.014$). At prospective analysis, we registered an overall improving trend in neurocognitive performance scores over the follow-up period, especially from diagnosis to T3.
Conclusion
Our data confirmed the presence of psychological symptoms in acromegaly. We underlined the relation between active disease and cognitive impairment with a possible improvement after disease control.

Consensus and controversies on the diagnosis of GH-deficiency in children and adults - A Delphi survey by the GH research society

Mai C. Arlien-Søborg[1], Sally Radovick[2], Margaret Cristina da Silva Boguszewski[3], Martin Bidlingmaier[4], Gudmundur Johannsson[5], Andrew R. Hoffman[6] & Jens Otto Jørgensen[1]
[1]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Denmark; [2]Robert Wood Johnson Medical School, United States; [3]University Hospital, Federal University of Parana, Curitiba, Brazil, Brazil; [4]Ludwig-Maximilians-University of Munich, Faculty of Medicine, Germany; [5]The University of Gothenburg, Sweden; [6]Stanford Medical Center, Division of Endocrinology, United States

Background
Growth hormone deficiency (GHD) is a rare disorder characterized by pronounced and symptomatic hypo secretion of growth hormone (GH) from the anterior pituitary gland. Biochemical tests are used as part of the diagnosis in both children and adults but controversies remain as regards whom, when, and how to test, and also how to interpret a given biochemical test result.
Aim
To map the current clinical practice of GHD diagnosing in children and adults.
Methods
A scientific committee (SC) composed of five members of the Growth Hormone Research Society (GRS) initiated a Delphi survey of the diagnosis of GH deficiency in children and adults. Dedicated pediatric ($n=18$) and adult ($n=25$) endocrinologists from fourteen different countries participated in the survey and rated their extent of agreement to 61 statements using a Likert-type-scale (1-7). Consensus was defined as $\geq$ 80% of panelists rating either ≥ 5 (agreement) or ≤ 3 (disagreement).
Results
Consensus was reached in 62% (38/61) of the statements. There was agreement to test for GHD in an appropriate clinical context such as neonates with persistent hypoglycemia and prolonged jaundice, growth deceleration and short stature in children, and overt pituitary disease in adults. Notwithstanding this, consensus was not reached regarding whether or not to test e. g. short children with obesity or adult patients without a classic phenotype. Low IGF-I levels were considered diagnostic in panhypopituitary children and adults. There was consensus to recommend the arginine stimulation test for the diagnosis of GHD in children whereas the insulin tolerance test (ITT) was recognized as the gold standard in adults. Controversy persisted regarding the utility of the macimorelin stimulation test in both children and adults. A stimulated GH cut-off < 3 µg/l was consistent with complete GHD in children, whereas assay-specific cut-offs were recommended in adults.
Conclusion
This Delphi survey reveals consensus (62%) but also considerable lack of consensus (38%) among clinical experts about diagnosing GHD in children and adults. Major areas of disagreement comprised both whom and how to test.

Replace: a randomized controlled trial on the effect of hydrocortisone or placebo in patients with reported symptoms of glucocorticoid-induced adrenal insufficiency after terminating prednisolone for polymyalgia rheumatic/giant cell arteritis

Anja Fenger Dreyer[1,2], Stina Willemoes Borresen[3,4], Simon Bøggild Hansen[5,6], Hajir Al-Jorani[1,2], Lise Sofie Bislev[5,6], Victor Brun Boesen[3,4], Louise Lehmann Christensen[1,2], Dorte Glintborg[1,2], Richard Christian Jensen[1], Nanna Thurmann Jørgensen[3,4], Marianne Klose[3,4], Marie Louise Lund[3,4], Jelena Stankovic[5,6], Randi Tei[5,6], Ulla Feldt-Rasmussen[3,4], Jens Otto Jørgensen[5,6] & Marianne Andersen[1,2]
[1]Odense University Hospital, Department of Endocrinology, Odense C, Denmark; [2]University of Southern Denmark, Department of Clinical Research, Faculty of Health Sciences, Odense C, Denmark; [3]Copenhagen University Hospital, Department of Endocrinology and Metabolism, Rigshospitalet, Copenhagen, Denmark; [4]Copenhagen University, Department of Clinical Medicine, Faculty of Health and Clinical Sciences, Copenhagen, Denmark; [5]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus, Denmark; [6]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark

Background
Glucocorticoid-induced adrenal insufficiency (GIA) may occur after termination of long-term glucocorticoid (GC) treatment. GIA is usually diagnosed by a short-synacthen-test (SST), but peak cortisol response to SST may not validly assess normalisation of the diurnal hypothalamic-pituitary-adrenal (HPA)-axis. In patients with polymyalgia rheumatic (PMR) and giant cell arteritis (GCA), we report at this meeting a surprisingly low prevalence of GIA of 1.6% after cessation of prednisolone treatment; whereas 33% of these patients reported symptoms of GIA (scores ≤ 85) according to the Addison's disease-specific quality-of-life questionnaire (AddiQoL-30) (ECE 2024 abstract ID: 5059). The primary study aim is to generate evidence-based guidance for management of GIA in patients using patient reported outcomes as a key tool for inclusion and outcome.

Methods
This is the first RCT to randomize patients with low AddiQoL-30 score after long-term GC use to hydrocortisone treatment or placebo. The REPLACE study is a multi-centre randomised, double-blinded, placebo-controlled study. Eligible patients have PMR and/or GCA and are in GC free remission for 2-12 weeks after long-term prednisolone treatment (>12 weeks). Patients are assigned to one of the study groups according to results of AddiQoL-30 and SST: All groups will participate in a standardized baseline visit. The RCT-group is randomized to either hydrocortisone or placebo for 16 weeks with repetition of baseline investigations at end of study.

RCT-group	AddiQoL-score ≤85 *or* 30 min. cortisol level >100 nmol/l and <420 nmol/l	$n=100$
Control-group 1	AddiQoL-score >85 *and* 30 min. cortisol level >420 nmol/l	$n=150$
Control-group 2	30 min. cortisol level ≤100 nmol/l regardless of Addi-QoL-score	$n=20$

Outcomes
Change in GIA symptom burden (AddiQoL-30) at 16-week follow-up is the primary outcome. Secondary outcomes are generic health-related QoL questionnaire scores (CushingQoL, SF-36v2, Single item Sleep Quality Scale, and the International Physical Activity Questionnaire-S7S). Participants will daily report on intercurrent illness and stress, and symptoms attributable to GIA, using a study smartphone application (app). Baseline and follow-up investigations of cardiovascular health, body composition, muscle function, and glucose homeostasis will be completed.
Ethics and dissemination
The REPLACE study is in accordance with the Declaration of Helsinki; registered at EudraCT (2020-006121-65) and publications will be according to the International Committee of Medical Journal Editors recommendations.
Funding
The REPLACE study is funded by the Novo Nordisk Foundation as part of a collaborative grant entitled 'DOUBLE EDGE – Characterization and mitigation of adverse effects of glucocorticoid treatment' (NNF20OC0063280).
Status: Recruiting.

Gonadotroph pituitary tumors: not always nonfunctioning
Anna Carretti[1,2], Mirela Diana Ilie[3], Alexandre Vasiljevic[4], Marie-Lise Jaffrain-Rea[5,6], Emmanuel Jouanneau[7] & Gerald Raverot[2]
[1]' Sapienza' University of Rome, Department of Experimental Medicine, Rome, Italy; [2]Reference Center for Rare Pituitary Diseases HyPO, 'Groupement Hospitalier Est' Hospices Civils de Lyon, Endocrinology Department, Bron, France; [3]Cancer Research Center of Lyon, Inserm U1052, CNRS UMR5286, Lyon, France; [4]Cancer Research Center of Lyon, Lyon 1 University, Pathology Department, Reference Center for Rare Pituitary Diseases Hypo, 'groupement Hospitalier Est' Hospices Civils de Lyon, Inserm U1052, Cnrs Umr5286, Lyon, France; [5]Neuromed Institute, Istituto di Ricovero e Cura a Carattere Scientifico, Pozzilli, Italy; [6]University of L'Aquila, Department of Biotechnological and Applied Clinical Sciences, L'Aquila, Italy; [7]Reference Center for Rare Pituitary Diseases HyPO, 'Groupement Hospitalier Est' Hospices Civils de Lyon, Neurosurgery Department, Bron, France

Gonadotroph pituitary tumors (GnPiT) account for ~40% of pituitary tumors surgically treated and 70-75% of non-functional pituitary tumors. Functional gonadotropin-secreting tumors are rare and clinical manifestations vary according to the age and sex of the patient. They are benign tumors which, due to their silent nature, can grow and invade surrounding structures, making complete resection impossible and leading to recurrence in ~30% of cases.
Objective
The aim of our study is to provide a comprehensive, up-to-date characterization of either clinically silent/whispering or functional GnPiT.
Patients and Method
Retrospective study of 151 adult patients (105 men and 48 women) with a histological diagnosis of GnPiT, operated at our referral pituitary center from January 2020 to December 2022. Clinical, hormonal, tumoral and pathological data were analyzed according to sex and age.
Results
Diagnosis was incidental in about half of patients. A different distribution of tumors based on age was found, with a normal distribution in male (median age 63 years (25-89)), and a bimodal one in female (median age 58 years (26-84)). Only one tumor showed a functioning hormonal secretion responsible of an ovarian hyperstimulation syndrome in a 40-year-old woman; while 8 tumors (1 F and 7 M) showed a possible, but clinically silent, secretory activity. FSH was elevated in all cases, accompanied by LH and testosterone in one. Hypersecretion did not cause a subsequent clinical picture, and tumors did not appear to behave differently compared to the non-secreting one. Four histological subtypes were described according to hormonal immunohistochemistry: FSH-LH ($n=96$), FSH ($n=41$), LH ($n=6$), non-immunoreactive (NIR; $n=8$). Sex-related distribution did not find relevant differences (FSH-LH: 65.62% M, 34.38% F; FSH: 75.60% M, 24.40% F; LH: 83.33% M 16.67%; NIR: 50% M, 50% F). No differences were found according to histological subtypes, especially regarding FSH and LH secretion. Spearman correlation analysis showed a weak, but significant, correlation between serum FSH and FSH staining (r: 0.21, p: 0.015), none between serum FSH and transcription factors SF1 and GATA3, and a weak, but significant, correlation between LH staining and GATA3 (r: 0.34, p: 0.0002).
Conclusion
Our results provide information possibly useful in future studies for a better understanding of the GnPiT subtype. Gonadotropins hypersecretion remains a rare finding and, when present, is mostly silent and not linked to specific pathological features. Moreover, a thorough pathological assessment did not highlight relevant differences among the four subgroups identified in this work.

Posterior pituitary tumours: a single institutional experience of 19 patients
Natalia Kremenevski[1], Yining Zhao[1], Coras Roland[2] & Michael Buchfelder[1]
[1]University of Erlangen-Nürnberg, Department of Neurosurgery, Erlangen, Germany; [2]University of Erlangen-Nürnberg, Institute of Neuropathology, Erlangen, Germany

Background
Posterior pituitary tumors (PPTs) present as clinically nonfunctioning space-occupying lesions of the sellar region. The diagnosis of PPTs is not possible on the basis of their clinical, radiological and biochemical features. Immunohistochemistry identifies them for their expression of TTF. They are virtually always mistakenly defined as one of the more common pituitary tumours. Due to their rarity, the long-term endocrine aspects and outcomes of PPTs are not well known.
Objective
The objective was to evaluate the clinical characteristics, surgical approaches, and survival of a single-center cohort of patients with PPTs who underwent surgical treatment at our institution.
Methods
19 patients (11 females and 8 males) with histologically confirmed PPTs were identified between the years 1982 and 2022 out of 8761 operated sellar lesions. Their data were retrospectively collected and analyzed.
Results
There were 3 pituicytoma (PC), 8 granular cell tumor (GCT), and 8 spindle cell oncocytoma (SCO) subtypes of what today all is called pituicytoma. The mean age at diagnosis was 58.65 ± 13.6 years (range 27-75). The most common presenting symptoms were visual disturbance and headache (47% each), followed by dizziness (26%) and decreased libido/erectile dysfunction (16%). Preoperative MRI scans were not predictive of PPTs. Preoperative endocrine dysfunction consisted of hypocortisolemia and hypogonadism (42% each), hyperprolactinemia and hypothyroidism (37% each). After surgery, corticotropic and gonadotropic dysfunction remained unchanged. A statistically significant reduction/normalization of prolactin levels was detected ($P<0.05$). Diabetes insipidus was observed in one patient preoperatively and in two patients postoperatively. The mean tumor volume was 2.14 ± 2.01 cm^3 (range 0.12-7.37). In most patients the surgery was performed through a transcranial approach (58%) and in 8 cases the transsphenoidal approach was used (42%). Gross total resection was achieved in 11 patients (58%). The mean follow-up in months was $58.89 \pm 43.13.5$ (median 63 [range 3-150]). Recurrence was observed in 3/19 (16%) patients.
Conclusion
PPTs are benign neoplasms and do not have specific presenting clinical, endocrinological and imaging findings. Histopathological examination with confirmation of TTF expression remains crucial in the diagnosis. The location and invasive growth with suprasellar tumour extension in this patient cohort makes them not amenable to total resection and more often dictates a transcranial approach as opposed to transsphenoidal surgery.

Usefulness of salivary cortisol in the diagnosis of adrenal insufficiency and evaluation of the hypothalamic-pituitary-adrenal axis

Pablo Fernández Velasco[1], Maria de la O Nieto de la Marca[1], Raquel Herrero Gómez[1], Paloma Pérez López[1], Beatriz Torres Torres[1], Daniel De Luis Román[1] & Gonzalo Díaz Soto[1]
[1]Hospital Clínico Universitario de Valladolid, Endocrinología y nutrición, Valladolid, Spain

Objective
This study aims to assess the utility of salivary cortisol (SC) in diagnosing adrenal insufficiency (AI) and to analyze the integrity of the hypothalamic-pituitary-adrenal axis. This involves evaluating cortisol rhythm, its correlation with plasma levels, and the impact of exogenous hydrocortisone (HC) substitution on SC determination.
Methods
A prospective study was conducted on all patients with suspected AI undergoing adrenocorticotropic hormone (ACTH) testing (ACTH-t) between 2014 and 2022 at the Endocrinology Department in an University Hospital. Ambulatory salivary cortisol rhythm was determined, and clinical and analytical variables were collected. Diagnostic performance of SC vs basal plasma cortisol (BC) was assessed using the area under the ROC curve (AUC), with ACTH-t results as the 'gold standard.' Correlation between SC and BC values was also determined.
Results
Sixty subjects (60.7% women, 42.9% evaluated for pituitary pathology) with a mean age of 50.7 ± 15.1 years were evaluated. Mean SC, BC, and ACTH levels were 0.378 ± 0.242 μg/dl, 11.3 ± 5.2 μg/dl, and 30.5 ± 45.8 pg/dl, respectively. 6.6% were excluded due to preanalytical contamination in SC determination. A moderate positive correlation ($r = 0.446$, $P < 0.001$) was found between SC and BC levels. The diagnostic yield of SC at 0800 hours was superior to BC (AUC = 0.804, $P < 0.01$ and AUC = 0.739, $P < 0.05$, respectively). CS values < 0.0975 μg/dl were diagnostic of AI, while values > 0.708 μg/dl ruled out AI, avoiding 21.4% of ACTH-t. However, SC rhythm determination at 13:00, 18:00, and 24:00 did not allow AI diagnosis (AUC = 0.202, 0.280, and 0.283, respectively). Determining SC in patients on HC treatment vs those without treatment demonstrated HC overdosage values at 13:00 (1.089 ± 1.120 vs 0.207 ± 0.227 μg/dl, $P < 0.01$), 18:00 (0.752 ± 0.971 vs 0.151 ± 0.130 μg/dl, $P < 0.01$), and 24:00 (1.069 ± 2.531 vs 0.094 ± 0.071 μg/dl, $P < 0.01$), except at 8:00 (0.274 ± 0.205 vs 0.409 ± 0.246 μg/dl, $P = 0.058$). Conclusions: Determination of SC at 0800 hours is a valid alternative for AI screening, showing good correlation with BC. Only 6.6% of the sample inadequately collected SC. In our population, values < 0.0975 μg/dl and > 0.708 μg/dl for SC confirmed and ruled out AI, respectively, preventing 21.7% of ACTH-t. SC determination at 13:00, 18:00, and 24:00 did not adequately identify patients with AI and showed overdose values in those on HC treatment.

Paradoxical responses to pasireotide in patient with cushing's disease

Anna Brona[1], Aleksandra Jawiarczyk-Przybyłowska[1], Aleksandra Zdrojowy-Wełna[1], Justyna Kuliczkowska-Płaksej[1] & Marek Bolanowski[1]
[1]Wrocław Medical University, Endocrinology, Diabetes and Isotope Therapy, Wrocław, Poland

69-year old male was diagnosed with non-secreting pituitary macroadenoma (25x 15x 15mm) in 2008. Patient underwent two transsphenoidal surgeries and stereotactic radiotherapy in 2008 and 2009. Tumor recurrence was noticed on MRI in 2016. In 2017 urgent right pterional craniotomy was performer due to right eyelid dropping with ocular nerves palsy. Despite surgery further growth of the tumor (32x 22x 31mm) was reported in 2018, followed by increased ACTH level and hypercortisolemia in 2019. It was decided to start therapy with pasireotide. Patient received 5 doses of pasireotide LAR between September 2019 and June 2020. In September 2019 cortisol level was 21μg/dl (3.7-19.4), and ACTH 107 pg/ml (0-46) before administration and increased up to 35.6μg/dl, and 176 pg/ml after it. This was the first time when paradoxical response was noticed. 2nd and 3rd doses were administered in October and in November 2019 without increase of cortisol or ACTH concentration and MRI showed marked regression of tumor one month later. 4th dose was administered in March and 5th dose in June 2020. There was no paradoxical response. Recurrence of hypercortisolemia and tumor progression were observed in February 2021. Cortisol level was 53.3μg/dl and ACTH 246 pg/ml. In March 2021 6th dose of pasireotide was administered. Then 2nd paradoxical response occured. Cortisol level increased up to 83.5μg/dl, and ACTH up to 392 pg/ml After metyrapone treatment cortisol concentration decreased and hydrocortisone was necessary. In April 2021 patient received 7th dose of pasireotide. Cortisol level was 10.2μg/dl and ACTH 149 pg/ml. After one week laboratory results confirmed 3rd paradoxical response to pasireotide (cortisol 59.3μg/dl and ACTH 186 pg/ml). In February 2022 cortisol level was very low (up to 4.6μg/dl) and ACTH decreased to 47.2 pg/ml. >MRI revealed marked regression of tumor mass. Pasireotide wasn't administered. In August 2022 it turned out that cortisol and ACTH concentration were increased (60.3μg/dl and 242 pg/ml). Severe hypercortisolemia was observed few weeks later despite metyrapone treatment. It was decided to administer pasireotide once again. In October 2022 patient received 8th dose and 4th paradoxical response occured. The rebounds in increase of cortisol were severe and required steroidogenesis inhibitors for few months. During this period the highest level of cortisol was 91μg/dl and ACTH 816 pg/ml. Treatment with pasireotide was considered as the emergency therapy. Pasireotide affects both tumor size and cortisol production and effects are likely to appear much earlier than after radiotherapy. Poor patient conditions and irregular growth of the tumor suggested against surgery.

Comparative efficacy and safety of osilodrostat vs metyrapone for the treatment of Cushing's syndrome – a matching-adjusted indirect comparison using LINC-3 and LINC-4

Rosario Pivonello[1], Beatrice Gueron[2], Conor Hickey[3], Emma Tyas[3], Grzegorz Binowski[4] & Fabian Schmidt[2]
[1]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy; [2]Recordati Rare Diseases, Puteaux, France; [3]Lumanity, London, United Kingdom; [4]MAHTA Intl., Warsaw, Poland

Objectives
Endogenous Cushing's syndrome (CS) is a rare, chronic condition that results in high morbidity, caused by prolonged exposure to elevated levels of circulating free cortisol. A previous comparative analysis showed osilodrostat increases the odds of complete response (CR; mean urinary free cortisol [mUFC] ≤ 1.0 x the upper limit of normal) at Weeks 12 and 36 vs metyrapone[1]; however, analyses were limited by small osilodrostat effective sample size (ESS; 25 patients). Therefore, we used pooled osilodrostat data from the LINC-3 and LINC-4 clinical trials ($n = 185$) to improve upon initial analyses of CR and discontinuation outcomes for osilodrostat vs metyrapone in CS.
Methods
The LINC-3/lINC-4 and PROMPT clinical trials investigated osilodrostat and metyrapone, respectively, in patients with endogenous CS. All LINC-3/lINC-4 patients and 90% of PROMPT patients had Cushing's disease. Unanchored matching-adjusted indirect comparisons were conducted using pooled LINC-3 and LINC-4 patient-level data and published summary data for PROMPT. CR at Weeks 12, 24 and 36; all-cause discontinuation and discontinuation due to treatment failure at Weeks 24 and 36 were analysed. Six baseline characteristics, identified as potential prognostic factors, were adjusted for: age, sex, time since diagnosis, mUFC, prior irradiation and prior surgery. Scenario analyses adjusted for race and explored an alternative categorization of mUFC. Scenario analyses also investigated a range of plausible discontinuation rates for six patients ineligible to enter the 6-month PROMPT extension at Week 12, but not considered discontinuations in the primary analysis.
Results
Populations were well balanced after matching; the ESS for the matched pooled osilodrostat population was 76 patients. Results suggested osilodrostat provides increased odds of CR vs metyrapone at Week 12 (odds ratio [OR]: 2.75; 95% confidence interval [CI]: 1.29, 5.88), Week 24 (OR: 3.28; 95% CI: 1.58, 6.84) and Week 36 (OR: 10.50; 95% CI: 1.84, 59.96), implying a greater proportion of patients experience normalized cortisol levels at these timepoints. Results are statistically significant as 95% CIs exclude 1. No evidence of a statistically significant difference between treatments for the discontinuation endpoints was found. Scenario analyses (described above) had consistent results.
Conclusion
Our analyses suggest osilodrostat increases the odds of achieving CR at Weeks 12, 24 and 36 vs metyrapone, implying osilodrostat is a more efficacious treatment option than metyrapone for normalizing cortisol levels in CS patients. These analyses improve upon previous comparisons by substantially increasing the osilodrostat ESS, providing consistent and more reliable results.

Is urine sαkl a potential biomarker in acromegaly?

Anica Pauline Gagliardo[1], Michael Haenelt[1], Júnia Ribeiro de Oliveira Longo Schweizer[1], Jun Thorsteinsdottir[2], Daniel Teupser[3], Jochen Schopohl[1], Sylvère Störmann[1], Martin Bidlingmaier[1] & Katharina Schilbach[1]
[1]LMU Klinikum, Medizinische Klinik und Poliklinik IV, München, Germany; [2]LMU Klinikum, Neurochirurgische Klinik und Poliklinik, München, Germany; [3]LMU Klinikum, Institut für Laboratoriumsmedizin, München, Germany

Background
Soluble alpha klotho (sαKL) is a peptide hormone, that has been shown to be elevated in serum of patients with uncontrolled acromegaly. One early pilot study suggested that sαKL is also detectable in urine from patients with acromegaly, and significantly drops after surgery. Notably, in this study, urine sαKL concentrations were undetectable in the control group, and fell consistently below the detection limit of the ELISA in postoperative patients in the acromegaly group. We previously found considerable impact of various preanalytical conditions on measured concentrations of urine sαKL, pointing to the need to define an appropriate pre-analytical process.
Aim
In this study, we evaluated urine sαKL collected under standardized conditions as a potential biomarker in a cohort with patients with acromegaly receiving a variety of therapy modalities as well as a healthy cohort.
Methods
Blood and corresponding spontaneous urine samples were collected from biochemically uncontrolled (IGF-I >1.3 times upper limit of normal ($\times$ULN); $n=20$) and controlled (IGF-I $<1.0\times$ULN; $n=31$) patients with acromegaly as well as from healthy subjects ($n=51$); Patients had a variety of therapy modalities. Serum was stored at -20°C and urine at -80°C. Anthropometric data and routine lab values were collected. SαKL was measured with a sandwich ELISA (IBL, Hamburg, Germany).
Results
No meaningful correlation could be established between urine sαKL and serum sαKL, IGF-I $\times$ ULN, IGFBP 3 $\times$ ULN, eGFR nor urine creatinine. A strong correlation was shown for urine sαKL and urine pH (Spearman's rho 0.770, $P<0.001$, $n=101$), with particularly low sαKL in samples with low pH. However, even after including only urine samples with pH greater or equal to 6.0, no correlation between the former mentioned parameters and urine sαKL was observed.
Conclusions
Interpretation of urine sαKL seems difficult at least. First, concentrations become very low or even undetectable in urine samples with a pH less than 6.0. Furthermore, even in samples with higher pH, concentrations of sαKL in urine do not correlate to serum concentrations. It is quite conceivable that additional factors impact urine sαKL concentration. Perhaps, more appropriate sampling conditions can be found. However, at present, our data do not support utilization of urine sαKL as a biomarker for growth hormone. In contrast, our data from this study further confirm serum sαKL correlates well with IGF-I.

Exploring the cardiovascular effects of recombinant human growth hormone therapy: a prospective study on endothelin-1 and asymmetric dimethyl arginine in adults with growth hormone deficiency

Maria Kościuszko[1,1], Angelika Buczyńska[2], Aleksandra Wiatr[2], Dorota Jankowska[3], Małgorzata Jacewicz-Święcka[1], Adam Krętowski[1] & Anna Popławska-Kita[1]
[1]Medical University of Białystok, Endocrinology, Diabetology and Internal Medicine, Białystok, Poland; [2]Medical University of Białystok, Clinical Research Center, Białystok, Poland; [3]Medical University of Białystok, Department of Biostatistics and Medical Informatics, Białystok, Poland

Adult growth hormone deficiency (GHD) is widely acknowledged for its association with heightened mortality, primarily linked to an increased risk of cardiovascular complications. Endothelin-1 (ET-1) is implicated in various cardiovascular conditions, including hypertension, atherosclerosis, and heart failure, where imbalances in its levels or signaling have been identified. Despite the distinct primary functions of growth hormone and endothelin within the body, both hormones assume a pivotal role in the intricate regulation of growth and developmental processes. Specifically, endothelin significantly contributes to the meticulous orchestration of blood flow regulation, exerting an indirect influence on the delivery of essential nutrients and oxygen to tissues. This intricate interplay carries profound implications for the sophisticated coordination of growth and metabolism within the organism. Furthermore, a critical non-traditional cardiovascular risk factor involves the heightened concentration of asymmetric dimethylarginine (ADMA), a potent inhibitor of nitric oxide synthase that contributes to vascular endothelial dysfunction. Elevated ADMA levels coincide with increased vascular tension, higher blood pressure, and the activation of numerous pro-atherogenic mechanisms. These include platelet aggregation, monocyte adhesion, smooth muscle cell proliferation, extracellular matrix expansion, and lipid accumulation in macrophages - elements that collectively contribute to the development of atherosclerosis. Consequently, this study aims to evaluate the effectiveness of recombinant human growth hormone (rhGH) in mitigating levels of ET-1 and ADMA in patients with GHD. The study focuses on assessing the efficacy of rhGH therapy in enhancing levels of ET-1 and reducing ADMA. The study encompassed 10 patients diagnosed with GHD who underwent a 12-month course of rhGH therapy. Measurements of ET-1 and ADMA levels were taken prior to the commencement of the therapy, at the 6-month mark, and at the conclusion of the 12-month period. Statistical analysis involved repeated-measures ANOVA and post hoc tests with Bonferroni correction.
Results
After 12 months of rhGH therapy, a significant decrease in the levels of ET-1 ($P=0.04$) was observed. Additionally, a statistically significant negative correlation between IGF-1 and ADMA levels were observed both after 6 and 12 months of therapy ($r=$-0.65, $P=0.02$; R-0.65, $P=0.01$, respectively). Post hoc tests confirmed significant differences between individual observation periods. The findings of this research suggest a potential link between growth hormone replacement therapy and a reduction in cardiovascular risk through its impact on ET-1 and ADMA levels. These results have the potential to contribute to the improvement of rhGH replacement therapy protocols, exerting a broader influence on the cardiovascular well-being of individuals undergoing such interventions.

Macroprolactin over time: Is there any point in rechecking it in people with a persistently elevated serum prolactin?

Adrian Heald[1,1], Syeda Hashimi[2], John Warner-Levy[1], Sudarshan Ramachadran[3], Ian Laing[4] & Mark Livingston[2]
[1]Salford Royal Hospital, Salford, Department of Endocrinology and Diabetes, Salford, United Kingdom; [2]Black Country Pathology Services, Walsall Manor Hospital, Walsall, United Kingdom, Department of Clinical Biochemistry, Wolverhampton, United Kingdom; [3]University Hospitals Birmingham NHS Foundation Trust, Sutton Coldfield, West Midlands, United Kingdom., Department of Clinical Biochemistry, Sutton Coldfield, United Kingdom; [4]Royal Preston Hospital, Preston, United Kingdom

Design
Macroprolactinemia may influence the interpretation of serum prolactin levels – a recognised phenomenon since 1978[1]. The degree of macroprolactinaemia over time is less well described. We determined how macroprolactin status (based on polyethylene glycol (PEG) precipitation varied by analysing serial measurements in hyperprolactinaemic individuals over nine years.
Patients and Measurements
Results from 1810 individuals were included. All serum total prolactin results (measured using Roche Cobas 8000 analyser) were extracted from the laboratory information system from 1 January 2012 to 1 April 2021, along with relevant patient demographic/test data. Samples with a macroprolactin screening test performed (on samples with prolactin >700 mu/l) were included in the main analysis.
Results
During the study period, 2782 macroprolactin checks were performed (12.5% of all prolactin tests) in 1810 (599 males/2183 females, median-age: 35, IQR:25-47, range:16-93 years) individuals. Multiple macroprolactin checks were carried out on 465 patients (1437 measurements) (see Table 1) with 94 patients (141 measurements) screening positive ($<60\%$ recovery). Only 19 patients (18 female) had at least one result above and one below the 60% screening cut-off. In terms of clinical details, six were on antidepressants/antipsychotics, four had a prolactinoma, one was pregnant, two were on an oral contraceptive pill (OCP) one person was on levothyroxine, and in five further clinical details were unavailable. 10 of these patients had results close to the 60% cut-off. 5 had clearly different results; 4 appeared to be outliers based on other results. In 7 cases the adjusted monomeric prolactin showed a potentially clinically significant difference.
Conclusions
In this study, only 19/465 patients appeared to change macroprolactin status based on a 60% PEG recovery cut-off. The majority of these 19 patients were on antipsychotic/antidepressant medication(s) or had a prolactinoma; In only 7

monomeric prolactin changed significantly. This suggests that once macroprolactin status has been determined, clinical decision-making is rarely affected by repeating it.

Intracranial Tumors comprise a diverse group of endocrine-related tumors [ERTs; e.g. craniopharyngiomas (CPs) and pituitary-tumors (PTs)], representing significant challenges for the diagnosis/prognosis/treatment of patients, their families and health systems due to their heterogeneity, associated neurological impairment and endocrine comorbidities. However, despite recent advances, the current treatment (e.g. surgery plus irradiation in CPs, pharmacological treatment with somatostatin/dopamine-agonists in PTs) originates adverse neurological effects, and drugs are not sufficiently effective in reducing the tumor mass size in a high proportion of cases. Therefore, the identification of novel therapeutic avenues to treat these devastating ERTs are urgently needed. Concretely, the Telomerase/Shelterin (TEL-SHEL) system, responsible for telomere maintenance, has been implicated in various cellular processes associated to cancer development/progression/aggressiveness. However, its interplay in the malignancy process of CPs and PTs remains poorly explored. Therefore, we aimed to analyze the: 1) expression of 17 critical TEL-SHEL components in CPs ($n=60$) and different PT types ($n=152$) compared to non-tumor pituitary tissues ($n=10$), using a microfluidic-array based on qPCR-technology; and 2) potential antitumor effects of modulating telomerase-activity and telomere-length through pharmacological modulation using BIBR1532 and *in vitro* cellula models. A profound dysregulation in the expression pattern of TEL-SHEL components was demonstrated in CPs and PTs. Notably, TERF2IP and TNKS were downregulated in CPs in three different human cohorts. Interestingly, enrichment analysis revealed a robust correlation between the low expression of TERF2IP and key cellular processes, such as the Wnt/β-catenin-pathway. Similarly, a significant alteration of the molecular profile TEL-SHEL was also observed in PTs, especially in somatotropinomas and corticotropinomas, but not in non-funcitoning PTs. Furthermore, BIBR1532-treatment showed a dose-dependent effect in different functional parameters in primary patient-derived cell-cultures and cell-lines [GH3 (somatotropinoma model) and AtT20 (corticotropinoma) models], including a reduction in cell-proliferation rates and stem-cell capacity. Altogether, we demonstrated a profound dysregulation of different key components of the TEL-SHEL system in CPs and PTs vs control samples, wherein some of these alterations may have clinical and/or functional relevance to improve the diagnosis/prognosis and management of these heterogeneous ERTs. Moreover, we demonstrated that the pharmacological modulation of the TEL-SHEL complex (using BIBR1532) exerted antitumoral effects in different ERTs, offering a clinically relevant opportunity that should be tested for use in humans.

Effect of oral urea on copeptin levels in healthy adults: a double-blind, randomized, placebo-controlled cross-over study

Sven Lustenberger[1], Cihan Atila[1], Sophie Monnerat[1], Julia Beck[1] & Mirjam Christ-Crain[1]
[1]Universitätsspital Basel, Endokrinologie, Diabetologie und Metabolismus, Basel, Switzerland

Background and Objectives
The differential diagnosis between arginine vasopressin (AVP) deficiency (AVP-D, formerly known as central diabetes insipidus) and primary polydipsia (PP) remains challenging. To date, the method with the highest diagnostic accuracy is osmotically-stimulated copeptin – a surrogate marker of AVP – using hypertonic saline infusion. However, this method is often limited to experienced hospitals, requires close monitoring, and may be cumbersome for patients. Therefore, an alternative simplified osmotic stimulation test would be highly desirable. It has been previously demonstrated that intravenous urea increases plasma osmolality and stimulates AVP release. However, no study investigated the effects of oral urea on copeptin levels.
Methods
The aim of this randomized double-blind placebo-controlled study was to investigate whether oral urea stimulates copeptin release in 22 healthy adults. Participants presented for two visits in the morning after an overnight food fasting and two-hour fluid fasting period. They received a single weight-adapted dose of oral urea (0.5 g/kg body weight; minimum 30g, maximum 45 g) and placebo in random order. Serum copeptin was measured at baseline and 30, 60, 90, 120, and 150 minutes after oral urea or placebo intake. The primary endpoint was the maximum increase in copeptin levels within 150 minutes after oral urea intake vs placebo.
Results
When stimulating with placebo, the median [IQR] copeptin level at baseline was 3.8 [2.9 – 6.6] pmol/l and remained stable after 120 minutes at 3.2 [2.8 – 5.6] pmol/l. In contrast, when stimulating with urea, the copeptin level at baseline was 4.6 [3.0 – 5.7] pmol/l and increased after 120 minutes to a maximum of 10.1 [7.2 – 11.6] pmol/l ($P < 0.001$).
Conclusion
Oral urea leads to an approximately two-fold increase in copeptin levels in healthy adults. Whether this applies to patients with PP and has the potential to discriminate them from patients with AVP-D remains uncertain and is currently being investigated.

Anastrazole in the treatment of a cabergoline-resistant male prolactinoma

Vittoria Favero[1,2], Andrea Saladino[3], Marcello Marchetti[3], Iacopo Chiodini[1,2] & Renato Cesare Cozzi[2]
[1]University of Milan, Department of Biotechnology and Translational Medicine, Milan, Italy; [2]Ospedale Niguarda Ca' Granda, Endocrinology Unit, Milan, Italy; [3]IRCCS Fondazione Istituto Neurologico Carlo Besta, Department of Neurosurgery, Milan, Italy

Introduction
Dopamine agonists are the first line treatment for prolactinomas. However, some patients may develop dopamine-agonist-resistant hyperprolactinemia, leading to surgery and/or radiotherapy. The persistence of hypogonadism requires testosterone replacement therapy which could theoretically reduce the efficacy of dopamine agonists due to the conversion of testosterone to estradiol, thus, in turn, increasing the resistance to dopamine agonists. Consequently, in these patients an anti-estrogen treatment has been advocated, but, to date, very few cases have been reported on the use of the anti-estrogen treatment in patients with prolactinomas.

Case report
We present the case of a 23-year-old man who presented with headache and visual impairment with bitemporal hemianopsia. Magnetic resonance imaging (MRI) of the pituitary revealed a large invasive intra- and supra-sellar pituitary adenoma. Prolactin levels were significantly elevated (3258 µg/l, normal values, nv: 5-25 µg/l), with low levels of booth testosterone (1.3 ng/ml, nv 2.4-9 ng/ml) and FT4 (0.82 pg/ml, nv 0.8-2.2 pg/ml). Treatment with cabergoline was initiated and gradually increased to 3 mg/week, with reduction in prolactin levels and improvement in visual field. After 12 months of therapy, the prolactin levels decreased to 352 mg/l, and due to the persistence of central hypothyroidism and hypogonadotropic hypogonadism, a replacement therapy with levothyroxine and testosterone was started. After starting testosterone treatment and obtaining low-normal testosterone levels, the prolactin levels increased to 551 mg/l. In addition, there was no significant reduction in the size of the pituitary lesion and the patient experienced more frequent headaches with a slight deterioration in visual field. Surgical intervention was then performed. Following surgery, the prolactin levels decreased to 88 mg/l and the MRI showed the persistence of an infra – and supra-sella adenoma remnant. However, in the subsequent years, despite continuing the treatment with cabergoline (3 mg/week), the prolactin levels gradually increased to 132 mg/l. Anastrozole 1 mg/daily was initiated, and, consequently, it was possible to reduce the cabergoline dose to 2 mg/week (by reducing the dose by 0.5 mg/week after 3 months and then by a further 0.5 mg/week after 12 months). A further decrease in prolactin levels to 55 µg/l and a shrinkage of the pituitary adenoma was then observed.
Conclusion
In cases of dopamine-agonist-resistant hyperprolactinemia, alternative treatment strategies may be required. In this case, the addition of anastrazole proved beneficial, resulting in improved hormonal control, tumor shrinkage, and better patient tolerability.

Challenges in the management of invasive macroprolactinomas: cranio-dural defect requiring surgery after cabergoline treatment

Ioana Balinisteanu[1,2], Stefana Bilha[1,2], Anca Matei[1,2], Raluca Lepsa[2], Alexandru Florescu[1,2], Daniel Rotariu[1,3], Maria Christina Ungureanu[1,2] & Cristina Preda[1,2]
[1]' Grigore T. Popa' University of Medicine and Pharmacy, Endocrinology, Iaşi, Romania; [2]Sf. Spiridon County Hospital, Endocrinology, Iaşi, Romania; [3]Emergency Hospital Professor Doctor Nicolae Oblu, Iaşi, Romania

Introduction
Prolactinomas, prevalent among young women, are the most frequently encountered secreting pituitary tumors. Pituitary apoplexy is a rare and severe complication of prolactinomas, which manifests with rapid onset symptoms like severe headaches, visual disturbances, hormonal imbalances, requiring urgent medical care.
Case report
We report the case of a 46-year-old female patient with history of type 2 diabetes, early menopause (30 years old, without prior investigations) that presented in the Emergency Department for symptoms of intracranial hypertension. Head CT scan revealed a pituitary adenoma of 24 x 32 x 33 mm, that proved to be an invasive macroprolactinoma, therefore she was started on Cabergoline 2 mg/week. After one month, the patient returned to the emergency room with recurrence of intracranial hypertension and CSF (cerebrospinal fluid) rhinorrhea. Both CT scan and pituitary MRI were performed, showing pituitary apoplexy, with important pneumoencephaly, lysis of the sellar floor and the prolaps of the pituitary adenoma into the sphenoidal sinus. The ablation of the tumoral mass with the repair of the craniodural defect were performed and the treatment with Cabergoline was stopped. However, meningitis was confirmed and double antibiotherapy was administered, with favorable outcomes. Pathological examination confirmed the presence of a mixed pituitary neuroendocrine tumor, with immunohistochemistry positive for prolactin and GH. Six weeks postoperative, the patient reported residual CSF rhinorrhea, and the prolactin level was 107 ng/ml (normal values: 5-25 ng/ml). The 3 months follow-up confirmed the presence of pituitary insufficiency (central hypogonadism and hypothyroidism), with normal somatotroph axis function, while prolactin levels were persistently elevated (1310 ng/ml). Therefore, the patient was started on levothyroxine 50 mg/day and cabergoline 0.5 mg twice per week, with favourable outcomes (repeated prolactin after 1 month of Cabergoline = 29 ng/ml).
Conclusions
The initial high doses of Cabergoline could have led to the fast and severe shrinkage of the tumour, causing pituitary apoplexy. The persistence of the CSF rhinorrhoea long after the repair of the CSF leak is uncommon and rises the risk of meningitis. CT scan is best for determining CSF rhinorrhea, while MRI for the characteristics of pituitary adenoma. While Cabergoline is recommended as first-line treatment for macroprolactinomas > Knosp 2 according to the latest international Consensus, surgery is needed in the case of pituitary apoplexy complicated with CSF rhinorrhea. At the same time, repairing the cranio-dural defect is more important than the complete removal of the tumour.

Pitfalls in diagnosis of the pituitary stalk lesion: infundibulo-neurohypophysitis or germ cell tumor?

