FOREWORD

The International Scientific and Professional Conference POLITEHNIKA 2023 represents the seventh edition of the POLITEHNIKA scientific and professional events, occurring biannually since its inaugural event in 2011. POLITEHNIKA 2023 upholds a distinguished tradition and commitment to integrating higher education and practical application across a diverse spectrum of disciplines represented by defined thematic scopes.

Organized with the patronage of the Ministry of Education of the Republic of Serbia, the Ministry of Environmental Protection of the Republic of Serbia, the Ministry of European Integration of the Republic of Serbia, the Directorate for Occupational Safety and Health, the Office for Dual Education and National Qualifications Framework, the Conference of Academies of Applied Studies in Serbia, the Chamber of Commerce of Serbia, the Chamber of Commerce of Belgrade, the Institute for Standardization of Serbia, the Association of Belgrade Architects, the City of Požarevac and the Tourist Organization of the City of Požarevac, POLITEHNIKA 2023 stands as a collaborative platform at the intersection of academia, governmental institutions and industry.

This year heralds a notable progression with its international status and the incorporation of 10 conference scopes. Expanding beyond the thematic domains featured in previous events, the Conference now encompasses Environment and Sustainable Development, Occupational Safety and Health and Fire Safety, Smart Management Systems, Graphic Engineering, Design, Traffic Engineering, Biotechnology and Healthcare, Mechanical Engineering, Ecotourism and Rural development, and Mechatronics. By engaging experts, emerging professionals, and practitioners from these domains, the conference unifies fields of study programs of the Academy of Applied Technical Studies Belgrade. The thematic scopes, coupled with the structure of the compiled papers in this Proceedings, exhibit a rich diversity and multidisciplinary approach, fundamentally contributing to a holistic examination and resolution of societal and scientific challenges.

Comprising over 220 peer-reviewed contributions, the Proceedings represent a substantial intellectual asset, aligning with the conference's overarching objective of fostering the exchange of knowledge, research findings, and professional experiences among experts from industry, research institutions, and higher education establishments.

The Proceedings of the International Scientific and Professional Conference POLITEHNIKA 2023 serve as a comprehensive snapshot of the current landscape within the thematic realms of the conference, offering both insights and directives for ongoing scientific and professional development. Moreover, they proffer concrete solutions to practical challenges grounded in contemporary trends and pertinent insights.

The Academy of Applied Technical Studies Belgrade extends its sincere appreciation to all conference supporters whose financial contributions played a pivotal role in its successful realization. Special acknowledgment is reserved for the authors of the papers, whose diligence and eagerness to present their work to a wider audience, alongside the reviewers and members of the International Scientific Committee, Program Committee and Organizational Committee, have collectively contributed to the triumph of the International Scientific and Professional Conference POLITEHNIKA 2023.

Belgrade, December 2023
EDITORS

ENVIRONMENT AND SUSTAINABLE DEVELOPMENT

INVITED PAPERS

Srećko Stopić, PhD, Bernd Friedrich, PhD, Process Metallurgy and Metal Recycling, RWTH Aachen University, Germany
Advances in understanding of a role of unit metallurgical operations for recycling

Svetlana Grujić, PhD, Faculty of Technology and Metallurgy, University of Belgrade
Emerging pollutants in the environment: contamination of the Danube river basin in Serbia

Marija Nikolić, PhD, Faculty of Technology and Metallurgy, University of Belgrade
Biodegradable polyesters – from ecology to medicine

DESIGN

INVITED PAPER

Jelena Ristić Trajković, PhD, Faculty of Architecture, University of Belgrade
Society, Ecology and Design Education: Transformative Learning for Future Sustainable and Healthy Environments

MECHANICAL ENGINEERING

INVITED PAPERS

Tamara Bajc, PhD, Faculty of Mechanical Engineering, University of Belgrade
Energy savings and CO_2 emission reduction potential through the existing building renovation

Marko S. Jarić, PhD, Innovation Centre of Faculty of Mechanical Engineering in Belgrade
Analysis of remediation of horizontal cylindrical tank for oil storage

ECOTURISAM AND RURAL DEVELOPMENT

INVITED LECTURES

Marko Perić, PhD, Faculty of Tourism and Hospitality Management, University of Rijeka, Croatia
Challenges of sustainable tourism: Example of Croatia

Snežana Štetić, PhD, Balkan Network of Tourism Experts, Igor Trišić, PhD, Faculty of Geography, University of Belgrade
Selective forms of tourism and sustainable development of rural tourist destinations

INVITED PAPERS

Radomir Stojanović, PhD, Western Serbia Academy of Applied Studies
Education as a pillar of sustainable agritourism in Serbia

Jelena Premović, PhD, Faculty of Economics, University of Priština & Faculty of Economics and Engineering, University Business Academy in Novi Sad
Cultural heritage as a generator of sustainable development of tourism in local communities in the countries of the Western Balkans

Vladimir Živanović, Nevena Majstorović, Zlatibor Tourism Organization, Zlatibor
Analysis of the real number of tourist overnights based on the estimation of water consumption in Zlatibor

MECHATRONICS

INVITED PAPER

Andrea Matta, PhD, Dept. of Mechanical Engineering, Politecnico di Milano, Italy Mohsen Jafari, PhD, Dept. of Industrial and Systems Engineering, Rutgers University, USA
Towards a theory of digital twins: fundamental definition

TABLE OF CONTENTS

SCOPE 1. ENVIRONMENT AND SUSTAINABLE DEVELOPMENT

Srećko Stopić, Bernd Friedrich 26
Advances in understanding of a role of unit metallurgical operations for recycling

Svetlana Grujić 32
Emerging pollutants in the environment: contamination of the Danube river basin in Serbia

Marija Nikolić 38
Biodegradable polyesters – from ecology to medicine

Alessandro Gasparetto, Stefano Grimaz 44
The ESPeRT project: a "polytechnic" strategic plan focused on sustainability

Ana Stojković, Miodrag Stanisavljević, Ivan Krstić, Nenad Krstić, Dragan Đorđević 50
Physical-chemical characterization of waste glass of general use

Ljiljana Tolić Stojadinović, Svetlana Grujić, Nikolina Antić, Tatjana Đurkić 54
Impact of wastewater antibiotics on river water quality in Belgrade area

Nataša Karić, Marija Vukčević, Marina Maletić, Mirjana Ristić, Aleksandra Perić Grujić, Katarina Trivunac 60
Removal of organic and inorganic pollutants from aqueous solutions using starch-diatomaceous earth adsorbent

Nataša Karić, Marina Maletić, Sara Živojinović, Marija Vukčević, Milena Milošević, Katarina Trivunac, Aleksandra Perić Grujić 66
Alkali modification of fly ash for adsorption of selected dyes

Katarina Popović, Davor Antanasijević, Jelena Antanasijević, Viktor Pocajt 71
Carbon footprint of bio-based and recycled plastic materials

Katarina Popović, Davor Antanasijević, Jelena Antanasijević, Viktor Pocajt 77
Application of machine learning for the simulations and modeling in environmental science

Jasmina Bašić, Danijela Pecarski, Dragana Dragaš Milovanović, Slavica Krsmanović, Daka Tešić 83
Air quality according PM concentration in the city of Belgrade in September 2023

Jelena Vesković, Milica Lučić, Slavica Ražić, Ivana Deršek-Timotić, Andrijana Miletić, Maja Đolić, Antonije Onjia 89
Multivariate analysis of the Morava river plain groundwater

Eleonora Gvozdić, Ivana Matić Bujagić, Tatjana Đurkić, Svetlana Grujić 95
Ecological risk assessment of aspartame and neotame in river sediments

Mirjana Ocokoljić, Djurdja Petrov 100
Impact of urban heat island on butterfly-bush (buddleja davidii franch.)

Mirjana Ocokoljić, Djurdja Petrov, Dragan Vujičić 106
Effects of urbanisation on simphoricarpos orbiculatus moench in the green infrastructure of Belgrade

Anja Bubik, Katrin Školnik Škrabe 112
Chemical variability of personal care and cosmetic products

Miloš Tošović 118
Technical-technological disasters, risk assessment and environmental security

Radule Tošović 124
Economic considerations of the relationship of national income, mineral reserves and environmental accounting

Slavica Krsmanović, Danijela Pecarski, Jasmina Bašić 130
Quality of swimming pool water and hygiene

Jelena D. Lukić, Latinka J. Slavković-Beškoski, Katarina V. Trivunac, Antonije E. Onjia 134
Analysis of heavy metal(loid)s in coal fly ash leachate by inductively coupled plasma optical emission spectrometry

Andrijana Miletić, Antonije Onjia 139
Analysis of carbon monoxide in ambient air using passive sensors

Ivana Trajković, Milica Sentić, Slobodan Cvetković, Andrijana Miletić, Antonije Onjia 145
Analysis of BTEX in sediments by purge-and-trap gas chromatography-mass spectrometry

Saša Marković, Darja Žarković 150
Economic instruments in the function of environmental protection

Jelena Milosavljević, Snežana Šerbula, Tanja Kalinović, Jelena Kalinović, Ana Radojević 156
Overview of air pollution in the city of Bor during the period of 2020–2022

Milan Trumić, Vladimir Nikolić, Mirjana Marić, Jelena Janković 162
Mining solid waste around Bor, yesterday, today, tomorrow

Danijela M. Jašin, Ljubica Lazić Vulićević, Valentina Mladenović, Aleksandar Rajić 167
The solution for reusing non-recyclable plastic-based materials

Filip Živković, Milica Stojković, Maja Đolić, Mirjana Ćujić 173
Elemental analysis of rare earth elements in coal fly ash from thermal power plants in the Republic of Serbia

Darja Žarković, Saša Marković 177
Sustainable production in cardboard industry

Marija Prosheva, Jadranka Blazhevska Gilev 182
Sensors for ammonia detection based on carbon nanofiller

Marija Prosheva, Jadranka Blazhevska Gilev 188
Investigation of the UV stability of lignin/polymer composites

Ana Momčilović, Marta Trninić 193
A comprehensive analysis: offshore renewable energy methodologies, benefits, and limitations

Danijela Đurić Mijović, Danijela Milanović, Jelena Savić, Miloš Nedeljković, Dušan Ranđelović 199
Wind comfort design based on building position

Zaga Trišović, Tomislav Trišović, Ana Virginia Socalici, Corneliu Banesa Birtok 204
Innovative system for electrochemical active chlorine production in coaxial and cabinet-type reactors

Đorđe Karić, Aleksandra Sretenović-Dobrić 209
Analysis of energy-saving measures in residential buildings connected to district heating systems using information technology

Bosiljka Srebro, Stefan Milojević, Miljan Adamović 214
Environmental accounting education for sustainable development: a comprehensive overview

Vladana Đurđević, Aleksandra Janićijević, Dominik Brkić, Ana Popović, Marina Stamenović, Aleksandra Božić 219
Validation of the ICP-OES method for determining the elemental composition of water

Vladana Đurđević, Jelena Pavlović, Bojan Obradović, Ana Popović, Marina Stamenović, Aleksandra Božić 225
Proficiency testing as a tool for quality control of laboratory test results in environmental pollution analysis

Radmila Marković, Zoran Stevanović, Zoran Štirbanović, Vojka Gardić, Renata Kovačević, Vesna Marjanović, Jelena Petrović 231
Monitoring of the surface water quality in copper mining and metallurgy operation areas in Bor

Biljana Angjusheva, Ildiko Merta, Emilja Fidancevski 237
Sustainable synergy: alkali-activated coal fly ash and CDW in sustainable construction