Salvatore Raia[1], Antonella Giampietro[1], Tommaso Tartaglione[1], Carmelo Caldarella[1], Mario Rigante[1], Marco Gessi[1], Liverena Lauretti[1], Pierpaolo Mattogno[1], Laura De Marinis[1], Alessandro Olivi[1], Alfredo Pontecorvi[1], Francesco Doglietto[1], Antonio Bianchi[1] & Sabrina Chiloiro[1]
[1]Fondazione policlinico universitario A. Gemelli IRCCS - Università Cattolica del Sacro Cuore

Introduction
Infundibulo-neurohypophysitis (INH) is an uncommon inflammatory disorder. Because of the location of inflammation, it selectively affects the neuropituitary and pituitary stalk. The differential diagnosis remains often challenging with neoplastic lesions, such as germ cell neoplasia, Langerhans cell histiocytosis, Erdheim-Chester Disease, metastasis. Our clinical case is emblematic for pitfalls in diagnosis of the pituitary stalk lesion
Case Report
A 18 years-old male patient was observed at our Center for Pituitary disease in July 2023, for pan-hypopituitarism due to a pituitary stalk lesion. The patient was also affected from Klinefelter syndrome. The patient medical history had started when he was 10 years-old with polyuria/polydipsia. On may 2021, the patient was admitted to another hospital, for asthenia, pubertal delay and persistence of polydipsia/polyuria. Pituitary hormone tests documented pan-hypopituitarism and diabetes insipidus. Hormonal replacement therapy with hydrocortisone, levothyroxine and desmopressin acetate was prescribed. Campimetry evaluation proved a bilateral hemianopsia. A pituitary and brain contrasted MRI proved a sellar and suprasellar lesion, suggestive for a germinoma. Pituitary biopsy was performed, resulting undiagnosed. Therefore, on June 2021, a second pituitary biopsy was conducted, with the detection of inflammatory infiltration of immune cells (B CD20+ and T CD3+), histiocytes and negative immunohistochemistry for c-Kit, PLAP, CD1a, SI 00, MPO, CD30, CD15. The patient was diagnosed for INH. On April 2022, the patient referred to another endocrinology department, where G4 immunoglobulins were dosed resulting normal, antinuclear antibodies were positive, and pituitary MRI showed unchanged the pituitary stalk lesion, and the empty sella due to previous pituitary biopsies. An 18- fluorodeoxyglucose (FDG) positron emission tomography computed tomography (PET-CT) showed a suprasellar tracer hyperaccumulation (SUV 23.2). Patient was treated with high dose corticosteroid therapy without a clinical and neuroradiology improvement. On October 2022, a pituitary MRI showed a reduction in size of the tissue sited in the suprasellar space, in absence of resolution of the campimetry deficit. The patient was referred to our Pituitary centre for an additional neurosurgical evaluation, for considering a third neurosurgical debulking. An endocrine evaluation confirmed the pan-hypopituitarism, the pituitary MRI showed unchanged the pituitary stalk lesion but a neuroradiological evaluation together with 18F-Fluorocholine PET-CT was suggestive for a germ cell tumor, then confirmed by histology.
Conclusion
Our case confirms the difficult in the differential diagnosis of pituitary stalk lesions, underlining the need of a multidisciplinary approach, through the application of clinical, molecular, pathology and imaging techniques, also considering the emerging role of functional imaging.

Elimination of fall in glucose during glucagon stimulation test does not completely abolish an increase in growth hormone and cortisol concentrations

Krzysztof Lewandowski[1,2], Joanna Kawalec[2], Wojciech Horzelski[3] & Andrzej Lewiński[1,2]
[1]The Medical University of Lodz, Department of Endocrinology & Metabolic Diseases, Lodz, Poland; [2]' Polish Mother's' Memorial Hospital Research Institute, Department of Endocrinology & Metabolic Diseases,

Lodz, Poland; [3]The University of Lodz, Department of Mathemathics & Computer Science, Lodz, Poland

Background
Precise mechanism(s) responsible for stimulation of growth hormone (GH) and cortisol during Glucagon Stimulation Test (GST) are not clear, but seem to be related to glucagon-induced fluctuations in glucose and/or insulin with an initial increase followed by a subsequent fall in glucose and insulin concentrations. We have endeavoured to assess whether elimination of fall in glucose concentrations during GST would obliterate any significant increase in GH and cortisol.
Subjects & Methods
We designed a cross-over study, where glucose, GH, cortisol and insulin were measured in six healthy subjects (age range 28-54, one male) during GST (0, 30, 60, 90, 120, 150 and 180 minutes), and subsequently in the same individuals, when a fall in glucose and insulin was prevented by infusion of 10% glucose that was started at 60 minutes after administration of intramuscular glucagon.
Results
As expected, administration of glucose prevented a fall in glucose and insulin concentrations observed during later time-points of GST (e.g. mean glucose at 180 minutes of GST 176.7 mg/dl vs 71.6 mg/dl, $P=0.001$, mean insulin 53.6 μU/ml vs 4.52 μU/ml, $P=0.003$). Despite that there was still an increase in GH concentrations though less pronounced than in cross-over controls ($GH_{glucose\ infusion}$: median lowest value 0.17ng/ml vs median maximal value 8.12 ng/ml, $P=0.04$, $GH_{cross\text{-}over\ controls}$: median lowest value 0.24 ng/ml vs median maximal value 15.12 ng/ml, $P=0.004$). The same applied to cortisol concentrations ($Cortisol_{glucose\ infusion}$: median lowest value 6.89 μg/dl vs median maximal value 15.15 μg/dl, $P=0.05$, $Cortisol_{cross\text{-}over\ controls}$: median lowest value 8.48 μg/dl vs median maximal value 19.75 μg/dl, $P=0.01$).
Conclusions
Fall in glucose concentrations during the second phase of GST contributes to stimulation of GH and cortisol secretion, but is not the only factor responsible for this phenomenon. Precise mechanisms involved in stimulation of GH and cortisol secretion during glucagon stimulation test still remain to be elucidated.

Maternal cortisol levels in pregnancy and intelligence quotient in children at 7 years of age. odense child cohort

Anja Fenger Dreyer[1,2], Tina Kold Jensen[3,4,5], Iben Have Beck[3], Dorte Glintborg[1,2], Niels Bilenberg[2,6] & Marianne Andersen[1,2]
[1]Odense University Hospital, Department of Endocrinology, Odense C; [2]University of Southern Denmark, Department of Clinical Research, Faculty of Health Sciences, Odense C; [3]University of Southern Denmark, Department of Clinical Pharmacology, Pharmacy and Environmental Medicine, Odense C, Denmark; [4]Odense University Hospital, Odense Child Cohort, Hans Christian Andersen Hospital for Children, Odense C, Denmark; [5]University of Southern Denmark, OPEN Patient data Explorative Network (OPEN), Odense C, Denmark; [6]University of Southern Denmark, Department of Child and Adolescent Mental Health Odense, Mental Health Services in the Region of Southern Denmark, Odense C, Denmark

Background
Maternal cortisol levels increase during pregnancy and prenatal cortisol exposure have been linked to cognitive function in childhood. Higher activity of the enzyme 11β-hydroxysteroid-dehydrogenase type 2 (11β-HSD2) downregulates the amount of maternal cortisol crossing the placenta by inactivation of cortisol to cortisone. In childhood, boys perform significantly poorer in tests of intelligence than girls.
Aim
To investigate associations between maternal 3rd trimester cortisol or cortisone and child IQ at 7-years-of-age, and to consider the impact of child sex.
Method
Odense Child Cohort is a prospective observational cohort study. In this current study, 943 mother-child dyads were included. Exposure was maternal 24 hour urine (u-) cortisol and cortisone, and fasting morning serum (s-) cortisol, obtained in 3rd trimester of pregnancy and measured by liquid chromatography–tandem mass spectrometry. Outcome was child intelligence at age 7 years assessed by trained psychologists using the Wechsler Intelligence Scale for Children version V. Estimations of full scale intelligence quotient (FSIQ) and verbal comprehension index (VCI) were calculated.
Results
Women carrying a boy had significantly lower s-cortisol levels than women carrying a girl (825 vs 865 nmol/l, $P=0.005$). Girls had a significant higher score in FSIQ (101.2 vs 98.2, $P<0.001$) and VCI (101.1 vs 98.9, $P=0.004$) compared to boys. In girls, levels of maternal u-cortisone were positively associated with VCI (B (95%-CI) = 6.2 (1.2; 11.2). In boys, maternal s-cortisol was negatively associated with FSIQ (B (95%-CI) = -3.9 (-6.5; -1.3)) and VCI (B (95%-CI) = -4.4 (-7.0; -1.9)). Child sex had a significant interaction with u-cortisone and s-cortisol in the associations.
Conclusion
Lower prenatal cortisol exposure of the fetus seems beneficial for cognitive development at 7-years-of-age. Girls were protected against high cortisol exposure via the inactivation of cortisol to cortisone by 11β-HSD2, while boys were more susceptible to high maternal cortisol levels. Child sex differences in prenatal cortisol exposure and cognitive development should be considered in future studies.

TGFBR3L gene expression and relevance for the gonadotroph non-functioning pituitary neuroendocrine tumours

Maren Wessel[1,2], Jens Petter Berg[3,4], Jens Bollerslev[1,3] & Nicoleta Cristina Olarescu[1,2,3]
[1]Section of Specialized Endocrinology, Department of Endocrinology, Oslo University Hospital (OUS), Oslo, Norway, Oslo, Norway; [2]Research Institute of Internal Medicine, Oslo University Hospital (OUS), Oslo, Norway; [3]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway; [4]Department of Medical Biochemistry, Oslo University Hospital (OUS), Oslo, Norway

Objective
Transforming growth factor beta receptor 3 like (TGFBR3L) has been recently described as a pituitary-specific membrane protein detected in a proportion of the gonadotroph cells in non-neoplastic and tumour tissue (1). Furthermore, mouse studies have indicated that TGFBR3L is an inhibin B co-receptor that regulates FSH levels (2). We hypothesized that TGFBR3L expression in gonadotroph non-functioning pituitary neuroendocrine tumours (NF-PitNETs) is related to clinical parameters as age, gender and tumour volume. Moreover, we aimed to decipher the possible function of this protein in tumorigenesis and hormone production in gonadotroph NF-PitNETs.
Methods
Gene expression of TGFBR3L was performed by RT-qPCR in immunohistochemically confirmed gonadotroph NF-PitNETs (SF1 and/or FSHβ/lHβ positive) in a cohort of prospectively included patients ($n=102$) diagnosed between 2014-2021. Clinical parameters as age, sex and tumour volume were recorded. RNA-sequencing was performed in a sub-cohort of 18 age and sex matched patients with high and low TGFBR3L gene expression ($n=9$ in each group). Posttranscriptional silencing of TGFBR3L by siRNA was performed in the LβT2 gonadotroph cell line and gene expression of FSHβ and LHβ were measured. Ongoing studies are performed on primary gonadotroph tumor cells isolated from gonadotroph NF-PiNETs.
Results
Of 102 patients 39 (32%) were women, age at diagnosis mean ± 1SD: 61 ± 14 years, tumour volume median (IQR) 5928 (3657-8717) cm3. TGFBR3L did not correlate to age, sex, and tumour volume. RNA-sequencing identified 1921 differentially expressed genes (DEGs) disclosing a distinct genetic profile associated with TGFBR3L expression, with 786 DEG up- and 1135 down-regulated genes. SF1/NR5A1, LHβ, GNRHR, ESR1, and SSTR3 were up-regulated in the high TGFBR3L group. Pathways analysis revealed an up-regulation of genes involved in the Notch signaling pathway along with downregulation of genes in the JAK/STAT pathway and partial suppression in the Wnt signaling pathway in the high-TGFBR3L group. Furthermore, pathways related to proliferation, cell survival and cell adhesion were differentially regulated between the groups. SiRNA-mediated suppression of TGFBR3L in LβT2 cells resulted in a significant increase in LHβ expression ($P=0.001$), without affecting FSHβ.
Conclusion
Although TGFBR3L gene expression is not related to primary clinical parameters, it is related to markers of gonadotroph cell differentiation. Analyses of the genes related to TGFBR3L expression and in vitro mechanistic studies may reveal distinct roles for this protein in NF-PitNETs pathogenesis.

A complex clinical scenario: chiari type ii malformation coexisting with suprasellar paraganglioma and associated succinate dehydrogenase subunit b (SDHB) genetic mutation

Stefano Testa[1,2], Erika Grossrubatscher[2], Paolo Dalino Ciaramella[2], Benedetta Zampetti[2], Vittoria Favero[1,2] & Iacopo Chiodini[1,2]
[1]University of Milan, Department of Biotechnology and Translational Medicine, Milan, Italy; [2]Ospedale Niguarda Ca' Granda, Endocrinology Unit, Milan, Italy

Introduction
Paragangliomas are rare neuroendocrine tumors, that manifest as painless, slow-growing masses, becoming evident only when symptoms of catecholamine overproduction or mass effects emerge. Paragangliomas exhibit a broad spectrum of characteristics, existing as solitary or multiple entities, and may be sporadic or hereditary. These tumors can be either benign or malignant and have origin in the sympathetic or parasympathetic tissues. Paragangliomas are commonly found in the pre-aortic and paravertebral sympathetic plexus or in the neck and head and they can be associated with hereditary syndromes, often linked to genes encoding different subunits of succinate dehydrogenase (SDHx). Carriers of SDHB gene mutations have the highest morbidity and mortality rates due to their malignant potential.
Case Report
We present the case of a 16-years-old female patient who had undergone neurosurgical intervention at birth due to Chiari malformation type II and myelomeningocele. The patient was referred for short stature and primary amenorrhea. A left wrist radiograph performed 5 months before indicated delayed skeletal maturation. Pituitary function tests were within normal range (FSH 6.4 mIU/ml, LH 7.5 mIU/ml, estradiol 34 pg/ml, TSH 2.1 mIU/l, FT4 11 pg/ml, 17-β-estradiol 67 pg/ml, cortisol 15 μg/dl, ACTH 35 pg/ml), except for reduced prolactin values (2 ng/ml). Surprisingly, a concurrent encephalic Magnetic Resonance Imaging (MRI), performed during the neurological follow-up, revealed a new left median-paramedian intra-suprasellar rounded lesion of 11 mm, hypointense in T1 and iso-hyperintense in T2, with features suggesting an uncertain nature. Based on the suspicion of astrocytoma or craniopharyngioma, a transnasosphenoidal surgery was performed six months later. The post-operative histologic examination was suggestive of paraganglioma, characterized by consistent morphologic and immunophenotypic features (focal CK+, S100+ in sustentacular cells, and diffuse synaptophysin+). Subsequently, the genetic examination revealed a variant in heterozygosity of exon 7 of the SDHB gene (c.688C>G), with a probable pathogenetic significance. The subsequent follow-ups indicated normal hypothalamic-pituitary-adrenal axis and the onset of menarche at 16.6 years. Postoperative pituitary MRIs confirmed no residual or recurrent disease. Further hormonal and radiological follow-ups were negative.
Conclusion
Despite advances, the imaging of paragangliomas remains challenging, with critical implications for the appropriate diagnostic-therapeutic approach and metastasis detection. The coexistence of paragangliomas and Chiari malformations has already been reported in patients with mutation of EPAS1 and neurofibromatosis type 1. This case suggests the need for further investigations into the genetic correlations of these two conditions, and highlights a possible role for SDHB gene mutations.

Validation of baseline laboratory levels and a novel probability score in the diagnosis of patients with suspected arginine vasopressin deficiency (Central Diabetes Insipidus)

Cihan Atila[1], Irina Chifu[2], Juliana Drummond[3], Deborah Vogt[1], Martin Fassnacht[2], Bettina Winzeler[1], Julie Refardt[1] & Mirjam Christ-Crain[1]
[1]University of Basel, Endocrinology, Basel, Switzerland; [2]University of Würzburg, Würzburg, Germany; [3]Medical School of the Federal University of Minas Gerais, Belo Horizonte, Brazil

Introduction
Distinguishing arginine vasopressin deficiency (AVP-D, central diabetes insipidus) from primary polydipsia (PP) is challenging. The method with the highest diagnostic accuracy, hypertonic saline-stimulated copeptin, is often limited to experienced hospitals, requires close monitoring, and may be cumbersome for patients. A standardised, validated stepwise assessment and probability score to rule out AVP-D in the initial baseline evaluation is currently lacking.
Methods
This analysis includes two independent patient cohorts from two international multicentre studies undergoing the hypertonic saline stimulation test (HST). Eligible adults with polyuria (>50 mL/kg body weight/day) or known AVP-D were included. The final diagnosis was based on medical history, clinical symptoms, laboratory/imaging data, results of the HST and therapeutic response at a three-month follow-up. Primary aim was to assess the diagnostic potential of baseline laboratory levels and to develop a novel probability score. In the probability score, the overall best cut-off, high-sensitivity cut-off (defined as ≥95% sensitivity), and high-specificity cut-off (defined as ≥95% specificity) were derived in the first cohort (development), and their diagnostic performance was determined in the second cohort (validation). The final scoring scheme included: (baseline plasma sodium x osmolality)/100), baseline plasma copeptin (–50 points, if > 4.9pmol/l), nycturia [+30 points, if ≥3 times], onset of polyuria/polydipsia [+20 points, if sudden onset], drinking amount at night [30points, if >1L], presence of anterior pituitary deficiencies [+50points], previous pituitary surgery [+50points].
Results
In total, 299 patients were included between July 2013 and September 2022; 141 in the development cohort ($n=59$ [42%] AVP-D; $n=82$ [58%] PP) and 158 in the validation cohort ($n=69$ [44%] AVP-D; $n=89$ [56%] PP). For diagnosing AVP-D, a baseline plasma sodium of >145mmol/l provided 100% sensitivity (95%CI:100-100) and <135mmol 100% specificity (95%CI:100-100), and baseline plasma copeptin >5.6pmol/l resulted in 100% specificity (95%:CI 100-100). In the validation cohort, a probability score cut-off of 441 points provided the highest overall diagnostic accuracy of 86% (95%CI:73–94) and an area under the roc curve (AUC) of 91% (95%CI:87–96); the high-sensitivity cut-off of 415 points had a 93% sensitivity (95%CI:86-99), and the high-specificity cut-off of 461 points a 93% specificity (95%CI:88-98).
Interpretation
Our findings show that a plasma sodium <135mmol/l or a copeptin >5.6pmol/l rule out AVP-D, whereas a sodium >145mmoL/l can be used as a rule-in test. A novel probability score, including baseline laboratory values, clinical symptoms, and medical history, had high accuracy for identifying AVP-D without the need for any further stimulation testing.

Gemelli, Department of Imaging, Radiation Therapy and Hematology, Università Cattolica del Sacro Cuore, Fonda-zione Policlinico Universitario Agostino Gemelli, Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS), Rome, Italy; [6]Catholic University of Sacred Heart, Section of Anatomic Pathology, Department of Life Sciences and Public Health, Università Cattolica del Sacro Cuore, Rome, Italy; [7]Catholic University of Sacred Heart, Neurosurgery, Rome, Italy

Genetic discoveries improved the understanding of the etiology and pathogenesis of several diseases, including acromegaly. Germline mutations involving AIP, MEN1, CDKN1B, GPR101, PRKAR1A, and GNAS genes have been described in GH-secreting PitNETs, but realistically many genetic alterations have not been identified yet. Nowadays, RET mutations have not been reported in acromegaly, if not exclusively in the context of a multiple endocrine neoplasia (MEN). A 48-year-old patient was affected by a cavernous sinus and bone-invasive somatotropinoma, resistant to first- and second-line medical therapies. The patient was also diagnosed with left breast cancer and right breast fibroadenoma. According to the somatotropinoma aggressive behavior and cancer history, a genetic study for germline mutations was performed through a specific panel designed for Pit-NETs. To our knowledge, we describe the first acromegalic patient with the RET gene pathogenic variant (PV) (Class 5): c.2410G>A; p.Val804Met; rs79658334. The presence of RET fusions is well documented in breast cancers, but RET germline PVs have never been reported in breast cancer. After excluding all the other possible RET-associated pathologies, including MEN, we speculated that our patient could be affected by Hereditary Cancer-Predisposing Syndrome (HCPS) since the association with this PV is known in the literature. The patient's first-degree relatives underwent genetic screening for the same RET PV, resulting

positive in heterozygosity in the patient's father and daughter. Clinical, hormonal, and imaging assessment ruled out abnormalities until now, but the 25-year-old daughter was also diagnosed with right breast fibroadenoma. This finding supported the hypothesis that RET c.2410G > A PV may cause HCPS. The RET mutation may have induced constitutive activation of tyrosine kinase expressed also in the pituitary, enhancing GH production and somatotroph cell proliferation, according to the invasive growth and the poor response to treatments of the proband. Furthermore, the occurrence of breast tumors, in addition to the early onset in the young daughter, in the absence of other variants strongly associated with familial cancers, hints at the possibility that the RET PV may contribute to tumor susceptibility. In conclusion, our clinical case describes a new phenotype associated with RET PV, represented by an acromegalic woman with breast carcinoma, suggesting that also pituitary tumors should be considered in the landscape of HCPS. RET mutations may be considered for screening if NGS for well-established PitNET-associated gene mutations renders negative, in patients with aggressive tumors and suggestive clinical history.

Corticotroph tumours, comprising around 15% of pituitary tumours, express ACTH and other peptides originating from TPIT-lineage adenohypophyseal cells. Their tumorigenesis involves a complex interplay of genetic and epigenetic factors and hormonal and growth factor stimulation. Silent corticotroph tumours (SCT) share immunopositivity for ACTH and TPIT with functioning corticotroph tumours (FCT) but do not exhibit evidence of hypercortisolism. Despite their aggressive growth and high recurrence rates, the reasons for their failure to induce hypercortisolism remain speculative, focusing on factors like cell origin, sensitivity to hypothalamic stimulants, POMC cleavage, and cell cycle regulation. This study delves into the role of USP8 mutations in the pathogenesis of corticotroph tumours. USP8 is involved in the regulation of the epidermal growth factor receptor (EGFR) signalling pathway. USP8, when mutated, cannot properly regulate the ubiquitination and degradation of EGFR, and prolonged activation of EGFR due to impaired degradation can lead to sustained signalling, promoting increased POMC expression and subsequent ACTH secretion. Sanger sequencing was performed on 10 SCTs and 13 FCTs from a unique centre. Comprehensive analysis encompassed demographic, clinical, radiological, and genetic variables, including genes associated with ACTH processing, secretion, glucocorticoid receptor (GR) pathway, and the immune microenvironment. The results unveiled somatic USP8 mutations in 70% of SCTs and 30.8% of FCTs, all heterozygous and located in exon 14. Mutated tumours were more prevalent in younger individuals and women, smaller, less invasive, and exhibited heightened expression of ACTH-related genes (POMC, CHRH, AVPR1, TBX19, PCSK1/3, USB, CABLES1, EGFR). No significant changes were observed in genes related to ACTH degradation (PCSK2, PAM, CPE) or the GR pathway. In SCTs, mutated tumours displayed increased immune activity, as indicated by elevated PDL-1 expression. We also explored the expression of somatostatin receptor levels as potential therapeutic targets on these tumours. Both mutated SCTs and FCTs expressed higher levels of SSTR5 than non-mutated ones, and FCTs additionally expressed more SSTR2. In conclusion, USP8 mutations are prevalent in corticotroph lineage pituitary tumours, encompassing both silent and functioning variants. Mutated tumours exhibit a more differentiated profile, suggesting potential implications for diagnosis and targeted therapies.

Background
Glucocorticoids (GC) are potent entrainers of the circadian clock, however their effect on biological rhythms in human chronic exposure have been poorly studied. Endogenous hypercortisolism (Cushing's Syndrome, CS) is a rare condition, in which circadian disruption is sustained by a tumorous source of GC excess, offering the unique opportunity to investigate the *in vivo* chronic effects of GC.
Methods
In a 12-month prospective multicenter trial, the daily fluctuations in the number of circulating peripheral blood mononuclear cells (PBMCs) and the time-specific expression of clock-related genes were analyzed by RT-qPCR in a cohort of 68 subjects, 34 affected by CS and 34 age- and sex-matched controls. Rhythmicity algorithms and machine learning techniques were applied to the multi-level dataset.
Findings
Multiple, 6-points, daily sampling revealed profound changes in the levels, amplitude, and rhythmicity of several PBMCs populations. More specifically, total ($CD14^+$), intermediate ($CD14^+CD16^+$) and non-classical ($CD14^+CD16^{++}$) monocytes increased, while classical ($CD14^{++}CD16^-$) monocytes decreased, all normalizing after remission, except for a persisting dampening of the amplitude of their daily variations. On the other hand, the decrease in total ($CD3^+$) and $CD4^+$ lymphocytes and the increase in $CD8^+$ lymphocytes only partially restored after CS remission, while regaining similar amplitude compared to controls. Mesor of total $CD56^+$ NK cells and all NK cells subsets were significantly reduced in CS as well. Clock gene analyses in isolated PBMCs showed a significant flattening of circadian oscillation of PER1, PER2, PER3, PRF1 and TIMELESS expression, and a paradoxical increase in the amplitude of PER genes after remission. In the active phase, the JTK_CICLE algorithm revealed a loss of rhythmicity of all genes which were circadian in the PBMCs of controls. Most, but not all, regained physiological oscillation after remission. Machine learning revealed that while combined time-course sets of clock-genes were highly effective in separating patients from controls, immune profiling was efficient even as single time-points.
Interpretation
In conclusion, the oscillation of circulating immune cells is profoundly altered in CS patients, representing a convergence point of circadian rhythm disruption, metabolic and steroid hormone imbalances. Machine learning techniques proved the superiority of immune profiling, over parameters such as cortisol, anthropometric and metabolic variables, and gene expression analysis, to identify CS activity.

Objective
To evaluate the natural history of Rathke's cleft cysts (RCC).
Materials and Methods
A multicenter retrospective clinical practice study of adult patients with radiologically diagnosed RCCs since 2000 in 15 tertiary hospitals (SPAIN-QBR study) with a diameter greater than 5 mm, in whom non-surgical follow-up was decided.
Results
A total of 177 patients were followed for 65.8 ± 42.3 months. The mean age was 42.8 ± 18.1 years, significantly ($P<0,01$) lower than that of other patients who underwent surgery (48.0 ± 16.4 years). The larger diameter was between 6 and 10 mm in 84 patients (49.7%), 11-20 mm in 86 patients (48.5%), and >20 mm in 11 patients (6.2%). Suprasellar extension was present in 44 (24.9%) and cavernous sinus extension in 3 (1.7%). The largest MRI tumor diameter remained stable or decreased in 133 patients (75.1%) and increased in 44 patients (24.9%). None of the baseline tumor or patient characteristics predicted the evolution of tumor size. During follow-up, 7 patients (3.9%) underwent surgery, in one case by patient decision without previous change, in three 3 cases after clinical events (two cases due to visual changes and one due to hormonal changes) and in another three patients because of significant growth observed on MRI with risk of chiasmatic involvement. Surgery was performed at 27, 43, 55, 80, 84, and 105 months after diagnosis. (Table 1) When baseline clinical covariates were included in a regression model, the only predictor of the need for surgery was the degree of hormonal involvement at baseline.
Conclusion
After a mean of 5 years of follow-up, 24% of patients experienced some increase in RCC size, but without clinical significance. Only 3% needed surgery, which was more likely in those with more hormonal involvement at diagnosis.

Impact of clinical and treatment characteristics on HR-QoL in patients with prolactinoma - cross-sectional analysis of a dutch multicenter prospective cohort study

Ingrid Zandbergen[1], Iris Pelsma[2], Wouter van Furth[1] & Nienke Biermasz[2]
[1]Leiden University Medical Center, Neurosurgery, Leiden; [2]Leiden University Medical Center, Endocrinology and Metabolism, Leiden

Introduction
Patients with prolactinomas suffer from a wide range of symptoms, of which the effect on health-related quality of life (HR-QoL) needs further investigation. Moreover, the first-line treatment for patients with prolactinomas, dopamine agonists (DAs), albeit being effective in lowering prolactin levels, might further hamper HR-QoL due to side effects. To assess the impact of symptoms and treatment modality on HR-QoL, a cohort of patients with prolactinoma was cross-sectionally investigated.
Methods
Baseline clinical characteristics, symptoms (measured using the PRO-CTCAE, and HADS questionnaire), treatment outcomes, and HR-QoL (measured using the SF-36 questionnaire) of 210 DA treated (DAT) patients (mean age 49.4 ± 15.4 years; 122 females (58.1%)), and 106 patients not treated with DA (mean age 40.9 ± 12.9 years; 87 females (82.1%)) are described in this Dutch multicenter prospective observational cohort study.
Results
Current prolactin levels -available for 229 patients- were elevated above the sex upper limit of normal in 54/210 DAT patients (34.8%), and in 52/106 patients not treatment with DA (70.3%, $P<0.001$). Galactorrhea was reported more frequently by 13/44 (29.5%) patients not treated with DA *vs* 15/119 (12.6%) DAT patients ($P=0.011$), and was more frequently reported by female patients (25.0% vs 1.8%, $P<0.001$). Side effects of DA treatment – reported by 155/210 DAT patients – were gastro-intestinal (GI) tract symptoms (total 63/155 (40.6%), males 14/68 (20.6%) *vs* females 49/87 (56.3%), $P<0.001$); fatigue (total 77/155 (50.0%), males 22/68 (32.4%) vs females 55/86 (64.0%), $P<0.001$), and concentration loss (total 41/155 (26.6%)). DA treatment did not influence risk for anxiety (36/143 *vs* 18/65, $P=0.747$) and depression (30/144 *vs* 17/65, $P=0.394$), and was not different in males and females. All HR-QoL domains, bar physical functioning and pain, were lower in patients with prolactinoma compared to the Dutch population (General Health domain 55.0 ± 14.5 in patients with prolactinoma *vs* 70.7 ± 20.7 in the Dutch population, $P<0.001$). Female patients had lower domain scores on Social Functioning (68.4 ± 29.0 vs 77.9 ± 26.1, $P<0.025$), Fatigue (48.4 ± 22.8 vs 59.9 ± 22.0, $P<0.001$), and Pain (77.0 ± 26.3 vs 85.3 ± 18.9, $P<0.025$).
Conclusions
Based on this cross-sectional analysis of the Dutch national cohort of patients with prolactinomas, 66.5% of patients were currently treated with DA. Despite DA treatment, a proportion of patients had prolactin levels above the ULN. Significant sex differences for most outcomes of interest (i.e. current treatment, current tumor size, symptoms at present) were observed, necessitating further research into sex differences in patients with prolactinoma. Moreover, HR-QoL was significantly affected in patients with prolactinoma, highlighting the impact of the prolactin-producing tumor.

Apelin and copeptin levels in patients with chronic SIAD treated with empagliflozin – a secondary analysis of the SANDx trial

Sophie Monnerat[1], Nikolaos Drivakos[1,2], Fiona A. Chapman[3,4], Neeraj Dhaun[3,4], Julie Refardt[1] & Mirjam Christ-Crain[1,5]
[1]University Hospital Basel, Department of Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]Hospital Center of Biel, Department of Nephrology, Biel, Switzerland; [3]Queen's Medical Research Institute, BHF/University of Edinburgh Centre for Cardiovascular Science, Edinburgh, United Kingdom; [4]Royal Infirmary of Edinburgh, Department of Renal Medicine, Edinburgh, United Kingdom; [5]University of Basel, Department of Clinical Research, Basel, Switzerland

Introduction
Glucose-induced osmotic diuresis and free water loss induced by the SGLT2 inhibitor empagliflozin effectively increase sodium levels in patients with a chronic syndrome of inappropriate antidiuresis (SIAD) where arginine vasopressin (AVP) levels are inappropriately increased in relation to osmolality. The hormone apelin opposes the actions of AVP in salt and water homeostasis and administering exogenous apelin increases sodium levels in rats with SIAD. In patients with type 2 diabetes mellitus and heart failure, apelin levels increased after a 6-month treatment with dapagliflozin. We aimed to investigate whether an increase in plasma apelin level may contribute to the therapeutic efficacy of empagliflozin in chronic SIAD.
Methods
Post-hoc secondary analysis of a double-blind, crossover, placebo-controlled trial performed from 12/2017 to 08/2021 at the University Hospital Basel, Switzerland, investigating the effect of a 4-week treatment with empagliflozin 25 mg/day as compared to placebo in 14 outpatients with chronic SIAD. The primary objective was to investigate the effect of empagliflozin on apelin levels. Secondary objectives included the effect of empagliflozin on copeptin levels and on the apelin/copeptin ratio. Absolute changes in apelin, copeptin and their ratio were compared using a paired Wilcoxon signed-rank test. The relationship between apelin and sodium levels was investigated by computing Spearman correlation coefficients.
Results
Fourteen patients, 50% female, with a median [IQR] age of 72 years [65–77] were included in the analysis. Median apelin levels were 956 pmol/l [853, 1038] at baseline. Median [IQR] apelin absolute changes were 102 [1, 166] pmol/l and 82 [-47, 199] pmol/l ($P=0.677$) at the end of the placebo and empagliflozin phase respectively. Baseline apelin levels did not correlate with baseline sodium levels ($\rho = 0.34$, $P=0.282$), nor did their absolute changes at week 4 ($\rho = -0.007$, $P=0.974$). Median copeptin levels were 2.6 [2.2, 4.5] pmol/l at baseline and increased by 0.2 [-0.1, 0.6] pmol/l and 0.6 [0.3, 0.9] pmol/l ($P=0.069$) over the placebo and empagliflozin phase, respectively. Median apelin/copeptin ratio was 369 [147, 503] at baseline and increased by 8 [-97, 36] and decreased by 4 [-72, 32] ($P=0.266$) during the placebo and empagliflozin phase, respectively.
Conclusion
Treatment with empagliflozin in patients with chronic SIAD did not lead to significant changes in either apelin or copeptin levels, or the apelin/copeptin ratio. Our findings suggest that the efficacy of empagliflozin in SIAD is not due to an alteration in plasma apelin concentration.

Introduction
Growth hormone (GH) replacement therapy is safe and confers significant benefits in body composition, bone health, cardiometabolic risk factors, and quality of life in adults with GH deficiency. However, longer term safety and efficacy data are limited by the lack of consistency in data collection between studies. The study aim was to develop a simple global register by standardising and developing a minimum data set (MDS) to facilitate international collection of safety and efficacy data.
Methods
This study was undertaken by the Adulthood GHD Expert Working Group (EWG) in GloBE-Reg, the Global Registry for Novel Therapies in Rare Bone and Endocrine Conditions (https://globe-reg.net/). Seventeen international clinical experts from 10 countries and two representatives from patient organisations participated in this initiative using published methodology for the grading system of MDS in childhood-onset GHD (cGHD) (doi: 10.1159/000533763). Inclusion criteria required $>70\%$ consensus for importance as defined for the MDS, provided $<50\%$ of the group deemed the item difficult to collect. The development of the finalised MDS took place over four months, which included two virtual meetings among the EWG members.
Results
A total of 190 data fields compiled from routine clinical practice of the EWG and fields in the cGHD MDS were graded. Of these, 111 items fulfilled the criteria for importance whilst 117 items were deemed easy to collect. Combining the criteria for importance and ease of data collection, 86 items fulfilled the criteria for MDS. Six items were excluded as one was redundant, another was a calculated field and four were designated as core data. Several fields such as adherence and patient reported outcomes while important, were considered difficult to assess objectively in routine clinical settings. Following detailed discussions, twenty items unrelated to safety and efficacy of GH therapy were removed, with the remaining 60 items merged into the finalised MDS recommendation of 43 items.
Conclusion
In summary, GloBE-Reg has developed a MDS suitable for monitoring the long-term safety and effectiveness of GH replacement therapy in adults during routine clinical practice world-wide. Such data harmonisation that bridges the monitoring of safety and efficacy of growth hormone therapy across the age span in patients of different healthcare settings will be pivotal in facilitating longer term surveillance and improving patient outcomes.

Predictors of corticotroph tumour recurrence after surgical resection

Prishila Fookeerah[1,2], Winny Varikatt[3,4], Meena Shingde[3,4], Mark Dexter[4,5], Sue Lynn Lau[1,2] & Mark McLean[1,2]

[1]Westmead Hospital, Diabetes and Endocrinology, Sydney, Australia; [2]Western Sydney University, School of Medicine, Sydney, Australia; [3]Westmead Hospital, Tissue Pathology and Diagnostic Oncology, Sydney, Australia; [4]University of Sydney, Westmead Clinical School, Sydney, Australia; [5]Westmead Hospital, Neurosurgery, Sydney, Australia

Background
Corticotroph tumours are a heterogenous group of pituitary neuroendocrine tumours (PitNETs) in terms of their histological type, clinical presentation and tumour behaviour. These tumours are overrepresented in recurrent PitNETs and pose an important clinical and therapeutic challenge[1]. Although risk factors such as radiological invasion and elevated proliferative markers have been identified for PitNET recurrence, an improvement in proposed prognostic models is necessary to optimise management and monitoring of corticotroph tumour after surgical resection[2]. We compared recurrent and non-recurrent corticotroph tumours to assess differences in clinical and histological parameters.
Methods
51 consecutive corticotroph PitNETs resected from 2011 to 2018 and archived at Westmead Hospital were reviewed in a retrospective study. All tumours were characterised using transcription factor and hormonal immunohistochemistry. Corticotroph PitNETs were identified by positive TPIT expression. Clinical, radiological and histological characteristics of recurrent tumours were compared with cases without recurrence. 5 cases were excluded due to lack of adequate follow up data.
Results
Twelve cases (26%) had radiological or biochemical recurrence with mean time to detection of 45 months (range 12-144). Proportion of sparsely granulated subtype was similar in both groups(75% vs 76.5%, $P=0.69$). There was no significant difference in the proportion of silent and functioning corticotroph tumours between the two groups (58.3% vs 67.6% silent and 41.7% vs 32.4% functioning, $P=0.72$). Maximum tumour diameter at presentation was greater for tumours that later recurred (25.4 vs 17.2mm, $P=0.046$). Radiological or histological invasion was more frequent in recurrent tumours, though not statistically significant (42.9% vs 30%, $P=0.67$). Recurrent tumours were more likely to have a visible residual tumour after first resection (66.7% vs 20.6%, $P=0.01$). Presence of tumour remnant after surgery was associated with recurrence (OR 7.42, 95% CI 1.72 to 32.05, $P=0.0072$). The 12 recurrent tumours required a total of 24 separate interventions. Of these, 66.7% were repeat surgery, 16.7% radiotherapy, 12.5% medical therapy and 9.5% bilateral adrenalectomy. 33.3% of recurrent tumours expressed SSTR5.
Conclusion
Persistent tumour remnant after surgery may be an important predictor of corticotroph PitNET recurrence requiring further therapeutic intervention. Silent corticotroph tumours or sparsely granulated subtype did not predict recurrence in our study.

Drug-induced hyperprolactinemia and granulomatous mastitis: a case report and literature review

Mohammed Alenazi[1], Sarah Howse[1] & Syed Imran[1]

[1]Dalhousie University, Division of Endocrinology and Metabolism, Halifax, Canada

Background
Granulomatous mastitis (GM) is a rare inflammatory condition of the breast typically affecting women during postpartum period. GM can mimic inflammatory breast cancer and only be reliably distinguished through histopathology. While there is no generally accepted treatment for GM, therapeutic options include - antibiotics, wide surgical excision, and corticosteroids.
Clinical Case
A 54-year-old female presented to her family physician with with a warm, erythematous lump on the right breast. She was prescribed a 7-day course of antibiotics and referred to the infectious disease clinic. A subsequent biopsy confirmed acute and chronic granulomatous inflammation and gram-positive cocci. She responded to the antibiotic therapy, but her symptoms recurred and was prescribed a 2-month course of doxycycline but her GM symptoms failed to resolve. She had an over 10-year history of hyperprolactinemia thought to be due to chronic opioid therapy and was referred to Endocrinology for further assessment. Serum prolactin (PRL) level had ranged between 63 to 81 µg/l (5-25 µg/l) and the sella MRI was normal. The patient declined to stop opioid therapy and considering the possibility of PRL-induced GM, she was prescribed cabergoline 0.5 mg once weekly. Her GM symptoms rapidly resolved and she has remained asymptomatic.
Discussion
This case represents a rare occurrence of acute on chronic GM in the setting of longstanding drug-induced hyperprolactinemia. A review of literature revealed three other cases of drug-induced hyperprolactinemia associated with GM and four cases were prolactinoma. The underlying etiological role of PRL in GM is not fully understood, but it is believed to have immunomodulatory effects, potentially triggering an inflammatory response in the breast tissue. This report emphasizes the importance of considering hyperprolactinemia in the diagnosis and treatment of GM, particularly in cases of recurrent GM.

Cyclic cushing's syndrome: a diagnostic challenge

Ioanna Tsironi[1], Labrini Papanastasiou[1], Athanasios Fountas[1], Eirini Kaliakatsou[1], Kostis Karachalios[1], Panagiota Christou[2], Stelios Tigas[2], Miltiadis Gravvanis[3] & Athina Markou[1]
[1]'G. Gennimatas' General Hospital of Athens, Unit of Endocrinology and Diabetes Center, Athens, Greece; [2]University Hospital of Ioannina, Department of Endocrinology, Ioannina, Greece; [3]G. Gennimatas' General Hospital of Athens, Radiology Department, Athens, Greece

Introduction
Cyclic Cushing's syndrome is a rare disease characterized by episodes of cortisol hypersecretion followed by periods of normal cortisol secretion, ranging from days to months. We report a case of cyclic Cushing's syndrome whose diagnosis was delayed for years.
Case presentation
A 50-year-old female with a 16-year history of non-Hodgkin's lymphoma was referred to the Endocrinology Unit due to suspected hypercortisolemia. She had a 2-year history of hirsutism, supraclavicular fat pads, irritability, and insomnia. During her first admission, ACTH-dependent hypercortisolemia [midnight serum cortisol: 404.5 nmol/l, cortisol levels post-dexamethasone suppression test (DST) 127.42 nmol/l, ACTH: 14.3 pg/ml] was confirmed. Patient was, also, diagnosed with osteoporosis, arterial hypertension, and dyslipidemia. Pituitary MRI was performed and a 4 mm lesion on the left side of the gland was identified. CRH and DDAVP stimulation tests were performed which were both indicative of Cushing's disease. Given, however, the size of the pituitary lesion, an inferior petrosal sinus sampling (IPSS) was scheduled. Patient was re-admitted 2 weeks later for the IPSS, and, interestingly, her hormonal investigations were found to be normal [24h urinary free cortisol levels (31.5 mg/24h, NR < 80), midnight serum cortisol (118 nmol/l), and cortisol post-DST levels (29.3 nmol/l)]. Because of the conflicting results between the later and the previous admission, the above-mentioned tests were repeated 1 month later, which, this time, confirmed hypercortisolemia [24h urinary free cortisol levels (178 mg/24h, NR < 80), midnight serum cortisol (300 nmol/l), and cortisol post-DST levels (218 nmol/l)]. Taking into account the results of the hormonal tests, the presence of a pituitary microadenoma, and the patient's sex, a working diagnosis of cyclical Cushing's disease was made. To confirm the diagnosis, two days later, an IPSS with desmopressin stimulation was performed but ACTH-dependent hypercortisolemia was not detected indicating disease shift to another inactive phase. A second IPSS with desmopressin stimulation was performed 1 month later, with the patient's disease being in active phase, as demonstrated by elevated midnight serum cortisol levels for 2 consecutive days prior to IPSS, and the results were consistent with left-sided pituitary ACTH hypersecretion. Subsequently, a transsphenoidal pituitary surgery was successfully performed and the patient's Cushing's disease is currently on remission.
Conclusion
Our case demonstrates that the diagnosis of cyclic Cushing's syndrome is particularly challenging. During a period of inactivity, tests may be negative. However, if the clinical suspicion is high, follow-up with repeated screening tests are suggested to establish the final diagnosis.