Vaishnavi Inamdar, Ana Popović 242
Global ESG perspectives and the changing world of 2023: a sustainability odyssey

Nikola Stojković, Dominik Brkić, Svetlana Čupić, Aleksandra Božić, Sladjana Glišić, Vladana Đurđević 247
Determination of polychlorinated biphenyls in waste oil

Dejan Vasić, Vladana Đurđević, Marina Stamenović, Aleksandra Božić, Aleksandra Janićijević, Dominik Brkić 252
Determination of PAHS in medical waste

Vesna Alivojovdić, Aleksandra Vučinić 256
EU taxonomy as a framework for a functioning circular economy

Milica Marković, Ana Momčilović, Maja Stanković 261
Environmental concerns of lithium battery disposal

STUDENTS PAPER

Miloš Kovačević, Nataša Radić 266
Air pollution caused by modern-day armed conflict

Danijela Jeremić, Daniela Ristić 272
Influence of "Stubo-Rovni" dam on climate change in the city of Valjevo

SCOPE 2. OCCUPATIONAL HEALTH AND SAFETY AND FIRE SAFETY

Marta Trninić 278
Application of 3D random e-glass fiber composites in construction hardhat design

Drago Pupavac, Ljudevit Krpan, Josip Knežević 284
Cost-benefit analysis in employee health and safety protection

Svetozar Sofijanić, Vladan Pantović, Veljko Ognjanović 290
Centralized information system for monitoring workplace injuries

Dragan Živanić, Nikola Ilanković 296
Safety concerning cableways

Dragan Živanić, Nikola Ilanković 302
Basic safety measures for chain conveyors

Nataša Ćirović, Ana Petrović, Marija Burilo 308
Testing of microclimate and physical harms in the sawmills

Ana Petrović, Nataša Ćirović 314
Noise level investigation in production process

Vesna Marjanović, Jelena Jelisić 320
Comparative analysis of risk assessment in the field of construction

Saša Kuzmanović 325
Analysis of assessed professional risks at the workplace of forklift drivers in the Logo company with comparative risk assessment methodologies and reference to the current law

Marija Mićanović, Tanja Radović 331
Implementation of strategies for the development of critical thinking in English language teaching among the students of the Occupational safety and health study program at the Academy of applied technical studies Belgrade

Tanja Radović, Marija Mićanović 335
Business communication obstacles in English language in occupational health and safety education

Radenko Rajić, Ivan Arandjelović, Nikola Tanasić 338
A novel tabular method for estimation of waterflow rate at the hydrant nozzle

Goran Đorđević, Martina Petković, Ljubinko Rakonjac, Marko Tomić, Anita Klikovac 342
Selection and use of mechanized equipment for extinguishing forest fires in order to increase efficiency - methodological approach

Darko Marković, Nebojša Ćurčić 350
Prevention of occupational risks in transport and installation of concrete prestressed T-girders on project Iverak-Lajkovac

STUDENTS PAPER

Milena Andrejević 357
"Near miss" events in the TPS Zemun reconstruction project: a research and analysis

Maja Đikić, Novak Milošević 363
Research and analysis of professional stress issues among employees in security roles

Lazar Milićević, Novak Milošević 368
The impact analysis of stress accumulated outside the workplace on the occupational safety and health of employees in Institute of Nuclear Sciences „VINČA"

Jelena Tintor, Jasmina Rajić, Igor Babić 374
Researching the harmful effects of cooling liquid on employees

Jelena Tintor, Jasmina Rajić, Igor Babić 380
Employee safety during plastic deformation metal processing

Milica Marković 385
Chemical hazards in horticulture from the aspect of occupational safety and health

Marijana Drakulić 391
Potentially explosive atmospheres in flour production

SCOPE 3. SMART MANAGEMENT SYSTEMS

Radoslav Raković 398
Information security management standard and personal data protection – practical experiences

Miloš Jelić, Ana Aksentijević Jelić 404
Deficiences and advancement in organizational strategic decision - making

Igor Milić 410
Civil protection management model at the local government level

Dragan Zlatković, Kostadinka Stojanović, Mirjana Tomić, Nebojša Denić 415
Artificial Intelligence as support for quality 4.0: a review of current applications and future directions

Koviljka Banjević, Jovana Femić 421
Adult education in Serbia and countries in the region

Dragana Gardašević, Dragana Rošulj, Mina Radišić, Koviljka Banjević 428
Application od the Pareto analysis in quality control

Aleksandra Nastasić, Dragana Rošulj, Koviljka Banjević, Aleksandra Pavlović 433
The influence of digital transformation on customer perception

Ana Maksimović 439
The effectiveness of environmental social and governance due diligence in driving sustainable outcomes in the outdoor apparel industry

Aleksandra Pavlović, Aleksandra Nastasić, Andrea Ivanišević 445
QMS and EMS implementation in Serbian organizations – a driving factor for sustainable development

Ana Maksimović 453
Socially responsible chains:investigating the social implications of supply chain due diligence in corporate sustainability

Aleksandra Pavlović, Aleksandra Nastasić, Predrag Drobnjak, Ana Langović Milićević, Andrea Ivanišević, Ivana Katić 459
PPP projects and economic growth in Serbia

Marija Marčetić, Danijela Misoloska, Bojan Kocić 467
The threats and opportunities in modern forwarding business

Jelena Pavlović, Dragica Stanković 472
Contemporary approach to leadership, management, knowledge and innovation

Marko Pavlović, Ana Petrović, Đorđe Pavlović 477
Study on the attitudes of electronic banking users in Serbia

Jelena Pavlović, Dragica Stanković 484
New technologies, labor market and human resources

Zorica Baroš 490
The impact of the kelvin redefinition within the SI System on the improvement of temperature measurement technologies

Ana Đokić, Hana Stefanović 496
Analysis and visualisation of COVID 19 data set in Phyton programming language

Sanja Pavlović, Dejan Crnoglavac, Aleksandar Starčević 501
Examining the role of drones as educational tools: an practical teaching example in enhancing learning experiences in STEM education

Đorđe Dihovični, Dragan Kreculj, Nada Ratković Kovačević 507
Experiences in teaching and mastering materials in WEB applications in vocational education

Marko Pavlović, Ana Petrović, Đorđe Pavlović 513
E-learning: study on students' opinions

SCOPE 4. GRAPHIC ENGINEERING

Aleksa Milovanović, Tomáš Babinský, Aleksandar Sedmak, Miloš Milošević 520
Printing parameter impact on PLA material fracture toughness results

Bojan Banjanin, Neda Milić Keresteš, Jelena Kerac, Rastko Milošević, Savka Adamović 526
Applications of real-time rendering game engine in education through practices and initiatives

Slađana Glišić, Predrag Živković, Aleksandra Janićijević 532
Examination of the possibility of dyeing printing papers with plant extracts

SCOPE 5. DESIGN

Jelena Ristić Trajković **539**
Society, Ecology and Design Education: Transformative Learning for Future Sustainable and Healthy Environments

Biljana Pejić, Bojana Škorc **545**
The effects of style on an aesthetic assessment of design

Biljana Pejić, Bojana Škorc **551**
Fammiliarity as aesthetic category in design

Dragica Nikodinović **557**
Analogous principle as an added value in graphic design in the post-industrial era

Dušanka Komnenić **563**
Design as a form of communication, deconstructive approach to design

Duško Trifunović, Anamarija Vartebedijan **567**
Graphic design by Miodrag Vartebedijan Varta, Vatra's graphic mark in Yugoslavian and world design

Emmanouil Tzimtzimis, Alexandros Papoutsis, Nikolaos Koumartzis, Konstantinos Tsongas, Dimitrios Tzetzis **573**
Utilizing parametric computer-aided design and modal analysis for the redesining of Anglo-Saxon medieval lyres

Emmanouil Tzimtzimis, Dimitrios Sagris, Constantinos David, Dimitrios Tzetzis **579**
Evaluating the influence of infill pattern and density in fused filament fabrication 3D printing technology through multimedia data analysis business communication

Ivana Desnica **585**
Leather recycling in the context of Haute Couture

Jelena Jocić, Maida Gruden **590**
Design and education: traditional and online environment

Jelena Zdravković **596**
Design fashion and the industry: The context of the emergence of fashion and ready-to-wear clothing production

Katarina Nikolić, Danica Glođović, Aljoša Ninković **602**
Design, ideology and propaganda

Ljubomir Maširević **607**
The social significance of video games

Maja Milinić Bogdanović **613**
Interdisciplinaryness of sustainable design

Marija Mićanović, Tanja Radović **619**
Motivation for English language learning among the students of the design study programs at the Academy of Applied Technical Studies Belgrade

Natalija Gaković **623**
Does Frank Lloyd Wright's Fallingwater House represent a precursor to sustainable design?

Natalija Gaković **628**
Children without parental care in social protection institutions – Park of support design

Natalija Đukić **634**
Analysis of the spatial organization of a modern apartment in Belgrade, case study New Dorcol

Predrag Maksić 639
Design to the measure of marketing

ADVANCES IN UNDERSTANDING OF A ROLE OF UNIT METALLURGICAL OPERATIONS FOR RECYCLING

Srecko Stopic[1], Process Metallurgy and Metal Recycling, RWTH Aachen University, Germany
Bernd Friedrich,[2] Process Metallurgy and Metal Recycling, RWTH Aachen University, Germany

Abstract: *Unit operations in non-ferrous extractive metallurgy have high importance for recycling processes, an environmental protection and sustainable development. Three categories are included in unit operations in non-ferrous extractive metallurgy: (1) hydrometallurgy (leaching under atmospheric and high pressure conditions, mixing of solution with gas and mechanical parts, neutralization of solution, precipitation and cementation of metals from solution aiming purification, and compound productions during crystallization), (2) pyrometallurgy (roasting, smelting, refining), and (3) electrometallurgy (aqueous electrolysis and molten salt electrolysis). The high demand for critical metals in modern life, such as rare earth elements (REE), indium, scandium, and gallium has highly increased the need for an advance in understanding of an application of the unit operations in non-ferrous metallurgy regarding to an environmental impact. Exhaustion of ore reserves, accumulation of waste materials after their use leads to the use of unit operations in the development of new strategies for recycling secondary raw materials. Successful cases for use of the unit operations in recycling of wastewater solutions, bauxite residues and spent magnets will be presented in this paper.*
Keywords: recycling, hydrometallurgy, pyrometallurgy, metal, sustainable technologies

1. INTRODUCTION

The permanent goal of recycling is to increase the use of secondary raw materials (SRM) in different metallurgical engineering processes. General recycling strategy is shown at Figure 1.

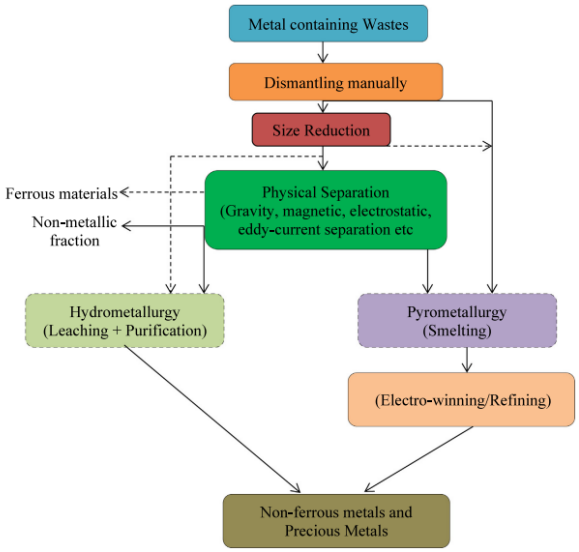

Figure 1. General recycling strategy containing Physical separation, hydro-and Pyro-treatment
Source: [1]