Deciphering microenvironment interactions during age-related pituitary tumour onset and through orthotopic mouse pre-clinical model

Álvaro Flores-Martínez[1,2], Marie Chanal[1], Marine Daura[1], Alexandre Vasiljevic[1,3], Radu Bolbos[4], Jean-Baptiste Langlois[4], Gerald Raverot[1,5] & Philippe Bertolino[1]
[1]Inserm U1052, CNRS UMR5286, Cancer Research Center of Lyon, Lyon 1 University., Lyon, France; [2]Maimónides Biomedical Research Institute (IMIBIC)/Reina Sofía University Hospital (HURS)/University of Cordoba, Department of Cell Biology, Physiology and Immunology, Córdoba, Spain; [3]Pathology Department, Reference Center for Rare Pituitary Diseases HyPO, 'Groupement Hospitalier Est' Hospices Civils de Lyon, Bron, France; [4]CERMEP-Life Imaging Center, Lyon, France; [5]Endocrinology Department, Reference Center for Rare Pituitary Diseases HyPO, Groupement Hospitalier Est' Hospices Civils de Lyon, Bron, France

Rationale
Pituitary tumours (PiTs) are a common and heterogeneous group of benign, slow-growing intracranial neoplasms arising from the sellar region. While recent advances have improved our knowledge of their cellular composition and the contribution of their tumour microenvironment (TME), most of PiT subtypes lack effective therapeutic treatments. Moreover, the mechanisms that occur in the early stage of PiT initiation remain to be elucidated partly due to the limited number of identified driver-mutations.
Objectives
Here, we aim to i) evaluate the consequences of pituitary tumorigenesis initiation on the remodelling of the native anterior pituitary microenvironment and ii) further model the dynamics of the functional interaction that exists between pituitary tumour cells and their microenvironment.
Approaches
We employed two main strategies based on: (1) the characterisation of the TME in spontaneous pituitary lesions found in aged mice and, (2) the development of an orthotopic mouse-model in which pituitary tumour cells were injected in the anterior pituitary gland.
Results
We confirmed that spontaneous lesions can be found in the anterior pituitary gland of aged mice. At the age of 20 months, we observed that 61.5 % of C57bl/6 mice ($n = 8/13$) developed histological abnormalities. While only one tumour could be found, all other lesions were characterized by the presence of a moderate cell hyperplasia in areas with haemorrhages associated with the presence of siderophages. All lesions showed matrix remodelling, as demonstrated by their reduced reticular fibre network. The spatial distribution of endocrine cells was also impacted compared to control animals. Additionally, we developed a novel preclinical model based on the orthotopic injection of tumour cells in the anterior pituitary. Using this setup, we evaluated the growth of injected tumour-cells through MRI to define early and late stages of tumour progression. This preclinical model was validated with gonadotroph (αT3, LβT2), corticotroph (AtT-20) and lacto-somatotroph (GH3) rodent cells. Then, we addressed the state of the anterior pituitary environment and evaluate the presence of endothelial and myeloid cells, as well as the network of reticulin fibres in early and advanced grafted-tumours.
Conclusion
Taken together, our results support that the native environment of the anterior pituitary is subjected to a remodelling during the onset of spontaneous PiTs. Also, preliminary observations using our orthotopic approach confirmed the usefulness of this preclinical model for studying the cellular interactions between the PiT cells and their TME.

High prevalence of vertebral fractures associated with age, GH, and bone mineral density in patients with acromegaly

Chen Shuaiming[1], Li Jing[1], Wang Chun[1], Tan Huiwen[1], An Zhenmei[1], Yu Yerong[1] & Li Jianwei[1]
[1]West China Hospital, Sichuan University, Department of Endocrinology & Metabolism, Chengdu, China

Objective
Studies have demonstrated that patients with acromegaly have compromised bone health and an increased risk of vertebral fractures (VFs). However, the prevalence of VFs in Chinese patients with acromegaly has not been investigated by far. This study aimed to evaluate the prevalence and determinants of VFs in patients with acromegaly in a tertiary hospital in China.
Methods
We enrolled patients diagnosed with acromegaly consecutively at West China Hospital between January 2021 and December 2023, and excluded patients with plurihormonal PIT-1 positive pituitary adenoma. Supine and lateral thoracolumbar spine X-ray was performed to detect vertebral morphometry, and Genant's semi-quantitative criteria was applied to determine VFs.
Results
We enrolled 74 participants (48 females/26 males) in total, and found that 38 patients (51.4%) had VFs, with the majority of fractures being multiple (65.7%) and moderate/severe (63.2%). Patients with VFs were older (median age 55 vs 39 years old), and had higher parathyroid hormone (5.45 pmol/l vs 4.77 pmol/l) and apnea hypoventilation index (43.3 times/hr vs 13.9 times/hr) than the non-fractured patients. In addition, more fractured females developed menopause compared with non-fractured females (72.7% vs 26.9%, $P=0.002$). Patients with VFs had slightly decreased bone mineral density (BMD) in spine, femoral neck and total hip by dual-energy X-ray absorptiometry, and dramatic lower BMD in spine by quantitative computed tomography compared with those without VFs (121.4 g/cm3 vs 171.6 g/cm3, $P<0.005$). However, growth hormone (GH) level was higher in patients without VFs. The insulin-like growth factor-1, beta-C-terminal telopeptide and total type I collagen N-terminal propeptide were not comparable in the two groups. Nevertheless, binary logistic regression analysis showed that GH level (OR 1.018; 95% CI, 1.000-1.035; $P=0.050$) and age $\geq$ 50 years/menopause (OR 4.462; 95% CI, 1.489-13.368; $P=0.008$) were two independent predicting factors of VFs.
Conclusion
This study indicates a high prevalence of VFs among patients with acromegaly in China for the first time. Findings in our study also remind us of the need to evaluate bone health in patients with acromegaly, especially in those with higher GH level, older age, or female patients with menopause.

Cytological, immunological and radiological predictors of the efficacy of first-generation somatostatin receptor ligands (fg-SRLs) in patients with acromegaly

Evgeny Pronin[1], Mikhail Antsiferov[1,2], Alexey Petraikin[3], Vyacheslav Pronin[1,2], Tatiana Alekseeva[1], Anastasia Lapshina[4], Lilia Selivanova[4], Anna Khoruzhaya[3] & Safi Tamaeva[5]
[1]Endocrinological dispensary, Moscow Health Department; [2]Russian Medical Academy of Continuing Professional Education, Ministry of Health of Russian Federation; [3]Scientific and Practical Clinical Center for Diagnostics and Telemedicine Technologies, Moscow Health Department; [4]National Medical Research Center for Endocrinology, Ministry of Health of Russian Federation; [5]I. M. Sechenov First Moscow State Medical University (Sechenov University), Ministry of Health of Russian Federation

Taking into account heterogeneity of somatotrophic tumors (STs), intragroup differential diagnostics is of practical importance, since it allows to predict scenario of acromegaly clinical course, as well as the efficacy of secondary drug therapy (DT).
The aim of this study was to determine prognostic power of cytological, immunological&radiological predictors of sensitivity/resistance to fg-SRLs in patients with pure somatotropinomas.
Materials and Methods
A retrospective morphological&radiological analysis was carried out in 83 (30m) patients who achieved/did not achieve [IGF-1 index (IGF-1/ULN) >1] acromegaly control against background of long-term secondary DT by fg-SRLs. Immunohistochemical analysis (IHA) included determination of antibodies to GH, Ki-67, CAM5.2, SSTR2& 5. Proportion of cells with presence of fibrous bodies (FB) was ranked according to scores 1-3 (1 – absence, 2 – $<70\%$ of cells, 3 – $>70\%$ of cells). Additionally, MRI recordings were reanalyzed with quantification of relative tumor signal intensity (RTSI) by comparing the area of interest with gray matter of the brain on T2-weighed MRI (T2-WI). Data obtained were compared with final results of fg-SRLs treatment.
Results
IHA revealed immunophenotypes of densely&sparsely granulated somatotrophic tumor (DGST&SGST) were identified in 41&42 patients, respectively. Microscopy with H&E staining identified several cytological variants of pure somatotropinomas. Among DGSTs,19 (46%) patients had eosinophilic tumors (ETs),22 (54%) – mixed tumors of eosinophilic&chromophobic cells [intermediate type of tumors (ITTs)]. Among SGSTs,29 (66%) patients had chromophobic tumors (CTs),11 (27%) – ITTs and 2 (7%) – ETs. ETs were distinguished by larger number of secretory cells and SSTR2 expression, as well as by smaller initial tumor volume, low proliferative activity and minimal presence of FB in cells. CTs, on the contrary, were distinguished by their larger size, low SSTR2 expression, higher proliferative activity and pronounced presence of FB in cells. ITTs demonstrated intermediate characteristics of expression varying degrees depending on affiliation with DGSTs/SGSTs. When assessing RTSI, it was shown ETs demonstrated hypointense, ITTs – isointense and CTs – hyperintense signal on T2-WI. As for DT results, with similar initial values of IGF-1 index, maximum dose and treatment duration, patients with ETs, ITTs&CTs had drug remission, partial&complete resistance to fg-SRLs, respectively (Table).
Conclusion
Determination of RTSI on T2-WI adds to IHA data, allows to clarify clinicopathological characteristics of STs and identify patients who are known to be sensitive/resistant to fg-SRLs treatment.

Daytime sleepiness and health-related quality of life in patients with childhood-onset craniopharyngioma

Laura Verena Mann-Markutzyk[1], Julia Beckhaus[1,2], Jale Oezyurt[3], Carsten Friedrich[1] & Hermann Müller[1]
[1]University Children's Hospital, Carl von Ossietzky Universität Oldenburg, Department of Pediatrics and Pediatric Hematology / Oncology, Klinikum Oldenburg AöR, Oldenburg, Germany; [2]Carl von Ossietzky Universität Oldenburg School VI - School of Medicine and Health Sciences, Division of Epidemiology and Biometry, Oldenburg, Germany; [3]Carl von Ossietzky Universität Oldenburg School IV - School of Medicine and Health Sciences, Biological Psychology Lab, Department of Psychology, Oldenburg, Germany

Background
Adamantinomatous craniopharyngioma (CP) is a rare embryonal malformation originating from remnants of the craniopharyngeal duct and located in the sellar and/or parasellar area. Overall survival rates are high (92%), but frequently quality of life (QoL) is severely impaired in patients with CP involving hypothalamic structures. Tumor- and/or treatment-related hypothalamic lesions result in disturbances of circadian rhythms including increased daytime sleepiness.
Patients and Methods
After a median follow-up interval of 10 years (range: 1-39 years), 119 patients (63 female / 56 male) with CP, recruited in KRANIOPHARyNGEOM 2000/2007 and KRANIOPHARyNGEOM Registry 2019 between 2000 and 2022, were analysed for daytime sleepiness by Epworth scale (ES) and for QoL by EORTC QLQ-C30 questionnaire.
Results
CP patients ($n=85$) with pathologically increased ES score (ES score >12) had worse QoL ($P=0.003$), when compared with CP patients with normal ES score ($n=34$). Pathologically increased daytime sleepiness (ES score) was negatively

Abstract P328

	Tumor volume (cm^3)	Antibodies to GH (%)	Ki-67 (%)	% cells with FB (scores)	SSTR2 (IRS scores)	RTSI on T2-WI (%)	IGF-1 index baseline	IGF-1 index final
ET	2.6±5.9	86.7±12.7	3.9±2.2	1.2±0.4	10.8±2.3	-27.0±15.5	3.1±1.0	0.95±0.34
ITT	3.8±5.7	73.1±29.1	4.5±3.4	1.9±0.8	8.7±3.5	-4.0±20.8	2.7±0.9	1.14±0.56
CT	10.1±11.6	36.7±16.5	8.9±5.4	2.9±0.4	5.7±3.6	20.6±22.9	2.7±0.9	1.65±0.8
p	$p^{1-2}=0.48$ **$p^{1-3,2-3}<0.05$**	**<0.05**	$p^{1-2}=0.495$ **$p^{1-3,2-3}<0.05$**	**<0.05**	**<0.05**	**<0.05**	N/A	$p^{1-2}=0.3458$ **$p^{1-3,2-3}<0.05$**

correlated with QoL ($r = -0.395$; $P < 0.001$). Surgical hypothalamic lesions (71% of patients) were associated with higher ES scores, wheras such impact could not be observed for presurgical hypothalamic involment of CP (73% of patients).
Conclusion
As increased daytime sleepiness plays an important role for QoL in survivors of CP, treatment of disturbances of circadian rhythms with medication such as central stimulating agents is recommended. For prevention of increased daytime sleepiness, hypothalamus-sparing surgical treatment startegies should be considered as state of the art in patients with CP.

A case of type 2 diabetes masked by insulinoma

Adrian Li[1] & Samira Khalilova[2,3]
[1]Princess Royal University Hospital, United Kingdom; [2]Princess Royal University Hospital, Diabetes and Endocrinology, Orpington, United Kingdom; [3]

Introduction
Insulinomas are the most common functioning endocrine neoplasms of the pancreas. 53% of patients are diagnosed within five years of experiencing their first symptoms. Surgical resection is the primary treatment modality. However, patients awaiting surgery or who are not surgical candidates have achieved symptomatic relief from medical therapy. Cases of insulinoma masking diabetes has been described but are rare and diabetes often presents following surgery. Here, we describe a case of insulinoma diagnosed four years after symptom onset with unmasking of type 2 diabetes mellitus following initiation of medical treatment.
Clinical case
An 89-year-old woman presented with severe hypoglycaemia, having been found by relatives in bed with neuroglycopenic symptoms. Capillary blood glucose was 1.4 mmol/l. She was given intramuscular Glucagon by paramedics. Upon further questioning, the patient reported having one to two similar episodes of hypoglycaemia per month over the past four years, which she was self-correcting at home or by help of the ambulance service. Pituitary, liver and renal profiles were within normal limits. During the admission, the patient underwent a prolonged fasting test. Although nadir blood glucose achieved was 2.5mmol/l due to significant symptom, hypoglycaemia screen revealed high level of C-peptide 2885 pmol/l (370-1470) though normal insulin(64 pmol/l) and beta-hydroxybutyrate levels (0.1 mmol/l) at hypoglycaemia episode. CT pancreas revealed a 14.5 mm enhancing nodule on the body of the pancreas consistent with a neuroendocrine tumour, which was confirmed by MRI imaging. After discussion at the MDT, the patient was started on diazoxide 50 mg TDS. A dotatate-PET scan was arranged and she was listed for surgery. Blood glucose was in range after starting diazoxide. However, the patient was readmitted after one month with hyperglycaemia (37.1 mmol/l), fever, cough and bilateral pitting oedema. Diazoxide was held and she was commenced on oral antihyperglycaemic agents, and then eventually switched to insulin management. Unfortunately, the patient deteriorated during the admission and passed away.
Discussion
Our case highlights the challenges with the diagnosis of insulinoma and how insulinoma can mask undiagnosed type 2 diabetes. This also highlights the importance of continuing glucose monitoring after starting medical management for insulinoma, even if stable glycaemia is initially achieved.

Pituitary involvement in familial hemophagocytic lymphohistiocytosis type 5 associated with homozygous mutation in the syntaxin-binding protein-2 gene (STXBP2)

Thin San[1], Diane Bray[1] & Jana Bujanova[1]
[1]University Hospital Southampton NHS Foundation Trust, Department of Diabetes and Endocrinology, Southampton, United Kingdom

35y male presented with extreme fatigue and symptomatic hypogonadism. He had history of multiple infections since childhood due to combined immunodeficiency syndrome and hypogammaglobulinemia, autoimmune haemolytic anaemia, sensorineural deafness, cytopenias, acute hepatitis with hepatosplenomegaly. Liver biopsy (age 15y) showed chronic hepatitis with necrosis. In 2020 (age 32y) he underwent bone marrow biopsy for progressive pancytopenia demonstrating hypercellularity, but no evidence of hemophagocytosis or malignancy. Historical notes revealed history of short stature and delayed puberty presumed to chronic illness (normal pituitary MRI, LH <0.07 iu/l, FSH 0.9 iu/l, testosterone 0.3 nmol/l (10-27.6) and IGF-1 44 mg/l (75-580) at 14y). Brief testosterone replacement at 18y was followed by spontaneous recovery of gonadal axis and pubertal progression to TV 15ml, G5, PH4. Participation in 100,000 Genomes Project at age 32y designed to identify rare genetic disorders through whole genome sequencing revealed homozygosity for STXBP2 c. 1247-1G $>$C pathogenic variant consistent with Familial Hemophagocytic Lymphohistiocytosis type 5 (FHL5), tying up previous issues. On examination he had small stature, hypogonadal appearance, testicular volume 15 mls, height 157 cm, weight 48 kg.
Results
LH 0.5 iu/l, FSH 0.3 iu/l, testosterone <0.4 nmol/l, prolactin 802 mu/l (55.4-276), IGF-1 2.4 nmol/l (9.3-30.7), cortisol-436 nmol/l, fT4 9.2 pmol/l (7.7-15.1), Hb 76 g/l (130-170), platelets 46×10^9/l (150-400), WBC 1.3×10^9(4-11). Patient had no symptoms of arginine vasopressin deficiency (AVP-D). Pituitary MRI showed thickening and enhancement of infundibulum extending to hypothalamus and floor of third ventricle. Anterior gland looked normal and posterior bright spot was absent. Testosterone replacement was commenced with excellent symptomatic response. Macimorelin test to confirm growth hormone (GH) deficiency followed by GH replacement was planned but is delayed due to recent admission with decompensated liver disease.
Discussion
FHL 5 is a rare genetic hyperinflammatory syndrome caused by an uncontrolled immune response mediated by T-lymphocyte, natural killer cells and activated macrophages and infiltration of several organs by activated lymphocytes and macrophages. Pituitary involvement is well reported in other types of histiocytic disorders such as Langerhans cell histiocytosis, but rarely in familial or acquired HLH. The lack of AVP-D symptoms here is unusual. Partial hypopituitarism in this case could have contributed at least partially to significant pancytopenia and it will be interesting to observe, if his cell count improves with hormone replacement. Results three months after staring testosterone showed rise in Hb (76 to 93 g/l), but no change in platelet and white cell count to date.

Sarcoma of the sphenoid sinus occurring 34 years after fractionated sellar 60Cobalt radiotherapy for acromegaly

Ana Maria Prunariu[1], Mihaela Popescu[2], Sergiu Stoica[3], Mariana Costache Outas[3], Anda Dumitrascu[1] & Monica Livia Gheorghiu[4]
[1]CI Parhon National Institute of Endocrinology, Bucharest, Romania; [2]University of Medicine and Pharmacy of Craiova & Clinical Emergency County Hospital, Craiova, Romania; [3]Brain Institute, Monza Hospital, Bucharest, Romania; [4]C Davila University of Medicine and Pharmacy & CI Parhon National Institute of Endocrinology, Bucharest, Romania

Introduction
Treatment options for acromegaly include surgery or radiation to remove or reduce the size of the tumor and medication to help normalize the hormone levels. While improving the prognosis, patients with acromegaly treated with radiotherapy are at risk of long-term development of secondary malignancies (1-2% at 10-20 years). We report the case of a 55-year old woman diagnosed with high-grade sarcoma of the sphenoid sinus developed 34 years after receiving 60Cobalt external beam radiation therapy for acromegaly.
Case report
The patient was diagnosed with acromegaly from a pituitary macroadenoma at 18 years (1986) and underwent 60Cobalt high voltage fractionated sellar irradiation in 1989 (total dose 6000 r), after which she was treated with Bromocriptine from 1989 to 2014 or a combination of Bromocriptine and Sandostatin LAR from 1998 to 2008. Apart from the modest and stable clinical picture of acromegaly she was asymptomatic, with a slowly decreasing pituitary mass (1.7 to 1.2 cm), but persistently elevated IGF1 levels (1.5 – 1.7 $\times$ ULN). In October 2023 she presented for a recent evidence of asymptomatic tumor increase, without hypopituitarism: a sellar mass of 3/3/1.9 cm, with large infrasellar extension, predominantly on the left side, involving the cavernous segments of the internal carotid arteries and apparently with a large extension into the sphenoidal sinus (Knosp 3b). IGF1 was $1.7\times$ULN. She began treatment with Lanreotide Autogel 120 mg monthly and underwent transsphenoidal surgery. Postsurgery she had a small residual tumor in the left cavernous sinus and stable GH hypersecretion ($1.7\times$ULN) with central hypocortisolism. Histopathology revealed a high-grade

(grade 3) sarcoma of the sphenoid sinus (leiomiosarcoma type). She was referred to an oncologist for radiation therapy but the treatment was postponed. A repeat MRI 2 months after surgery revealed a large invasive and erosive sellar and perisellar inhomogeneous mass (4.4/4.7/4.2 cm). The patient started stereotactic fractionated radiation therapy and was planned for chemotherapy.
Conclusion
Our case fulfills the diagnostic criteria of radiation-induced tumors: it occurred within the irradiated field, a sufficient latency period elapsed between irradiation and secondary tumor occurrence (>30 years) and the secondary tumor was proven to be of a different histological type from the original one. Clinicians should be vigilant about the possibility of post-radiation cranial sarcoma development (notably after conventional radiotherapy), suggested in this case by a tumor re-growth long-term after radiotherapy for acromegaly, not associated with a correspondent increase in hormonal activity.

Additive effect of combined treatment with the small peptide GH receptor antagonist, AZP-3813, and the somatostatin analog, octreotide, in decreasing IGF1 levels in the rat

Guillaume Ravel[1], Corentin Berardet[1], Clémentine Chalmey[1], Haruaki Kurasaki[2], Tatsuya Tomiyama[2], Patrick Reid[2], David Duracher[1], Rakesh Datta[3], Myriam Aouadi[1] & Michael Culler[3]
[1]Amolyt Pharma, Écully, France; [2]PeptiDream Inc, Kawasaki City, Kanagawa, Japan; [3]Amolyt Pharma, Cambridge, Massachusetts, United States

While somatostatin analogs (SSA) are the primary medical therapy for treatment of acromegaly, they fail to normalize insulin-like growth factor 1 (IGF1) levels in the majority of patients when used as monotherapy. Even in patients with controlled IGF1, growth hormone (GH) levels can remain elevated and induce symptoms by interacting with GH receptors throughout the body. AZP-3813 is a 16-amino acid, bicyclic peptide GH receptor antagonist (GHRA) which has been demonstrated to potently decrease IGF1 in both rats and dogs. To examine the effect of adding AZP-3813 to SSA treatment to decrease IGF1, 8-week old, male, Sprague Dawley rats were implanted subcutaneously with Alzet model 2002 minipumps containing either vehicle or the SSA, octreotide (OCT), at a dose of 20µg OCT/kg/day. Blood samples for IGF1 measurement were collected before, and 48 and 72 hours after pump implantation. Immediately following the 72-hour blood collection, rats from both infusion groups were injected subcutaneously with either vehicle or AZP-3813 at 0.3, 1, 3, 10 or 30 mg/kg ($n=7$/group). A subsequent blood sample was collected 24 hours after the injection of vehicle or AZP-3813, which also corresponded to 96 hours after pump implantation. Plasma levels of IGF1 were assessed by radioimmunoassay. Seventy-two hours after initiating OCT infusion, IGF1 was decreased by -10 ± 3.6%, as compared to baseline, while vehicle-infused rats showed a 2 ± 2.8% increase. Injection of AZP-3813 into the vehicle-infused rats produced a dose-related decrease in IGF1 that was significantly different from baseline with doses from 3 to 30 mg/kg, decreasing IGF1 by -13 ± 2.8 to -29 ± 2.0%, respectively. When AZP-3813 was injected into OCT-infused rats, a clear, additive effect was observed with the same 3 to 30 mg/kg doses of AZP-3813 now producing a dose-related decrease in IGF1 ranging from -23 ± 3.3 to -38 ± 3.4%. The magnitude of the decrease in IGF1 obtained with the 3 mg/kg dose of AZP-3813 combined with OCT infusion was not statistically different from the decrease in IGF1 obtained with the 30 mg/kg dose of AZP-3813 alone in vehicle-infused rats; thus, demonstrating a 10-fold increase in the effectiveness of AZP-3813 when combined with OCT. These results demonstrate the enhanced efficacy of AZP-3813 in decreasing IGF1 when combined with the SSA, OCT, and support the development of AZP-3813 as an add-on treatment for patients inadequately controlled with SSA monotherapy.

[1]University Hospital Ramón y Cajal, Department of Endocrinology and Nutrition, Madrid, Spain; [2]University Hospital La Paz, Department of Neurosurgery, Madrid, Spain; [3]University Hospital 12 de Octubre, Department of Neurosurgery, Madrid, Spain; [4]University Hospital Ramón y Cajal, Department of Neurosurgery, Madrid, Spain; [5]University Hospital La Paz, Department of Endocrinology, Madrid, Spain; [6]University Hospital 12 de Octubre, Department of Endocrinology, Madrid, Spain; [7]University Hospital Puerta del Sur, Department of Neurosurgery, Madrid, Spain; [8]Institute for Biomedical Research Ramón y Cajal, Department of Endocrinology and Nutrition, Madrid, Spain

Aim
Evaluate the predictive value of the Pituitary Apoplexy Score (PAS) for predicting hormonal and visual recovery after surgery or conservative management of patients with pituitary apoplexy (PA).
Methods
Multicenter retrospective study of patients presenting with clinical PA in three Spanish tertiary hospitals between 2008 and 2022. The PAS was calculated following the UK Pituitary Apoplexy Guidelines Development Group evaluation grid.
Results
A total of 71 patients with PA were included, with a median age of 60 years and 67.6% were male. Most patients had macroadenomas, with the exception of one with microadenoma. A total of 33 cases had a PAS ≥3 and 25 ≥4. Only 16 patients had a Glasgow Coma Scale lower than 15 at diagnosis. There were 20 patients with visual loss, 17 with diplopia and 13 with visual loss and diplopia. Of the whole cohort, 61 patients underwent pituitary surgery and 10 were conservatively managed. After surgery or conservative treatment, 38.5% of the 52 patients with hormonal deficits at diagnosis recovered the pituitary function and 61.2% of the 49 patients with visual involvement at diagnosis had a normal visual function. Based on ROC curve, the optimal threshold in the PAS to identify those patients with a lower probability of visual recovery was 3, and for hormonal recovery was 4. Patients with PAS ≥3 had larger tumors (30.3 ± 9.49 vs 23.7 ± 12.80 mm, $P=0.019$) and panhypopituitarism was four times more common (OR 4.0, 95% CI 1.32 to 12.15) than in patients with PAS <3. The proportion of patients who underwent conservative management did not differ between patients with PAS ≥3 and PAS <3. Patients with a score ≥3 had a probability of non-visual recovery 3.8 times higher than those with a score <3 (OR 3.8, 95% CI 1.01 to 13.96). These differences lost significance after adjusting by tumor size (adjusted OR 3.68, 95% CI 0.96 to 14.07). No differences in the rate of hormonal recovery (OR 0.61, 95% CI 0.19 to 1.93) nor in the rate of visual normalization (OR 0.69, 95% CI 0.22 to 2.19) were observed between patients with a PAS ≥4 and PAS <4.
Conclusion
PAS score equal or greater than 3 seems more accurate than the classical threshold of 4 to identify those patients with PA with a lower chance of visual recovery after surgical/conservative management. This association is related to a larger tumor size in patients with PAS score exceeding 2.

Cardiovascular disease and gender differences in non-functioning pituitary tumors: preliminary data of a prospective study

Elisa Sala[1], Veronica Lotito[1,2], Giulia Carosi[1], Giulia Del Sindaco[1,2], Roberta Mungari[1], Arianna Cremaschi[1], Angela Pagnano[1,2], Alessandra Mangone[1,2], Emanuele Ferrante[1] & Giovanna Mantovani[1,2]
[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy

Background
In the last few decades, the association between pituitary disorders and cardiovascular disease has been demonstrated. Furthermore, the importance of gender as a non-modifiable risk of factor is increasingly emerging.
Methods
We retrospectively analyzed data of 112 patients diagnosed with nonfunctioning pituitary tumor (NFPT) attending the outpatient clinic at our tertiary center. In this study we report only preliminary data of the retrospective analysis, while a subsequent prospective analysis is ongoing.
Results
In our cohort of patients (51M/61F; mean age 58 ± 16 years), males showed a more aggressive presentation with a significantly higher number of macroadenomas and of tumors needing surgery than females ($P=0.04$ and $P=0.03$, respectively). Concerning the presence of pituitary deficits as well, they were significantly more frequent in males compared to females (central hypothyroidism: 45% vs 16%, $P=0.03$; hypogonadism with exclusion of menopausal state:

47% vs 16%, $P<0.01$), hypoadrenalism: 37% vs 19%, $P=0.05$; GH deficiency: 35% 11%, $P<0.01$). In the whole group, 46 patients (41%) had hypertension, 11 (9.8%) cardiovascular ischemic disease while cerebrovascular disease appeared only in 3 (2.6%) patients. Diabetes mellitus was diagnosed in 10 patients (9%), 42 patients (37.5%) presented dyslipidemia, 12 patients (11%) obesity. Comparing male and females, we found a significantly higher presence of cardiovascular morbidities in the male group compared to the female one (hypertension, cardiovascular events and cerebrovascular events, for all $P<0.05$), while concerning metabolic comorbidities no differences were found. Comparing our data to the general Italian population in the same age range we did not find any difference in the female group, while in the NFPT male group a significantly higher percentage of cardiovascular events and hypertension compared to the general population was found ($P=0.04$ and $P=0.01$ respectively; data reported by the Italian National Institute of Statistic - ISTAT).

Conclusion

Our data confirmed that the presence of NFPT is related to cardiovascular complications. In particular, our data showed that NFPT in males have a more aggressive presentation compared to females both in endocrinological and cardiovascular comorbidities. We interestingly reported that males with NFPT present a greater risk of hypertension and cardiovascular disease than the general population of the same age, suggesting the need for a targeted approach with greater surveillance in this specific group of patients.

Evaluation of new prognostic clinicopathological classification of pituitary adenomas proposed by trouillas *et al*. in patients with giant pituitary adenomas

Barbara Buchalska[1], Wiesław Bonicki[1], Maria Maksymowicz[2] & Jacek Kunicki[1]

[1]The Maria Sklodowska-Curie National Research Institute of Oncology, Department of Neurosurgery, Warsaw, Poland; [2]The Maria Sklodowska-Curie National Research Institute of Oncology, Department of Pathology, Warsaw, Poland

Introduction

In 2013 Trouillas *et al*. reported a new prognostic clinicopathological classification of pituitary adenomas. This classification analyses the impact of the intensity of proliferation and invasiveness of the tumor on patients' prognosis. The aim of the study was to review this new classification in giant pituitary adenomas (GPAs) treated with endoscopic transsphenoidal approach.

Material and methods

The study is a retrospective analysis of a series of 176 patients (66 women and 110 men) treated from the 2007 to 2023 by the endoscopic transsphenoidal surgeries for GPAs (>40mm). The mean age of the patients was 57.0 years (20-81 years), and the mean follow up period was 7.5 years (0-16 years). The patients were divided into the control group without the evidence of disease (EoD) and the study group with EoD.

Results

In the group with EoD the most commonly observed were grade 2a tumors (71.7%), followed by grade 1a (13.3%), 2b (12.4%), and 1b (2.7%). In the control group (with favorable outcomes – no EoD) grades 2a and 1a were reported in similar numbers of patients (46.0% and 41.3% respectively), followed by grade 2b and 1b (both observed in 6.3% of patients). Overall, more invasive or proliferative tumors classified either as grade 2a or 2b were observed in the group with EoD (OR=2.97 and OR=2.09 respectively, $P<0.001$).

Conclusion

Our results indicate that the new classification proposed by Trouillas *et al*. is a reliable tool in predicting prognosis of patients with GPAs.

Clinical and radiological predictive factors of dopamin agonist resistance in prolactinoma

Sandra Pekic Djurdjevic[1,2], Marko Stojanovic[1,2], Mirjana Doknic[1,2], Dragana Miljic[1,2], Toplica Milojevic[3], Mihailo Milicevic[1,3], Aleksandar Stanimirovic[1,3], Vuk Scepanovic[1,3], Emilija Manojlovic Gacic[1,4], Ivana Cekic[2], Ivan Jevtic[2], Zvezdana Jemuovic[2], Marina Nikolic Djurovic[1,2], Danica Grujicic[1,3], Vera Popovic[1] & Milan Petakov[1,2]

[1]Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Center of Serbia, Department of Neuroendocrinology, Belgrade, Serbia; [3]Clinic for Neurosurgery, University Clinical Center of Serbia, Belgrade, Serbia; [4]Institute of Pathology, Belgrade, Serbia

Background

A subset of patients with prolactinomas does not respond satisfactorily to first-line medical therapy with dopamine agonists (DA). DA resistance is defined as failure to normalize prolactin (PRL) levels and/or to achieve ≥50% reduction in maximal tumor diameter under maximally tolerated doses (or a weekly cabergoline dose of ≥3mg). The predictive factors for DA resistance are male gender and tumor invasiveness.

Aim

To characterize patients with DA resistant prolactinoma patients.

Methods

We retrospectively analysed clinical, hormonal and radiological features, management and outcome of DA therapy of 527 patients with prolactinoma who were treated at the Department of Neuroendocrinology of a tertiary hospital between 2005 and 2023.

Results

Thirteen prolactinoma patients with cabergoline resistance were identifed (2.5%). The mean age at diagnosis was 36.5±3.3years (range: 17-64) and seven patients (53.8%) were male. PRL level at baseline was 70.110±41.425mIU/l (range: 1796-505.978). The average tumor size was 27.3±7.0mm (range: 9-58), ten (76.9%) were macroadenomas. Of ten macroadenomas, all were invasive and three were giant tumors (>40mm). Males had larger tumors than females (40.0± 6.8mm vs 10.3±0.9mm; $P<0.001$) and higher PRL levels at baseline (137.562±75.700 vs 2657±380mIU/l; $P<0.01$) Prolactinomas were graded as KNOSP-3 in 2 (15.4%), and KNOSP-4 in 3 (23.1%) patients, more frequent in males ($P<0.01$). The mean maximal cabergoline dose was 4.1±0.4 mg/week (range: 3-7), higher in males (5.0±0.6 mg/week vs 3.0±0.8 mg/week; $P<0.01$). The median follow-up was 86.8±17.0months (range: 18-233). Nine patients were treated only with cabergoline in escalating doses, two underwent transsphenoidal surgery combined with cabergoline, one underwent surgery and radiotherapy combined with cabergoline and one patient was treated with all these modalities plus temozolomide. PRL level after therapy (only cabergoline, or multimodal therapy) was 9383±7099mIU/l (range: 400-94.000). Two patients developed apoplexy during cabergoline therapy and two patients had nasoliquorrhea. One patient treated with multimodal therapy and temozolomide died after eighth operation. At the last visit five patients had controlled PRL levels and most of them had a stable tumor size.

Conclusion

The prevalence of cabergoline resistance in our series was around 2.5%. Our data support a male gender, large tumor size and tumor invasiveness as the risk factors for DA resistance. We were able to control 5/12 (41.6%, 1 patient died) of resistant prolactinomas. Resistant prolactinomas usually require a multi-modal treatment strategy.

Efficacy of pasireotide treatment in acromegaly: a systematic review and meta-analysis

Turkan Aliyeva[1], Juliana Muniz[2], Gustavo Meira[3], Sarah Firdausa[4] & Lubna Mirza[5]

[1]Özel Koru Hastanesi, Internal Medicine, Ankara, Turkey; [2]Kliniken Schmieder Heidelberg, Heidelberg, Germany; [3]Universidade Católica de Brasília - Câmpus Taguatinga, Brazil; [4]Syiah Kuala, Indonesia; [5]Norman Regional Hospital, Norman, United States

Background

Acromegaly is an uncommon chronic endocrine disorder which is associated with considerable comorbidities. Many patients fail to achieve biochemical control with current medical therapies, including surgery and first-generation somatostatin analogs. We aimed to perform a systematic review and single-arm meta-analysis to evaluate the efficacy of the multi-receptor ligand somatostatin analog Pasireotide in patients with acromegaly.

Methods

We systematically searched PubMed, EMBASE, and Cochrane databases for studies that assessed the efficacy of Pasireotide in patients with acromegaly and reported the outcomes of (1) biochemical control and its composite indicators; (2) normalized IGF-1 level and (3) GH< 2.5 mg/l. Random effect models were used for all Statistical analysis, which were conducted using R software. Heterogeneity was assessed with I2 statistics.

Results

We included twelve studies with a total of 664 patients: eight clinical trials and four observational cohorts. The overall population consisted of 67% of

inadequately controlled acromegaly patients. In a pooled analysis, the biochemical control rate was 30% (95% CI: 16; 49). The frequency of normalization of IGF-1 and reduction of GH level were 45% (95% CI: 33; 57) and 34% (95% CI: 24; 45) respectively. A long-term effect (>12 months) of Pasireotide on biochemical control was observed, with a rate of 45% (95% CI: 26; 65). The most commonly reported adverse events were hyperglycemia in 42% (95% CI: 25; 59) and gastrointestinal disturbances in 41% (95% CI: 16; 71) of patients. Moreover, Pasireotide treatment was associated with a 31% (95% CI: 22; 41) incidence of new-onset diabetes mellitus.

Conclusion

Our findings suggest that Pasireotide has superior efficacy in patients with acromegaly. Although a high rate of hyperglycemic adverse events and diabetes mellitus related to treatment were observed, most of them were manageable.

T2-weighted MRI signal intensity of a somatotroph PitNETs-assessed with quantitative and qualitative methods- how our predictions are verified in the histopathological examination?

Magdalena Godlewska[1], Anna Grochowska[2], Anna Bogusławska[1], Grzegorz Zielinski[3], Dariusz Adamek[4], Maria Maksymowicz[5], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]
[1]Jagiellonian University Medical College, Department of Endocrinology, Cracow, Poland; [2]Jagiellonian Uniersity Medical College, Department of Radiology, Cracow, Poland; [3]Military Institute of Medicine, Department of Neurosurgery, Warsaw, Poland; [4]Jagiellonian University Medical College, Department of Pathomorphology, Cracow, Poland; [5]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Cancer Pathomorphology, Warsaw, Poland

Aim

To investigate T2-signal intensity (SI) and histopathological characteristics of the somatotroph PitNETs (S-PitNET).

Methods

41 out of 109 consecutive patients with newly diagnosed acromegaly and available histopathological results were included. 36 results contained the electron microscope examination. Tumors were divided into 3 SI groups: hyperintensive (HyPER), isointensive (ISO) and hypointensive (HyPO). SI was assessed qualitatively using Visual Method (visual comparison between S-PitNET and white and grey matter of the temporal lobe (WM and GM, respectively) and quantitatively by measurement of SI within the Region of Interest in the solid part of S-PitNET and in the WM and GM. Relative Signal Intensity (rSI, calculated ratio of S-PitNET's SI and the SI of GM) ≤ 0.8 classified S-PitNET as HyPO, >0.8 but <1.2 as ISO, ≥ 1.2 as HyPER. Three Tissue Method classified tumors with SI equal or lower to WM as HyPO, with SI equal or higher than GM as HyPER, while the remaining tumors were classified as ISO.

Results

31.7% of tumors expressed only GH, 17.1% co-expressed GH and PRL, other S-PitNETs expressed GH and at least one hormone other than PRL (the most frequent combination: GH, PRL, alpha subunit). We found no differences between HyPER, ISO and HyPO in hormone expression. In electron microscope 58.3% of tumors were classified as densely granulated, 27.8% as sparsely granulated and 13.9% as bihormonal. According to Visual Method and rSI HyPER and ISO had both dense and sparse granulation. Bihormonal tumors presented as HyPO (60-80%) and ISO (20- 40%). According to Three Tissue Method, no HyPO specimens had sparse granulation. Ki-67 $<1\%$ was the most frequent diagnosis among all tumors. None of the HyPO had Ki-67 $\geq 3\%$. Detailed results are depicted in Table 1.

Table 1. Results of electron microscope verification

Tumor type	Densely granulated	Sparsely granulated	Bihormonal	
		Visual Method		
HyPER	72.7%	27.3%	0%	$P=0.159$
ISO	50%	41.7%	8.3%	
HyPO	53.8%	15.4%	30.8%	
		rSI		
HyPER	71.4%	28.6%	0%	$P=0.514$
ISO	52.9%	35.3%	11.8%	
HyPO ($n=12$)	58.3%	16.7%	25%	
		Three Tissue Method		
HyPER	64.7%	29.4%	5.9%	$P=0.056$
ISO	53.8%	38.5%	7.7%	
HyPO	50%	0%	50%	

Conclusion

Tumors manifesting as HyPER or ISO are verified in histopathological examination as both densely and sparsely granulated, regardless of SI assessment method. No HyPO tumor had sparse granulation. Interestingly, no bihormonal tumor presented as HyPER.