[1]sstopic@ime-aachen.de
[2]bfriedrich@ime-aachen.de

The SRM contain mining and flotations tailings [2], flying ash [3], metallurgical slag [4], spent magnets [5], spent Li-Ion batteries [6], acid mine drainage water [7], and bauxite residues [8]. A proper combination of the unit operations was used to develop innovative solutions with added economic value for different applications of rare earth elements [9]. Most of the proposed activities have already been studied and tested at a research level (laboratory, demonstration plant and scale up conditions) [10, 11]. The aim is to present the recycling of different materials using a combination of pyrometallurgical and hydrometallurgical operations and explain their importance for environmental protection and recovery of metals.

2. METAL RECOVERY FROM WASTEWATER

2.1 Treatment of acid mine drainage water

Acid mine drainage (AMD) as wastewater solution formed by mining activities contain high concentration of dissolved heavy metals and sulfates, as shown in Table 1.

Table 1. Chemical composition of the AMD-Solution from South Africa

Species	Al	Fe	Mg	Ca	Mn	Si	Co	Cu	Zn	Ce	Nd	SO_4^{2-}
Conc, mg/L	396	4.290	474	592	93.9	47.5	1.42	0.78	14.3	5.35	1.23	12.100

As shown in Table 1 the content of valuable critical metals such as Co, Ce and Nd are very small (few milligrams per Liter). pH values can to be as low as 2.5. Therefore, AMD with these characteristics should not been discharged into public streams. In AMD systems, natural nanoparticles such as amorphous hydroxides, ferrihydrites, and goethite seemed to be formed, which could induce lethal and sublethal toxicity toward aquatic organisms.
Neutralization of an AMD Solution was performed using sodium hydroxide at different pH-values between 1 and 11 at room temperature, in order to study a precipitation of cerium and other elements. This strategy for removal of Fe, Al and Ca was previously studied in a cascade line reactor using a wastewater from an electrolytic plant [12]. The new step is precipitation of cerium.

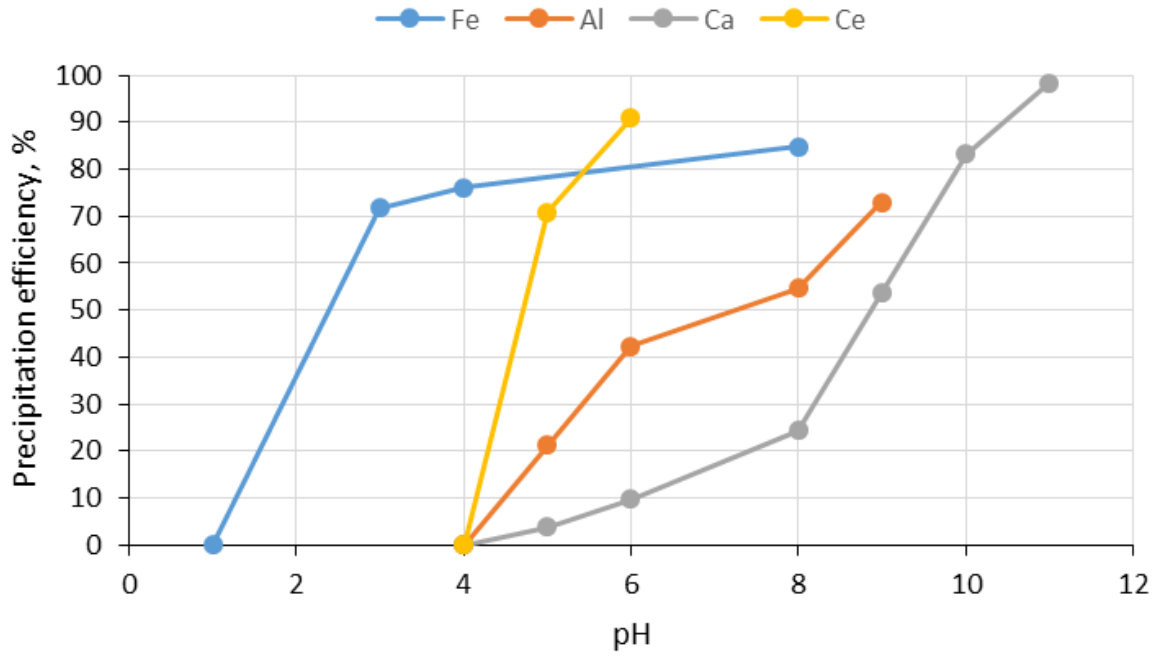

Figure 2. Precipitation efficiency during neutralization of AMD-solution with NaOH

As shown the best precipitation selectivity for iron was reached at pH-4 (at about 75 % removal degree). This is explained by the formation of $Fe(OH)_3$. A further increase of the pH-value to 6 leads to the precipitation efficiency of 85 %, more than 95 % can only be reached using an oxidation reagent such as H_2O_2 in order to oxidize $Fe^{2+}$to Fe^{3+}. The precipitation of cerium took place between pH-value of 4 and 6 in form of sodium cerium sulfate hydrate ($NaCe(SO_4)_2 \cdot H_2O$) reaching a precipitation efficiency of about 90 %, as shown with Eqs. (1) and (2):

$$H_2SO_4 + NaOH \rightarrow Na_2SO_4 + 2\ H_2O \quad (1)$$

$$Ce_2(SO_4)_3 + Na_2SO_4 + 2\ H_2O \rightarrow 2\ NaCe(SO_4)_2 \cdot H_2O \quad (2)$$