Introduction

Diabetes mellitus (DM) and hypertension are common comorbidities that pose significant clinical burden in Cushing's syndrome patients and may be improved by normalising cortisol. In two Phase III trials (LINC3 [NCT02180217]; LINC4 [NCT02697734]), osilodrostat, a potent oral 11β-hydroxylase inhibitor, provided reductions in cortisol and improved clinical manifestations of hypercortisolism in most Cushing's disease (CD) patients. Here, we describe changes in glycaemic parameters and blood pressure (BP) in a pooled patient population, according to baseline hypertensive and diabetic status.

Methods

LINC3 comprised a 48-week (W) core phase, including an 8W randomised-withdrawal phase for eligible patients. LINC4 included an initial 12W, double-blind, randomised, placebo-controlled period, then 36W of open-label osilodrostat. Both studies included an optional extension. Baseline DM was defined as prior diagnosis, taking antidiabetic medication, HbA_{1c} $\geq 6.5\%$, and/or fasting plasma glucose (FPG) ≥ 126 mg/dl. Baseline hypertension was defined as prior diagnosis, taking antihypertensive medication, and/or systolic/diastolic BP (SBP/DBP) $>130/>90$mmHg. Data were pooled in a secondary exploratory analysis for all patients with data at baseline and W72; periods whereby patients received placebo are excluded. No formal statistical testing was performed; all analyses are descriptive.

Results

Of patients with baseline DM ($n=84/210$; 40.0%), mean (SD) FPG and HbA_{1c}, respectively, decreased from 90.9 (17.3) mg/dl and 5.8 (0.8)% at baseline to 87.1 (9.9) mg/dl and 5.4 (0.6)% at W72 for those not receiving antidiabetic treatment during the study, and decreased from 118.1 (33.5) mg/dl and 6.9 (1.0)% at baseline to 102.7 (27.6) mg/dl and 6.1 (0.8)% at W72 in those receiving antidiabetic medication. Higher baseline FPG and HbA_{1c} was associated with greater improvements at W72, demonstrated by a negative correlation between change in FPG and HbA_{1c} from baseline to W72 and baseline FPG and HbA_{1c} ($r=-0.60$ and -0.68, respectively; $P<0.0001$). Most patients ($n=174/210$; 82.9%) had baseline hypertension. ~50% of patients with baseline SBP >130mmHg had SBP ≤ 130mmHg at W72, and ~60% with baseline DBP >90mmHg had DBP ≤ 90mmHg at W72. Higher baseline SBP/DBP was associated with greater improvements at W72, demonstrated by a negative correlation between change in SBP/DBP from baseline to W72 and baseline SBP/DBP ($r=-0.69/-0.64$; $P<0.0001$).

Conclusion

DM severity and prevalence of hypertension reduced over long-term osilodrostat treatment. Patients with higher baseline FPG, HbA_{1c}, SBP and DBP experienced the greatest reductions in these parameters at W72. These findings highlight the importance of treating hypercortisolism to improve comorbidities in CD patients.

A case of meningitis mimicking pituitary macroadenoma

Natalia Ostrowska-Mrozowska[1], Sonia Kaniuka-Jakubowska[1], Olivia Cyran-Stańczak[1] & Renata Świątkowska-Stodulska[1]
[1]Department of Endocrinology and Internal Medicine, Faculty of Medicine, Medical University of Gdansk, Poland,

The spectrum of lesions in the sellar and parasellar region includes a wide range of diseases, from the most common adenoma to various non-adenomatous lesions i.a. empty sella syndrome, stroke and congenital conditions. We identified a case of meningitis in which the images initially suggested the presence of a pituitary macroadenoma. The 45-year-old patient without chronic diseases was admitted to the Department of Neurology due to severe headaches and vomiting that had woken him up the night before. Neurological examination showed no signs of focal CNS damage, meningeal symptoms were negative. A non-contrast CT brain revealed in the sellar region a heterogeneous, hypodense lesion 18x18mm. The diagnostics were extended to head MR which showed a mass in the sella 22x19x19mm, with a heterogeneous high signal, intensity, focally in the central and slightly peripheral part, enhanced after contrast administration. A suspicion of pituitary macroadenoma or Rathke's pouch was made. Additionally, the image of dura mater suggested meningitis and inflammatory changes in the nasal sinuses. CSF analysis revealed lymphocytic or viral meningitis. The patient reported the deterioration of vision in the right eye and the temporal disturbances in visual field examination in this eye were confirmed. Blood tests revealed increased inflammatory markers, intravenous antibiotics were initiated, leading to a favourable clinical outcome. Initial analysis of pituitary function revealed normal low morning cortisol concentration (166nmol/l) with a normal ACTH concentration (25.7 pg/ml) preserved other pituitary axes, however, the supplementation of the hydrocortisone has been implemented. The patient was referred to our department. Pituitary MR was performed which confirmed previous intrasellar and parasellar meningitis, complicated by bleeding into the encapsulated space in the sella and post-hemorrhagic areas in the suprasellar and intrasellar region; intrasellar lesions had decreased from 21mm to 5mm. The sellar diaphragm remained in post-inflammatory conglomerates with the optic chiasm, which remained deformed and pulled strongly downwards. The optic chiasm showed a heterogeneous increase in T2 weighted signal. In this situation, there were no indications for neurosurgery. In subsequent follow-up imaging examinations, further regression of the sellar region lesions occurred, with no progression in the involvement of the optic nerves. This case illustrates an atypical type of meningitis mimicking a pituitary macroadenoma. This proves that due to the complex nature of pituitary diseases, most patients require coordinated care. It shows the need for an integrated, multidisciplinary approach to the diagnosis, assessment and treatment of patients with pituitary disorders.

Is histological subtyping important in the prognostication of acromegaly?

Prishila Fookeerah[1,2], Winny Varikatt[3,4], Mark Dexter[4,5], Sue Lynn Lau[1,2] & Mark McLean[1,2]
[1]Westmead Hospital, Diabetes and Endocrinology, Sydney, Australia; [2]Western Sydney University, School of Medicine, Sydney, Australia; [3]Westmead Hospital, Tissue Pathology and Diagnostic Oncology, Sydney, Australia; [4]University of Sydney, Westmead Clinical School, Sydney, Australia; [5]Westmead Hospital, Neurosurgery, Sydney, Australia

Background
Pituitary neuroendocrine tumours (PitNETs) that cause acromegaly are often collectively categorised as 'growth hormone (GH) secreting adenomas'. The 2022 WHO classification however identifies 7 histological variants that can secrete GH: densely granulated somatotroph (DGST), sparsely granulated somatotroph (SGST), mammosomatotroph (MST), mixed somatotroph and lactotroph (MSLT), mature plurihormonal PIT1 (MPPT), immature PIT1 (IPT) and acidophil stem cell (ASCT) tumours. Although differences in clinical behaviour have been outlined in studies comparing select tumour subgroups, there is currently insufficient evidence to include tumour histotype in therapeutic or prognostic algorithms for acromegaly. We analysed all tumour variants of acromegaly to assess differences in clinical characteristics.
Methods
We conducted a retrospective assessment of all PitNETs resected from 2011 to 2018 at Westmead Hospital. Tumour specimens underwent assessment for expression of transcription factors, co factors, anterior pituitary hormones, cytokeratin and somatostatin receptor (SSTR) 2 and 5 using immunohistochemistry. All PitNETs were then assigned a morphological subtype according to the 2022 WHO classification. Variants that can cause acromegaly were selected. Multilineage PIT1 and SF1 tumours (MPST) were identified as an eighth distinct subtype that causes acromegaly and included in our analysis. Correlation was sought with clinical data from medical records.
Results
Of the 47 tumours, 40 (85.1%) had clinical or biochemical acromegaly at presentation. Tumour size differed by histological type; SGSTs (mean diameter 23.4 $\pm$5.9mm) larger than DGSTs (13 $\pm$7.1mm, $P=0.03$) or MSTs (11.8 $\pm$ 7.6mm, $P=0.002$). The number of therapeutic interventions after initial surgery was not different between SGST and MST groups (1.11 $\pm$0.93 vs 1.00 $\pm$0.82, $P=0.40$), but was lower for the MPST group (0.29 $\pm$0.49, $P=0.03$ vs SGST). At 3 months after surgery, normalisation of IGF-1 was achieved in a higher proportion of MPST than SGST (66.7% vs 14.3%, $P=0.05$). 17 PitNETs (42.5%) required treatment with somatostatin receptor ligands (SRL), 29.4% were SGST and 29.4% were MST. Over a mean follow up duration of 75 months, tumour regrowth or recurrence was observed in 25% of SGST and 40% of IPT, but was not seen with any other variants. Proportion of 'high-risk' variants (SGST and IPT) needing radiotherapy was higher than other groups combined (42.9% vs 9.1%, $P=0.01$).
Conclusion
Our data suggests that there are differences in clinical behaviour and outcome among histological variants that cause acromegaly. Tumour histotype potentially has a role in directing individualised management plans for acromegaly and may be useful for prognostication.

Comparative analysis of giant and 'nearly giant' pituitary adenomas

Barbara Buchalska[1], Wiesław Bonicki[1], Maria Maksymowicz[2] & Jacek Kunicki[1]
[1]The Maria Sklodowska-Curie National Research Institute of Oncology, Department of Neurosurgery, Warsaw, Poland; [2]Maria Sklodowska-Curie National Research Institute of Oncology, Department of Pathology, Warsaw, Poland

Introduction
Giant pituitary adenomas (GPAs) are traditionally defined as the tumors with the greatest diameter at or above 40 mm. However, some clinical series of GPAs include tumors with maximal diameter of 35 to 40 mm, and those tumors can be named 'nearly giant' pituitary adenomas (nearly GPAs). The treatment of GPAs is challenging and has a higher risk of complications due to the size and complex anatomical relations. This study was conducted to compare GPAs and nearly GPAs treated in The Maria Sklodowska-Curie National Research Institute of Oncology.
Material and methods
The study is a retrospective analysis of case series of GPAs and nearly GPAs treated with an endoscopic transsphenoidal approach in The Maria Sklodowska-Curie National Research Institute of Oncology from 2007 to 2023. The first study group included 176 patients with GPAs (66 women, 110 men), and the second group comprised 32 patients with nearly GPAs (6 women, 26 men). The mean age of patients at the time of surgery and observation time in the first group were 57.0 and 7.5 years, respectively, and in the second group 54.9 and 6.7 years.
Results
Patients with nearly GPAs had total resections more frequently (75.0%) compared to patients with GPAs (42.0%). The most common histopathologic diagnosis was the gonadotroph adenoma in both groups. GPAs more commonly showed invasion of the adjacent structures (73.3%) than nearly GPAs (46.9%). The treatment of GPAs was more often associated with complications. Moreover, patients with GPAs experienced serious complications (hematoma, hydrocephalus, coma, death), which were not observed in the nearly GPAs group.
Conclusion
GPAs differ significantly from nearly GPAs in clinical and morphological aspects. The diagnosis of a pituitary adenoma with a maximum diameter above 40 mm is associated with a poorer prognosis and should prompt a more intense treatment.

Growth hormone potently stimulates fibroblast activation protein activity and collagen turnover – a prospective study in newly diagnosed patients with acromegaly before and after treatment

Amanda Bæk[1,2], Anne Kathrine Pedersen[2], Mai Arlien-Søborg[1], Niels Jessen[2], Mette Bjerre[1,3] & Jens Otto Jørgensen[1]

[1]Aarhus University, Department of Clinical Medicine - The Department of Endocrinology and Diabetes, Aarhus, Denmark; [2]Aarhus University, Department of Clinical Medicine - SDCA-Steno Diabetes Center Aarhus, Aarhus, Denmark; [3]Aarhus University, Department of Clinical Medicine - Medical Research Laboratory, Aarhus, Denmark

Background
GH potently stimulates collagen turnover which underlies its anabolic effects on bone in children, whereas it may promote fibrosis in adults. Fibroblast activation protein-α (FAPα) is involved in collagen turnover by its collagen-cleaving and fibroblast-stimulating activity, which predominantly is expressed in association with fibrosis. FAPα also cleaves and inactivates fibroblast growth factor 21 (FGF21), a multi-faceted metabolic hormone. We have previously recorded elevated FAPα protein levels in uncontrolled acromegaly but it remains to be studied if FAPα activity is GH-dependent.
Aim
To prospectively measure serum FAPα levels and activity, FGF21, and collagen turnover biomarkers in patients with acromegaly at time of diagnosis and after treatment.
Methods
Using immunoassays and an activity assay, we measured FAPα levels and activity, total and intact FGF21, PINP, PIIINP and CTx in serum from 15 acromegaly patients before and after treatment.
Results
Serum FAPα protein levels (μg/l) and enzymatic activity (RFU/min) decreased by 35% (101.7 ±9.4 [before] vs 63.1 ±5.9 [after] (mean ±SEM); $P<0.001$) and 34% (373.2 ±26.5 [before] vs 248.3 ±14.9 [after]; $P<0.0001$) after treatment, respectively. Serum PINP, PIIINP and CTx levels decreased by 60% ($P<0.001$), 69% ($P<0.01$) and 53% ($P<0.001$) after treatment, respectively. The change in FAPα protein levels before and after treatment correlated positively with the change in FAPα activity before and after treatment ($r=0.74$; $P<0.01$).
Conclusion
1. Our study document for the first time that GH stimulates FAPα activity in human subjects *in vivo*.
2. The concomitant increase in markers of collagen turnover and the lack of change in FGF21 suggest that GH-driven FAPα activity predominantly involves collagen breakdown.
3. FAPα is a novel and promising biomarker of GH/IGF-I activity and may be causally linked to GH-induced fibrosis.

Expression pattern of select cell proliferation and apoptotic markers in non-functioning pituitary adenomas predictive of tumour growth/recurrence: a pilot project

Andrea Hebb[1], Sidney Croul[2], Jae Han[1], Emad Massoud[3], Lisa Tramble[4], Syed Imran[4] & David Clarke[1]
[1]Dalhousie University, Division of Neurosurgery; [2]Dalhousie University, Division of Pathology; [3]Dalhousie University, Division of Otolaryngology-Head and Neck Surgery; [4]Dalhousie University, Division of Endocrinology & Metabolism

Introduction
While there is a significant risk of recurrence in nonfunctioning pituitary adenoma (NFPA) after surgery, it is challenging to predict which NFPAs will recur based solely on routine histopathology. To better understand markers of recurrence, we assessed the established tumor markers linked to aggressive tumor behavior including X-linked IAP (XIAP), the most potent inhibitor of the apoptosis protein family, vascular epithelial growth factor (VEGF) which facilitates angiogenesis and tumour cell proliferation as well as leptin.
Purpose
The purpose of this pilot study was to determine if the expression pattern of select cell proliferation and apoptotic markers in NFA is predictive of tumour quiescence and growth/recurrence compared to normal pituitary tissue in a clinical population.
Methods
Informed consent was obtained from patients during a clinic visit. Tissue microarrays were constructed from paraffin-embedded tissue microarrays (representing pituitary tissues from growing or stable tumours, or normal controls). Immunohistochemical staining using mouse anti-human XIAP monoclonal antibody (BD Biosciences); VEGF monoclonal antibody (Dako); leptin polyclonal antibody (R & D systems) and leptin receptor (Abcam) was completed. Slides were analyzed using Aperio Image Scope-pathology slide viewing software. Chi square and Fishers exact test ($P<0.05$) were employed.
Results
Tissue samples from 98 patients with NFA (52 males) were analyzed. TMA analysis of normal pituitary tissue ($n=24$) revealed low levels (weakly positive) of XIAP relative to VEG-F, leptin, and leptin-receptor. VEG-F levels and leptin were moderately positive, while staining for leptin receptor strongly positive in normal pituitary tissue ($P<0.0001$). XIAP levels in overall tumor tissue revealed moderate and strongly positive staining of XIAP relative to the low staining present in normal pituitary tissue ($P<0.00001$). VEGF levels in overall tumor tissue were moderately positive in normal pituitary tissue and weakly positive in tumor tissue ($P<0.00001$). The pattern of leptin and receptor staining in normal tissue was moderately to strongly positive while there was more variability amongst tumor samples ($P<0.05$). Analyses are ongoing to correlate the pattern of staining with clinical and tumor variables.
Conclusion
Preliminary data show altered expression of markers in tumors compared with normal pituitary tissue. Further clinical data are being analyzed to assess the impact of these changes on recurrence.

DOI: 10.1530/endoabs.99.P345

Incidence of nephrogenic diabetes insipidus during prolonged sevoflurane sedation in the intensive care unit: a retrospective analysis and predictive model

Joost Glissenaar[1], Bastiaan Sol[2], Karel Van Eeckhout[1], Lynn De Mey[3], Bert Bravenboer[4], Kurt Barbé[5] & Jeroen M.K. de Filette[6]
[1]University Hospital of Brussels, Anesthesiology and Perioperative Medicine, Brussels, Belgium; [2]AZ Alma, Endocrinology, Eeklo, Belgium; [3]University Hospital of Brussels, Nuclear Medicine, Brussels, Belgium; [4]University Hospital of Brussels, Endocrinology, Brussels, Belgium; [5]Free University Brussels (VUB), Research group Biostatistics and Medical Informatics, Brussels, Belgium; [6]CHU Brugmann, Endocrinology, Brussels, Belgium

Study Objective
Sevoflurane is a halogenated inhalational anesthetic increasingly used in the intensive care unit (ICU) for its potentially beneficial effects in patients with acute respiratory distress syndrome. However, safety data on prolonged sevoflurane sedation are lacking and cases of diabetes insipidus (DI) have been observed. The objective of this study was to assess the incidence and risk factors of DI during prolonged sevoflurane sedation.
Design & Setting
A single-center retrospective analysis in the ICU of the University Hospital of Brussels (March 2013 - March 2021).
Patients
One hundred and six (106) ICU patients receiving prolonged sevoflurane sedation were divided into three groups: 1) no DI, 2) suspected for DI (polyuria >40ml/kg/24h and hypernatremia >145 mmol/l but without available urine sampling) and 3) confirmed DI (polyuria and hypernatremia with urine osmolality <300 mOsm/kg [complete DI] or between 300-600 mOsm/kg [partial DI]).
Measurements
The electronic medical records of the University Hospital of Brussels were retrospectively explored. Logistic regression modelling was used to build a predictive model for DI in patients with prolonged sevoflurane sedation.
Main Results
Twenty-two (22/106; 20.8%) patients developed polyuria-hypernatremia. DI was suspected in 13 patients (12.3%) but could not be confirmed due to the absence of urine sampling. DI was confirmed in 9 patients (8.5%), of which 5 were partial and 4 complete. Desmopressin test was performed in 5/9 patients of which none responded, diagnostic for nephrogenic DI. Sevoflurane was administered for a median duration of 96, 155 and 166 hours (p 0.003), at a median end-tidal concentration of 1.11, 1.25 and 1.22% (p 0.09), respectively. The variables identified in the logistic regression model were: higher sevoflurane end-tidal concentration (p 0.02), longer sevoflurane exposure time (p 0.07) and admission for COVID-19 (p 0.16). A cutoff value of >3 for the linear discriminator was predictive for suspected/confirmed DI.
Conclusion
DI occurs frequently during prolonged sevoflurane sedation in the ICU. Intensive care physicians should be vigilant for the development of polyuria-hypernatremia. Monitoring of plasma osmolality, sodium, creatinine, and urine output is advisable for early detection of DI in this setting. This study established a model for DI associated with prolonged sevoflurane sedation, including longer sevoflurane use, higher end-tidal concentrations and COVID-19 infection.

Safety profile of growth hormone replacement (GHr) in GH deficient patients during transition period treated for intracranial tumors and malignancy in childhood- Single center expirence

Mirjana Doknic[1,2], Mihajlo Curcic[2], Marko Stojanovic[1,2], Tatjana Milenkovic[3], Vera Zdravkovic[2,4], Maja Jesic[2,4], Slaana Todorović[3], Mihailo Milicevic[2,5], Aleksandar Stanimirovic[2,5], Vuk Scepanovic[2,5], Katarina Mitrović[2,3], Rade Vukovic[2,3], Dragana Miljic[1,2], Sandra Pekic Djurdjevic[1,2], Ivana Cekic[1], Ivan Jevtic[1], Emilija Manojlovic Gacic[2,6], Danica Grujicic[2,5], Milan Petakov[1,2] & Ivan Soldatovic[2,7]
[1]University Clinical Centre of Serbia - Clinic for Endocrinology, Diabetes and Metabolic Diseases, Neuroendocrine Department, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [3]Mother and Child Health Care Institute of Serbia'Dr Vukan Cupic', Belgrade, Serbia; [4]University Children's Clinic 'Tirsova', Belgrade, Serbia; [5]Clinic for Neurosurgery, University Clinical Centre of Serbia, Belgrade, Serbia; [6]Institute for Pathology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [7]Institute of Medical Statistics and Informatics, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Introduction
Considering the mitogenic potential of GH and IGF1, the safety profile of growth hormone therapy since the beginning of its use has been debated. From that point of view, adolescents in transition to adulthood who were treated in childhood for endocranial tumors or malignancies require special caution.
Patients and Methods
In a monocentric, observational, retrospective cross-sectional study spanning 18 years, we analyzed 251 childhood onset growth hormone deficiency - COGHD patients (16-25 years old, 181 males) at time-point of pediatric to adult endocrine care transfer and over transition period on GHr. Fifty-three subjects experienced childhood-onset cranial tumor or acute lymphoblastic leukemia-ALL (TUM, 21.1%). Other patients had congenital (CON, 46.2%) or idiopathic COGHD (32.6%). Craniopharyngiomas predominated among TUM group (39.6%), followed by germinoma (15.2%), Langerhans cell histiocytosis (11.3%), medulloblastoma (9.4%), astrocytoma and ALL (each 5.6%), pituitary pseudotumor (TSH hyperplasia-3.8%), PNET, ganglioglioma, hamartoma, thalamic tumor, and malignant triton tumor (1.8% each). We monitored possible tumor recurrence using cranial MRI and hematological evaluation every 12 months in TUM group. Monitoring for recurrent lesions on GHr also extended to 6 of CON patients who underwent non-cranial childhood surgery due to benign tumors of kidney (2), skin (2) adrenals (1) or mediastinum (1).
Results
Median age of patients at time of transfer from pediatrics was 18.1 ± 3.3 years. Patients with persistent GHD (65.8%) continued GHr in daily doses of 0.5 ± 0.2 mg (range 0.3-1.4 mg) with follow-up IGF-I maintained mid-ranged. Duration of GHr during childhood was 5.7 ± 4.9 years (1-16 years), while during the transition period it was 3.6 ± 1.9 years (1-7 years). We detected papillary carcinoma of the thyroid gland in a male patient who had the experience of thalamic germinoma treated by surgery and radiotherapy at the age of 18. He started GHr (0.3 mg daily) at the age of 22 and stopped 3 years later after a malignant thyroid tumor was discovered. His brother was also treated for cranial germinoma and the same mutation on the KRAS gene was proven in both of them. During GHr no benign tumors regrowth was detected in the CON group.
Conclusion
In 53 patients with tumor-related COGHD, we monitored the safety of GH therapy in the transition period. Through follow-up, we detected papillary thyroid carcinoma in a patient previously treated for cranial germinoma. Patients should be carefully monitored on GH treatment due to the possibility of developing not only the recurrence of the tumor causing GHD, but also secondary neoplasms.

Diabetes insipidus and cerebral malaria: a rare etiology to be considered

Mariana Lopes-Pinto[1] & Ema Paula Ricca Lacerda Nobre M Caetano[1]
[1]Unidade Local de Saúde de Santa Maria, Hospital de Santa Maria, Endocrinology Department, Lisbon, Portugal

Background
Cerebral malaria may present with altered cognition, severe hemolysis, renal and metabolic dysfunction. The endocrine abnormalities induced by malaria include: hypoglycemia, hypocalcemia, hypercortisolism and compromised pituitary function due to sequestration of drepanocytes in hypothalamo-pituitary portal microvasculature.
Aim
To raise awareness for the risk of pituitary dysfunction in severe malaria.
Case
A previously healthy 22 years old woman was admitted at the emergency department with fever, rigors, vomiting and altered cognition after a flight from Guinea. Malaria was suspected and *P.falciparum* parasitemia was of 3% at admission. Anemia, pulmonary edema, acute renal lesion (maximum creatinine 9.2 mg/dl (N:0.5-0.9)), thrombocytopenia, hyperbilirubinemia, hypocalcemia and elevated inflammatory markers were present. She had a normal head CT scan. After quinine and doxiciclin treatment a generalized cognition and hematologic improvement was followed by acute renal lesion KDIGO 3, with oliguria and uremia requiring hemodyalisis. Spontaneous miction was followed by prompt increase in urinary output reaching a maximum of 4.9L without fluids or diuretics. After fluid treatment, negative fluid balance reached -5.5L (urinary output 15.5L), followed by dehydration and sinusal tachycardia. The progression and duration of polyuria raised suspicion of diabetes insipidus (DI). Hypotonic polyuria was confirmed, serum osmolality ranged between 269-277mOsmol/Kg (N: 275-298), and sodium levels between 136-138 mmol/l (N:135-145). Low basal copeptin level (1.14pmol/l) was suggestive of central DI and a therapeutical trial with desmopressin was started and titrated up to 0.6 mg/day with clinical improvement. Pituitary function was assessed and elevated ACTH 135.6 pg/ml (N: 7.2-63.3) and 0800 hours cortisol of 23.2 mg/dl required further study. Lack of suppression in 1mg dexamethasone suppression test (18.4 mg/dl) was documented and a sellar MRI obtained. No pituitary adenomas were present, but a neurohypophysis with right deviation and hypersignal in T2 of 'imprecise meaning' was described. The hypercortisolism was admitted as a result of hospitalization and acute disease, and was resumed after hospital discharge. After two weeks, desmopressin was stopped without relapse of polyuria, and normal sodium and osmolality levels were documented in urine and serum evaluation, as previously described in DI due to malaria.
Conclusion
In conclusion, cerebral malaria may present with compromised pituitary function, such as diabetes insipidus, requiring prompt diagnosis and treatment.

Prolactin-related challenges in two critical moments of womens' life: postpartum and menopause

Catarina Silvestre[1], Tânia Matos[1], Daniela Dias[1], Filipa Serra[1], Pedro Marques[1,2] & Inês Sapinho[1]
[1]Hospital CUF Descobertas, Lisboa, Portugal; [2]Catholic University of Portugal, Lisboa, Portugal

Introduction
Prolactin is involved in lactation and reproduction. Endocrinologists should be familiar with physiological effects of prolactin in women, particular in key moments: breastfeeding and menopause. We aimed to report two females with unusual prolactin-related challenges: the first case corresponds to a postpartum woman with normoprolactinemia and breastfeeding problems; the second case concerns a menopausal woman with a prolactinoma who developed hot flashes following normalization of prolactin levels.
Clinical cases
A 32 year-old woman was referenced 2 months after delivery of her first child, after evaluation by a Lactation consultant. She sought help for not being able to exclusively breastfeed since the birth, with no let-down reflex/draught. She had two normal serum prolactin measurements (14.3 and 8.3ng/ml, normal range <25). Her baseline pituitary function was normal. She was advised to breastfeed on full-demand, mainly at night, to increase her lactation function. A 50 year-old woman was diagnosed with a macroprolactinoma after complaining of headache, although she had a secondary amenorrhea since 26 years-old-not previously investigated. At diagnosis, she had elevated prolactin levels at 2500ng/ml, and low LH and FSH levels at 0.36 and 5.26 mUI/ml, respectively; remaining pituitary function was normal. Pituitary MRI showed a 3.6 cm-cystic pituitary mass with cavernous sinus invasion compressing the optic chiasm. She initiated cabergoline, with good biochemical and structural response. Within 6 months on cabergoline, prolactin levels normalized, with a concomitant increase of LH/FSH levels up to the range for a postmenopausal woman, respectively 19.27 and 34.31 mUI/ml. At this point in time, the patient started to report menopause-like symptoms, particularly hot flashes, which she never experienced before, even when she became amenorrheic.
Conclusion
Despite the fact that lactation is a well-known cause of secondary hyperprolactinemia, normal prolactin levels can be found in breastfeeding women. Since delivery and during breastfeeding, serum prolactin levels may slowly decline over time; also serum prolactin peaks throughout the day in breastfeeding women, and

correlate with moments of suckling stimulation. With the second case, we learned that hyperprolactinemia contributed to abolishment of menopause-related hot flashes, due to gonadotropin/GnRH suppression. Although hot flashes in menopausal women are classically attributed to estrogen deficiency, this case suggested that elevated FSH/lH may also play a role. This may be due to proximity of hypothalamic GnRH neurons with thermoregulatory neurons, explaining a possible association of pulsatile LH-release and occurrence of hot flashes.

Assessment of insulin resistance and its associated factors in women with hypopituitarism

Salma Salhi[1], Ibtissem Oueslati[1], Emna Talbi[2], Kacem Ben Fradj[2], Ahmed Mezioud[2], Meriem Yazidi[1], Moncef Feki[2] & Melika Chihaoui[1]
[1]La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia; [2]La Rabta University Hospital, Laboratory of Biochemistry, Tunis, Tunisia

Introduction
Insulin resistance (IR) is prevalent in patients with hypopituitarism receiving conventional replacement therapy. Recognizing and addressing IR in women with hypopituitarism is crucial for comprehensive patient management and prevention of other metabolic complications. The aims of this study were to determine the prevalence of IR and to assess its associated factors in women with hypopituitarism.
Methods
This was a monocentric cross-sectional study including 50 patients with complete anterior hypopituitarism secondary to Sheehan's syndrome (SS) and 50 age, and body-mass index (BMI)-matched women controls. Participants underwent physical examination and laboratory tests including fasting blood glucose and baseline insulin. Homeostatic Model Assessment of IR (HOMA-IR) index was calculated using the following formula: [Fasting Blood Glucose (mmol/l) $\times$ Basal Insulin (mIU/l)] / 22.5. IR was defined by an HOMA-IR index $\geq$ 2.4.
Results
The mean age was 62.2 $\pm$ 9.4 years in women with SS and 60.6 $\pm$ 8.4 years in controls ($P=0.385$). The mean BMI was 29.6 $\pm$ 6.0 kg/m^2 in patients and 30.0 $\pm$ 5.0 kg/m^2 in controls ($P=0.741$). The baseline insulin level was significantly higher in women with SS than in controls (respectively: 15.0 $\pm$ 11.6 µIU/ml vs 10.6 $\pm$ 5.5 µIU/ml, $P=0.030$). The HOMA-IR index was significantly higher in patients than in controls (respectively: 3.4 $\pm$ 3 vs 2.4 $\pm$ 1.2, $P=0.017$). The prevalence of IR was 38% in patients and 56% in controls ($P=0.070$). In patients with SS, factors associated with IR included age $\leq$ 62 years (OR=4.43, IC95%: 1.26-15.48, $P=0.016$), family history of obesity (OR=3.78, IC95%: 1.01-14.17, $P=0.042$), BMI $\geq$30 kg/m^2 (OR=1.21, IC95%: 1.06-1.40, $P=0.004$), body-fat ratio $\geq$ 30% (OR=1.13, IC95%: 1.02-1.26, $P=0.021$), and waist circumference $\geq$94 cm (OR=1.86, IC95%: 1.40-2.47, $P=0.009$). However, the risk of IR was not associated with the diagnostic delay of SS, disease duration, GH levels, FT4 levels, levothyroxine dose, daily or cumulative dose of hydrocortisone, and oestrogen-progesterone therapy.
Conclusions
Women with hypopituitarism had a significantly higher insulin levels and HOMA-IR ratio than controls. However, the prevalence of insulin resistant was comparable in the two groups. Age, family history of obesity, BMI, body fat ratio, and waist circumference were positively associated with IR.

ER stress causes variable ACTH production and secretion in corticotroph tumour cells

Merisa Abusdal[1,2,3], Jens Petter Berg[3,4], Maria Walewska[1], Hemaseh Bideli[1], Jens Bollerslev[1,3] & Nicoleta Olarescu[1,2,3]
[1]Section of Specialized Endocrinology, Department of Endocrinology, Oslo University Hospital (OUS), Oslo, Norway; [2]Research Institute of Internal Medicine, Oslo University Hospital (OUS), Oslo, Norway; [3]Institute of Clinical Medicine, Faculty of Medicine, University of Oslo, Oslo, Norway; [4]Department of Medical Biochemistry, Oslo University Hospital (OUS), Oslo, Norway

Objective
Cushing's disease is caused by hypercortisolism due to adrenocorticotropic hormone (ACTH) hypersecretion from functioning pituitary adenomas (FCA). Endoplasmic reticulum (ER) protein processing is important for hormone production and is upregulated in FCA as shown previously. ER protein processing can be disturbed by ER stress. We hypothesized that ACTH production and secretion can be inhibited by agents that cause ER stress by attenuating ER protein processing.
Methods
Cells from the AtT-20 mouse pituitary corticotroph tumor cell line and primary cells isolated from FCA were treated for 6 and 24 hours with 50-µM-Hsp90 inhibitor 17-N-allylamino-17-demethoxygeldanamycin (17-AAG, tanespimycin) and 250 nM of the sarco- and endoplasmatic reticulum Ca-ATPase inhibitor thapsigargin (Tg) to induce ER stress. The stimulation was followed by gene and protein expression analyses, and ACTH measurement in culture media and cell lysate.
Results
In AtT-20 cells, gene expression involved in ER protein processing, including CALR, GRP78, GRP94, UGGT1 were significantly upregulated by Tg and 17-AAG at 24 h compared with controls. Tg increased all unfolded proteins signalling pathway responses (ATF4, IRE1 and ATF6) at both 6 and 24 h, whereas 17-AAG increased only ATF4 at 6 h, and IRE1 at 24 h, and no effect was observed on ATF6. The ratio of s/uXBP1, member of IRE1 pathway, was downregulated by 17-AAG at both time points ($P<0.001$ for both), suggesting that the cells are in recovery phase from ER stress. POMC gene expression was downregulated by Tg at both 6 and 24 h ($P<0.0001$, both), whereas 17-AAG was upregulated at 6 h ($P=0.0497$). At 24 h, Tg decreased secreted ACTH in media by 24% in AtT-20 cells ($P<0.0001$) and 32% in primary cells ($P<0.0001$) compared with controls. However, 17-AAG increased secreted ACTH by 64% ($P=0.0052$) with marked response variation between FCA patients' tumor cells. No effect of 17-AAG was observed in AtT-20 cells. Intracellular ACTH level in both cell types showed no change by Tg, while 17-AAG increased it in AtT-20 by 17% ($P=0.0075$) and by 38% in primary cells ($P=0.0354$).
Conclusion
ER stress may disturb ACTH production and secretion from the corticotroph tumour cells. The broad induction of ER stress by Tg effectively reduced ACTH production and secretion. On the contrary, targeted ER stress induced by 17-AAG showed increased ACTH production and secretion by FCA primary cells, possibly by inducing ER compensatory mechanisms.

Plasma apelin levels in patients with polyuria-polydipsia syndrome undergoing copeptin stimulation tests

Chiara Bizzozero[1], Sophie Monnerat[1], Fiona Chapman[2], Neeraj Dhaun[2], Julie Refardt[1] & Mirjam Christ-Crain[1]
[1]University Hospital Basel, Department of Endocrinology, Diabetology and Metabolism, Basel; [2]Royal Infirmary of Edinburgh, Department of Renal Medicine, Edinburgh, United Kingdom

Introduction
In polyuria-polydipsia syndrome (PPS) the differentiation between arginine vasopressin deficiency (AVP-D) and primary polydipsia (PP) remains challenging and a stimulation test is required. Apelin is an endogenous hormone that antagonises AVP and seems to play an important role in regulating salt and water homeostasis. The dynamic of apelin plasma levels in patients with PPS undergoing copeptin stimulation tests is unknown.
Methods
Post-hoc secondary analysis of the multicentric randomised cross-over diagnostic CARGOx study (NCT03572166) performed from 09/2018 to 12/2022. Apelin levels from patients with PPS included at the University Hospital Basel were measured upon stimulation with hypertonic saline and arginine infusions. The primary objective was to compare the changes in plasma apelin levels during copeptin-stimulation tests among patients with PPS. Secondary objectives included comparing changes in the apelin/copeptin ratio and comparing the diagnostic ability of apelin, copeptin and their ratio.
Results
Of the 38 patients enrolled at the University Hospital of Basel, 23 (60%) patients had PP and 15 (40%) patients had AVP-D. At baseline median [IQR] apelin levels were 1079 [912, 1225] and 910 [756, 1039] and apelin/copeptin was 336 [218, 336] and 426 [369, 509] in PP and AVP-D respectively. During the hypertonic saline stimulation test, apelin decreased by -241 [-326, -124] and -47.2 [-198, 5.86] ($P=0.022$) and apelin/copeptin ratio decreased by -300 [-425, -235] and -69 [-150, -15] in PP and AVP-D respectively ($P=0.001$). The AUC [95%-CI] to differentiate PP from AVP-D was 97.1% [90.5, 100] for copeptin, 49.3% [30.4, 68.1] for apelin and 95.6 [87.2, 100] for apelin/copeptin ratio. During the arginine stimulation test, apelin decreased in PP by -39.2 [-96.4, 39.8] and increased in AVP-D by 25.8 [2.8, 113.0] ($P=0.1$), and apelin/copeptin ratio decreased by -188 [-326, -68] and -59 [-171, 8] in PP and AVP-D respectively ($P=0.034$). The

AUC [95%-CI] was 97.1% [79.6, 98.0] for copeptin, 60.5% [39.8, 80.0] for apelin and 83.0% [67.0, 95.3] for apelin/copeptin ratio.
Conclusion
Our findings suggest that apelin and apelin/copeptin ratio decrease during hypertonic infusion to a greater extent in patients with PP as compared to patients with AVP-D. Copeptin remains the best marker to differentiate AVP-D from PP upon hypertonic saline and arginine stimulation. Whether apelin would provide greater diagnostic accuracy using other provocation tests should be further investigated.

Assessment of GH/IGF1 axis in relation to pituitary volume and MRI intensity in subjects with obesity: A controlled, cross-sectional, observational study

Gabriele Veroi[1], Dario De Alcubierre[1], Davide Masi[1], Rebecca Rossetti[1], Maria Elena Spoltore[1], Elena Gangitano[1], Mikiko Watanabe[1], Stefania Mariani[1], Lucio Gnessi[1] & Carla Lubrano[1]
[1]Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Sapienza University of Rome, Rome, Italy

Background
It has been reported that some Magnetic Resonance Imaging (MRI) pituitary findings may reflect specific endocrinological alterations, as in the case of adult-onset growth hormone deficiency (GHD), which has already been associated with lower MRI-derived pituitary height and volume in pediatric patients.
Purpose
The objective of this study was to investigate potential associations between pituitary morphology and signal intensity on MRI with GH secretory function in a cohort of patients with varying degrees of adiposity.
Methods
We conducted a retrospective observational study on 297 patients (235 females, median age 46 years, IQR: 20 years), admitted to our institution between January 2015 and December 2023, who had signs and symptoms suggestive of GHD. Our cohort included 243 patients with obesity and 54 age- and sex- matched controls. We assessed GH-IGF1 axis and pituitary morphology with MRI. To quantify the mean and standard deviation (SD) of pituitary signal intensity, we used Horos software, employing T2-weighted sequences and gray matter intensity as a normalizer. In addition, we measured pituitary height and calculated pituitary area in coronal section as a surrogate for pituitary volume.
Results
In the entire study population, we found an inverse correlation between BMI and pituitary area (r=-0.357, P=.000), height (r=-0.406, P=.000) and normalised pituitary signal intensity (r=-0.197, P=0.05). Patients with obesity showed significantly lower pituitary height and area (P=.000) along with a higher prevalence of empty sella (X2= 13.996, P=.000) compared to controls. Regarding GH secretory capacity, we found a direct correlation between the area under the curve of the GHRH+arginine test and pituitary area (r = 0.479, P= .000) and height (r=0.513, P=.0.00) and a negative correlation with BMI (r= -0.481, P=.000). Finally, by fitting ROC curves, we identified cut-offs for pituitary area (lower than 27.8 mm^2, AUC= 0.696, P=.000) and pituitary height in coronal scan (lower than 3.1 mm, AUC= 0.729, P=.000) as predictors of GHD with a sensitivity of 69% and 72% and specificity of 61% and 62%, respectively. After stratifying the cohort by the degree of adiposity, we showed a progressive reduction in GH secretory capacity and pituitary size from the control group to gradually higher degrees of obesity (P=.000 for all parameters).
Conclusion
Consistent with current evidence, our study demonstrates that patients with obesity have impaired GH-IGF1 axis and reduced pituitary size compared to controls, suggesting a close relationship between pituitary morphology and functional capacity.

Aim
To evaluate the efficacy of transsphenoidal surgery in patients with Rathke cleft cysts (RCCs), and recurrence rates after follow-up
Methods
A multicenter retrospective clinical practice study in patients with RCCs operated through transsphenoidal route and followed in 15 tertiary hospitals (SPAIN-QBR study) during 64.0 ± 49.0 months.

Table 1. Pre and post-surgery clinical alterations

	Pre-surgery	Post-surgery	
Visual field defects	39 (47.1%)	12 (14.3%)	P<0,001
Neurologic alterations	5 (5.9%)	2 (2.2%)	ns
Headache	44 (4.4%)	6 (6.7%)	P<0,001
Diplopia	3 (3.5 %)	2 (2.2%)	ns
Any pituitary deficiency	41 (48.2%)	50 (58.8%)	P<0,001

Table 2. Complications of surgery

Increased anterior pituitary damage	21 (24.7 %)
Permanent arginine vasopresin deficiency	13 (15.3%)
Reinterventions	11 (12.9 %)
Cerebrospinal fluid leakage	8 (9.4%)
Meningitis	4 (4.7 %)
Intracranial hemorrhage	2 (2.4%)
Abscess	1 (1.2 %)
Mortality	1 (1.2%)

Results
A total of 85 patients with a diagnosis of RCCs underwent transsphenoidal surgery, 62 (72.9%) due to secondary clinical symptoms and 23 (27,1 %) for risk of chiasmatic compression. Most surgeries were endoscopic (74 patients) and only 11 were microscopic. Men represented 30.6% (n=26 of the cases) and 59 (69.4%) were women. The mean age was 47±19 years for men and 47±16 years for women. After surgery visual field alterations and headache improved in more than 67% of the patients but the number of patients with hormonal deficiencies increased due to new cases of arginine vasopresin deficiency (Table 1). Other complications can be seen in table 2. Total resection was achieved in 58 % of patients and after a long follow-up (64.0 ± 49.0 months) growth of cysts was seen in nine patients (10.6%) and only one required new surgery.
Conclusion
In patients with symptomatic Rathke cleft cysts, transsphenoidal surgery achieves an improvement in signs and symptoms due to mass-effect with low rate of complications. However, up to 11% of the cases may experience recurrence during follow-up; thus, long-term follow-up is recommended after surgery.

Background
Pachydermoperiostosis (primary hypertrophic osteoarthropathy, PHO) is a rare genetic disease characterised by clinical signs and symptoms which may overlap with acromegaly (pachydermia, hyperhidrosis and enlargement of hands and feet). In the majority of cases, the disease is due to biallelic loss-of-function variants in either of two genes, *SLCO2A1* and *HPGD* playing an important role in prostaglandin metabolism. Although PHO patients are often referred to endocrinologists, a detailed hormonal assessment is not available for these patients.
Patients and methods
Patients ($n=16$, all males), referred to endocrinology centres with a possible diagnosis of acromegaly and eventually diagnosed with PHO, were assessed for biochemical and hormonal abnormalities. Acromegaly was excluded based on normal IGF-1 concentration and/or GH suppression during an oral glucose tolerance test (OGTT). Sanger sequencing for *HPGD* and *SLCO2A1* variants on peripheral blood DNA was performed. The identified variants on both genes were classified using the American College of Medical Genetics classification guidelines.
Results
The mean ($\pm$ standard deviation) age at PHO diagnosis was 27.8 years $\pm$11.3 (range 9-43 years). Digital clubbing and periostosis were present in all patients. Arthralgia of large joints was present in 15/16 patients (94%), periarticular oedema in 13/16 (81%), pachydermia in 14/16 (88%) and facial features suggesting acromegaly in 12/16 (75%). Further characteristic features included eyelash trichomegaly (10/16 patients), blepharoptosis (9/16), high-arched palate (9/15), gastrointestinal symptoms (7/16), gingival hypertrophy (1/16) and marfanoid habitus (2/16). All tested patients ($n=13$) suppressed GH on OGTT <1.0 µg/l, but 4 (31%) did not supress GH <0.4 µg/l. Nine patients (57%) had abnormally low serum IGF-1 level and the other three patients (19%) had IGF-1 levels in the lower quartile of the reference range. While testosterone and prolactin levels were normal, oestradiol concentration was increased above the normal range in eight patients (62%). Two families harboured homozygous *HPGD* changes (one of these is a novel variant). Ten families had 12 different pathogenic/likely pathogenic variants in *SLCO2A1* (eight novel variants). Eight kindreds had homozygous change while two kindreds had compound heterozygous mutation. Two patients from two different kindreds had no identifiable pathogenic/likely pathogenic variant in *HPGD* or *SLCO2A1*. Their phenotype was not different from the other patients.
Conclusion
Low IGF-1 and elevated oestradiol levels are typical features for patients with both *HPGD* or *SLCO2A1* mutations while analysing the data of 14 kindreds with PHO carrying nine novel and five known pathogenic/likely pathogenic genetic variants.

A Novel CDKN1B mutation in multiple endocrine neoplasia type 4

Christina Millou[1], George Chrousos[2] & Amalia Sertedaki[3]
[1]University Hospital Coventry & Warwickshire, Endocrinology Diabetes and Metabolism, coventry, United Kingdom; [2]University Research Institute of Maternal and Child Health and precision medicine, National and Kapodistrian University of Athens, Athens, Greece; [3]Division of Endocrinology, Diabetes and Metabolism, Aghia Sophia Children's Hospital ENDO-ERN Center for Rare Paediatric Endocrine Diseases, National and Kapodistrian University of Athens, Athens, Greece

Multiple endocrine neoplasia (MEN) includes a group of autosomal dominant disorders, associated with the development of a variety of endocrine and non-endocrine manifestations. MEN4 is a rare and the latest reported type in the spectrum of the MEN syndromes. MEN4 was discovered initially in rats (MENX) and later in humans. It is caused by germline and somatic mutations in the cyclin-dependent kinase inhibitor 1B (CDKN1B) tumor suppressor gene, which encodes nuclear protein p27 (IFI27), a key regulator of cell cycle progression. The most common phenotype of MEN4 is primary hyperparathyroidism (PHPT), followed by pituitary adenomas and rarely NETs. MEN4 and MEN1 syndromes have similar phenotypes. However, in MEN4 the disease manifestations appear later in life, associated with an improved life- expectancy and a different prevalence. We present an adult woman with MEN4 who presented with a non-functioning pituitary adenoma, an adrenocortical adenoma causing mild Cushing syndrome, a parathyroid adenoma associated with mild PHPT and benign intestinal polyps. We identified that she is harboring a novel heterozygous CDKN1B gene pathogenic variant, p.Lys96GInfsTer 29.

Introduction
IGF-1 dependence on sex is a well-known fact; however, whether IGF-1 is also influenced by body weight is still questionable, and the mechanism of a potential relationship between GH, IGF-1 and body weight is not fully explained. The effect of gender (or rather oestrogens) on IGF-1 is visible in acromegaly - women are diagnosed at an older age than men (approximately 4 years) (potentially by suppressive effect on the axis of GH-IGF-1). The aim of the study was to assess whether BMI is a factor influencing the age of diagnosis of acromegaly - potentially by influencing (like oestrogens) the GH-IGF-1 relationship.
Materials and Methods
In a retrospective analysis of the UK Acromegaly Register (UKAR, 22 centres, 1997-2017) we enrolled 1136 patients (53.4% males) with available BMI results, which were reported +/- 2 years before diagnosis. We assessed the correlation between gender, BMI and age of diagnosis, age of first symptoms, diagnostic delay and the number of treatments in our selected group.
Results
We found, that that females are significantly older at diagnosis of acromegaly than males (approximately 4.3 years, $p<0.001$). However, there was no correlation between BMI and age of diagnosis ($p=0.072$). There was also no correlation between BMI and age of first symptoms ($r=0.0947$, $P=0.002$) and the time between first symptoms and diagnosis ($r=0.0065$; $p=0.835$). Patients with a higher BMI did not receive more treatment modalities in their course of follow-up ($r=-0.0491$; $p=0.150$).
Conclusions
BMI does not influence the age of diagnosis of acromegaly as the gender does. If oestrogens are responsible for a delay in diagnosis, it is probably by influencing the GH-IGF-1 axis - which is not visible in the BMI and age at diagnosis relationship. Mechanisms other than GH-IGF-1 should be considered when assessing differences in IGF-1 for different BMI. on behalf of the UKAR Steering Group 2024

Cytokeratin 18: An early biomarker of increased liver fibrosis in newly diagnosed acromegaly

Meric Coskun[1], Halit Nahit Sendur[2], Afruz Babayeva[1], Mahi Nur Cerit[2], Ethem Turgay Cerit[1], Mehmet Muhittin yalcin[1], Alev Eroglu Altinova[1], Mujde Akturk[1], Mehmet Ayhan Karakoc[1] & Fusun Balos Toruner[1]

[1]Gazi University, Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey; [2]Gazi University, Faculty of Medicine, Radiology, Ankara, Turkey

Purpose
The liver is known to be protected from steatosis under the influence of high GH/IGF-1. Cytokeratin 18 (CK18) and insulin-like growth factor binding protein 7 (IGFBP7) increase in liver steatosis and fibrosis. Whether decreasing lipid content completely protects the liver from metabolic alterations and the response of CK18 and IGFBP7 to liver changes in acromegaly is unknown.
Methods
This single-center, multidisciplinary, cross-sectional study included 23 patients with newly diagnosed acromegaly and 46 age, sex, body mass index (BMI) and waist circumference (WC)-matched healthy controls. Liver steatosis was assessed using tissue attenuation imaging (TAI), and stiffness, indicative of fibrosis, was assessed using shear wave elastography (SWE). Serum IGFBP7 and CK18 were studied by ELISA.
Results
The acromegaly group had significantly lower liver steatosis ($P=0.006$) and higher liver stiffness ($P=0.004$), serum IGFBP7 ($P=0.048$) and CK18 ($P=0.005$) levels than the control group. The presence of fibrosis ($P=0.012$) was significantly higher in the acromegaly group than in the control group. Moreover, CK18 was positively correlated with liver stiffness, WC, HOMA-IR, HbA1c, and triglyceride. In the acromegaly group, liver steatosis was negatively correlated with GH level. Stepwise multiple linear regression analysis revealed that BMI ($P=0.008$) and CK18 ($P=0.015$) were independent risk factors for increased liver stiffness.
Conclusion
This study showed that newly diagnosed acromegaly had low hepatic steatosis with a protective effect of GH, and metabolic changes caused an increase in liver fibrosis. Additionally, elevated CK18 in patients with acromegaly may be an early biomarker of increased liver fibrosis due to metabolic alterations.

Management of prolactinomas before, during and after pregnancy: results from the italian association of clinical endocrinologists (AME) survey

Irene Gagliardi[1], Rita Indirli[2,3], Maria Rosaria Ambrosio[1] & On behalf of AME Pituitary Disorders Committee[4]
[1]University of Ferrara, Section of Endocrinology, Geriatrics and Internal Medicine, Department of Medical Sciences, Ferrara, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [4]Italian Association of Clinical Endocrinologists, Rome, Italy

Background
Prolactinomas are the most common functioning pituitary adenomas and are mostly diagnosed in fertile women. Dopamine-agonists (DAs) have always represented the cornerstone of prolactinoma treatment in terms of hormonal control and tumor shrinkage. Recent guidelines suggest surgery as an alternative option in selected cases after a joint evaluation with an expert surgeon. Prolactinoma management in women seeking fertility and during pregnancy remains challenging, and areas of uncertainty are still present, especially concerning drug safety. The management should be personalized. Herein, we present the results of a cross-sectional survey conducted among Italian endocrinologists, focusing on managing prolactinomas in fertile women and during pregnancy.
Methods
Italian Association of Clinical Endocrinologists members were invited to participate in an online anonymous survey. 578 responded to the survey (61% women, equal distribution between 30-50 and 50-70 years of age).
Results
88% of responders declare to be acquainted with prolactinoma management, and they almost systematically provide counseling on fertility and pregnancy to women of reproductive age. The choice of first-line therapy (DAs vs surgery) is influenced by pregnancy desire (80%) and adenoma size (84%). In particular, 34% of participants opt for surgery in macroadenomas, 22% discuss the choice with the patient in microadenomas, and 77% prefer medical therapy in microadenomas. In women under medical therapy and seeking pregnancy, most clinicians continue the ongoing DAs; 22% switch from cabergoline to bromocriptine, while 18% discontinue therapy. Once pregnancy is confirmed, 58% of participants may continue DAs in selected cases. Great heterogeneity can be observed in prolactinoma management during pregnancy: according to 25% of respondents, women need clinical follow-up. Conversely, nearly 20% require visual field testing only in case of new-onset visual impairment. More than half of responders require prolactin measurement during pregnancy. Finally, 39% advise against vaginal delivery in macroprolactinomas, but the majority do not generally discourage breastfeeding. After delivery and breastfeeding, only half of the participants systematically reassess prolactin concentrations and repeat magnetic resonance imaging before restarting DAs.
Conclusion
Prolactinoma management in fertile-age women is still a challenge in clinical practice. Clinical, hormonal, and ophthalmological follow-ups are largely heterogeneous among endocrinologists. Moreover, a lack of compliance with current guidelines emerged concerning DAs therapy in women seeking fertility and during pregnancy, indications for delivery modalities, and the need for prolactin re-evaluation before restarting DAs. An effort is required from endocrinological societies to spread knowledge about prolactinomas in reproductive-age women and promote management uniformity among endocrinologists.

Long-term pharmacotherapy of giant prolactinomas

Vaclav Hana[1], Manuela Vaněčková[2], Michal Krsek[1], Mikuláš Kosák[1], Jana Ježková[1], Václav Hána jr.[1], Adela Krausova[1], Pavel Diblík[3], Pavel Kuthan[3], Petr Sklenka[3], David Netuka[4], Václav Masopust[4], Martin Májovský[4] & Roman Liščák[5]
[1]First Faculty of Medicine, Charles University, 3rd Department of Internal Medicine, Prague, Czech Republic; [2]First Faculty of Medicine, Charles University, Department of Radiodiagnostics, Prague, Czech Republic; [3]First Faculty of Medicine, Charles University, Department of Ophtalmology, Prague, Czech Republic; [4]First Faculty of Medicine, Charles University, Department of Neurosurgery, Prague, Czech Republic; [5]Hospital Na Homolce, Department of Stereotactic and Radiation Neurosurgery, Prague, Czech Republic

Giant prolactinomas (GPs) are prolactin secreting pituitary adenomas (PitNETs) $\geq$4 cm, usually with prolactinaemia over 1000 mg/l and without co-secretion of other hormones.
Aims
evaluation of long term treatment of GPs, the effect of D2 agonists and of different doses on prolactinaemia, tumour shrinkage and complications.
Patients and methods
33 patients (27 males, 82%) diagnosed with GP in our department between 1997 - 2020 and subsequently on pharmacotherapy (cabergoline, bromocriptine, terguride) as a first line treatment. Mean age was 41.7 years (range 23 - 71 years). The follow-up ranged 30 months - 23 years. Tumor size was evaluated as the largest diameter (LD) on MRI. Fast tumor shrinkage was considered as LD regression $\geq$20% in less than 6 months. Fast prolactin normalisation was considered when in $<$6 months.
Course of pharmacotherapy and Results
24 patients were on pure D2 agonist pharmacotherapy and 9 had to undergo a surgery during the course of therapy (3 rhinorhea, 3 symptomatic intratumoral bleeding and 3 partial resistance). Three patients underwent stereotactic radiosurgery. The largest tumor was 53x76x65 mm. Suprasellar progression was present in all patients. Dominating clinical signs were visual field defect (26), headache (16), hypogonadism (12). Initial prolactin levels were 250 - 45 500 mg/l. In 3 patients were $<$1000 mg/l. Tumor shrank in all patients. Fast shrinkage was present in 22/29 (76%) evaluated patients. Slow regression in 7 (24%). Visual field defects improved/normalised in 25/26. Prolactinaemia decreased in all patients and normalised in 31/33. Prolactin normalised on pure pharmacotherapy in $<$6 months in 14/24, in 6-12 months in 2/24, in $>$12 months in 6/24 patients and never normalised in 2. Different effects of pharmacotherapy on prolactin normalisation and shrinkage were observed. Eleven patients had both fast normalisation of prolactin and shrinkage; 12 slow normalisation of prolactinaemia, but fast shrinkage; 5 normalised prolactin quickly, but shrinkage was slower. Slow decrease of both was in 1.
Conclusion
Pharmacotherapy of GPs was fully effective as monotherapy in 73%. Complications (rhinorhea, bleeding, resistance) needed neurosurgery (27%) and/or radiosurgery. Fast prolactin normalisation was observed in 71%. Shrinkage of GPs was observed in all and fast in 76%. Discrepance between speed of biochemical and graphical regression is frequently observed and patience is required. High initial D2 agonist doses (cabergoline 3.5mg weekly) led to faster prolactin normalisation, but not to faster shrinkage. Regression of hypogonadism was observed in 39%.

Machine learning in differential diagnosis of ACTH-dependent hypercortisolism

Zhanna Belaya[1], Olga Golounina[1], Kirill Voronov[2], Alexander Solodovnikov[2,3], Liudmila Rozhinskaya[1], Galina Melnichenko[1], Natalia Mokrysheva[1] & Ivan Dedov[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Statandocs LLC, yekaterinburg, Russian Federation; [3]Ural State Medical University, yekaterinburg, Russian Federation

Objective
To develop a non-invasive method of differential diagnosis for ACTH-dependent hypercortisolism using machine learning methods based on clinical data analysis.
Materials and methods
This is a single-center study of a retrospective cohort to predict the probability of EAS among patients with ACTH-dependent hypercortisolism using artificial machine learning algorithms. Patients were randomly stratified into 2 samples: training (80%) and test (20%). Eleven machine learning algorithms were used to develop predictive models: Linear Discriminant Analysis, Logistic Regression, elastic network (GLMNET), Support Vector machine (SVM Radial), k-nearest neighbors (kNN), Naive Bayes, binary decision tree (CART), C5.0 decision tree algorithms, Bagged CART, Random Forest, Gradient Boosting (Stochastic Gradient Boosting, GBM).
Results
The study included 223 patients (163 women, 60 men) with ACTH-dependent hypercortisolism, of which 175 patients had Cushing's disease (CD), 48 had EAS. As a result of preliminary data processing and selection of the most informative signs, the final variables for the classification and prediction of EAS were selected: morning ACTH level, potassium level (the minimum value of potassium in the active stage of the disease), 24-h urinary free cortisol, late-night serum cortisol, late-night salivary cortisol, the largest mesurement of pituitary adenoma according to MRI. The best predictive ability in a training sample of all trained machine learning models for all three final metrics (ROC-AUC (0.867), sensitivity (90%), specificity (56.4%)) demonstrated a model of gradient boosting (Generalized Boosted Modeling, GBM). In the test sample, the AUC, sensitivity and specificity of the model in predicting EAS were 0.920; 77.8% and 97.1%, respectively.
Conclusion
The GBM machine learning algorithm is useful to differentiate patients with EAS and CD based on basic clinical results and can be recommended as primary screening of patients with ACTH-dependent hypercortisolism.

Use of artificial intelligence to predict survival of patients with acromegaly: is it really better?

Cem Sulu[1], Serdar Sahin[1], Hande Ozkaya[1] & Pinar Kadioglu[1]
[1]Cerrahpasa Medical Faculty Hospital, Turkey

Aim
To identify the causes and predictors of mortality in acromegaly patients diagnosed, treated, and followed in the Pituitary Center of Istanbul University-Cerrahpasa over the last three decades using machine learning (ML) models.
Methods
The study sample consisted of 607 consecutive patients diagnosed with acromegaly at Cerrahpasa Faculty of Medicine during the period 1990 – 2023. The main inclusion criteria were age $>$ 18 years and a clear-cut diagnosis of acromegaly according to standard criteria at the time of presentation. There were 556 alive patients (91.6%) and 51 deceased patients (8.4%), indicating a class imbalance. Synthetic Minority Over-sampling Technique (SMOTE) was applied due to imbalanced data. Minimum Redundancy Maximum Relevance (mRMR) and Recursive Feature Elimination (RFE) methods were used to select features. Logistic Regression, Random Forest, and XGBoost models were used to generate feature importance. The accuracy of the models were assessed through 4-fold cross validation and precision used as the performance metric. The importance of potential predictors were measured by SHAP values.
Results
Of 607 patients, 42% ($n=257$) were male. The median age at diagnosis and last visit were 40 [32–50] and 54 [45–64] years, respectively. The median follow up duration was 99 [40–150] months. Macroadenoma, cavernous invasion, and hypopituitarism was present in 66.9%, 8.5%, and 10.7% of the patients at diagnosis, respectively. Transsphenoidal surgery (TSS) was the initial treatment in 90.3% of the patients with a success of achieving remission in 28.7%. After TSS, 16.1% of patients received additional radiotherapy and 57.1% received postoperative drug treatment. Somatostatin receptor ligands (SLAR) was the most common drug and 36.1% of the patients were SLAR resistant. At last visit, 22% of the patients had active disease. Hypertension was the most common comorbidity (37.2%), followed by diabetes mellitus (36.4%), cardiovascular disease (CVD) (15.7%), colon polyps (12.2%), and malignancy (10%). Thyroid carcinoma was the most common malignity (5.03%), followed by gastrointestinal cancers (1.6%). The main cause of death was CVD (41.2%) and malignities (21.6%). XGBoost had the highest accuracy and precision scores. Top-ranked features in XGBoost model with decreasing importance were malignity and cardiovascular disease.
Conclusion
Malignity and cardiovascular diseases are important causes of morbidity and mortality in patients with acromegaly. ML models may a better understanding of patients' mortality risk, assisting healthcare professionals to tailor management strategies.

Introduction
Potent 11β-hydroxylase inhibitor osilodrostat provides cortisol level control in patients with Cushing's syndrome (CS), as demonstrated by the LINC clinical development programme in Cushing's disease (CD) patients.[1] We report data from year 1 of the prospective observational LINC6 study (NCT05382156), evaluating long-term safety and efficacy of osilodrostat in CS patients during 3 years of routine clinical practice.
Methods
Irrespective of prior osilodrostat use, adult patients with endogenous CS are being enrolled in countries where osilodrostat is approved and available (USA and Europe). Incidence of osilodrostat-related adverse events (AE) and serious AEs (SAE) is the primary endpoint. Secondary endpoints include change in mean urinary free cortisol (mUFC), serum cortisol and late-night salivary cortisol (LNSC). AEs are recorded at baseline and each visit. Outcomes were separately analysed in patients with prior (any time before study entry) and new osilodrostat use. We report changes for patients with baseline and month (M) 3 assessments. All assessments are descriptive.
Results
The safety population (received ≥ 1 osilodrostat dose) comprises 94/106 enrolled patients: CD, $n=78$; non-CD CS, $n=16$ (adrenal adenoma, $n=3$; adrenal hyperplasia, $n=3$; ectopic, $n=9$; other, $n=1$). For prior and new users, mean (SD) age was 53.0 (12.8), $n=71$ and 54.0 years (12.7), $n=23$, respectively; 73.2% and 60.9% were female; median (min–max) on-study osilodrostat exposure and dose were 6.0M (0.1–13.9) and 5.0 mg/day (1.0–60.0), and 2.7M (0.7–9.2) and 5.7 mg/day (2.0–50.0), respectively. Seven prior and five new users reported 33 and 11 treatment-related AEs, most commonly (>1 occurrence) acute adrenocortical insufficiency, diarrhoea, dizziness (each 3/33, 9.1%) and vomiting (2/33, 6.1%) in prior users, and vomiting (2/11, 18.2%) in new users. In both groups, most AEs were mild or moderate. Two patients discontinued because of five treatment-related AEs (worsening hypertension, uncontrolled blood pressure and dizziness, $n=1$, prior user; nausea and vomiting, $n=1$, new user). SAEs occurred infrequently, in 2.8% of prior ($n=2/71$) and 17.4% of new ($n=4/23$) users. At M3, mUFC, serum cortisol and LNSC were normalised in 72.7% ($n=8/11$), 70.0% ($n=14/20$) and 54.5% ($n=6/11$) of prior users, and in 66.7% ($n=2/3$), 66.7% ($n=4/6$) and 33.3% ($n=1/3$) of new users.

Conclusion
Building on Phase III trial evidence (LINC3, NCT02180217; LINC4, NCT02697734), preliminary results from real-world clinical settings show that osilodrostat is generally well-tolerated in endogenous CS patients and provides control of cortisol production in most prior and new osilodrostat users.

Beyond idiopathic arginine vasopressin deficiency: unveiling its etiology after over a decade

Patricia-Maria Anton[1], Serban Radian[1,2], Căpăţînă Cristina[1,2] & Cătălina Poiană[1,2]
[1]National Institute of Endocrinology 'CI Parhon', Pituitary and Neuroendocrine Disorders, Bucharest, Romania; [2]University of Medicine and Pharmacy 'Carol Davila', Bucharest, Romania

Introduction
Arginine vasopressin deficiency (AVP-D) is a rare disorder with diverse etiologies. Approximately 30% of cases are labelled idiopathic, often associated with an underlying autoimmune process. This case report presents a previously presumed idiopathic AVP-D, revealing its aetiology after more than a decade of follow-up.
Case presentation
A 19-year-old male presented in 2012 with symptoms of AVP-D and non-pruritic papular skin lesions on the limbs. Hormonal evaluation confirmed complete AVP-D, and Desmopressin treatment was started. Pituitary MRI revealed the absence of physiologic hyperintense signal of the posterior pituitary on T1-weighted images and a moderate pituitary stalk thickening (PST), with an anteroposterior diameter of 3 mm at the level of the optic chiasm and 2 mm at the pituitary gland insertion, along with a transverse diameter of 5.1 mm, exhibiting a round shape. Thoracic radiography showed normal findings. The dermatological evaluation considered both guttate psoriasis and pityriasis rosea Gilbert as possible diagnostics, and treatment with erythromycin and corticosteroids was recommended, with remission of the skin lesions. After two years of follow-up, hypogonadotropic hypogonadism developed (FSH < 0.2 mU/ml, LH = 0.84 mU/ml, Testosterone = 0.17 ng/ml), and testosterone substitution was given. Additionally, the IGF-1 levels were lower than the sex- and age-specific limits (IGF-1 = 89.2 ng/ml, RR 197-333). Serial pituitary MRIs indicated stable stalk thickness until 2022 when an increase was noted (transverse diameter 5.9 mm). In the same year, abdominal pain, cough and weight loss of 16 kg in 6 months led to the presumed diagnosis of sclerosing cholangitis (SCH) in the context of cystic fibrosis. SCH progressed to severe liver cirrhosis, necessitating transplantation. The patient received Tacrolimus 3 mg/day and oral Methylprednisolone 6 mg/day. Subsequently, considering the presumed diagnosis, a pulmonary consultation was performed, ruling out the diagnosis of cystic fibrosis. Nine months post-transplantation, endocrinological reassessment in the absence of testosterone substitution showed remission of hypogonadism (LH = 4.82 mU/ml, FSH = 2.63 mU/ml, Testosterone = 3.75 ng/ml). The coexistence of SCH, pulmonary cysts and AVP-D raised the suspicion of Langerhans cell histiocytosis (LCH), confirmed by immunohistochemistry on the hepatic specimen. The patient was referred to a haematologist for appropriate treatment.
Conclusion
Regular, long-term follow-ups for AVP-D and PST patients, assessing 'risk' organs, remain essential. A definitive diagnosis for biopsy-worthy conditions may enhance early detection and optimise care. The intriguing observation of hypogonadism reversibility prompts exploration of immunosuppression impact. Following LCH treatment, while diabetes insipidus is usually irreversible, a reduced desmopressin requirement can be anticipated.

Background
Growth hormone deficiency (GHD) in children comes in different etiologies and can be either isolated or combined with other pituitary hormone deficiencies. The diversity in GHD types and the variable duration of GH therapy complicate assessments of long-term treatment outcome. We characterized GHD patients at the end of GH therapy in Belgium and Luxemburg and evaluated height and adiposity outcomes in relation to GHD type.
Methods
Anthropometric and clinical characteristics of children with GHD who stopped GH therapy between January 2019 and December 2021 were retrieved from the binational BeLUX database (BELGROW).
Results
In total, 179 (119 male and 60 female) patients stopped GH therapy after a median (P10; P90) duration of 6.8 (2.6; 12.9) years. Eight patients received GH therapy for less than 2 years. In total, 113 (63 %) patients had isolated GHD and 66 (37%) combined GHD. Forty-five had congenital GHD (i.e., identified structural or genetic cause), 45 acquired and 89 (50%) idiopathic. All diagnostic categories showed male preponderance (>66 %). Isolated GHD was most prevalent in idiopathic GHD (93.3 % vs 44.2 % in congenital vs 22.2 % in acquired GHD). Ten patients stopped GH therapy before 13 years of age. Ninety -two male and 25 female patients stopped GH therapy after the age of 16 years at a mean (SD) height of 171.2 (7.3) cm and 159.5 (8.9) cm, respectively. Their mean (SD) height (-1.05 (1.0) vs -1.11 (1.48)) and BMI (0.06 (1.65) vs 0.18 (1.5)) z-scores were comparable. In this subgroup older than 16 years, the 66 patients with isolated GHD had significantly ($P = 0.016$) lower height z-scores than the 51 patients with combined GHD (-1.28(1.06) vs.-0.78 (1.13). Mean height and BMI z-scores at the end of GH therapy in patients > 16 years were similar between congenital ($n = 29$), acquired GHD ($n = 32$) and idiopathic GHD ($n = 56$), while mean duration of GH therapy was longest in congenital GHD (9.78 (4.3) vs 6.9 (3.8) vs 6.46(3.7) year; $P = 0.001$).
Conclusion
In GHD patients stopping GH therapy in BeLUx, we see a two-fold male preponderance and 1.7-fold preponderance of isolated GHD. Less than 6 % discontinue GH therapy before 13 years or receive less than 2 years of treatment. In those discontinuing GH therapy after 16 years of age, the height was superior in patients with combined GHD.

Differences in the efficacy of second-line therapies on the biochemical control of acromegaly in patients with GH secreting pituitary neuroendocrine tumors (Pit-NETs) and GH and PRL cosecreting Pit-NETs

Marta Araujo Castro[1], Almudena Vicente[2], Fernando Cordido[3], Edelmiro Luis Menendez Torre[4], Eider Pascual-Corrales[1], Eva Venegas Moreno[5], Rogelio García Centeno[6], Rocio Villar Taibo[7], Fernando Guerrero[8], Pablo Abellán Galiana[9], Felicia A Hanzu[10], Carmen Fajardo-Montañana[11], Cristina Novo[12], Rosa Camara[13], Maria Dolores Aviles Perez[14], Mónica Marazuela[15], Betina Biagetti[16] & Manel Puig-Domingo[17]
[1]Ramón y Cajal Hospital, Endocrinology & Nutrition, Madrid, Spain; [2]Hospital Universitario de Toledo, Endocrinology & Nutrition, Toledo, Spain; [3]Hospital Universitario de Coruña, Coruña, Spain; [4]Hospital Universitario Central de Asturias, Asturias, Spain; [5]Hospital Universitario Virgen del Rocío, Sevilla, Spain; [6]Hospital Gregorio Marañón, Madrid, Spain; [7]Hospital Santiago de Compostela, Spain; [8]Hospital Universitari de Bellvitge., Spain; [9]Hospital Universitario de Castellón, Spain; [10]Hospital Clinic de Barcelona, Spain; [11]Hospital Ribera, Spain; [12]Hospital Virgen de las Nieves, Spain; [13]Hospital Universitario La Fe, Spain; [14]Hospital Universitario San Cecilio., Spain; [15]Hospital Universitario la Princesa, Spain; [16]Hospital Universitario Vall d'Hebrón, Spain; [17]Hospital Germans Trias i Pujol, Spain

Aim
To evaluate the efficacy of second-line therapies in patients with acromegaly caused by a GH and PRL cosecreting pituitary neuroendocrine tumor (GH&PRL-Pit-NET) and those caused by a GH-Pit-NET.
Methods
A multicenter retrospective clinical practice study of 679 patients with acromegaly in follow-up in 33 tertiary hospitals (ACRO-SPAIN study). For this analysis, only patients on treatment with pasireotide or pegvisomant in monotherapy or in combination with other drugs were included ($n=150$; 22.1%). Patients were classified in two groups: GH-Pit-NET if PRL levels were normal ($n=122$) and GH&PRL-Pit-NET when evidence of hyperprolactinemia and immunohistochemistry (IHC) for GH and PRL was positive or if PRL levels were >100ng/dl regardless of the PRL IHC ($n=28$).
Results
A total of 150 patients with acromegaly accomplish the inclusion criteria. A total of 124 patients were treated with pegvisomant and 49 with pasireotide at any time **(Table 1).** The median time of treatment was of 30.8 months (IQR = 15.9-58.2) with pasireotide and 100 months (IQR = 34.4-138.5) with pegvisomant. No differences in IGF1 control with pasireotide neither with pegvisomant were observed between GH&PRL-Pit-NETs and GH-Pit-NETs **(Table 1).** All GH&PRL-Pit-NET cases treated with pasireotide ($n=6$) and 82.6% ($n=19/23$) of the cases treated with pegvisomant normalized PRL levels. No differences in the rate of IGF1 control between pegvisomant (in monotherapy or combined with dopamine agonists) vs pasireotide (in monotherapy or combined with dopamine agonists) were detected in patients with GH&PRL-Pit-NET (84.9% vs 66.7%, $P=0.178$). Neither in the rate of PRL control (80% vs 100%, $P=0.234$). **Table 1**. Differences in the acromegaly presentation and in the response to second-line medical therapies between GH-Pit-NETs and GH&PRL-Pit-NETs
Conclusion
GH&PRL-Pit-NETs are invasive tumors and present at a younger age than GH-Pit-NETs. However, no differences in the rate of IGF-1 biochemical control with second line therapies were observed between both groups.

Pituitary apoplexy during the SARS-CoV-2 pandemic. role of acute covid-19 and covid vaccination

Fanny Valsecchi[1,2], Alberto Vassallo[1,2], Marco Losa[3,4], Stefano Frara[1,2], Pietro Mortini[3,4] & Andrea Giustina[1,2]
[1]Vita-Salute San Raffaele University, Institute of Endocrine and Metabolic Sciences, Milan, Italy; [2]IRCCS Ospedale San Raffaele, Endocrinology Unit, Milan, Italy; [3]Vita-Salute San Raffaele University, Chair of Neurosurgery, Milan, Italy; [4]IRCCS Ospedale San Raffaele, Departments of Neurosurgery and Gamma Knife Radiosurgery, Milan, Italy

Background
Pituitary apoplexy (PA) is a rare endocrine and neurosurgical syndrome characterized by pituitary hemorrhage/infarction. SARS-CoV-2 infection and vaccination have been described as possible risk factors for PA, but the real impact of COVID-19 burden on PA epidemiology is still unknown.
Purpose
To investigate the incidence of PA in the pandemic period during exposure to SARS-CoV-2 infection and vaccination and possible peculiar clinical characteristics of COVID-related PA.
Methods
Of retrospectively evaluated 581 consecutive patients who underwent transsphenoidal surgery (TNS) at Neurosurgery Department of IRCCS San Raffaele Hospital between Jan 2017 and Dec 2022, 21 were diagnosed with PA. Patients were divided into pandemic (Jan2020-Dec2022) and pre-pandemic groups (Jan2017-Dec2019). Data on known risk factors for PA, clinical presentation signs/symptoms, radiological and pituitary hormonal status at inpatient evaluation and 6 months after surgery were collected. During the pandemic, a SARS-CoV-2 nasopharyngeal swab was obtained at hospital admission in all patients.
Results
Patients with PA had a mean age of 53.9 ± 14.8 years, a mean BMI of 26.6 ± 3.77 kg/m^2 and were more frequently males (14/21). Number of TNS procedures decreased by 16.7% from pre- to pandemic with similar incidence of PA (12 - 3.8%- vs 9 -3.4%-, respectively). Between the two groups, there were no differences among known risk factors for PA ($P=0.95$), clinical presentation ($P=0.82$), radiological ($P=0.128$) and hormonal ($P=0.21$) status at PA onset. Only pathophysiological difference was that in the pandemic group 3 patients (33%) were highly suspect for COVID-19-related PA: of them 1 experienced PA during hospitalization for SARS-CoV-2 pneumonia and 2 within 8 weeks after mRNA SARS-CoV-2 vaccination. Moreover, during pandemic a significantly better hormonal axes recovery (58.3% vs 22.2%, $P=0.002$) and also a trend toward a prompter neurological improvement at six-month follow-up ($P=0.091$) was observed.
Conclusion
Overall PA incidence was not increased during the SARS-CoV-2 period although data highlight that one third of the patients operated for PA during the pandemic had relevant COVID-19-related issues. This finding may represent paradigm shift in pathogenesis and clinical course of PA in pandemic era although data may be interpreted with caution possibly either overestimating (a casual association can not be excluded) or even underestimating (less severe cases may not be operated upon and shifted to conservative medical treatment) the impact of COVID-19 on PA. Multicenter collaborative studies enrolling a higher number of patients are needed to confirm our results.

Epidemiology of hypothalamic obesity in craniopharyngioma and other rare sellar and suprasellar tumors

Julian Witte[1], Bastian Surmann[1], Manuel Batram[1], Markus Weinert[1], Mathias Flume[2], Nicolas Touchot[3], Julia Beckhaus[4,5], Carsten Friedrich[4] & Hermann Müller[4]
[1]Vandage GmbH, Bielefeld, Germany; [2]Gene Access GmbH, Dortmund, Germany; [3]Rhythm Pharmaceuticals, Boston MA, United States; [4]University Children's Hospital, Carl von Ossietzky University Oldenburg, Klinikum Oldenburg AöR, Department of Pediatrics and Pediatric Hematology / Oncology, Oldenburg, Germany; [5]Carl von Ossietzky University Oldenburg, Division of Epidemiology and Biometry, Oldenburg, Germany

Background
Hypothalamic obesity (HO) is defined as abnormal weight gain resulting in severe persistent obesity due to physical, tumor- and/or treatment related damage of the hypothalamus. The HO epidemiology is poorly understood. We developed a database algorithm supporting the standardized identification of tumor/treatment-related HO (TTR-HO) patients.
Methods
The algorithm is used to estimate incidence rates of TTR-HO patients in the German healthcare context from a representative claims database ($n=5.42$ million) covering 2010-2020. Patients were identified based on surgery/radiotherapy procedures and HO-associated tumor diagnoses ($n=3,976$). TTR-HO was defined by incident obesity and validated based on incident diabetes insipidus diagnosis and desmopressin prescription within a twelve-month period after surgery/radiotherapy. Uncertainty due to algorithm definitions is explored in sensitivity analyses.

Abstract 524

Table 1. Differences in the acromegaly presentation and in the response to second-line medical therapies between GH-Pit-NETs and GH&PRL-Pit-NETs

	GH-Pit-NET ($n=122$)	GH&PRL-Pit-NET ($n=28$)	P value
CLINICO-RADIOLOGICAL DATA AT ACROMEGALy DIAGNOSIS			
Age (years)	46.2±16.03	38.0±13.77	0.017
Knosp>2 ($n=118$)	51.7% ($n=47/91$)	74.1% ($n=20/27$)	0.039
EFFICACy OF SECOND-LINE MEDICAL THERAPIES (IGF normalization)			
Pasireotide monotherapy or combined with DA ($n=43$)	66.7% ($n=24/36$)	71.4% ($n=5/7$)	0.806
Pasireotide monotherapy ($n=24$)	69.6% ($n=16/23$)	100% ($n=1$)	0.512
Pasireotide+DA	61.5% ($n=8/13$)	66.7% ($n=4/6$)	0.829
Pegvisomant monotherapy or combined with DA/f-SRL ($n=118$)	84.4% ($n=81/96$)	77.3% ($n=17/22$)	0.423
Pegvisomant monotherapy ($n=45$)	85.7% ($n=30/35$)	80% ($n=8/10$)	0.660
Pegvisomant+f-SRL ($n=43$)	79.5% ($n=31/39$)	100% ($n=4$)	0.315
Pegvisomant+DA ($n=20$)	86.7% ($n=13/15$)	60% ($n=3/5$)	0.197
Pegvisomant+pasireotide ($n=6$)	40% ($n=2/5$)	100% ($n=1$)	0.273

DA = dopamine agonists; f-SRL = first generation somatostatin receptor ligands

Results
Estimated annual incidence of TTR-HO in Germany is between 0.7 and 1.7 cases per 1,000,000 persons (2019 prevalence: $n=1,262$ patients). With observed cases in all age groups, two HO-incidence peaks are identified: children/young adults aged 10-14 years and adults aged 40-44 years. Most frequent HO-validated tumor diagnoses are benign sellar/suprasellar tumors (6.1/1,000,000 persons over nine-years), including tumors of the craniopharyngeal duct (3.1/1,000,000), neoplasms of the pituitary gland (4.1/1,000,000), and nonspecific brain tumors of endocrine glands (2.4/1,000,000).
Conclusion
This is the first real-world database analysis of TTR-HO epidemiology, refining current estimates of HO-epidemiology and early patient identification. A more comprehensive characterization of HO patients, along with a better understanding of its clinical implications, will be crucial in developing optimal treatment strategies to improve patient outcomes.

Soluble alpha klotho concentrations are resistant to short-term stimulation and suppression of growth hormone

Junia Ribeiro de Oliveira Longo Schweizer[1], Katharina Schilbach[1], Olivia Tausendfreund[1], Michael Haenelt[1], Anica Gagliardo[1], Jochen Schopohl[1], Michael Drey[1] & Martin Bidlingmaier[1]
[1]Ludwig Maximilians University, LMU Klinikum; Med. Klinik und Poliklinik IV, München

Background
Serum soluble alpha klotho (sαKL) is a circulating protein which had been shown to be very high in active acromegaly, and significantly reduced after disease control. Therefore, sαKL has been suggested as a new biomarker for growth hormone (GH) excess. In this study, we aimed to evaluate the impact of short-term stimulation and suppression of GH and acute modulation of glucose metabolism on sαKL concentrations.
Methods
Serum sαKL was measured by ELISA (IBL, Hamburg, Germany). Samples were collected during GHRH-Arginine test (0, 30, 60, 90 and 120 min.) in geriatric patients without GH deficiency ($n=9$, 72-94 years, 5 males) and in a cohort of patients with proven GH deficiency (GHD, $n=10$, 22-71years, 5 males). We also evaluated sαKL in healthy participants ($n=22$, aged 22-52 year, 8 males) during oral glucose tolerance test (OGTT: 0,30,60,90,120 and 180 min.).
Results
As expected, GH concentrations (mean ± SD, ng/dl) significantly increased during GHRH-Arginine test in participants without GHD (baseline: 0.78 ± 0.48 vs $_{peak}$GH: 14.7 ± 7.8, $P<0.05$) but not in patients with GHD (baseline: 0.36 ± 0.5 vs $_{peak}$GH: 1.26 ± 1.1, $p>0.05$). Neither in aged patients without GHD (baseline sαKL: 668 ± 174 vs $_{120min}$sαKL: 654 ± 168, $p>0.05$) nor in patients with GHD (baseline: 831 ± 221 vs $_{120min}$sαKL:827 ± 271, $p>0.05$) sαKL concentrations (mean ± SD, pg/ml) varied significantly during GHRH-Arginine test. During OGTT, GH concentrations decreased, and glucose and insulin increased, but sαKL concentrations did not change significantly ($p>0.05$ for all comparisons).
Conclusion
In contrast to chronic GH excess in acromegaly, sαKL concentrations are not significantly affected by short-term stimulation and suppression of GH. Furthermore, acute elevation of glucose and insulin do not significantly impact sαKL concentrations in healthy subjects.