The obtained sodium cerium sulfate hydrate might be used for winning of this metal using solvent extraction for separation of cerium and an additional treatment of obtained cleaned solution using an ultrasonic spray pyrolysis method, what is innovative and used for the formation of rare earth oxide. With an increase of pH-value from 4 to 9, aluminium was removed in form of $Al(OH)_3$, as shown with Eq. 3.

$$Al_2(SO_4)_3 + 6\ H_2O \rightarrow 2\ Al(OH)_3 + 3\ H_2SO_4 \quad (3)$$

2.2 Treatment of wastewater from an electrolytic plant

Chemical precipitation of heavy metals is viable for selective removal of heavy metals from metal-bearing effluents in three reactor systems in a continuous process cascade line, as shown at Figure 3. The chemical composition of wastewater is shown in Table 2:

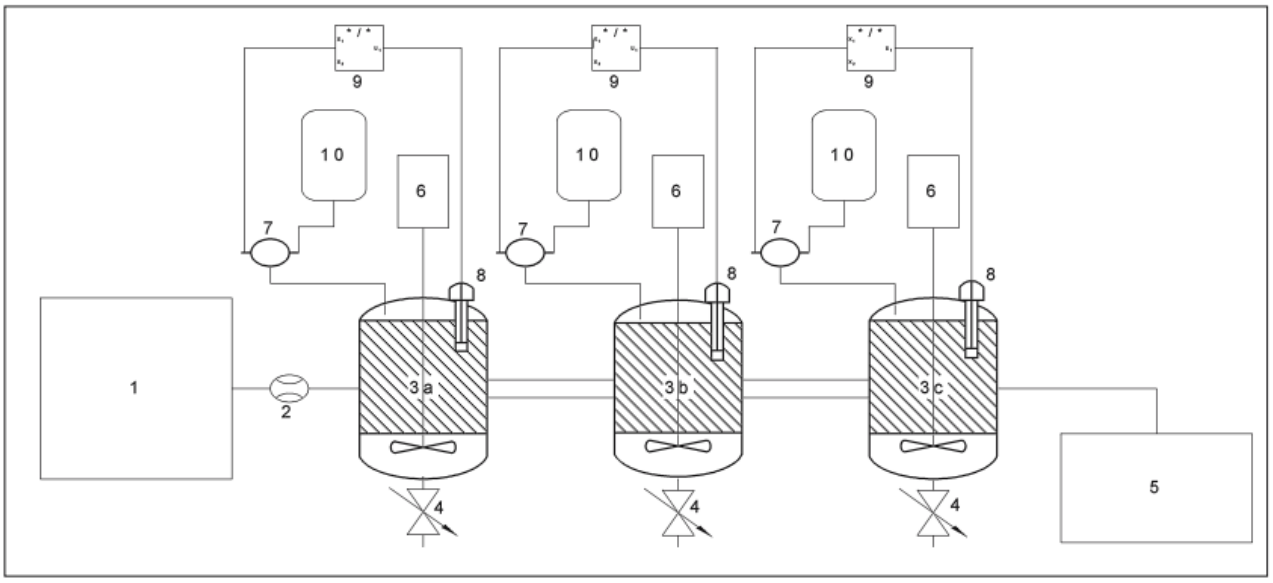

Figure 3. Cascade line reactor for continuous process of precipitation/chemical precipitation [12]. 1. tank with wastewater (200 dm^3); 2. flow meter; 10 dm^3 vessel for feed adjustment of solution; 3. three 10 dm^3 reactors; 4. valve for regulation of wastewater injection; 5. tank (200 dm^3) for purified solution; 6. mixers; 7. solenoid metering pumps; 8. protected electrodes; 9. pH transmitters; 10. tank with precipitation agent

Table 2. Chemical composition of the wastewater from an electrolytic plant

Species	Al	Fe	Cu	As	Mn	Si	Sb	Bi	Ni	Te	Se	SO_4^{2-}
Conc, g/L	0.04	0.09	8.33	0.66	0.001	0.02	0.08	0.03	0.66	0.07	0.26	117.0

The precipitation agent was 1M NaOH, which was injected into all three reactors using a solenoid diaphragm-dosing pump (BT4a 1005 ProMinent) with self-dosing head and a maximum capacity of 7.0 dm3/h (about 1 h was a retention time in a reactor).The obtained results for precipitation efficiency are shown in Table 3:

Table 3. Precipitation efficiency with NaOH at different pH-values

pH	Cu	Ni	As	Fe	Bi	Zn	Pb	Mn	Al	Si	Sb	Ca
4.0-4.5	48	27	67	**99**	**98**	86	**96**	74	52	57	84	-
6.5-7.0	**99**	45	**99**	-	-	79	-	27	**100**	79	84	14
9.0-9.5	-	**100**	-	-	-	**100**	-	68	-	83	100	25

Maximal precipitation efficiencies are for Fe, Bi, and Pb between 4.0-4.5, for As, Cu and Al at 6.5-7.0, and for Ni and Zn between 9.0 and 9.5 for Mn and Zn. The flow of metals from reactor to reactor and exothermic reaction could cause deviations from thermochemical prediction.

3. METAL RECOVERY FROM SOLID RESIDUE

3.1 Recovery of rare earth elements from spent magnets

Treatment of spent NdFeB-powder (%): 21.7 REE, 73.8 Fe, 0.66 B, is shown at Figure 4.