Aim
To investigate the impact of pituitary surgery on glucose metabolism and to identify predictors of diabetes remission after surgery in patients with acromegaly.
Methods
A national multicenter retrospective study of acromegaly patients undergoing transsphenoidal surgery for the first time at 33 tertiary Spanish hospitals (ACRO-SPAIN study, $n=604$) was performed. Surgical remission was evaluated according to the 2000 and 2010 criteria. Glucose metabolism and metabolic control were evaluated before, within 3 months after surgery and at the long-term follow up (last available visit).
Results
A total of 604 acromegaly patients were included in the study with a median follow up of 91 months (IQR 45-163). The mean age was 47.8 ± 14.0 years and 58.9% ($n=356$) were women. At baseline, 23.8% of the patients had type 2 diabetes mellitus (T2DM) with a median of glycated hemoglobin (HbA1c) levels of 6.9% (IQR 6.4-7.9) and of fasting plasma glucose (FPG) levels of 143 mg/dl (IQR 124-169). We observed a positive correlation between IGF-1 levels at acromegaly diagnosis and FPG($r=0.16$, $P<0.001$) and HbA1c($r=0.18$, $P=0.001$) levels. No correlation between initial GH levels and FPG or HbA1c levels was found. In the multivariate analysis, an older age(OR 1.02 per each in increase in year, 95%CI 1.00-1.05), having dyslipidemia(OR 5.26, 95%CI 2.82-9.79) and higher IGF-1 levels (OR 1.30 per each increase in standard deviation above the upper limit of normal, 95%CI 1.05-1.60) were associated with a greater prevalence of T2DM. At the last follow-up visit after surgery, 53.4% of the patients achieved surgical remission based on the Cortina criteria and 41.4% based on the 2010 criteria. A significant improvement in FPG and HbA1c levels was observed in the global cohort, being greater in the group of T2DM patients($P<0.001$). No differences in the rate of reduction of HbA1c or FPG levels were observed between patients pretreated and not pretreated with first generation somatostatin receptor ligands; neither between patients cured of acromegaly after surgery and those who did not. After surgery, 21.3% of the T2DM patients, 56.7% of them with surgical remission of acromegaly(2010criteria), experienced diabetes remission. The cure of T2DM was more common in older patients(HR 1.77), when surgical cure was achieved(HR 2.10) and when anterior pituitary function was not affected after surgery(HR 3.38).
Conclusion
Glucose metabolism improved in patients with acromegaly after surgery, especially in T2DM patients. The remission of T2DM was more frequent in patients with older age, with surgical cure and preserved anterior pituitary function after surgery.

A peculiar case of ectopic ACTH-syndrome – multiple challenges during diagnostic and therapeutic workup

Annamária Kövesdi[1,2], Judit Tőke[1,3], Katalin Eitler[1,4], Gergely Kiss[1,5], Nóra Nyilas[1,6], Bálint Scheich[1,7] & Miklós Tóth[1,8]

Case description
A 32-year-old male patient was treated with remdesivir and high-dose steroid for severe COVID-19 pneumonia in an ICU for one month. He was later diagnosed with steroid-induced diabetes mellitus. An endocrinological consultation raised the possibility of endogenous Cushing's syndrome. He was then referred to our department for further investigation of suspected Cushing's syndrome (CS). The patient presented with typical physical signs and symptoms of CS. Severe ACTH-dependent hypercortisolism was diagnosed. The high dose dexamethasone test, the marked ACTH response to iv. desmopressin and a pituitary microadenoma revealed by MRI suggested Cushing's disease. However, chest CT showed a 1 cm mass compatible with a pulmonary NET in the left S7. In the first phase of investigations, the origin of the ACTH-dependent CS was equivocal. All of the non-invasive tests argued for the pituitary source of ACTH excess. Because of the high radiological suspicion of pulmonary NET, and despite the results of the traditional hormone tests, both our pituitary and pulmonary boards suggested pulmonary surgery as a first-line intervention. Thus, a segmentectomy was performed; histology confirmed a typical bronchial carcinoid with intense ACTH expression. Postoperatively, persisting hypercortisolism was proved, necessitating an inferior petrosal sinus sampling (IPSS). IPSS excluded CD and unambiguously confirmed the ectopic nature of ACTH secretion. Unfortunately, all the postoperative imaging modalities, including ^{18}FDG-PET-CT and Tc-99m-Tektrotyd SPECT/CT, were negative, suggesting an occult residual metastatic tumour. ^{68}Ga-DOTATOC-PET-CT was suggested; however, the patient could not afford it. Metyrapone, followed by osilodrostate, was started. Severe resistant hypercortisolism persisted, leading to pathological vertebral compression fractures, despite 6 months of treatment with osilodrostate in a daily doses of up to 2x15 mg. However, no metastatic lesion could be identified. We decided to perform a bilateral total adrenalectomy, which resulted in a prompt resolution of hypercortisolism. The localization of suspected metastatic tumour(s) is still uncovered.

The analgesic effect of pasireotide in aggressive, giant pituitary neuroendocrine tumors-case series

Karol Ciszek[1], Anna Bogusławska[1], Maria Aleksandra Komisarz-Calik[1], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]
[1]Chair and Department of Endocrinology, Jagiellonian University, Medical College, Cracow, Poland

Pasireotide is a a synthetic polypeptide second-generation somatostatin analogue that can be used in the treatment of GH- and ACTH- secreting pituitary neuroendocrine tumors (PitNETs), however, there are single reports of pasireotide treatment in other subtype of PitNETs. We present a case series of aggressive, giant PitNETs treated with pasireotide alone or as multimodal therapy.
Case 1
A 33-year-old male reported to the Clinic due to severe headaches and vomiting. In MRI pituitary mass 33×39×55 mm and a cerebral oedema were revealed. TSS with external ventricular drainage were performed. Histopathology results showed densely granulated silent corticotroph adenoma subtype 1, Ki67 < 1%. After 3 months, MRI showed tumour progression to 39×40×30 mm. Two emergency TSS followed by stereotactic radiotherapy were performed. Combined therapy with cabergoline and temozolomide was introduced. Due to sever headaches pasireotide was introduced. After 18 months, stabilization of the disease was observed with complete remission of headaches.
Case 2
A 59-year-old male underwent transsphenoidal surgery (TSS) ten years ago due to severe headaches and visual deficits. Histopathology results showed partially acidophilic adenoma (FSH- LH- GH- ACTH- PRL-). Control MRI showed tumour regrowth - 56×56×89 mm mass invading local structures. The patient was qualified for radiotherapy, to which he did not consent. Due to the progression of symptoms, temozolomide and pasireotide were introduced. After 5 months, significant improvement in headaches and vision was observed. In MRI stable pituitary mass was noted.
Case 3
A 59-year-old male presented with severe headaches and life-threatening tumour mass effect. In MRI a 48x48x33mm mass was observed. The patient underwent two non-radical TSS, 4 cycles of pasireotide, and cyberknife treatment. Histopathology showed gonadotroph PitNET, Ki < 67%. MRI showed tumour shrinkage to 45×46×29 mm, with persistent severe headaches. The patient was re-qualified for pasireotide treatment.
Case 4
A 17-year-old male with dopamine resistant giant prolactinoma underwent after recent two non-radical surgeries presented in the clinic due to daily severe headaches and peripheral vision loss. In control MRIs progressing mass 38×34×33 mm invading local structures was observed. Due to worsening of the symptoms, pasireotide was introduced resulting in a decrease of headaches and improvement in vision. The tumour size remained stationary.
Conclusion
Our study demonstrates the clinical potential and the efficacy of pasireotide treatment in aggressive, giant PitNETs. The therapy alone, or in combination has a potential role to reduce the tumour size, decrease the headaches, and allows the stabilization of the disease.

Potential antitumoral effects through modulation of VEGF-A splicing in rat somatotroph and lactotroph pituitary tumoral cells

Donatella Treppiedi[1], Sonia Di Bari[2], Federica Mangili[1], Giusy Marra[2], Anna Maria Barbieri[2], Federico Arlati[2], Marco Locatelli[3,4], Andrea Lania[5,6], Erika Peverelli[1,2] & Giovanna Mantovani[1,2]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [3]University of Milan, Department of Pathophysiology and Transplantation, Milan, Italy; [4]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Neurosurgery Unit, Milan, Italy; [5]IRCCS Humanitas Research Hospital, Endocrinology, Diabetology and Medical Andrology Unit, Milan, Italy; [6]Humanitas University, Department of Biomedical Sciences, Milan, Italy

Alternative splicing is a crucial mechanism of gene regulation and this process can be dysregulated in cancer. In pituitary tumors (PitNETs), alteration in the serine/arginine-rich splicing factors (SRSFs) has been reported. Newly synthetized SRSFs are phosphorylated by serine-arginine protein kinase 1 (SRPK1) to facilitate their nuclear import. In response to extracellular stimuli SRPK1 may translocate to the nucleus as well to hyperphosphorylate SRSFs and favor their interaction with mRNA and the initiation of alternative splicing. SRPK1 is considered a proto-oncogene and its inhibition by small molecule inhibitors have shown antitumoral effects via the SRPK1-SRSF1-VEGF-A pathway modulation in different cancer types, however, so far, no studies have been carried out in the pituitary. This project aims to explore the role of SRPK1 inhibitors SRPIN340 and SPHINX31 in pituitary somato-lactotroph tumoral cells (GH4 and MMQ cells) by looking at the VEGF-A alternative splicing regulation, and to investigate SRPK1 protein expression levels in GH-secreting PitNETs. First, an abolishment of the EGF-mediated SRPK1 nuclear translocation in GH4 cells upon 10μM SRPIN340 incubation was observed by immunofluorescence experiments. This data, along with immunoblot results showing a reduction of phosphorylation of SRSFs induced by SRPIN340 and SPHINX31, demonstrated the efficacy of these compounds in impairing SRPK1 activity. SRPIN340 reduced cell proliferation (-38.9(43.9)%, p $0 < 0.05$ vs basal at 1μM), cell migration (-65(46.3)%, $P < 0.001$ vs basal at 10μM) and induced cell apoptosis (+40.5(26.6)%, $P < 0.05$ vs basal at 10 μM), in GH4 cells. Similar results were obtained in MMQ cells and comparable effects between SRPIN340 and SPHINX31 were observed in both cell lines. Moreover, both SRPIN340 and SPHINX31 reduced PRL secretion in MMQ cells (-30.2(49)% $P < 0.05$ vs basal, -39.2(18)% $P < 0.001$ vs basal, at 10μM SRPIN340- and SPHINX31-treated cells, respectively). In addition, the pro-angiogenic and pro-mitotic VEGF-A_{164a} transcript isoform was significantly decreased by both inhibitors in GH4 cells (-61(33.5)% $P < 0.05$ vs basal, -55(20.5)% $P < 0.05$ vs basal, in SRPIN340- and SPHINX31-treated cells, respectively). Finally, SRPK1 was expressed at variable levels in 14 GH-secreting PitNETs. Interestingly, an overexpression of SRPK1 was found in GH-secreting PitNETs tissues whose corresponding primary cultures were *in vitro* resistant to octreotide in terms of GH suppression (0.09(0.31) vs 0.02(0.03), $P < 0.05$ vs *in vitro* responder group). In conclusion, SRPK1 inhibition may represent a novel strategy to exert antitumoral effects in

somato-lactotroph tumoral cells via SRPK1-SRSF1-VEGF-A pathway regulation. Further studies are needed to investigate the role of SRPK1 as a potential marker of octreotide responsiveness in GH-secreting PitNETs.

Electronic health technologies for comprehensive acromegaly management. preliminary data from a single center experience

Giulia Carosi[1], Giulia Del Sindaco[1,2], Elisa Sala[1], Alessandra Mangone[1,2], Roberta Mungari[1], Arianna Cremaschi[1], Emanuele Ferrante[1] & Giovanna Mantovani[1,2]
[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

Background
Acromegaly is a chronic disease which causes multiple impairments that negatively affect daily life. Telemedicine is proving to be useful in diagnosing and treating these disabling aspects, including psycho-physical comorbidities, which are difficult to investigate during conventional visits.
Aim of the study
To improve the management of acromegaly, both in cured and active disease, through the use of telemedicine technologies in addition to conventional visits, tailoring individual healthcare pathways.
Methods
We conducted a prospective study in patients with a diagnosis of acromegaly. We randomly assigned to participants a web-based email system (electronic Health Device group or 'eHD group'). For 12 months, this group received periodic questionnaires that explored different areas such as adherence to therapy, quality of life, psychological and disease-specific symptoms (e.g. Acromegaly Quality of Life Questionnaire 'AcroQoL', Epworth Sleepiness Scale 'ESS', Beck-Depression-Inventory-II 'BDI-II'). Additionally, all patients underwent conventional on-site clinical assessments. Data collected were stored on a dedicated portal and statistically analysed.
Results
We enrolled 60 acromegalic patients (50% in the eHD group and 50% controls), 50/60 completed the study. Females were 56% and mean age was 59.6 years. Sex distribution and age were comparable in the two groups. Patients in the eHD group actively answered questionnaires for a mean time of 4 months (range = 2-11), with higher compliance for monthly and trimestral questionnaires as compared to weekly ones (adherence of 91%, 88%, and 64%, respectively). Periodical questionnaires in eHD group revealed that some patients experienced severe clinical deterioration, which required specialist consultation during the study (e.g. BDI-II results showed that two patients experienced severe depression and two patients suffered from obstructive sleep apnea according to ESS results). At baseline, 70% of the participants were on medical treatment for acromegaly (pegvisomant or somatostatin analogues) and 30% were on remission. At the end of the study, biochemical disease control improved in 20% of the eHD group vs 8% of controls ($P = 0.42$). A worsening was observed in 8% of participants in the control group only ($P = 0.53$) and disease was stable in the remaining patients. Data collected from the eHD group showed a high adherence to medical therapy for acromegaly (95%, both with pegvisomant and somatostatin analogues).
Conclusion
our preliminary data indicates that telemedicine may be used to monitor and manage symptoms, personalize follow-up, and promote treatment compliance, thereby improving the clinical management of acromegaly.

The relations between serum growth hormone, seminal plasma growth hormone, and sperm count in acromegaly patients

Ebru Cicek[1], Cem Sulu[1], Serdar Sahin[1], Hamdi Ozkara[1], Hande Ozkaya[1], Rosario Pivonello[2] & Pinar Kadioglu[1]
[1]Cerrahpasa Medical Faculty Hospital, Turkey; [2]University of Naples Federico II, Napoli, Italy

Aim
To investigate the relationship between serum growth hormone (GH) and insulin-like growth factor-1 (IGF-1) levels, seminal plasma GH and IGF-1 levels, and sperm parameters in acromegalic patients.
Methods
A cross-sectional study was conducted on 24 acromegaly patients (acromegaly group), 11 non-functioning adenoma (NFA) patients (NFA group), and 16 healthy men (control group). Seminal plasma GH and IGF-1 levels were measured. Semen parameters and seminal plasma hormone levels were compared. Mediation analysis using SPSS PROCESS macro was performed to evaluate the relations between serum and seminal plasma GH/IGF-1 levels and sperm parameters.
Results
Acromegaly group had higher levels of serum GH (0.475 IQR[0.245 -0.770] mg/l) compared to NFA (0.08 IQR[0.054 - 0.260] mg/l) and control groups (0.08 IQR[0.03 - 0.159] mg/l) ($P < 0.001$). Although seminal plasma GH levels were higher in acromegaly group (114 $\pm$ 82 pg/ml) than NFA (43 $\pm$ 19 pg/ml) and control groups (61 $\pm$ 39 pg/ml) ($P = 0.004$), seminal plasma IGF-1 showed no difference among groups ($P = 0.203$). The serum GH was positively correlated with seminal plasma GH ($r = 0.530$, $P < 0.001$). The mediation analyses showed that serum GH directly affected sperm count ($\beta = 80.2$, $P = 0.0026$), and this effect was not mediated by an increase in seminal plasma GH ($\beta = 0.06$, $P = 0.720$).
Conclusion
The findings of this study suggest that sperm count may be negatively affected in acromegalic patients despite intact hypothalamic-pituitary-gonadal axis, and this association could be linked to elevated serum GH levels rather than increased seminal plasma GH. While our study provided important preliminary data regarding the seminal plasma GH and IGF-1 levels, the underlying the specific effects of seminal plasma GH and IGF-1 on testicular function of acromegaly patients require more in-depth research.

Implications of somatotroph axis in the behaviour of silent corticotroph tumours

Cristina Guillen[1,2,3], Johana Sottile[1], Elena García-Garrigós[1,2,2,4], Maria Eugenia Torregrosa[1,2,5], Maria Niveiro[1,2,6], Javier Abarca[1,2,7], Luis Valor[1] & Antonio Pico[1,2,3,8,9]
[1]Instituto de Investigación Sanitaria y Biomédica de Alicante (Isabial), Endocrinology & Nutrition, Alicante, Spain; [2]Hospital General Universitario Dr. Balmis, Radiology; [3], Endocrinology & Nutrition; [4], Radiology; [5], Clinical Analysis-Hormones; [6], Pathology; [7], Neurosurgery; [8]University Miguel Hernandez, Clinical Medicine, Alicante; [9]Ciberer, Neuroendocrinology

Silent corticotroph tumors (SCT) represent a distinct subtype of pituitary tumors (PT) known for their potential aggressiveness, surpassing other silent PTs like gonadotroph tumors (SGT). Despite their aggressive clinical behavior, the mechanisms underlying their aggressiveness remain unclear. Recent studies in various cancers, such as breast cancer, have implicated the IGF1 axis in the presence of metastases. This study aims to investigate some components of the somatotroph axis in a cohort of 31 SCTs and a control group of 67 SGTs, all monitored in a PTOCE since 2012. Demographic, biochemical, and radiological variables were analyzed, alongside the expression (quantitative PCR) of GH, GHRH, and somatostatin subtype receptors ($sst_{1,2,3,5}$). Results showed that SCT patients were predominantly women and younger compared to SGT patients. While tumor size and invasion percentages showed no significant differences between groups, SCTs exhibited a significantly higher Signal Intensity Ratio (SIR) and increased proliferation (Ki67 qPCR), along with a higher recurrence rate than SGTs. Cortisol levels were comparable, but SCTs displayed significantly elevated levels of ACTH and, notably, IGF1 compared to SGTs. SCTs had significantly higher expression of sst2, and lower expression of sst3, with no significant differences in the expression of GH, GHRH, and $sst_{1,5}$ between the two groups. In conclusion. Elevated levels of ACTH and IGF1 in SCTs underscore the intricate interplay between the somatotroph and corticotroph axes. These findings suggest a potential crosstalk mechanism that contributes to the unique characteristics of SCTs, influencing their aggressiveness and clinical course and offering a more tailored and effective therapeutic approach

Assessment of endothelial dysfunction in cushings syndrome

Tugce Apaydin[1], Ceyda Dinçer yazan[2] & Dilek Gogas yavuz[2]
[1]Alanya Alaaddin Keykubat University Training Hospital, Endocrinology and Metabolism, Antalya, Turkey; [2]Marmara University Faculty of Medicine, Endocrinology and Metabolism, Istanbul, Turkey

Introduction
Cushingˋs Syndrome (CS) is associated with endothelial dysfunction and premature atherosclerosis, which occurs due to hypercortisolism itself and associated comorbidities including diabetes and hypertension. Advanced glycation end products (AGE) are heterogeneous compounds produced endogenously from the non-enzymatic glycation of proteins, lipids, and nucleic acids, leading to the activation of various stress-induced transcription factors through the stimulation of oxidative stress, and pro-inflammatory mediators such as cytokines and acute phase proteins, and consequently causes vascular dysfunction. Cardiovascular disease is the main cause of mortality in subjects with CS, and endothelial dysfunction is an early parameter for cardiovascular risk. With the hypothesis that hypercortisolemia in CS may itself lead to endothelial dysfunction by increasing AGE production, we aimed to evaluate microvascular function in CS with carotid intima-media thickness (CIMT) and to investigate the relationship between endothelial dysfunction and AGE.
Methods
Forty patients with active CS and 56 age- and sex-matched subjects without known inflammatory disease were enrolled in this cross-sectional study. Measurement of CIMT was performed by a single blind vascular sonographer using Doppler USG. Serum AGE and carboxymethyl lysine (CML) levels were measured by ELISA.
Results
Age, gender, BMI, the frequency of diabetes mellitus and hypertension were similar in the CS and control groups. While 65% of cases had pituitary Cushingˋs disease ($n=26$), the remaining 14 cases were adrenal CS (35%). CIMT was higher in CS than in the control group (0.615 ± 0.076 mm vs 0.517 ± 0.152 mm; $P<0.001$), but CML and AGE levels were similar in both groups ($p>0.05$). After adjustment for diabetes and hypertension, CIMT was still higher in CS but there were no significant differences between the CS and control groups in terms of CML and AGE levels ($p>0.05$). According to univariate regression analysis, there was no statistically significant association between CIMT and CML, AGE levels.
Discussion
CIMT, an early predictor of subsequent cardiovascular events or mortality, was increased in subjects with CS. Large-scale studies are needed to make definite conclusions about the effect of AGE levels on CIMT.

Prevalence of steatosis and cardio-metabolic complications in a cohort of adult patients with growth hormone deficiency: a cross-sectional study

Alessandro Risio[1], Eriselda Profka[1,2], Giulia Rodari[1,2], Giovanna Oberti[3], valeria citterio[1], Valentina Collini[1], Federico Giacchetti[2], Anna Ludovica Fracanzani[3,4], Rosa Lombardi[3,4], Giovanna Mantovani[1,2] & Claudia Giavoli[1,2]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Unit of Internal Medicine and Metabolic Diseases, Milan; [4]University of Milan, Department of Pathophysiology and Transplantation, Milan

Introduction
Adults with growth hormone deficiency (AGHD) have increased prevalence of hepatic steatosis (HS) that might be improved by growth hormone replacement therapy (rhGH). However, data on this topic are conflincting and scanty. Aim: to evaluate prevalence of HS, organ-specific distribution of adipose tissue and cardiovascular impairment in AGHD.
Methods
cross-sectional collection of clinical, biochemical and instrumental data (abdominal ultrasound, fibroscan, assessment of epicardial fat, supra-aortic trunks ultrasound and body composition through bio impedence) in AGHD.
Results
Fifty subjects (M/F 25/25, median age 54.5 years, IQR 46-65, median disease duration 14 years, IQR 9-21 years) were consecutively enrolled. Among them, 32/50 patients were currently on rhGH (median dose 2.4 mg/week, IQR 1.2-5.2, duration 15.6 ± 8.2 years). In the whole cohort, 37/50 patients showed HS (74% vs around 20% in the worldwide general population), with 38% prevalence of moderate and severe forms and 6% of hepatic fibrosis. The prevalence of carotid plaques was 32% and of increased epicardial fat was 27.7%. Prevalence of hypertransaminasemia was higher in untreated than treated AGHD (27.8% vs 3.2%, $P=0.02$). Although not statistically significant, possibly due to sample size, untreated patients showed higher prevalence of steatosis (15/18, 83% vs 22/32, 69%), cardiovascular events (4/18, 22.2% vs 1/32, 3.1%), increased epicardial fat (41.2% vs 20%), and carotid plaques (44% vs 25%) than treated ones, with a negative association between rhGH dose and intima-media thickness ($P=0.02$). No difference was found in median age ($P=0.27$) an sex ($P=0.56$) between the two groups. Lastly, AGHD with HS were compared to a cohort of 42 patients with non-alcoholic fatty liver disease (NAFLD). Despite a similar prevalence of hypertension, atherosclerosis and dyslipidemia, AGHD showed lower fat mass (33.2%, IQR 25.2-38.5% vs 40.2%, IQR 35.7-45.6, $P<0.001$) and lower prevalence of metabolic syndrome (36.1% vs 66.7%, $P=0.01$) and diabetes (5.4% vs 23.8%, $P=0.02$). Interestingly, AGHD were younger than NAFLD patients (53.4 ± 15.8 years vs 64.5 ± 12.2 years, $P=0.001$).
Conclusion
HS, carotid atherosclerosis and increased epicardial fat are highly prevalent in AGHD. When compared with NAFLD patients, AGHD with HS, though younger and with lower percentage of fat mass and metabolic syndrome, showed a similar prevalence of hypertension, atherosclerosis and dyslipidemia. These findings suggest a pathogenetic role of GHD in the development of metabolic complications, while the higher prevalence of hepatic derangement in untreated AGHD supports a possible impact of rhGH. We ought to confirm our findings by comparing them with age and sex- matched NAFLD patients.

Panhypopituitarism and diabetes mellitus in a woman with HIST1H1E syndrome

carlien de herdt[1] & De Block Christophe[1]
[1]Antwerp University Hospital, Endocrinology, diabetology and metabolism, Edegem, Belgium

Introduction
HIST1H1E syndrome is a rare disorder caused by a de novo gene mutation encoding for histone H1-4 affecting a whole range of cellular processes. The phenotype is dominated by neurodevelopment disorders and facial deformities. Endocrinopathies and diabetes mellitus are not the main clinical features. The case of a woman with HIST1H1E syndrome associated with diabetes mellitus and panhypopituitarism is presented.
Case presentation
A 19-year-old woman was referred to the endocrinology department because of primary amenorrhea and absence of secondary sexual characteristics. At the age of 12 years she was diagnosed with HIST1H1E syndrome. Growth curve was not available and height at the moment of consultation was 156 cm and BMI 20 kg/m^2. Pituitary function revealed central hypothyroidism, hypogonadotropic hypogonadism and low IGF-1. GH deficiency was confirmed with an insulin tolerance test. Cortisol deficiency was excluded and there were no arguments for AVP deficiency. Reviewing a blood sample at the age of 9 years, a normal thyrotropic axis was measured. MRI of the pituitary was normal. X-ray of the hand showed an almost closed growth plate. Bone density showed osteoporosis. The blood sample showed hyperglycaemia with an HbA1c of 13.9% (128 mmol/mol) and low c-peptide (0.08 nmol/l). Insulin therapy was started.
Conclusion
HIST1H1E syndrome is rare as only 52 cases have been described in the literature. Endocrinopathies are rarely associated with this syndrome as only 6 previous cases had hypothyroidism. In 2023 the first case of a young girl with HIST1H1E syndrome and short stature due to panhypopituitarism (TSH, LH/FSH, GH deficiency) was published. MRI showed a hypoplastic pituitary gland. We present the second case of a woman with panhypopituitarism (TSH, LH/FSH, growth hormone deficiency), associated with HIST1H1E syndrome after presenting with primary amenorrhea. Corticotropic axis is preserved in both cases. We hypothesize the dysfunctional histones lead to a PROP1-related combined pituitary hormone deficiency. However, it is unclear why the other published cases did not show hypopituitarism except for these cases concern children and pituitary deficiency may not have already developed. Diabetes mellitus type 2 has previously been described in only one 19-year-old woman with HIST1H1E syndrome. Our case has an impaired insulin secretion questioning the possible association of the pathogenic histone variants with loss of β cell function. Given the rareness of this syndrome, it is however uncertain if clinical features as hypopituitarism and diabetes mellitus are related to the dysfunctional histones or are incidental findings.

Patient with granulomatous hypophysitis in the course of granulomatosis with polyangiitis (GPA) misdiagnosed as craniopharyngioma

Monika Piasecka[1], Anna Lewczuk-Myślicka[1], Łukasz Obołończyk[2], Sonia Kaniuka-Jakubowska[1] & Renata Świątkowska-Stodulska[1]
[1]Medical University of Gdansk, Department of Endocrinology and Internal Medicine, Gdansk, Poland; [2]Institute of Maritime and Tropical Medicine, Medical University of Gdansk, Depatrment of Occupational, Metabolic and Internal Medicine, Gdynia, Poland

Introduction
Idiopathic granulomatous hypophysitis (IGH) is a rare inflammatory disease that may present with radiological changes in the pituitary gland. Diagnosis with non-specific syndromes becomes challenging. Secondary causes of granulomatous hypophysitis include tuberculosis, sarcoidosis, syphilis, Langerhans cell histiocytosis, GPA, and Rathke's cleft cyst rupture. GPA is a multisystem disease, characterized by necrotizing small-vessel vasculitis, mostly affecting the lung, kidneys, ears, nose, and throat, but potentially it can involve any organs. Pituitary involvement in GPA is rare, estimated occurrence is about 1 % of all cases.
Case description
The history of the 18-year-old woman began a few months before admitting to our Department, with a throbbing headache and dropping the right eyelid. Her CT revealed no pathology, however in head MR the sellar mass (12x14x14mm) was described. Additionally, mucosal changes filling almost completely the left maxillary sinus and the ethmoid on the left side were found. The lesion was described as craniopharyngioma. Four months later pituitary MR demonstrated a sellar lesion ($17\times21\times11$ mm) with compression of the optic chiasm. The pituitary gland could not be delineated in the sellar region. Mucosal thickening was observed in all sinuses. It has been described again as intrasellar and suprasellar mass which might correspond to a craniopharyngioma. Additional tests revealed high antinuclear antibodies ANA titer, positive anti-RNP/Sm antibodies, and antibodies against B centromeres and DFS 70. Due to the positive result of the Schrimer test, the suspicion of Sjögren's syndrome was raised. During the next month, the patient's clinical status deteriorated. She reported fever, fatigue, and headache, along with nausea and vomiting, occurring mostly in the morning. She underwent transsphenoidal resection of the pituitary region mass. After the surgery the pituitary hormonal assessment was done, confirming panhypopituitarism. Despite the surgical procedure and the hormonal replacement therapy, the patient's general condition did not improve as it was expected. The obtained pathomorphological results indicated granulomatous inflammation. Once the histopathologic diagnosis was established, the patient underwent further tests for systemic granulomatous disease. GPA was diagnosed based on recurrent sinusitis, and positive autoantibodies c-ANCA.
Conclusion
The correct diagnosis is essential to avoid surgical treatment, which is not recommended in pituitary GPA. Publications present satisfactory responses to steroid and immunosuppressive treatment. It is important to keep in mind the rare causes of damage of the sellar region and not neglect of coexisting symptoms even those not specific to pituitary diseases.

COVID-19 and hyponatremia: from possibility to probability

Kristina Steiner[1], Silvija Canecki-Varžić[1,2], Ema Schönberger[1,2], Romana Marušić[2,3], Klara Ormanac[1,2] & Ines Bilić-Ćurčić[1,2]
[1]Clinical Hospital Center Osijek, Department of Endocrinology, Osijek, Croatia; [2]Faculty of Medicine Osijek, Osijek, Croatia; [3]General Hospital Vukovar, Department of Internal Medicine, Vukovar, Croatia

Introduction
Hyponatremia is the most common electrolyte imbalance in hospitalized patients and frequent finding in intensive care units. Hyponatremia is characterized with serum sodium values less than 135 mmol/l and defined by the ratio of total sodium and total body water. It presents with lethargy, confusion, neuromuscular excitability, hyperreflexia, stupor and even coma. In addition to neurological signs and symptoms, assessment of hyponatremia is based on severity and duration. There are several etiological factors leading to hyponatremia, so diagnosis and treatment present a challenge in everyday clinical practice.
Case report
In this case report we present a 71-year-old woman who presented herself to the emergency department due to weakness. Besides general fatigue, she reported a tingling sensation in the whole body and flatulence which lasted for 3-4 days. She has been vomiting lately. No other neurological symptoms have been observed. Based on her previous medical documentation we ascertain that due to similar symptoms, she has visited the emergency department several times. In her medical history, she has been treated with indapamide due to arterial hypertension, and a month ago she was treated for COVID-19. In physical examination, euvolemia was present, with normal vital parameters. An initial examination was performed and severe hyponatremia was verified with a serum sodium level of 110 mmol/l. Urine analysis showed an osmolality of 406 mOsmol/kg and sodium level of 45 mmol/l, X-ray examination was described as normal. Endocrinological workup excluded adrenal insufficiency and hypothyroidism, thus the diagnosis of SIADH was the most probable one. Additional investigation of medical records revealed that a month ago, while being treated due to COVID-19 patient had unrecognized serum sodium levels of 127 mmol/l and 116 mmol/l, respectively. In the emergency department, hyponatremia was corrected by intravenous administration of 3% NaCl for 20 minutes, with an increase in serum sodium by 4mmol/l. The patient was hospitalized and the gradual increase in serum sodium levels was monitored with fluid withdrawal to 800 mL per day which led to complete recovery and correction of electrolyte disbalance.
Conclusion
In this case report we intended to emphasize how important it is to recognize hyponatremia in COVID-19 patients, which can be caused by two mechanisms: SIADH due to Interleukin-6 induced non-osmotic release of vasopressin or loss of Na due to diarrhea and vomiting. Distinguishing between the two is essential for timely and correct treatment to avoid severe hyponatremia that can have potentially fatal consequences.

Pituitary apoplexy – a tertiary centre experience

Matej Rakusa[1,2], Roman Bošnjak[3] & Tomaž Kocjan[1,2]
[1], Department of Endocrinology, Diabetes and Metabolic Disease, University Medical Centre Ljubljana, Ljubljana, Slovenia; [2]Department of Internal Medicine, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; [3], Department of Neurosurgery, University Medical Centre Ljubljana, Ljubljana, Slovenia

Background
Pituitary apoplexy (PA) is a rare, potentially life-threatening endocrine emergency, due to abrupt pituitary haemorrhage and/or infarction, usually within a pituitary adenoma. PA most commonly presents with severe headache, visual and oculomotor activity disturbances, nausea/vomiting and/or altered mental status. The outcome is variable and difficult to predict. Most proposed risk factors are hypertension (HTN), diabetes mellitus (DM), and anticoagulant treatment. Optimal management of PA is still controversial due to rarity of the condition.
Aim
To assess the characteristics and the outcomes of our patients with PA.
Material and methods
We retrospectively analysed medical records of patients with PA managed at the national tertiary care centre from 2010 to 2023. We collected data for adenoma size, hormone deficiency, visual and oculomotor activity disturbances at the time of presentation and after at least 3 months later. We also checked for operative treatment or spontaneous reduction of adenoma when not operated on, presence of HTN, DM or anticoagulant treatment.
Results
Sixteen patients (11 males, 68,8%) of median age 66,5 (IQR 20) with PA were identified during the studied period. At presentation, 14 of them (87,5%) had adrenocorticotropic and 15 (93,8%) thyrotropic deficiency, 7 (43,8%) had hyponatremia, and 2 (12,5%) developed diabetes insipidus (DI). Median sodium was 134 (IQR 7,25) mmol/l, overall. Visual disturbances were present in 6 (37,5%) and oculomotor palsy in 10 (62,5%) patients. Eight (50%) patients were treated surgically, including all 6 patients with visual disturbances. Visual field improvement was noted in all patients and oculomotor palsy resolved completely. HTN was present in 6 (37,5%), DM in 4 (25%) patients, while two (12,5%) patients received anticoagulant treatment. Median adenoma size was 22,5 (IQR 12,50) mm. There was no statistically significant difference in adenoma size between surgically and conservatively managed patients ($P=0{,}162$). Adenoma decreased in size in 4 (50%) patients without surgery. The adenoma shrinkage was statistically significant from median 18,5 (IQR 9,75) mm to 13 (IQR 7,50) mm ($P=0{,}044$). At follow-up, 12 (75%) had adrenocorticotropic and thyrotropic deficiency, 11 (68,8%) also had secondary hypogonadism, 7 (43,8%) had low IGF-1, 4 (25%) patients had low prolactin levels. Six (37,5%) patients had DI, including 4 after surgery. Multiple hormonal deficiencies were more common in surgically managed patients.
Conclusion
Our observations suggest that conservative management of PA is feasible in carefully selected milder cases without important visual deficit. Further studies on optimal stratification of PA patients are needed.

Surgical factors, in particular a higher volume of operations and a dedicated neurosurgeon, are considered the main determinants of surgical complication rates in transsphenoidal surgery (TSS). We evaluated postoperative complications in a large series of TSS for non-producing adenomas included in TESSPAIN, a retrospective multicenter nationwide registry. All TSS performed at the 29 participating centers between 2018 and 2022 were included. Globally, 1421 non-producing pituitary adenomas were included, representing 50,.5% of all TSS in these centers. An expert endocrinologist reviewed the feasibility of total pituitary adenoma resection in each case, and assessed outcome and permanent complications, including reoperation for bleeding or CSF leak, infection, anterior pituitary damage, permanent ADH deficiency, venous thromboembolism, cerebrovascular accident, death, cranial oculomotor or optic nerve damage, and others (including pneumocephalus, regrowth with second surgery and vasospasm). The most common reason for performing a TSS was optic nerve damage, which occurred in 615 cases (43.3%). Slightly more than half of the adenomas were considered amenable to total resection (n:759; 53.4%), which was achieved in 616 cases (81.2%). A quarter of the cases (n:355) had permanent surgical complications, the most common being additional antehypophyseal damage, which was reported in 16,8% of cases. Permanent ADH deficiency occurred in 91 cases (6.4%). Immediate reintervention due to bleeding, CSF leakage or vasospasm was required in fifty patients (3.5%). Forty-five cases (3.2%) presented with CSF leak on admission and 14 patients (1.0%) suffered cranial nerve damage as a complication of surgery. There were nine deaths related to TSS (0.63%), five cerebrovascular accidents and four thromboembolic events. The overall complication rate was not correlated with the number of surgeons performing TSS (mean rate: 25.9 ± 16.9% vs 24.2 ± 13.2% between centers with one or two dedicated neurosugeons vs more neurosurgeons; p: 0.77), nor with the total volume of TS surgeries during the study period (p: 0.91), nor with the number of non-producing pituitary adenomas operated on (p: 0.54). Only the rate of permanent ADH deficiency showed a trend towards a negative correlation with the cure rate of producing adenomas at the center evaluated (p: 0.08; r: -0.334). In conclusion, the rate of surgical complications reached 25% in a large series of TSS for non-producing pituitary adenomas, without apparent relation to surgical volume, number of neurosurgeons, or surgical goal of complete resection. These findings may be explained by the fact that more experienced centers assumed the most difficult cases and planned a stricter resection.

DXA-derived lumbar bone strain index corrected for kyphosis is associated with vertebral fractures in acromegaly

Simona Jafaar[1,2], Giacomo Cristofolini[1,2], Emanuela Morenghi[1,3], Luca Rinaudo[4], Maria Francesca Birtolo[1,2], Elisa Sala[5], Emanuele Ferrante[5], Roberta Mungari[5], Elisabetta Lavezzi[2], Lorenzo Leonardi[6], Pasquala Ragucci[6], Fabio Massimo Ulivieri[7], Luca Balzarini[6], Giovanna Mantovani[5,8], Andrea Lania[1,2] & Gherardo Mazziotti[1,2]
[1]Humanitas University, Department of Biomedical Sciences, Pieve Emanuele, Italy; [2]IRCCS Humanitas Research Hospital, Endocrinology, Diabetology and Andrology Unit, Rozzano, Italy; [3]IRCCS Humanitas Research Hospital, Biostatistics Unit, Rozzano, Italy; [4]Tecnologie Avanzate S.r.l, Turin, Italy; [5]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [6]IRCCS Humanitas Research Hospital, Department of Radiology, Rozzano, Italy; [7]Casa di Cura la Madonnina, Bone Metabolic Unit, Milan, Italy; [8]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

The bone strain index (BSI) is a marker of bone deformation based on a finite element analysis inferred from dual X-ray absorptiometry (DXA) scans, that has been proposed as a predictor of fractures in osteoporosis. BSI value represents the average equivalent strain in a skeletal site, assuming that a higher strain level (higher BSI) indicates a lower bone's resistance to loads with consequent higher risk of fractures. BSI index is usually calculated for specific loading condition (e.g. standing for the lumbar site), but for particular reasons the load may vary due to external conditions (e.g. load bearing) or spine. These conditions possibly affecting BSI have been frequently described in patients with acromegaly. We aimed to investigate the association between lumbar BSI and vertebral fractures (VFs) in acromegaly. Twenty-three patients with acromegaly (13 males, mean age 58 years; three with active disease) were evaluated for morphometric VFs, trabecular bone score (TBS), bone mineral density (BMD) and lumbar BSI, the latter being corrected for the kyphosis as measured by low-dose X-ray imaging system (EOS®-2D/3D). In particular, for each degree increase of the sagittal Cobb angle, the force applied to the upper surface of the vertebra was increased by approximately 6% according to uncompensated position and the information derived from the lateral image coming from EOS device. Impaired TBS (i.e., TBS <1.310), low BMD (i.e., BMD T-score $\leq$-1.0 SD) at either skeletal site and pathological lumbar BSI (i.e., BSI ≥ 2.4) were found in 10 (43.50%), 13 (56.50%) and 6 (26.09%) patients, respectively. Patients with pathological lumbar BSI showed more frequently impaired TBS as compared to those with normal lumbar BSI (83.30% vs 29.40%; $P=0.05$), without differences in age, duration of active disease, serum IGF-I values, current medical therapies of acromegaly, coexistent hypopituitarism, previous treatment with bone-active drugs and low BMD at either skeletal site. Lumbar BSI was significantly higher in patients with VFs (*13 cases*) as compared to those without fractures (2.26, 95%C.I. 1.3-5.7 vs 1.85, 95%C.I. 1.16-2.22; $P=0.040$). 6 out of 13 (46.15%) patients with VFs had pathological BSI, whereas all patients without VFs had normal BSI ($P=0.019$). Patients with VFs had also more frequently impaired TBS vs patients without VFs (61.50% vs 20.00%; $P=0.04$). In conclusion, lumbar BSI corrected for kyphosis could be proposed as integrated parameter of spine arthropathy and osteopathy in acromegaly helping the clinicians in identifying patients predisposed to VFs.

Presentation and treatment response in men with micro, macro or giant prolactinoma

Stefan Matei Constantinescu[1], Orsalia Alexopoulou[1] & Dominique Maiter[1]
[1]Cliniques universitaires Saint-Luc (UCLouvain), Department of Endocrinology and Nutrition, Bruxelles, Belgium

Introduction
Men with prolactinoma often present with larger tumors than women. Whether giant prolactinomas ($\geq$4 cm, GP) present differently and achieve the same outcomes as non-giant macroprolatinomas (1-3.9 cm, MP) or microprolactinomas ($<$1 cm, mP) is not clearly established.
Methods
We report retrospective data from a monocentric cohort of 129 men with prolactinoma and we compare baseline characteristics and treatment response in patients with different tumor sizes. We excluded patients with very small tumors (maximal diameter $<$5mm or PRL initially $<$45 mg/l).
Results
Among the 129 patients, 25 (19%) harbored a GP (median PRL 9270 mg/l; size range: 40-60 mm), 83 (64%) had MP (median PRL 776 µg/l; 10-39mm), and 20 (15%) had mP (median PRL 103 µg/l; 5-9.9mm). The mean age at presentation was similar in the three subgroups (41 ± 17, 45 ± 17 and 45 ± 16 years in the mP, MP and GP groups, respectively; NS). BMI and testosterone levels also did not differ significantly between the groups. Mean testosterone concentration at diagnosis was 6.3, 6.2 and 4.7nmol/l for mP, MP and GP, respectively. Patients with GP and MP

suffered from more visual field deficits (60% and 24% respectively) than those with mP (0%, $P<0.001$). The same was true for cavernous sinus invasion ($P<0.001$), ACTH deficit ($P=0.036$) and TSH deficit ($P<0.001$). However, the frequency of LH deficit was similar in the three groups (mP 94%, MP 82%, GP 96%, $P=0.132$). The prevalence of gynecomastia was significantly higher ($P<0.01$) in mP (68%) than in MP (25%) or GP men (16%), although the prevalence of decreased libido or erectile dysfunction was similar in all three groups. The need for surgery during follow-up was significantly more important in GP (44%) than MP (31%) or mP (5%, $P=0.015$). At last follow-up, normal prolactin was achieved in 80% of mP patients, 68% of MP patients, and in only 40% of GP patients ($P=0.010$). At last follow-up more patients in the GP (65%) and MP (38%) group suffered from persistent hypogonadism than mP patients (20%) ($P=0.008$). The same was true for TSH deficit ($P<0.001$) and ACTH deficit ($P=0.067$).
Conclusion
In men, 83% of prolactinomas at diagnosis reach a size of 1 cm or more and 19% reach or exceed 4 cm. Interestingly, patients with mP more often present with gynecomastia than those with MP or GP, despite similar age, BMI and testosterone levels, perhaps leading to earlier diagnosis. Endocrine outcomes and resistance to treatment worsen with increasing tumor diameter.

A case of sporadic metastatic medullary cancer with distant metastases and negative RET mutation

Samira Khalilova[1,1] & Adrian Li[1]
[1]Princess Royal University Hospital, United Kingdom

Introduction
Medullary thyroid cancer accounts only 1% to 4% of thyroid cancer cases (1). 25% of cases are familial secondary to germline RET mutation, while the remaining 75% are sporadic and also harbour a somatic RET mutation in more than half of all cases. Up to 15–20% of patients will present with distant metastatic disease. The standard treatment for MTC is total thyroidectomy and dissection of cervical lymph node compartments. Post-operative levels of serum calcitonin $>$ 150 ng/l generally indicate distant metastases. We present a case of sporadic RET-negative medullary cancer with distant metastases.
Clinical case
72 y.o man referred for thyroid USS with neck swelling and supraclavicular lymph node enlargement in March 2023. USS revealed left sided conglomerate of the slightly hypoechoic nodules with internal calcifications measuring up to 51 mm in diameter (U4/5) and rounded lymph node in the left neck measuring 1.6x9.2x11 mm. FNA confirmed suspicious for malignancy (Thy4). CT neck showed extracapsular extension focally anteriorly to the SCM and extensive lymph nodes extending from level 2-6 on the left. After discussion at MDT calcitonin level has been checked which showed 12100 ng/ml. Meanwhile screen for pheochromocytoma, hyperparathyroidism and RET-gene was negative. Subsequently, patient underwent total thyroidectomy with level 6 lymph adenectomy and bilateral neck dissection in June 2023. Repeated calcitonin level in September 2023 showed calcitonin 7380. MRI liver in October 2023 showed multiple bilobar liver metastases which were Dotate-PET negative, but positive on FDG-PET scan. Furthermore, both PET scans showed positive uptake in the left supraclavicular fossa, which is concerning for residual/metastatic disease. Latest calcitonin level is 8770 and after MDT discussion there is plan for tyrosine kinase inhibitors therapy.
Discussion
Medullary thyroid cancer is a rare thyroid cancer with high mortality rate requiring multidisciplinary approach. Our case represent challenges in diagnosis and ongoing care of the patients with medullary cancer. While surgical management is a main treatment approach for medullary cancer, metastatic and recurrent cases can be treated with new treatment modalities, like thyrosine kinase inhibitors.

Effects of recombinant growth hormone treatment on metabolic fitness, body composition and echocardiographic parameters in a population of patients with overweight or obesity and adult GH deficiency

Maria Elena Spoltore[1], Davide Masi[1], Rebecca Rossetti[1], Gabriele Veroi[1], Maria Ignazia Curreli[1], Mariangela Peruzzi[2], Valentina Ventimiglia[1], Giorgia Maria Baldazzi[1], Elena Gangitano[1], Mikiko Watanabe[1], Stefania Mariani[1], Lucio Gnessi[1] & Carla Lubrano[1]
[1]Sapienza University of Rome, Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Rome, Italy; [2]Sapienza University of Rome, Department of Clinical Internal, Anaesthesiological and Cardiovascular Sciences, Rome, Italy

Introduction
Adult growth hormone (GH) deficiency has been associated with the onset of sarcopenic obesity, reduced bone mineral density, and the progression of metabolic syndrome, often accompanied by the accumulation of ectopic fat at the epicardial level and changes in echocardiographic measures.
Objective and Design
This prospective pilot study aimed to assess the impact of recombinant human GH (rhGH) replacement therapy on glyco-metabolic parameters, body composition, and echocardiographic measures within a cohort of patients presenting both obesity/overweight and adult GH deficiency (aGHD). Inclusion criteria were as follows: age between 18 and 65, BMI $\geq$ 25 kg/m^2, peak GH secretion post GHRH + arginine stimulation test $<$ 4.2 ng/ml, and either partially or entirely empty sella turcica. Exclusion criteria included pregnancy/lactation, presence of active neoplasia, alcohol dependence, tobacco use, and medication potentially influencing the hypothalamic-pituitary axis.
Results
Our study involved 13 patients with obesity/overweight and aGHD (5 males, 8 females, mean age: 57.15 $\pm$ 6.29 years). Following enrollment, patients underwent rhGH replacement therapy and assessments were conducted at baseline (T0), after 6 months (T1), and after 12 months (T2), involving anthropometric, biochemical, DEXA-based body composition, and echocardiographic evaluations. At T1 and T2, notable reductions in waist/hip ratio ($P=0.05$), trunk fat ($P=0.03$), and trunk fat/low limb lean mass ratio ($P=0.05$) were observed, indicating substantial improvements in fat distribution. Concurrently, positive alterations were noted in cardio-metabolic risk markers, including reduced systolic blood pressure ($P<0.003$), total cholesterol/HDL cholesterol ratio ($P<0.004$), and increased HDL cholesterol levels ($P=0.05$). Moreover, a decrease in epicardial adipose tissue, indexed ventricular mass, interventricular septal thickness, and left ventricular posterior wall thickness was evident ($P=0.04$), with a tendency toward enhancement in left ventricular ejection fraction and telediastolic diameter.
Conclusion
The presence of GHD exacerbates cardiovascular risks in patients with overweight/obesity. Treatment with rhGH in our study cohort demonstrated improvements in adipose tissue distribution, lipid profiles, and notable effects on specific echocardiographic parameters. Notwithstanding, our study's limitations encompass a small sample size and a 12-month follow-up duration. Future investigations with expanded cohorts and extended follow-ups up to 36 months are planned. If substantiated, these results could advocate for rhGH replacement therapy in aGHD individuals with obesity/overweight to mitigate cardiometabolic risks and enhance cardiac structure and function.

Pregnancy in a lady with pre-existing cyclical cushing's disease

Cheuk Wah Ho[1]
[1]United Christian Hospital, Hong Kong

A 35-year-old lady presented in Feb 2022 for lower limb weakness for 2 months, easy fall and amenorrhoea for 6 months. Her potassium was 2.4mmol/l. Clinically, she had moon face and proximal muscle weakness. Her workup showed metabolic alkalosis, renal loss of potassium and high 24-hour urine free cortisol (UFC) 825 nmol/l (24-140), which was 5.9x above the upper limit of normal (ULN). The paired baseline ACTH and morning cortisol were 22.1 and 469nmol/l respectively. 1mg ONDST was 580nmol/l. 8mg DST was suppressible. CRH and DDAVP stimulation test respectively confirmed Cushing's disease. MRI pituitary showed 3mm hypoenhancing lesion on the right of the pituitary gland. IPSS was done in 10/2022 with successful cannulation and confirmed Cushing's disease (CD). Serial monthly 24-hour UFC showed cortisol was 21, 208, 612nmol/l. Cyclical CD was suspected. The patient resumed spontaneous monthly menses and got pregnant due to misunderstanding. At 9th gestational week (GW), 24-hour UFC was 8.7x above ULN with muscle weakness. As she was having active CD, TSS at second trimester was advised. Before surgery, cabergoline and enoxaparin were given. 24-hour UFC reduces to 6.5x ULN on cabergoline 1.5mg 2x/week. TSS was done at 17 GW. Specimen was stained positive for prolactin, GH and ACTH. Cabergoline and potassium was stopped post-operatively. Stress dose of hydrocortisone was given then tapered to replacement dose. After TSS, the 24-hour UFC was at 2x ULN. The patient sustained left distal fibula fracture after stepping on uneven ground at GW 33+ weeks. She had preterm premature rupture of membrane the next day. A healthy baby was delivered weighing 1.97 kg and was observed in the neonatal ICU. It

was finally discharged home at 23 days old, weighing 2.51 kg. The patient was on hydrocortisone replacement. She is planned to reassess for any cortisol excess after 3 months. Up to 2021, 62 cases of CD complicated pregnancy are reported. The risk of maternal complication such as pre-eclampsia, gestational hypertension, gestational diabetes and risk of fetal complication including preterm birth, low birth weight, intrauterine death are higher in active CD. Therefore, TSS at the second trimester was advised in this patient. Secondly, it is difficult to assess for any remission after surgery. As the cortisol level is higher in normal pregnancy up to 2-3x ULN, the usual reference for CD remission cannot be applied. Thirdly, as this patient had cyclical CD, the periodically near normal cortisol level may not indicate a remission.

The protean manisfestations of erdheim-chester disease

Shyam Seshadri[1], Adrian Jennings[1] & Manoj Thomas[1]
[1]The Queen Elizabeth Hospital Foundation NHS Trust, Department of Endocrinology, Kings Lynn, United Kingdom

A 43-year-old female presented to the endocrine clinic with a 6-month history of polyuria and polydipsia. Investigations revealed a raised prolactin and a water deprivation test confirmed cranial diabetes insipidus. Subsequent pituitary MRI showed a likely pituitary microadenoma which however on further radiology review was thought to represent a hypothalamic/stalk lesion measuring up to 5 mm. She was commenced on intranasal desmopressin and cabergoline initially. Repeat MRI 2 years and 5 years post initial scan showed unchanged appearances to the stalk lesion. The patient found good symptom relief with desmopressin. A decision was made to stop cabergoline as this was not thought to be related to her stalk lesion. The patient had intermittent breathlessness which was investigated by lung function and a CT which did not show any interstitial lung disease but picked a borderline decreased transfer factor and low iron levels. The patient then subsequently developed intermittent haematuria which was investigated by a CT scan which showed mesenteric panniculitis and borderline mesenteric lymph nodes. Laparoscopic biopsy confirmed panniculitis with fibrosis while immunohistochemistry showed only a small number of IgG4 cells. A year later patient presented with features of an acute ischemic stroke from which she made an uneventful recovery. Over the next 2 years patient developed bilateral knee pain which appeared to get progressively worse. X-rays of her knees and a subsequent CT picked up expansile bony lesions in the distal femur and proximal tibia. She was investigated by haematology including a bone marrow biopsy which ruled out any plasma cell dyscrasias or metastases. The patient underwent a distal femoral biopsy which confirmed xanthomatous histiocyte infiltration of the trabecular bone and marrow spaces in keeping with a diagnosis of Erdheim-Chester disease. The patient had also noticed yellow deposits on her neck and face which appeared to have worsened subsequently. She was seen by dermatology who suspected large xanthelasma plaques and biopsy of the neck lesions confirmed the above diagnosis. A DNA analysis revealed an activating BRAF mutation, p. (Val600Glu) which is reported in more than 50% of patients with Erdheim-Chester disease which is a rare form of non-Langerhans-cell histiocytosis with the propensity to involve the following organs in decreasing order of frequency, namely long bones, maxillary sinus, large vessels, retroperitoneum, heart, lungs, central nervous system, skin, pituitary gland, and orbit. Our patient had endocrine manifestations preceding her eventual diagnosis a decade later.

Effects of MIA-602, GHRH receptor antagonist, on emotional disorders in mice

Maria Loreta Libero[1,2,3], Lucia Recinella[1], Andrew V. Schally[4], Roberto Salvatori[5], Luigi Brunetti[1] & Sheila Leone[1]
[1]D'Annunzio University of Chieti - Pescara, Department of Pharmacy, Chieti, Italy; [2]Instituto Maimónides de Investigación Biomédica de Córdoba, Córdoba; [3]University of Cordoba, Córdoba; [4]University of Miami Leonard M. Miller School of Medicine, Division of Medical/Oncology and Endocrinology, Miami, United States; [5]The Johns Hopkins University School of Medicine, Department of Medicine, Division of Endocrinology, Diabetes and Metabolism, Baltimore, United States

The role of growth hormone-releasing hormone (GHRH) in brain function has been suggested. Recent behavior studies by our group clearly demonstrate a powerful anxiolytic and antidepressant-like effects of a novel growth hormone releasing hormone (GHRH) antagonist of MIAMI class, MIA-690, probably related to modulatory effects on the inflammatory and oxidative status [1]. Our investigation in this work was focused on the potential beneficial effects of MIA-602, another recently developed GHRH antagonist on emotional disorders and examined how mood disorders are related to the endocrine system. In this context, the effects induced by MIA-602 were also analyzed in comparison to vehicle-treated mice with GH deficiency due to generalized ablation of the GHRH gene (GHRH knock out (GHRHKO)). The beneficial effect of MIA-602 on inflammatory and oxidative status and synaptogenesis resulting in anxiolytic and antidepressant-like effects could be related by increases of nuclear factor erythroid 2-related factor 2 (Nrf2) and of brain-derived neurotrophic factor (BDNF) signaling pathways in the hippocampus and prefrontal cortex. MIA-602 exhibited antinflammatory and antioxidant effects in ex vivo and *in vivo* experimental models, inducing anxiolytic and antidepressant-like behavior in mice subcutaneously treated for 4 weeks. Moreover, immunohistochemical and Western blot analyses suggested an evident activation of Nrf2, HO1, and NQO1 in the prefrontal cortex of both +/+ mice treated with MIA-602 (+/+ MIA-602) and homozygous GHRHKO (−/− control) animals. Finally, we also found significantly decreased COX-2, iNOS, NFkB, and TNF-α gene expressions, as well as increased P-AKT and AKT levels in +/+ MIA-602 and −/− control animals compared to +/+ mice treated with vehicle (+/+ control). We hypothesize that the generalized ablation of the GHRH gene leads to a dysregulation of neural pathways, which is mimicked by GHRH antagonist treatment.

Effects of glucagon-like peptide-1 analogs on prolactin: a randomized, double-blind, placebo-controlled crossover trial

Cyrill Müller[1], Sophia Lengsfeld[1], Leila Probst[1], Fabienne Baur[1], Emara Yara[1], Laura Werlen[1], Deborah Vogt[1], Cemile Bathelt[1] & Bettina Winzeler[1]
[1]University Hospital Basel, Endocrinology, Diabetes & Metabolism, Basel, Switzerland

Background
Research indicates that prolactin, a hormone linked to lactation, may influence the brain's reward system by interacting with dopamine. GLP-1 analogues, prescribed for diabetes and obesity, are known for their appetite-suppressant effects. With GLP-1 receptors found in mood and reward-related brain regions, a potential role of GLP-1 in reward regulation is suggested. A knowledge gap exists regarding the interaction between GLP-1 and prolactin in the context of the reward system. This study aims to explore this gap by investigating changes in prolactin on GLP-1 analogue and placebo treatment.
Methods
This is a predefined secondary analysis of a single-center, randomized, double-blind, placebo-controlled, crossover trial conducted at the University Hospital Basel in Switzerland. We enrolled 26 healthy eugonad men of normal weight (BMI 18.5-25 kg/m^2 or BMI 25.1-30 kg/m^2 and waist circumference $<$102 cm), aged between 18 and 50 years. Participants were randomized to a 4-week treatment of the GLP-1 analogue dulaglutide 1.5 mg/week and placebo in random order. We evaluated the changes in prolactin from baseline to week 4 in dulaglutide and placebo treated participants using paired t-tests.
Results
Between May 2021 and February 2022, 24 out of 26 randomized participants completed the study. Median age at inclusion was 24.5 years old (IQR [21.0, 29.0]), median BMI was 23.9 kg/m^2 (IQR [22.2, 25.0]). The average change in prolactin levels from baseline to 4 weeks of dulaglutide was -31.1 mU/l (SD 87.0 mU/l) and +44.6 mU/l (SD 113.1 mU/l) on placebo (estimated differences in prolactin levels from baseline to end of treatment under dulaglutide and under placebo -75.68 mU/l (95% CI: [-158.68, 7.33])).
Conclusion
In healthy men, dulaglutide led to a decrease in prolactin levels after 4 weeks of dulaglutide compared to placebo. These preliminary results support the hypothesis that GLP-1 analogues may interact with the dopamine-prolactin pathway.

Copeptin and oxytocin in MDMA-induced hyponatremia:incidence and severity, mechanisms of action, and the effect of fluid restriction

Cihan Atila[1], Isabelle Straumann[1], Patrick Vizeli[1], Julia Beck[1], Sophie Monnerat[1], Friederike Holze[1], Matthias Liechti[1] & Mirjam Christ-Crain[1]
[1]University of Basel, Basel, Switzerland

Importance
3,4-Methylenedioxymethamphetamine (MDMA, 'ecstasy') is a trending recreational drug but also has potential to enter clinical practice. Acute hyponatremia is a serious complication arising from ingesting even a single dose of MDMA. The assumed aetiology is a vasopressin release inducing the syndrome of inappropriate anti-diuresis combined with increased thirst causing polydipsia and thus water intoxication.
Methods
Pooled analysis of experimental MDMA-sessions of four placebo-controlled cross-over trials in 96 healthy participants conducted at the University Hospital Basel, Switzerland. The aim was to investigate the incidence and severity of hyponatremia after a single dose of MDMA, underlying mechanisms of action, and potential effect of fluid restriction on lowering the risk of hyponatremia. Single oral dose of 100 or 125 mg MDMA. 81 participants were not restricted to fluid intake, while in 15 participants, fluid intake was controlled. Plasma oxytocin, copeptin (surrogate marker of vasopressin), and sodium were measured repeatedly within 360 minutes after drug intake.
Results
At baseline, the mean (SD) sodium level was 140 mmol/l ($\pm$3) and decreased in response to MDMA by 3 mmol/l ($\pm$3), leading to hyponatremia in 31%(n=33/96) of the participants. Among hyponatraemic participants, the mean sodium level was 133 mmol ($\pm$2). In participants not restricted to fluid intake, at baseline, the plasma sodium was 140 mmol/l ($\pm$3) and decreased in response to MDMA by 4 mmol/l ($\pm$3), leading to hyponatremia in 41% (n=33/81). In contrast, in participants restricted to fluid intake, at baseline, the plasma sodium was 141 mmol/l ($\pm$1) and decreased only slightly in response to MDMA by 1 mmol/l ($\pm$2), leading to no hyponatremia (n=0/15), suggesting that fluid restriction significantly prevented hyponatremia (P=0.002). At baseline, plasma oxytocin was 87 pg/ml ($\pm$45) and increased in response to MDMA by 474 pg/ml ($\pm$309). At baseline, plasma copeptin was 4.9 pmol/l ($\pm$3.8) and only slightly decreased in response to MDMA by 0.3 pmol/l ($\pm$1.1). The decrease in sodium levels was significantly correlated with the increase in oxytocin (r=-0.4; P<0.001), while no correlation was observed between the change in sodium and copeptin (r=-0.1; P=0.220).
Conclusion
We report a high incidence of acute and mainly mild hyponatremia in response to MDMA, which can effectively be prevented by fluid restriction. Hyponatremia is associated with acute strong oxytocin but not copeptin release - this challenges the current hypothesis of direct vasopressin release and rather indicates that the increase in oxytocin mimics the effect of vasopressin in the kidneys due to close structural homology.

Decoding desire: a neurofunctional exploration of distressing low sexual desire reveals sexually dimorphic brain responses

Jovanna Tsoutsouki[1], Natalie Ertl[1,2], Edouard G Mills[1], Matt B Wall[1,2], Layla Thurston[1], Lisa Yang[1], Tia Hunjan[1], Maria Phylactou[1], Paul Bassett[3], Bijal Patel[1], Jonathan Howard[2], Ali Abbara[1], David Goldmeier[4], Alexander Comninos[1,5] & Waljit Dhillo[1,5]
[1]Imperial College London, Section of Endocrinology and Investigative Medicine, United Kingdom; [2]Invicro London, London, United Kingdom; [3]Statsconsultancy Ltd, Amersham, United Kingdom; [4]Imperial College Healthcare NHS Trust, Jane Wadsworth Sexual Function Clinic, London, United Kingdom; [5]Imperial College Healthcare NHS Trust, Department of Endocrinology, London, United Kingdom

Background
Distressing low sexual desire, termed Hypoactive Sexual Desire Disorder (HSDD), affects 10% of women and 8% of men. The established 'top-down' neurofunctional model of HSDD in women suggests that in response to erotic cues, excessive activation of higher-level cognitive brain regions (involved in introspection/self-monitoring) suppresses lower-level sexual brain centres, thereby impeding normal sexual function. By contrast, the neurodysfunction in men with HSDD remains to be fully characterised and crucially unlike in women, there are currently no licensed therapies. Herein, we report the first direct comparison of the neural bases of HSDD in women and men.
Methods
32 premenopausal women with HSDD [mean age $\pm$ SD(y) 29.2 $\pm$ 6.7] and 32 men with HSDD [age 37.9 $\pm$ 8.6] underwent a task-based functional MRI (fMRI) measuring sexual brain activity during erotic vs control (exercise) videos. Participants completed psychometric questionnaires before and after the fMRI scan, providing functional relevance for the brain activity changes.
Results
Women displayed significantly greater activation in higher-level cortical regions (e.g. inferior frontal gyrus, superior frontal gyrus) and lower-level limbic brain regions (e.g. amygdala, striatum, thalamus) in response to erotic videos, compared to the men. Lower activation in lower-limbic sexual regions in women correlated with more severe HSDD, which along with a hyperactivation in the inferior-frontal gyrus relative to the men, supports the 'top-down' mechanism underlying HSDD in women. By contrast, men exhibited lower activation in both higher-cortical and lower-limbic regions, but greater activation than the women in the visual cortex in response to erotic videos. Hence, a heightened sensitivity to visual erotic cues in men might not be effectively relayed to the limbic system. In women only, hypothalamic hyperactivation in response to erotic videos correlated with 'increased heartbeat' (r=0.5, P=0.001), and 'tingling all over' (r=0.6, P<0.001), while higher striatal activation correlated with feeling more 'stimulated' (r=0.4, P=0.001) and 'genital tingling' (r=0.6, P<0.001) on the psychometric questionnaires. Crucially, these findings were specific to erotic stimuli as no differences were identified in the control comparison (exercise > baseline contrast).
Discussion
This is the first study to directly compare the neural bases of distressing low sexual desire in women and men. While supporting the 'top-down' mechanism of HSDD in women, it suggests a different neurodysfunctional process in men with HSDD, highlighting a potential functional disconnection between sensory/attention and sexual centres. Our findings have key clinical implications as they identify a sexual dimorphism in the neural bases of low sexual desire relevant to the escalating development of therapeutics for patients with HSDD.

Receptor-mediated internalisation of the long-acting growth hormone analogue somapacitan in comparison with recombinant human growth hormone and pegvisomant

Matthäus Brandt[1], Elena Kassianidou[1], Carsten Behrens[1] & Peter Thygesen[2,2]
[1]Novo Nordisk A/S, Måløv, Denmark; [2]Novo Nordisk A/S, Rare Endocrine Disorders, Maaloev, Denmark

Growth hormone receptor (GHR) internalisation plays a crucial role in GHR activation and signalling by controlling the availability of the receptor for binding growth hormone (GH), regulating the intensity and duration of the GH signal, initiating unique signalling pathways, and maintaining homeostasis in the GH signalling pathway. GHR internalisation occurs mainly through clathrin-mediated endocytosis. Upon GH binding, the GHR undergoes ubiquitination, which is a signal for internalisation. The GHR is then included in clathrin-coated pits and internalised into early endosomes. From here, GHR can be recycled back to the plasma membrane. Here we present a quantitative study of the internalisation of human GH, the long-acting GH analogue somapacitan and the GHR antagonist pegvisomant using human GHR-expressing baby hamster kidney fibroblasts (BHK21). Human GH, somapacitan and pegvisomant were conjugated with Alexa Fluor 647 dye to follow the internalisation. Receptor internalisation could be observed for all three compounds in the concentration range 0.005–10 nM. Cells were fixated at predetermined timepoints from 0–4 hours and fluorescence determined for each combination of time point and concentration level. Internalisation was reduced in the presence of a non-labelled competitor showing that uptake is specific to the receptor. The results showed that all three compounds were internalised by the GHR. The internalisation rate was highest for human GH followed by somapacitan and with pegvisomant having the slowest rate. Addition of non-labelled pegvisomant to cells together with labelled human GH or somapacitan showed a displacement effect of pegvisomant of both compounds on the GHR with a stronger effect on somapacitan. While the competition effect for GH is higher at 4 hours after addition of pegvisomant compared to 24 hours, the displacement effect for somapacitan lasted for 24 hours. In conclusion, somapacitan undergoes receptor-mediated internalisation by the GHR at a slower rate than human GH, but faster than pegvisomant. Somapacitan is more easily displaced from the GHR by pegvisomant compared to human GH.

Adopted transgender subjects are over represented and have a different psychosocial profile than their non-adopted counterparts: a case-control study

Iris Yaish[1], Yona Greenman[1,2] & Karen Tordjman[1,2,2]
[1]Tel Aviv Sourasky Medical Center, Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv, Israel; [2]Tel Aviv University, Sackler Faculty of Medicine, Internal Medicine, Tel Aviv, Israel

Background and Aim
We previously demonstrated (1) that in our transgender clinic, adoptees are significantly overrepresented compared to the general population, suggesting early life traumas may play a role in the etiology of transgenderism. We had also shown a large preponderance (close to 80%) of female sex-assigned-at-birth (SAB), and a trend for presenting for treatment at an older age than non-adopted subjects. In the current study we aimed to further characterize this subgroup by comparing them to contemporary, non-adopted matched control subjects.
Subjects and Methods
Between 01.05.2014 and 31.12.2022, 671 new adult subjects presented to our center for gender-affirming hormonal treatment (GAHT), 14 of whom were adoptees (2.09%). These were matched in a 1:4 for age and SAB, with non-adopted transgender subjects from the same cohort. The 2 groups were compared for multiple psychosocial and life-style characteristics. Comparisons of categorical variables were performed by cross-tabulation statistics.
Results
By design, the current age of subjects (25.0 $\pm$ 6.1 y] range 20-40), and the age at initiation of GHAT (22 y [IQR 20-27.5]), were identical, but so was the mean age of dysphoria onset (10 y, range 3-30); 77.1% were transgender men. Groups did not differ with respect to their marital status, altogether 75.7% were single, none had biological children. Adoptees came from families with significantly higher socioeconomic status (SES), 28.6% from high SES vs none among controls. Despite this, none of the adoptees had any college education vs 28.3% of the controls ($P=0.028$). Employment rate, however, was generally similar in both groups at 72.1% of the cohort. Adoptees tended to carry a psychiatric co-morbidity more often (57.1% vs 28.6%, $P=0.061$). The number of psychiatric co-morbidities was also higher among adoptees (0.38 per subject vs 0.79, $P=0.042$). Among non-adopted subjects 62.2% were still living with their parents, as opposed to only 21.4% of adoptees ($P=0.013$). Lastly, adoptees were more often smokers (57.1% vs 16.4%, $P=0.004$), and cannabis users (21.4% vs 1.9%, $P=0.028$).
Conclusion
Adoptees are not only overrepresented among the transgender population treated at our center, but they also have a more fragile psychosocial profile despite coming from higher SES families. These observations might shed some light into the etiology of transition among adoptees that should prompt further exploration. Additionally, they should heighten the attention of clinicians to the vulnerability of this special population.

Background
Although polycystic ovary syndrome (PCOS) constitutes a common endocrinopathy, there are several issues which confuse clinicians during everyday practice.
Objective
To define the current status of knowledge of the full spectrum of PCOS among European endocrinologists.
Methods
A detailed questionnaire comprising 41 items covering various aspects of diagnosis and management of women with PCOS was shared via web among members of European Society of Endocrinology.
Results
505 European endocrinologists (64% females), with a mean age of 47 $\pm$ 11.6 years answered the questionnaire. Rotterdam criteria were used by 85% of endocrinologists. The most frequent age at referral was between 20-40 years (87.1%). A quarter of doctors have access to mass spectrometry for the evaluation of androgen levels. Extended metabolic profile was part of workup by the vast majority, but there was significant uncertainty regarding the diagnosis of chronic anovulation. Diabetes, gestational or type 2, was considered a major consequence for women with PCOS and screening is carried out regardless of BMI status. Lifestyle modification and metformin are considered a standard approach of all participants and oral contraceptives are a standard therapeutic modality, but there is significant discrepancy on the duration of treatment.
Conclusions
Rotterdam diagnostic criteria are currently an established diagnostic approach within the European endocrine community. This updated survey showed an advance in using steroid profiling for diagnosis and strong position on recognizing PCOS as a metabolic condition with potential broader consequences. Therapeutic aspects are currently changed into the need for more lifestyle intervention involvement and the use of metabolic therapies either as monotherapy or in combination with standard hormonal compounds.

The role of menstrual cycle changes in the evaluation of women's reproductive, sexual and mental health – lessons learned from the covid-19 pandemic

Kristina Saravinovska[1], Ljiljana Marina[1], Neda Delic[2], Antoan Stefan Sojat[1], Nevena Radonjic[3], Sladjana Mihajlovic[4], Milan Lackovic[4], Ilija Gunjic[5], Tijana Petkovic[1], Natalija Antic[1], Emilija Jankov[2], Zorana Arizanovic[1], Miomira Ivovic[1] & Svetlana Vujovic[1]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, National Centre for Infertility and Endocrinology of Gender, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade; [3]Upstate Medical University, Department of Psychiatry and Behavioral Sciences, Syracuse, United States; [4]Clinical Hospital Centre "Dragisa Misovic, Department of Obstetrics and Gynecology, Belgrade, Serbia; [5]Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia

Introduction
It has been shown that women with a previous Sars-CoV-2 infection have long-lasting menstrual cycle (MC) changes.
Aim
To investigate the MC changes and their relationship with women's reproductive, sexual and mental health disturbances during the COVID-19 pandemic.
Methods
Anonymous survey about reproductive, sexual and mental health was shared with women of reproductive age between May 2022 and November 2023. All women used MC diary while filling out the survey. Surveys were stratified based on RT-PCR/Antigen test Results Positive (CP) or negative (CN). All reported changes in CP referred to time after the Sars-CoV-2 infection and in CN to a pandemic timeframe in general.
Results
1270 women completed the survey. Based on inclusion, exclusion, and complete data availability 676 surveys were taken into the final analysis. 186/28% CN-mean age 29.8 $\pm$ 9.2, mean BMI 22.6 $\pm$ 3.8 kg/m^2, and 490/72% CP, mean age 29.6 $\pm$ 9, mean BMI 22.4 $\pm$ 3.8 kg/m^2, no difference in age or BMI between the groups ($P>0.05$). When compared to CN, 365/74.5% CP had MC changes ($P<0.001$), with 3 different MC patterns detected. 33/6.7% CP had a triad (TR1) - shortening of MC length (sMC), heavier menstrual bleeding (HMB) and PMS worsening (wPMS) ($P=0.003$); 25/5.1% CP had a different TR (TR2) - sMC, wPMS and painful menstrual bleeding (pMB) ($P=0.006$); 17/3.5% CP reported a tetrad (TT) - sMC, HMB, wPMS and pMB ($P=0.034$). 63/14% CP with MC changes reported decreased libido ($P<0.001$). When compared to CN, 226/46% CP reported low mood ($P<0.001$) and 125/25% CP poor sleep ($P=0.015$). 109/22% CP reported difficulty accessing healthcare as the main stressor

($P=0.002$). 137/38% CP reported that the MC changes are still present ($P<0.001$) - mean duration 308 days. 208/47% of all surveys reported being vaccinated which had no effect on MC changes ($P>0.05$). 244/49.8% CP reported gaining weight with a median of 5 kg which had no effect on MC changes ($P>0.05$). In CP, TR1 was the predictor of decreased libido ($R^2$0.044, $P<0.001$, OR 4.25, 95% CI = 1.942-9.3) and poor sleep ($R^2$0.02, $P=0.008$, OR 2.629, 95% CI = 1.282-5.390) and TR2 was the predictor of low mood ($R^2$0.026, $P=0.004$, OR 3.947, 95% CI = 1.548-10.062). In CP, Sars-CoV2 was the predictor of MC changes ($P<0.0001$, B = 1.577, OR 4.838; 95% CI = 3.29-7.09).

Conclusion

Sars-CoV-2 causes long-term MC changes and patterns associated with low mood, poor sleep, and decreased libido. Tracking MC is an easily accessible tool that provides a simple and cost-effective method, making it easy to detect potential health changes.

Revised adolescent PCOS criteria: implications for women's metabolic well-being

Maria Nowak-Ciołek[1], Julia Stachowiak[1], Katarzyna Krok[1], Julia Sokal[1], Zaneta Malczyk[2] & Agnieszka Zachurzok[2]

[1]Medical University of Silesia, Students' Scientific Association at the Department of Pediatrics, Zabrze, Poland; [2]Medical University of Silesia, Department of Pediatrics, Zabrze, Poland

Introduction

Polycystic ovary syndrome (PCOS) is one of the most common endocrinopathies in women. In recent years revised diagnostic criteria for PCOS in adolescent females were disseminated. These new criteria notably encompass the specification of irregular menstrual cycles and hyperandrogenism, with the exclusion of polycystic ovarian morphology. In our study, we aimed to verify whether the clinical presentation of adolescent patients meeting the new criteria is associated with an increased risk of metabolic disorders in adulthood.

Methods

We conducted a retrospective analysis of the medical records of adolescent patients in a singular medical center scrutinizing individuals with PCOS (meeting adolescent or Rotterdam criteria). Subsequently, after 4 to 11 years from the first visit, 35 women were reassessed with 19 meeting the new criteria as adolescents (study group, SG) and 16 serving as controls (CG) – not meeting adolescent criteria. Comprehensive blood tests encompassed assessments of alanine aminotransferase (ALT), aspartate aminotransferase (AST), lipids, insulin, and glucose. A concurrent clinical assessment complemented the laboratory analyses. Statistical analyses were conducted utilizing Student's T-test and Pearson's correlation.

Results

In SG, 8 out of 19 individuals (42%) are afflicted with obesity as opposed to CG comprising 4 (25%) individuals living with obesity. The disparity in BMI values between the groups in this cohort did not attain statistical significance (SG 30.3 ± 8.9 kg/m^2 vs CG 26.4 ± 6.6 kg/m^2; $P=0.16$). However, analyzed data revealed a significant increase in BMI between the first and second assessment in SG ($\Delta=2.0\pm3.7$ kg/m^2; $P=0.03$), which was not observed in CG ($\Delta=1.4\pm3.9$ kg/m^2; $P=0.17$). Other significant differences were identified in AST(SG 23.4 ± 5.9 U/l vs CG 19.3 ± 3.6U/L; $P=0.02$), ALT (SG 24.0 ± 14.2U/L vs CG 15.9 ± 6.2U/l; $P=0.04$), and insulin levels (SG 13.0 ± 8.5uIU/ml vs CG 7.9 ± 3.8uIU/ml; $P=0.03$). There was no significant difference in lipids and glucose levels between the groups. The study further unveiled a significant correlation in SG between testosterone levels during adolescence and glucose levels in adulthood ($r=0.91$, $P<0.05$).

Conclusion

Our study on PCOS patients, diagnosed using adolescent criteria, reveals a significant increase in BMI within the SG over time. Despite non-significant BMI differences between SG and CG, notable variations in AST, ALT, and insulin levels were observed in SG. These findings emphasize the importance of addressing and managing of PCOS during adolescence to mitigate potential metabolic risks in adulthood.

Use of combined oral contraceptive pills in women with and without PCOS: A longitudinal population-based cohort study

Maria Forslund[1,2], Johanna Melin[3], Deborah Loxton[4], Helena Teede[2], Anju Joham[2] & Chau Thien Tay[2]

[1]Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Department of Obstetrics and Gynecology, Gothenburg, Sweden; [2]Faculty of Medicine, Nursing and Health Sciences, Monash University, Monash Centre for Health Research & Implementation, Melbourne, Australia; [3]University of Helsinki, Department of Obstetrics and Gynecology, Helsinki, Finland; [4]University of Newcastle, Centre for Women's Health Research, Callaghan NSW, Australia

Objective

Combined oral contraceptive pills (COCP), primarily used for contraception; are also indicated in other conditions including polycystic ovary syndrome (PCOS). Evidence on the prevalence and patterns of COCP use in PCOS compared to those without the condition are unknown, and studies in unselected populations, especially longitudinally, are very limited. The aim of this study was to examine prevalence and patterns of COCP use in women with PCOS, compared to the background population and to explore patterns of use in different subgroups by age and BMI.

Study design

Women born 1973-78 were randomly selected and included in the Australian Longitudinal Study of Womeńs Health (ALSWH), $n=$ 981 women with and 13 266 women without PCOS. They were followed during a 25-year period.

Results

Altogether, more than 70% of all women had used COCP at some point. More women with than without PCOS reported ever having used COCP (77% vs 71%, $P<0.001$). However, cross-sectionally at different ages, use was less common in women with PCOS (at mean age 25 years 43% vs 51%; 31 years 31% vs 37%). Usage rates decreased with age in both groups. In the subgroup with BMI ≥30 kg/m^2, women with PCOS were more likely to use COCP than women without PCOS at different ages (mean age 25 years 16% vs 9%; 31 years 20% vs 8%; 42 years 5% vs 3%, respectively, $P<0.001$).

Conclusion

COCP usage was common among all women, more common overall in PCOS, but duration of use appeared shorter in PCOS. COCP usage was also more common among women with PCOS in the subgroup with obesity. Considering the increased indications and the increased metabolic risks associated with PCOS, there is a clear need for high-quality studies on COCP use in women with PCOS, to inform a risk-benefit assessment.

The impact of testosterone on TLR expression in transgender men

Hüseyin Cihan[1], Özge Güngör[2], Gökçen Ünal Kocabaş[3], Esma Pehlivan Köroğlu[3], Kübra Gülpınar[3], Erhan Parıltay[2], Fatma Ömür Ardeniz[4], Bettina Winzeler[1] & Banu Şarer yürekli[3]

[1]University Hospital of Basel, Department of Endocrinology, Basel, Switzerland; [2]University Hospital of Ege, Department of Medical Genetics, Izmir, Turkey; [3]University Hospital of Ege, Department of Endocrinology, Izmir, Turkey; [4]University Hospital of Ege, Department of Allergy and Immunology, Izmir, Turkey

Background

Sex based differences in the immune system are well-documented in the literature. The influence of sex on the immune system is primarily attributed via chromosomal and sex hormone mediation. Cis men generally exhibit a weaker immune response compared to cis women. This contrast extends to various immune-mediated diseases, where cis men show a higher incidence of cancer but fewer autoimmune diseases than cis women. Testosterone is part of gender affirming masculinizing hormone therapy. Transgender men often take testosterone to align with their gender identity. Despite the safety of testosterone use in this population, limited data exist regarding its effects on the immune system in transgender men. Questions persist about whether the immune modulation in transgender men on testosterone aligns with their assigned sex at birth or if a unique modulation occurs.

Methods

This study conducted between October 2022 and November 2023, as a prospective observational study involving 21 healthy transgender men with XX chromosomes. All participants were testosterone-naïve at baseline. Over a 6-month period, participants underwent routine clinical care, with testosterone levels targeted towards cis-men ranges. Immunological, hormonal, and biochemical parameters were assessed. TLR receptor expressions were measured on whole blood using real-time PCR at baseline and 6 month. β-actin and GAPDH served as housekeeping control genes.

Results

At the 6-month assessment, changes in TLR expressions were evaluated, revealing noteworthy alterations. TLR2, TLR3, TLR6, TLR10, CD14 and MD2 displayed varying degrees of modulation. Of particular interest, TLR8 exhibited a significant

decrease expression from 3.5 [3.1, 4.3] to 2.6 [1.2, 3.3] ($P = 0.0016$), a similar decrease was also observed for TLR10 from 6.2 [5.3, 6.7] to 4.7 [3.5, 5.4] ($P < 0.001$).
Conclusion
This study sheds new light on the intricate dynamics of immune modulation in transgender men undergoing testosterone therapy, revealing specific alterations in TLR expressions. The statistically significant changes observed for TLR8 and TLR10 suggest a nuanced impact of testosterone on immune markers and once again demonstrates the immunosuppressive mechanism of testosterone. This study advances our understanding of hormone therapy's immunological effects in transgender individuals. Furthermore, these findings can offer the potential to deepen comprehension of immune variations between genders, extending beyond the scope of transgender health.