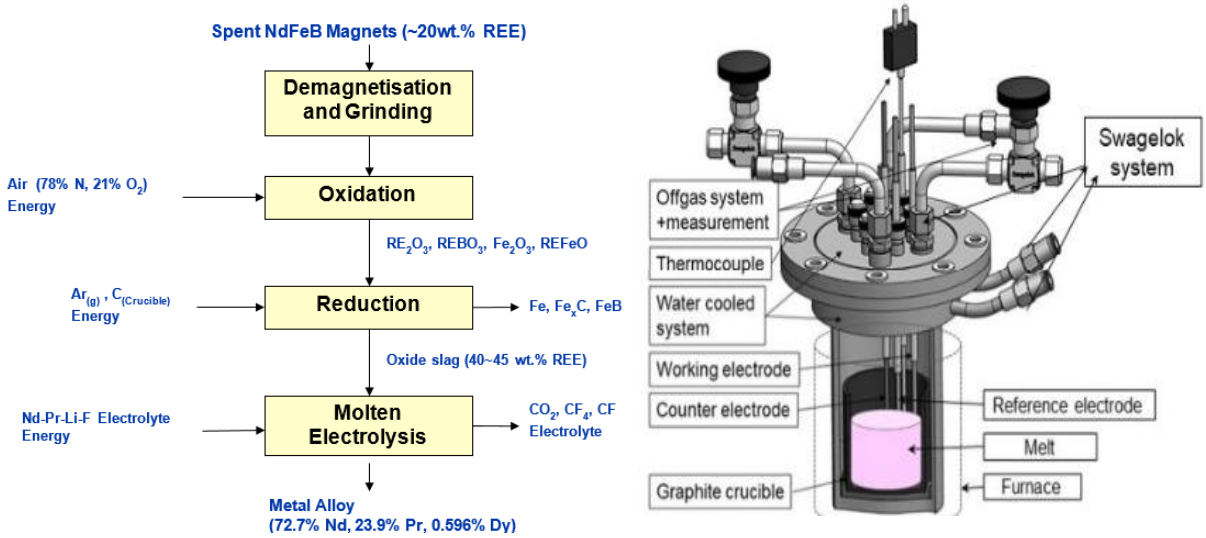

Figure 4. Pyrometallurgical strategy for recycling of spent NdFeB-magnets (left) with a reactor for molten salt electrolysis (right)

Source: [5]

This study includes the next operations: 1. demagnetisation and grinding of spent magnets, 2. oxidation of demagnetised and grinded solid residue, 3. Carbon reduction of oxidized material, 4. molten salt electrolysis as final step. The magnet recycling-derived oxide (MRDO) was produced from spent NdFeB magnets through oxidation in air and subsequently carbothermic reduction under an 80 mbar Ar gas atmosphere. This MRDO contained roughly 33 wt.% Nd and 10 wt.% Pr. The electrochemical reduction process of the MRDO on molybdenum electrodes in NdF_3 + LiF and NdF_3 + PrF_3 + LiF fused salts systems was investigated by cyclic voltammetry and chronoamperometry measurements. The resulting electrolytes and electrodes were examined after potentiostatic deposition by scanning electron microscopy (SEM), inductively coupled plasma optical emission

spectroscopy (ICP-OES), and X-ray diffraction (XRD) analysis. The electrodeposited metals appeared to accumulate on the cathode and X-ray diffraction analysis confirmed the formation of metallic Nd and Pr on the working substrate. The suitability of the obtained alloy intended for the remanufacturing of NdFeB magnets was then evaluated.

3.2 Recovery of titanium and valuable elements from bauxite residues

Bauxite is a clay-like sediment that is the principal host for alumina. Generally, bauxite is a naturally occurring mineral, soil, or rock formation comprising a conglomerate of multiple aluminum-bearing minerals with other valuable impurities. Iron oxides (Fe_2O_3 and FeO(OH)), clay minerals, silica, kaolinite, titanium minerals, rutile, and anatase are among the contaminants. Bauxite is mined for aluminum production because of high concentrations of the following aluminum-bearing minerals: Gibbsite: $Al(OH)_3$, Boehmite: AlO(OH), and Diaspore: AlO(OH). From an industrial perspective, bauxite is a material from which alumina is extracted using the Bayer Process. The process is based on contacting aluminium-bearing ores with a concentrated NaOH solution at temperatures between 150 – 250 ºC in an autoclave as shown with Eq. 4 and Eq. 5. It is a reddish-brown sludge containing iron, titanium, and silicon oxides, the majority of aluminum oxides that were not extracted during the clarification step, and other valuable metals. It is a large aspect of aluminum production, and it is a highly alkaline residue, as sodium hydroxide is added in the digestion step during the Bayer Process; each ton of processed alumina generates approximately 4-5 tons of red mud as a byproduct.

$$Al_2O_3 + 2\ NaOH \rightarrow 2\ NaAlO_2 + H_2O \quad (4)$$

$$2\ NaOH + SiO_2 \rightarrow Na_2SiO_3 + H_2O \quad (5)$$

EURO-TITAN concept will be studied in unlocking continuous Ti resources from metallurgical waste streams from alumina and Ti-dioxide production, creating the roadmap for producing 54 ktpy of Ti metal upon full industrialization, as shown at Figure 4. Titanium (Ti) is a grey metal and highly corrosion resistant with a high melting temperature and has a very low density but high strength, being a critical metal according to the 2023 CRM 5th list of EU. EURO-TITAN unlock domestic sources from Alumina, Zvornik, Bosnia and Herzegowina through its environmentally friendly, safe, and resource efficient extraction sustainable technologies.