Prevalence of polycystic ovary syndrome in women with prediabetes

Cem Sulu[1], Hande Ozkaya[1], Taner Damci[1], Fahrettin Kelestimur[2] & Mustafa Gonen[1]
[1]Cerrahpasa Medical Faculty Hospital, Turkey; [2]yeditepe University Hospital, Turkey

Objective
To determine the frequency of polycystic ovary syndrome (PCOS) in women with prediabetes compared to control women.
Methods
Digital screening and tele-interviews remotely excluded 3218 out of 3465 consecutive women applied for routine check-up. In-person assessments were performed on 247 women, excluding 49. Final analyses included 198 premenopausal women without endocrine disorders (other than prediabetes and PCOS) or conditions affecting gonadal functions. Prediabetes and PCOS were determined according to American Diabetes Association and Rotterdam criteria, respectively.
Results
One-hundred women had prediabetes and 98 women had normoglycemia. The frequency of PCOS were 21% and 19.4% in prediabetes and control groups, respectively ($P = 0.860$). PCOS frequency was 32% in impaired glucose tolerance (IGT) only subgroup. Prediabetes group had higher insulin-like growth factor-1(IGF–1) levels and lower anti-Müllerian hormone (AMH) levels ($P = 0.013$ and $P = 0.016$ respectively). Insulin levels were correlated with testosterone, antral follicle count (AFC), and ovarian volume only in prediabetes group ($P < 0.05$ for all). Mediation model in prediabetes group showed that insulin levels increased testosterone levels both directly, and indirectly through increasing IGF-1 levels ($b = 0.4$, $P = 0.0006$).
Conclusion
While risk of PCOS was not increased in overall prediabetes group, a trend for an increased risk in IGT only subgroup was noteworthy. Positive correlation of insulin levels with testosterone levels, AFC, and ovarian volume being only found in prediabetes group suggested that prediabetes might render ovaries susceptible to the PCOS-like changes induced by insulin. The lower AMH levels in prediabetes group, indicating diminished ovarian reserve, implied that even mild hyperglycemia might have deleterious effects on ovaries. The glucotoxicity of prediabetes on ovaries merits further attention.

Thyroid autoimmunity can negatively influence placental angiogenic factors and hormone secretion

Kamila Tańska[1], Piotr Glinicki[1,2], Beata Rebizant[3], Wojciech Zgliczyński[1] & Małgorzata Gietka-Czernel[1]
[1]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [2]Centre of Postgraduate Medical Education, EndoLab Laboratory, Warsaw, Poland; [3]Centre of Postgraduate Medical Education, Department of Obstetrics, Perinatology and Neonatology, Warsaw, Poland

Introduction
Thyroid autoimmunity (TAI) commonly defined as the presence of thyroperoxidase antibodies (TPOAbs) and/or thyroglobulin antibodies (TgAbs) affects up to 15 percent of women of reproductive age and is a well-known risk factor of pregnancy loss. One of the possible explanations of obstetrical complications might be the disturbed process of placentation caused by thyroid antibodies. To test this hypothesis, we evaluated placental hormonal function and placental angiogenic factors in women with TAI.
Materials and methods
91 hypothyroid pregnant women and 39 healthy pregnant controls were enrolled to the study. Patients were divided into two groups: positive for TPOAbs/TgAbs ($n = 58$) and negative for TPOAbs/TgAbs ($n = 33$). All hypothyroid women were diagnosed before pregnancy or at the 1st trimester of pregnancy and treated with L-thyroxine to maintain TSH < 2.5 mIU/l. Maternal thyroid function tests (TSH,fT4,fT3) were established every month throughout pregnancy and angiogenic placental factors: proangiogenic placental growth factor (PlGF), and 2 antiangiogenic factors: soluble vascular endothelial growth factor receptor 1 (sFlt-1), soluble endoglin (sEng) as well as placental hormones: estradiol, progesterone, and human chorionic gonadotropin were determined at each trimester.
Results
Obstetrical and neonatal outcomes did not differ between the groups. TAI negatively impacted placental hormone secretion. Group 1 characterized by lower estradiol concentration compared to group 2 in the 1st trimester: 1682.00 vs 2440.00 pg/mL, $P = 0.016$ and lower progesterone concentration compared to controls in the 2nd trimester: 37.00 vs 50.25 ng/mL, $P = 0.003$. Thyroid autoimmunity was connected with unfavorable placental angiogenic factors profile. Antiangiogenic sEng was higher in group 1 than in group 2 in all three trimesters (1st trimester: 6.79 ± 2.18 vs 5.73 ± 1.41, $P = 0.026$, 2nd trimester: 5.81 ± 1.76 vs 4.68 ± 0.75, $P = 0.022$, 3rd trimester: 7.80 vs 5.60 ng/mL, $P = 0.003$). In group 1 positive correlation between TPOAbs and sFlt-1 in the 3rd trimester: rho = 0.31, $P = 0.040$, and negative correlation between TgAbs and estradiol in the 3rd trimester, and between TgAbs and PIGF in 1st trimester was found (rho = -0.29, $P = 0.043$, and rho = -0.27, $P = 0.037$, respectively).
Conclusion
Our preliminary results suggest that thyroid autoimmunity can negatively influence placental development and function, but further research is needed.

Comparative analysis of pain characteristics in women with and without endometriosis

Lana Oren[1], Lijamol Thoppil[1], George Mkheidze[1], Yaron Meerzon[2], Salome Kaldani[1] & Lela Tandashvili[3]
[1]Tbilisi State Medical University, T'bilisi, Georgia; [2]Georgian American University (GAU), T'bilisi, Georgia; [3]Aversi Clinic, T'bilisi, Georgia

Objective
Endometriosis is a condition marked by presence of endometrial tissue outside the uterus, causing inflammation, adhesions, and pelvic structural changes.[1] Despite its impact on women's quality of life, endometriosis symptoms are viewed as nonspecific, overlapping with other gynecological diseases and are normalized [2], all contributing to a long delay in diagnosis. This cross-sectional study aimed to address these issues by analysing distribution and intensity of chronic pain in laparoscopically confirmed endometriosis patients compared to other gynecological conditions and healthy controls. Compared the severity of cyclic pain between the three cohorts, explored correlations between rASRM staging and common endometriosis pain symptoms (cyclic pain, dyspareunia, dyschezia, and dysuria), and assessed the impact of lifestyle factors (coffee consumption, exercise intensity) on the intensity of chronic pain.
Methods
237 participants were categorized into endometriosis ($n = 76$), other gynecological conditions ($n = 60$), and healthy controls ($n = 101$). Participants provided data by completing a custom questionnaire, including an interactive body map for chronic pain localization.
Results
Women with endometriosis exhibited a higher chronic pain intensity and broader distribution compared to other gynecological conditions or healthy individuals, particularly in the abdomen, pubic, lower back, anterior thighs, and gluteal regions. Similarly, cyclic pain was significantly elevated in endometriosis compared to the other cohorts. Additionally, no significant correlation was found between rASRM staging and the severity of common endometriosis pain symptoms. Finally, lifestyle factors showed no clear associations with chronic pain severity in endometriosis patients.
Conclusion
This study provides insights into the complex landscape of chronic pain in endometriosis, as it revealed higher pain intensities and distribution compared to other gynecological conditions. The findings contribute to a deeper understanding of pain patterns, diagnostic considerations and reconfirm the limitations of the rASRM classification system.

Sexual function, quality of life and gender-related differences in patients with well-differentiated neuroendocrine tumors

Rossella Mazzilli[1], Virginia Zamponi[1], Roberta Modica[2], Cristiano Scandurra[3], Camilla Mancini[1], Franz Sesti[4], Tiziana Feola[4], Elisa Giannetta[4], Nelson Mauro Maldonato[3], Annamaria Colao[2] & Antongiulio Faggiano[1]
[1]Sapienza University of Rome, Department of Clinical and Molecular Medicine, Rome, Italy; [2]Federico II University of Naples, Department of Clinical Medicine and Surgery, Naples, Italy; [3]University of Naples Federico II, Department of Neuroscience, Reproductive Sciences, and Dentistry, Naples, Italy; [4]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy

Introduction
Neuroendocrine neoplasms (NEN) represent a group of rare neoplasms characterized by wide heterogeneity in terms of biological characteristics and clinical behavior. Despite their increasing relevance in the oncology field, health-related quality of life (HRQoL) and sexual function remain poorly investigated.
Aim
To investigate sexual function in patients affected by NEN; to evaluate the impact of clinical severity (presence or absence of metastases and tumor grade), heterogeneity (location of primary tumor and presence or absence of endocrine syndrome) and NEN therapies on sexual function and HRQoL; to study the possible correlation between these features and biochemical and psychological parameters.
Materials & Methods
In this cross-sectional, multicenter study, patients with a new diagnosis of gastroenteropancreatic (GEP) or bronchial NEN, aged 18 to 75 years, were recruited. Tumor severity, clinical heterogeneity, therapies performed were valuated. Through validated questionnaires, data about sexual function, sex-related distress, HRQoL, anxiety and depression were also collected. Furthermore, blood concentrations of LDL, glucose, HbA1c, and sex hormones were measured.
Results
To date, a total of 50 patients (28 men and 22 women) has been included. The mean age was 59.2 and 58.7 years, respectively. Of them, 71.6% were GEP, 33.4% bronchial; furthermore, 73.7% of patients were on systemic therapy, 35.0% had a metastatic form and 21.1% had an endocrine syndrome. The prevalence of erectile dysfunction (ED) was 60.7% (17/28) and the prevalence of female sexual dysfunctions (FSD) was 50.0% (11/22), without significant gender differences regarding the prevalence of dysfunctions and sex-related distress ($P=$ 0.5). Furthermore, only 17.9% (5/28) of men were satisfied with their sexual life, compared to 31.8% of women (7/22; $P=0.32$). A different impact of tumor severity on men and women was found; while tumor grading mainly influenced sexual function in men ($P=$ 0.001), the presence of metastases would seem to be the most impacting factor on sexual function in women ($P=$ 0.023). Higher levels of sexual distress reported higher glucose levels and greater perceived psychological distress, as well as a lower HRQoL (P = 0.039, $r=$ 0.45). Furthermore, only female sexual function was related with LDL values ($P=0.03$, $r=0.8$).
Conclusion
These results highlighted the relationship between NEN clinical severity, sexual dysfunction, and sex-related distress, suggesting that more attention should be paid to sexual function and distress in the clinical management of NEN patients, including female population, to promote better QoL and minimize psychological distress.

Aromatase inhibitors and abrupt increase obesity rates among in males during puberty

Rezo Jamburia[1], Tekle Bakhtadze[1], Shota Janjgava[1], Ana Davitashvili[1], Natia Goletiani[1], Medea Zhgenti[1] & Elene Giorgadze[1]
[1]National Institute of Endocrinology - ენდოკრინოლოგიის ეროვნული ინსტიტუტი, Tbilisi, Georgia

Even in the presence of normally circulating androgens, the imbalance between estrogen and androgen in males between the prepubertal and pubertal periods may have an impact on male reproductive function. While there are many variables that affect how each person reaches puberty at different times, boys who are becoming more obese have higher aromatase activity. This enzyme turns testosterone into estradiol permanently, which lowers testosterone levels and raises estrogen levels. It has been observed that aromatase inhibitors enhance boys' pubertal condition and increase height prediction in boys of short stature. The study aims to establish the safety and efficacy of aromatase inhibitors in pediatric male patients with hypoestrogenic hypogonadism, as well as the relevance of analysis in interpreting the rise in obesity and the advantages of treatment among children. A retrospective investigation was carried out on guys between the ages of 12 and 17 who were in the process of puberty and had a confirmed diagnosis of hypoestrogenism along with symptoms of delayed puberty. Information was taken from medical records who visited the clinic between 2020 and 2023. A BMI-for-age percentile calculation was made using CDC growth charts as a guide. Three groups comprised us: The first group, consisting of fifty-five patients, underwent lifestyle modification, A second group of fifty-five individuals received aromatase inhibitors in conjunction with lifestyle modification, Third Group: fifty-five patients where used Life style modifation with Placebo. Findings: We examined 165 boys' medical records. In 2021, out of the 35 patients that underwent evaluation, 34% were overweight, 54% were obese, and 12% had severe obesity. In 2022, out of the 54 individuals that underwent evaluation, 35% were overweight, 43% were obese, and 22% had severe obesity. As of 2023, out of the 76 patients that underwent evaluation, 31% were overweight, 46% were obese, and 23 severely obese. Following a half-year of therapy, the II group experienced a statistically significant rise in testosterone and a statistically significant drop in estradiol. The same outcomes were observed for HOMA-IR, metabolic indices, and pubertal development.
Conclusions
Recent research indicates that the prevalence of obesity and the metabolic syndrome is correlated with the increase in hypoestrogenic, hypogonadotropic teenagers. Aromatase inhibitors are more beneficial when used in this type of patient, although more controlled research is required to confirm the safety and effectiveness of aromatase inhibitors in juvenile patients.

Diagnosis experiences in an international sample of lean women with PCOS

Melissa Masters[1], Kenlee Dropping[1], Amie Parry-Jones[2] & Rachel Sinley[1]
[1]Metropolitan State University of Denver, Department of Nutrition; [2]No Affiliation

Background
Polycystic Ovary Syndrome (PCOS), an endocrine disorder affecting 9-18% of reproductive-aged women, impacts all body types including those with a normal body mass index (BMI) often termed lean or atypical PCOS. This study aimed to investigate the diagnosis experience in an international sample of lean women with PCOS.
Methods
Participants were recruited from social media sites aimed at women with PCOS. Eligibility criteria included being ≥18 years of age, having a prior diagnosis of PCOS, and having a self-reported BMI ≤25 kg/m^2. Survey questions were adapted from previously published research. Categorical data were analyzed as count and proportions. Chi-squared tests were conducted to test for associations between various factors and satisfaction with the diagnosis experience. Strengths of associations were further assessed using Cramer's V coefficients. Post-hoc analysis was conducted using adjusted standardized residuals. Statistical significance was set at $P<0.05$. Qualitative data was analyzed utilizing an inductive thematic approach.
Results
Participants ($n=150$) represented 31 countries. Approximately 49.0% reported PCOS diagnosis experience dissatisfaction, 72.8% disagreed that there is adequate information about lean PCOS and 80.2% disagreed that health professionals have adequate knowledge about lean PCOS. Significant associations were found between length of time to diagnosis and diagnosis satisfaction ($P=0.001$, X2= 18.133, df=4, Cramer's V=0.258) as well as number of medical professionals seen and diagnosis satisfaction ($P<0.001$, X2=18.095, df=2, Cramer's V= 0.362). The top three PCOS concerns reported included irregular menstrual cycles (72.0%), hormone imbalance (64.7%), and anxiety (49.3%). Online blogs, support groups or forums (69.3%) and social media sites (48.7%) were the primary sources participants turned to for PCOS information. Qualitative analyses revealed the following primary theme across all questions: participants received limited information from providers about PCOS management. Secondary themes included participants reporting the need to conduct their own research on the condition and a focus on weight throughout the diagnosis process. Participants reported feeling that providers dismissed PCOS as a possible diagnosis, or focused on weight management in the treatment plan, despite their normal BMI. Overall, the diagnosis experience was reported to be an emotional journey.
Conclusions
This study demonstrates that the diagnosis experience in lean women with PCOS includes high feelings of dissatisfaction and is an emotional journey. The results of this study highlight opportunities for improvement in PCOS healthcare given and received worldwide, including in patients with lean PCOS. Future research should further examine lived experiences of women with lean PCOS.

The impact of motivational interviews and hospitalization in themanagement of obesity associated infertility

Dijana Jankovic[1], Kristina Saravinovska[1], Neda Delic[2], Antoan Stefan Sojat[1], Ilija Gunjic[3], Miomira Ivovic[1], Tijana Petkovic[1], Natalija Antic[1], Dragana Mitrovic[1], Suzana Mutavdzic[4], Zorana Arizanovic[1], Svetlana Vujovic[1] & Ljiljana Marina[1]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Centre, National Centre for Infertility and Endocrinology of Gender, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [3]Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia; [4]General Hospital of Novi Pazar, Department of Psychiatry, Novi Pazar, Serbia

Introduction
The interplay between obesity and hormones has a profound impact on women's reproductive health, reducing the likelihood of successful conception.
Methods
We performed a 6-month longitudinal study. The inclusion criteria were: women aged 20-40 with infertility, regular anovulatory menstrual cycles, BMI 35-40 kg/m^2, unrelated to other diseases. 30 eligible women were categorized into three groups: Group 1 (G1) received motivational interviews, hospitalizations, and nutritionist check-ups; Group 2 (G2) underwent hospitalization and nutritionist check-ups, while Group 3 (G3) served as the control without any interventions.
Results
G1-mean age 32.2±5.5, mean starting BMI (BMI1) 35.6±6.4 kg/m^2, G2-mean age 36.4±4.1, mean BMI1 38.2±4.9 kg/m^2, G3-mean age 33.7±4.9, mean BMI1 35±1.0 kg/m^2, with no difference in age or BMI between the groups ($P>0.05$). After 6 months, G1 lost 15.5±7.4% of their initial body weight (BW) i.e 14.5±9.09% of the BMI1, G2 lost 10.9±8.07% BW i.e. 11.05±8.2% BMI1, G3 lost 0.38±1.8% BW i.e. 0.41±1.08% BMI1 ($P<0.0001$). When compared based on percentage of BMI loss, there was a difference between G1-G3 ($P<0.001$), G1-G2 ($P<0.01$), but no difference between G2-G3 ($P>0.05$). When compared based on percentage of BW loss, there was a difference between G1-G3 ($P<0.0001$), G2-G3 ($P=0.02$), but no difference between G1-G2 was observed ($P>0.05$). After 6 months, only in G1 progesterone reached ovulatory levels 10.88± 8.72 nmol/l ($P<0.05$), where in G2/8.6±5.9 nmol/l and G3/3.4± 1.65 nmol/l, this effect was absent ($P<0.05$). Progesterone levels were significantly higher in G1 than in G3 ($P=0.034$) although there was no difference between the groups G1 and G2 ($P>0.05$) and G2 and G3 ($P>0.05$). The number of hospitalizations with motivational interview was a linear predictor of percentage of weight loss ($P<0.0001$, B=3.785, 95% CI 2.08-5.48, OR 4.553).
Conclusion
The motivational interview emerges as a promising and effective method with a significant role in the reduction of excessive body weight. The combined approach of motivational interviews and hospitalization presents a synergistic strategy in the comprehensive treatment of obesity and its associated reproductive health challenges.

Early response with fezolinetant treatment of moderate-to-severe vasomotor symptoms associated with menopause in women considered unsuitable for hormone therapy: phase 3b daylight study

Angelica Lindén Hirschberg[1], Céline Bouchard[2], Antonio Cano[3], Katrin Schaudig[4], Karla Martins[5], Kentaro Miyazaki[6], Xi Wu[7] & Xuegong Wang[7]
[1]Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden; [2]Clinique de Recherche en Santé de la Femme, Quebec City, Canada; [3]University of Valencia, Valencia, Spain; [4]Hormone Hamburg, Hamburg, Germany; [5]Astellas Pharma Europe Ltd, Addlestone, United Kingdom; [6]Astellas Pharma Inc., Tokyo, Japan; [7]Astellas Pharma Global Development, Northbrook, IL, United States

Introduction
There is a need for well tolerated and effective nonhormonal therapies for vasomotor symptoms (VMS) associated with menopause. Fezolinetant is a nonhormonal, selective neurokinin 3 receptor antagonist that is approved for the treatment of moderate-to-severe VMS associated with menopause.
Objective
To assess how early a response to fezolinetant in frequency and severity of moderate-to-severe VMS was observed in the 24-week placebo-controlled DAyLIGHT study.
Methods
Daylight (NCT05033886) was a phase 3b, randomised, double-blind, 24-week placebo-controlled study. Participants were women aged ≥40 to ≤65 years with moderate-to-severe VMS who were unsuitable for hormone therapy (HT) based on four categories - contraindications, caution (prior medical history), stoppers (lack of efficacy, side effects, or medical advice), or averse (made informed choice not to take HT after discussion with clinician) - and randomised 1:1 to placebo or fezolinetant 45 mg once daily. The primary endpoint was mean change in daily VMS frequency of moderate-to-severe episodes from baseline to week 24. Mean change in VMS severity (key secondary endpoint) and safety were also assessed.
Results
Overall, 453 women were enrolled (placebo $n=226$; fezolinetant $n=227$), including HT contraindicated (51, 11%), caution (165, 36%), stoppers (69, 15%), and averse (168, 37%). Participants treated with fezolinetant 45 mg had a greater reduction from baseline in the daily mean change in frequency of moderate-to-severe VMS compared with placebo during the first week of treatment (day 7 least squares [LS] mean difference: –2.20; 95% CI: –2.78, –1.61; $P<0.001$). VMS frequency consistently decreased from days 1 to 6, with the strongest decrease during the first 3 days. Participants treated with fezolinetant 45 mg had a greater reduction from baseline in the daily mean change in VMS severity compared with placebo from days 2 to 7 (day 7 LS mean difference: –0.17; 95% CI: –0.23, –0.10; $P<0.001$). Improvements in VMS frequency and severity were sustained through week 24. No safety signals of concern were apparent for the 45 mg fezolinetant dose through week 24.

Conclusions
Daylight is the first study of fezolinetant to investigate efficacy vs placebo over 24 weeks. Fezolinetant 45 mg was efficacious and well tolerated for moderate-to-severe VMS in women considered unsuitable for HT. An effect on VMS frequency was seen as early as day 1 and maintained through the 24-week placebo-controlled period, demonstrating a rapid onset of action and sustained efficacy with fezolinetant treatment.

Renal 11β-hydroxysteroid dehydrogenase type 2 is of central importance for 11-oxygenated androgen biosynthesis and is disrupted in chronic kidney disease

Maria Tomkins[1,2], Tara McDonnell[1,2], Leanne Cussen[1,2], Michael S Sagmeister[3], Imken Oestlund[4], Fozia Shaheen[3], Lorraine Harper[3], Rowan S Hardy[3], Angela E Taylor[3], Lorna C Gilligan[3], Wiebke Arlt[3,5,6], Marie McIlroy[1], Declan de Freitas[7], Peter Conlon[7], Colm Magee[7], Mark Denton[7], Conall O'Seaghdha[7], Jacky Snoep[4], Karl Heinz-Storbeck[4], Mark Sherlock[1,2] & Michael W O'Reilly[1,2]
[1]Royal College of Surgeons in Ireland, Academic Division of Endocrinology, Department of Medicine, Dublin, Ireland; [2]Beaumont Hospital, Department of Endocrinology, Dublin, Ireland; [3]University of Birmingham, Institute of Metabolism and Systems Research, United Kingdom; [4]Stellenbosch University, Department of Biochemistry, Stellenbosch, South Africa; [5]MRC Laboratory of Medical Sciences, London, United Kingdom; [6]Institute of Clinical Sciences, Imperial College London, London, United Kingdom; [7]Beaumont Hospital, Department of Nephrology, Dublin, Ireland

11-oxygenated androgens are a group of adrenal-derived C19 steroids that require activation in peripheral tissues. 11β-hydroxysteroid dehydrogenase type 2 (HSD11B2) has been shown *in vitro* to be essential for 11-oxygenated androgen activation, converting 11β-hydroxyandrostenedione (11OHA4) to 11-ketoandrostenedione (11KA4), the direct precursor of the potent androgen 11-ketotestosterone (11KT). As the kidney is the major site of HSD11B2 expression, we hypothesized that patients with chronic kidney disease (CKD) would have reduced 11-oxygenated androgen activation due to impaired renal HSD11B2 activity. In this cross-sectional multicentre cohort study of patients with CKD and healthy controls, serum and urinary multi-steroid profiling by liquid chromatography-tandem mass spectrometry (LC-MS/MS) was performed to measure 11-oxygenated androgens, classic androgens and glucocorticoids. Serum and urinary cortisol/cortisone ratios, previously established as validated surrogate markers of HSD11B2 activity, were calculated. A computational model of peripheral 11-oxygenated biosynthesis was fitted to the serum data and used to calculate relative HSD11B2 expression levels for each patient and control. We performed serum and urinary multi-steroid profiling in 90 patients with CKD [65% male, median age 64 (IQR 52-70) years, median estimated glomerular filtration ratio (eGFR) 23 (IQR 13-39) ml/min] and 56 healthy controls [11% male, median age 34 (IQR 30 – 41) years, median eGFR 103 (IQR 90 – 119) ml/min]. HSD11B2 activity declined with reducing eGFR. Serum concentrations of cortisone, 11KA4, 11KT and 11β-hydroxytestosterone (11OHT) were all significantly lower in patients with CKD compared to controls ($P<0.01$ for each). There was a strong correlation between eGFR and HSD11B2-dependent steroids in serum [cortisone ($r=0.77$, $P<0.01$), 11KA4 ($r=0.48$, $P<0.01$), 11OHT ($r=0.35$, $P<0.01$) and 11KT ($r=0.58$, $P<0.01$)], and urine [cortisone ($r=0.59$, $P<0.01$), 11β-hydroxyandrosterone ($r=0.32$, $P<0.01$) and 11-oxoandrosterone ($r=0.39$, $P<0.01$)]. Significant associations between classic androgens and eGFR were not observed. Patients with CKD had an increased ratio of 11OHA4 /(11KA4 + 11KT + 11OHT), reflective of reduced HSD11B2 activation of 11-oxygenated androgens. This ratio declined significantly across each stage of CKD from III-V ($P<0.01$). Using a computational model based on enzyme kinetic parameters of 11β-hydroxysteroid dehydrogenase type 1, HSD11B2, 17β-hydroxysteroid dehydrogenase type 2 and aldoketoreductase 1C3, we accurately predicted HSD11B2 as the key enzyme responsible for reduced 11-oxygenated androgen activation in CKD, with predicted HSD11B2 expression correlated with eGFR. This is the first study to demonstrate impaired 11-oxygenated androgen biosynthesis in patients with CKD. It confirms a central role for renal HSD11B2 in the activation of 11OHA4 to the potent 11-oxygenated androgen 11KT.

Gonadal and sexual function in men living with HIV: a real-life single centre experience

Ilaria Bonaventura[1,1], Valeria Hasenmajer[1], Valentina Sada[1], Lorenzo Cerroni[1], Nicolò D'Addario[1], Gabriella D'Ettorre[2], Claudio Mastroianni[2], Carlotta Pozza[1] & Daniele Gianfrilli[1]
[1]Sapienza University of Rome, Experimental Medecine; [2]Sapienza University of Rome, Department of Public Health and Infectious Diseases

Background
Hypogonadism and sexual dysfunction, particularly erectile dysfunction (ED), are common in men living with HIV (MLWH), but the link between testosterone levels and sexual function remains unclear in this population. The aim of this study was to estimate the prevalence of hypogonadism and sexual dysfunction and to explore the relationship between HIV-related variables and gonadal and sexual function in MLWH.
Materials and Methods
Serum total testosterone (TT), sex hormone binding globulin (SHBG), luteinizing hormone (LH), follicle-stimulating hormone (FSH) and estradiol (E2) were assessed in sixty MLWH. Free testosterone was calculated (cFT) by using the Vermeulen equation. Sexual function was assessed through the International Index of Erectile Function-15 (IIEF-15). According to guidelines, diagnosis of biochemical hypogonadism was made when serum TT $\leq$ 12 nmol/l and/or cFT $<$ 0.22 nmol/l. Body mass index (BMI), waist circumference (WC) and HIV-related variables (duration of HIV infection, $CD4^+$ cells count, and antiretroviral therapy used, ART, such as Integrase Strand Transfer Inhibitor, INSTI, Non-Nucleoside Reverse Transcriptase Inhibitor, NNRTI, Nucleoside Reverse Transcriptase Inhibitor, NRTI and Protease Inhibitor, PI), were also evaluated.
Results
Out of 60 MLWH, 42 (70%) presented ED. Subgroup analysis was performed according to the presence or absence of hypogonadism, that was observed in 11 MLWH (18.3%), 8 of whom (72.7%) presented hypogonadotropic hypogonadism. Interestingly, no differences in the five domains of IIEF-15 were found between MLWH with hypogonadism and those with eugonadism, despite pathological scores in both groups. In addition, MLWH with hypogonadism compared to those with eugonadism had significantly increased BMI ($P=0.046$) and smoking habits prevalence ($P=0.002$) and lower E2 ($P=0.017$). Considering gonadal function in the whole cohort, TT was negatively related to BMI ($r=$-0.595, $P=0.001$) and WC ($r=$-0.656, $P=0.011$), and positively related to E2 ($r=0.457$, $P=0.006$) and SHBG ($r=0.325$, $P=0.033$). cFT was related to BMI ($r=$-0.519 $P=0.023$) and WC ($r=$-0.719, $P=0.019$). Considering ART, higher TT, SHBG and E2 were found in MLWH using PI (respectively, $P=0.018$, $P=0.015$ and $P=0.020$). Moreover, prevalence of ED was higher in MLWH using INSTI ($P=0.017$).
Conclusion
Sexual dysfunction is a highly prevalent multifactorial disorder in MLWH. Decreased serum testosterone levels, which are also related to increased visceral fat accumulation, are not the only driver of the onset of ED. HIV-related factors, such as ART, also appear to have an impact on gonadal and sexual function. Consequently, the clinical management of sexual health in MLWH requires a multidisciplinary approach, involving experts in infectious diseases and sexual medicine.

Background
Sex chromosome mosaic aneuploidy 46,XX/47,XXy (mKS-XX) is a very rare syndrome, with only twenty-one cases previously reported. No patients' series with mKS-XX and no comparative studies between mKS-XX and the common homogeneous Klinefelter syndrome (KS) have so far been described.
Aims
To describe the clinical, biological and socio-professional characteristics of the first series of previously unpublished patients with mKS-XX. To find predictors discriminating patients with mKS-XX from those with KS.
Patients and Methods
MOSAI-XX is a retrospective study providing descriptive analyses of consecutive patients having mKS-XX diagnosed across different European tertiary referral centers. The clinical presentation, the prevalence of disorders of sex development/ovotesticular disorder (DSD/OT), anthropometric measures, hormone levels, gonadal characteristics and socio-professional statuses (schooling, precariousness scores and job positions) of mKS-XX have been compared to those from a cohort of 121 KS patients.
Results
Fifteen patients (fourteen adults) with mKS-XX have been identified and confirmed from 1986 to 2022 from four European tertiary referral centers. The mean ($\pm$SD) percentage of XX lineage in peripheral karyotypes was 57$\pm$27% (range 7-82%). The prevalence of DSD/OT was higher in mKS-XX than in KS patients (26.7% vs 1.1%, $P=0.0067$). 3/30 gonads from mKS-XX and 0/242 from KS patients had an ovarian component ($P=0.0012$). However, the number of gonads harboring ovarian tissue was lower in our series than in pooled previous case reports (17/36, $P=0.01$). The final height and the statural gain over midparental height were both lower in mKS-XX than in KS patients (173.6$\pm$14.3 vs 181.3$\pm$7.9 cm, $P=0.016$, and -3.8$\pm$6.8 vs +7.9$\pm$7.4 cm, $P=0.0003$, respectively). Testicular volumes did not differ between mKS-XX and KS (2.4$\pm$0.7 vs 3.0$\pm$1.8 mL), nor did concentrations of LH, FSH, total testosterone, estradiol and testicular peptides ($P=$ns for all comparisons). Individuals with mKS-XX performed better in schooling achievements and more frequently occupied high intellectual professions than KS ($P=0.017$ and $P=0.015$, respectively). Precariousness scores were lower in mKS-XX than in KS patients ($P=0.017$).
Conclusion
We describe the first European series of patients carrying a 46,XX/47,XXy mosaic KS. We found a lower DSD/OT and a higher KS-like phenotype prevalence than those previously known from case reports. Beyond DSD/OT, we found that anthropometric measures and socio-professional statuses were also able to discriminate mKS-XX from KS. Our results improve the current knowledge about the mKS-XX syndrome. In addition, our results may have an impact on the genetic counseling for pregnant women and couples confronted with offspring carrying this rare chromosomal formula.

Regulation of PGR gene expression in immortalized human endometrial stromal cells

Alejandra Monserrat Retis Resendiz[1], Martha Paloma Domínguez Mora[1], yesenia Cid-Cruz[1], Moisés León-Juárez[2], Jessica Romero Reyes[1], Elizabeth García-Gómez[1], Ignacio Camacho-Arroyo[1] & Edgar Ricardo VÁZquez Martínez[1]
[1]Instituto Nacional de Perinatología "Isidro Espinosa de los Reyes"-Facultad de Química, UNAM., Unidad de Investigación en Reproducción Humana, Mexico City; [2]Instituto Nacional de Perinatología "Isidro Espinosa de los Reyes", Inmunobioquímica, Mexico City

Background
Decidualization, a crucial process for successful pregnancy establishment and maintenance, involves endometrial stromal cell differentiation. This process is orchestrated by estradiol (E2), progesterone, and other stimuli that increase intracellular cyclic adenosine monophosphate (cAMP) levels. The progesterone receptor (PR) plays a pivotal role in regulating decidualization, and alterations in its expression are linked to endometrial pathologies. However, the mechanisms governing PR gene (*PGR*) expression in endometrial stromal cells during decidualization are not fully understood. This study aimed to identify the mechanisms of *PGR* expression regulation in immortalized human endometrial stromal cells.
Methods
Immortalized human endometrial stromal cells (T-hESC, ATCC, CRL4003) were exposed to individual and combined treatments of E2, medroxyprogesterone (MPA), and cAMP. To understand the underlying action mechanisms of the decidualization stimulus components, we examined the effect of estrogen receptors and PR antagonists, as well as a Protein Kinase A (PKA) inhibitor. We evaluated the expression of *PGR* isoforms and decidualization-associated genes by RT-qPCR. ChIP-seq and 4C experiments were also performed to identify putative distal regulatory regions involved in *PGR* expression in T-hESC treated with E2, MPA, and cAMP (EMC).
Results
The expression of *PGR-AB* and *PGR-B* was induced after 24 hours of treatment with EMC compared to the vehicle. Interestingly, cAMP induced *PGR-AB* and *PGR-B* expression by activating the PKA signaling pathway, while MPA downregulated their expression through the PR. Furthermore, four distal regions interacting with the *PGR* promoter were identified, three characterized by the presence of H3K4me1 and an increase in the enrichment of H3K27ac when T-hESC were treated with EMC for 24 hours.
Conclusion
This study provides evidence that during *in vitro* decidualization with EMC, cAMP plays a crucial role in inducing the expression of *PGR-AB* and *PGR-B* through PKA signaling pathway. Moreover, the identification of distal regions interacting with the *PGR* promoter, enriched with H3K4me1 and H3K27ac, suggests the existence of complex networks of genetic regulation influencing *in vitro* decidualization in T-hESC cells.

Congenital hypogonadotropic hypogonadism by PNPLA6 mutations: identification of a wide phenotypic spectrum and functional correlations with the NTE *in vitro* activity

Luigi Maione[1], Jerome Bouligand[2], Antoine Rousseau[3], Salome Prevost[4], Lydie Naule[5], Sylvie Salenave[1], Philippe Chanson[1], Ursula Kaiser[6] & Jacques young[7]
[1]Saclay University, Endocrinology and Reproductive Diseases, Le Kremlin-Bicêtre, France; [2]Saclay University, Genetics, Le Kremlin-Bicêtre, France; [3]Saclay University, Ophtalmology, Le Kremlin-Bicêtre, France; [4]Kremlin-Bicètre, Genetics, Le Kremlin-Bicêtre, France; [5]Paris, Sorbonne University, Paris, France; [6]Brigham and Women's Hospital, Boston, United States; [7]Saclay University, Endocrinology and Reproductive Diseases, Le Kremlin-Bicêtre, France

Background
PNPLA6 mutations are associated with complex autosomal recessive disorders including congenital hypogonadotropic hypogonadism (CHH): Gordon-Holmes syndrome, Boucher-Neuhauser syndrome and hereditary spastic paraplegia, which include ophthalmologic and neurologic disorders in addition to CHH. *PNPLA6* gene encodes the neuropathy target esterase (NTE), an endoplasmic reticulum-associated enzyme intervening in the metabolism of membrane phospholipids.

Aim
Analysis of prevalence of *PNPLA6* mutations within a large cohort of CHH patients. Clinical, biological, neuroendocrine and molecular characterization of six patients from three unrelated families, carrying five *PNPLA6* biallelic mutations.
Patients and Methods
Neuroendocrine profile: measurement of 4 hours-spontaneous LH pulsatility and response to bolus and repeated GnRH (by pump), neurological and ophthalmological examinations of affected patients. Assessment of the enzymatic activity on cell lysates expressing wild-type (WT) and mutant NTE.
Results
Biallelic *PNPLA6* mutations are very rare (<1% among 800 exomes in CHH patients). Two brothers harbored a homozygous, four patients a composite heterozygous mutation. Phenotypic spectrum was wide, ranging from severe neurological and ophthalmological manifestations (spastic paraplegia, cerebellar ataxia and chorioretinitis) to a very mild phenotype. Neuroendocrine profile showed apulsatile and unresponsive LH to bolus and repeated GnRH exposure. Molecular analyses showed a variable degree of loss of activity of NTE function according to various mutations. A phenotype-genotype correlation was observed, with a low impact NTE disruption seen in patients with the mildest phenotype.
Conclusion
PNPLA6 mutations are associated with a more diverse phenotype than that previously known. *PNPLA6* mutations cause a pituitary deficiency at the level of gonadotropes. Following our results, we recommend to include the sequencing of *PNPLA6* gene in all patients with CHH.

Expression of the serotonin signaling pathway in a testicular adrenal rest tumor in a patient with 21-hydroxylase deficiency

Lola Menager[1], Aurelie Rives-Feraille[1,2], Laura Moutard[1], Nathalie Rives[1,2], Hervé Lefebvre[1,3] & Estelle Louiset[1]
[1]Univ Rouen Normandie, Inserm, NorDiC UMR 1239, Rouen, France; [2]Rouen University Hospital, Biology of Reproduction-Cecos Laboratory, Rouen, France; [3]Rouen University Hospital, Department of Endocrinology, Diabetes and Metabolic Diseases, Rouen, France

Testicular adrenal rest tumors (TART) are frequently detected in male patients with 21-hydroxylase (21-OH) deficiency. Increase in plasma ACTH levels, due to cortisol deficit, is responsible for TART growth. Indeed, glucocorticoid substitution reduces both plasma ACTH and TART development in the majority of patients. Nevertheless, some patients with TART are resistant to the glucocorticoid treatment, suggesting the existence of other factors stimulating TART growth. The aim of the study was to characterize the phenotype of TART cells in the testicular tissue of a treatment-resistant 38-year-old patient. It also aimed to investigate the expression of the serotonin (5-HT) signaling pathway in TART, similar to that described in adrenal hyperplasias of patients with 21-OH mutations (Le Mestre *et al*. JCEM 2019; 104:4967-80). Immunostainings showed the presence of ACTH receptor (MC2R), 3β-hydroxysteroid dehydrogenase (3β-HSD2), a steroidogenic enzyme involved in the synthesis of glucocorticoids and androgens, and 11β-hydroxylase, the key enzyme for cortisol production, in the majority of TART cells. In addition, some tumor cells were immunopositive for 17β-HSD type 5 (17β-HSD5, AKR1C3), the enzyme responsible for testosterone synthesis in adrenal glands, whereas they were immunonegative for 17β-HSD3, the testicular isoenzyme. The study revealed the expression of TPH1, the limitant enzyme in 5-HT synthesis, and 5-HT receptor types 4 and 6 in the tissue. These data confirm the adrenal phenotype of TART cells and demonstrate expression of several actors of the 5-HT signaling pathway in the patient's TART tissue. This work should be extended to a series of TART tissues. Moreover, *in vitro* functional studies conducted on TART cell cultures might evaluate a possible role of locally-produced 5-HT on tumor cell proliferation.

Background
Polycystic ovary syndrome (PCOS) is the most common endocrine disorder in reproductive-age women. PCOS women often have hyperandrogenemia that is associated with adiposity and a worse metabolic profile. However, the depots-specific effect of different white adipose tissues (WAT) in mediating the systemic metabolic dysfunction is not fully understood in PCOS. Therefore, using a well-established mouse model of PCOS, we aim to test the hypothesis that excess androgen will induce systemic metabolic dysfunction and depot-specific WAT derangements.
Methods
Three-week old female mice (C57BL/6N) were implanted with Silastic tubes filled with DHT (8 mg, s.c.) or vehicle ($n=6$/grp) for 30 days. Weekly body weight (BW, gravimetry), body composition (EchoMRI), retroperitoneal fat (RPF) mass- visceral fat depot and inguinal-gluteal subcutaneous fat (SCF) mass (gravimetry) were assessed. Serum leptin, adiponectin, and non-esterified free fatty acid (NEFA) were measured with ELISA. RPF and SCF, the lipogenesis markers acetyl coA carboxylase (ACC) and fatty acid synthetase (FAS), the lipolytic markers adipose triglyceride lipase (ATGL) and hormone sensitive lipase (HSL) and adipogenesis marker peroxisome proliferator-activated receptor-γ (PPAR-γ) protein levels were assessed by Western blot.
Results
PCOS mice showed significant ($P<0.05$) increases in BW (1.15-fold), lean mass (1.14-fold), total fat mass (2-fold), RPF mass (2-fold), SCF mass (1.2-fold), leptin (1.2-fold), NEFA (1.3-fold) and lower insulin-sensitizing adipokine adiponectin levels (50%) compared to their vehicle. At the molecular level, in RPF, DHT downregulated ACC and FAS by 50% and 20% respectively. PCOS mice has lower lipolysis in the RPF represented by lower expression of lipases ATGL (50%) and HSL (40%). There was also decrease in the adipogenesis marker PPAR-γ (40%) in RPF in PCOS mice. On the other hand, in SCF ATGL (15%) and HSL (20%) was increased with no changes in FAS and ACC in PCOS mice compared to their vehicle.
Conclusion and significance
Our findings suggest systematic metabolic dysfunction is associated with the depot specific alteration or changes in the markers of adipogenesis and lipogenesis, where both were increased in RPF and decreased in SCF. The observed decrease in SCF could be protective and could help to ameliorate some of the metabolic changes associated with PCOS. Therefore, depot specific targeting may be a possible therapeutic approach for PCOS associated metabolic dysfunction.