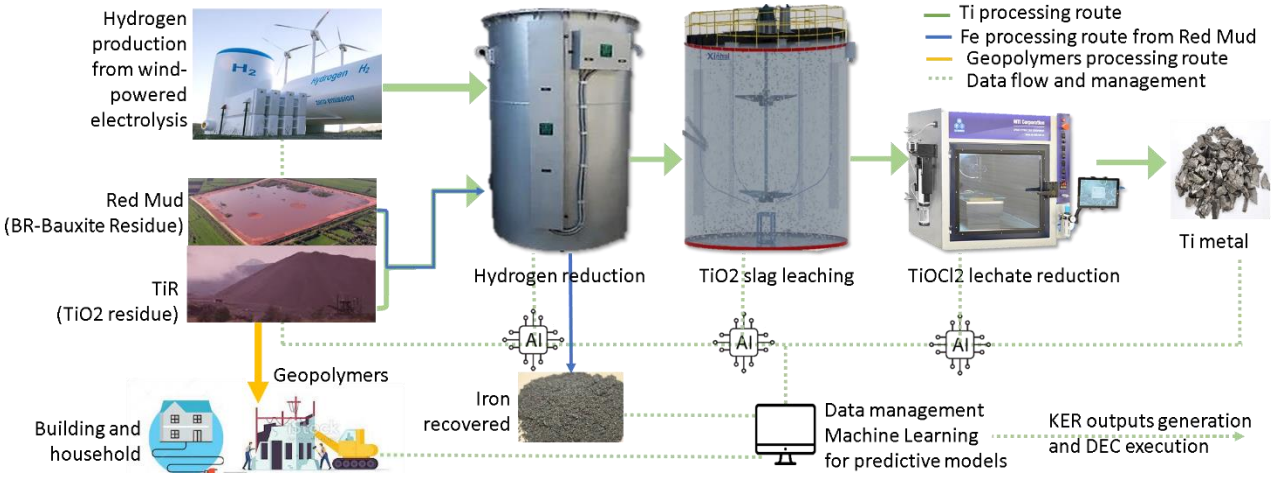

Figure 5. EURO-Concept (Decarbonized Titanium Recovery from Aluminium and Titanium Production Residues), Grant. No. 101135077 (Call: HORIZON-CL4-2023-RESILIENCE-01)

4. CONCLUSION

Advances in understanding of role of unit operation in recycling of waste materials helps to increase of recycling efficiency of metals from secondary materials, what is current problem in different industrial sectors in order to improve an environmental protection. General recycling strategy containing physical separation, hydrometallurgical and pyrometallurgical operations. Treatment of wastewater from electrolysis plant and acid mine drainage solution was mostly performed using neutralisation, filtration and precipitation method in order to remove some impurities from solution. Pyrometallurgical strategy was used for treatment of spent NdFeB-Magnets including demagnetisation and grinding, oxidation in air, reductive smelting in carbon crucible and final molten salt electrolysis. Decarbonized titanium recovery from bauxite Residues is new European sustainable concept based on pyrometallurgical and hydrometallurgical operations aiming a minimal of 20 % reduction of on-site energy and water consumption.

EMERGING POLLUTANTS IN THE ENVIRONMENT: CONTAMINATION OF THE DANUBE RIVER BASIN IN SERBIA

Svetlana Grujić[1], Faculty of Technology and Metallurgy, University of Belgrade

Abstract: *The quality of river water ecosystems is severely threatened by ever-increasing number of chemicals introduced through the wastewater treatment plants effluents, untreated sewage, agricultural runoff and industrial wastewater. Unregulated substances that may be candidates for future regulation depending on (eco)toxicity, potential health effects and monitoring data are considered to be emerging pollutants. For these substances, research indicates that they may pose a significant risk to or via the aquatic environment, but data are insufficient to reach a conclusion on the risk level. To support future prioritization, the Danube River and three main tributaries in Serbia (the Tisza, the Sava and the Morava) have been studied for the last 15 years. In Serbia, there is not a single treatment plant constructed along the entire course of the Danube, and only 8.1% of wastewater is treated. The results for about 100 pharmaceuticals, steroid hormones, sterols, pesticides and artificial sweeteners showed severe contamination of the investigated area, especially in the capital Belgrade. It was also determined that emerging pollutants detected in river sediments pose a significantly greater risk than those in surface water. The results indicate the much-needed treatment of municipal wastewater and inclusion in future monitoring of the most harmful substances.*
Keywords: Emerging Pollutants, the Danube, Environmental Risk Assessment, River Water, River Sediments

1. INTRODUCTION

Emerging pollutants (EPs), also known as contaminants of emerging concern (CECs), represent a global water quality challenge with potentially serious threat to human health and ecosystems. The rising concern is not only related to the widespread and growing use of diverse chemicals, but also to the improvement of analytical techniques that have enabled EP detection at trace levels in any environmental matrix. The primary route for their wide distribution in the environment is municipal and industrial wastewater, as well as agricultural run-off. As wastewater treatment plants (WWTPs) are not designed to completely remove most EPs, they are discharged into receiving waters. Due to their high water solubility and often poor degradability, many EPs pass through all natural filtrations and reach ground water, and ultimately drinking water. The major problem is the presence of antibiotics, because it can lead to the generation and spread of new strains of resistant bacteria. Nevertheless, most EPs are not regulated by national or international environmental legislation, as there is still limited knowledge about their environmental levels, fate and (eco)toxicological effects. Depending on research on their occurrence and impact in different environmental compartments, as well as toxicity and potential adverse health effects, many of them are candidates for future regulations [1].

For the purpose of supporting future prioritization of EPs relevant to the aquatic environment in the Republic of Serbia (RS), the Danube River Basin (DRB) has been studied for the past 15 years. The key source of water pollution in the RS is wastewater discharged into the recipient without any treatment, since only 8.1% of wastewater generated by agriculture, forestry and fishing, households and industry is treated [2]. Unlike neighbouring countries, there is not a single WWTP that has been

[1]svetlana.grujic@tmf.bg.ac.rs

constructed along the entire course of the Danube in the RS, so the environmental risk from exposure to EPs in the aquatic environment is expected to be high, especially in highly populated areas with high wastewater burden. The Danube River and its tributaries are an important resource for the drinking water production and agricultural irrigation for about 83 million people. It is a unique river ecosystem with the highest freshwater biodiversity in Europe. About 92% of the RS lies within the DRB, accounting for 10% of the total basin. Three major Danube tributaries on the territory of the RS are the Tisza, the Sava and the Morava. Considering the importance of the Danube River, the potential threat from unregulated discharge of untreated municipal wastewater along the entire course of the Danube in the RS was evaluated and the environmental risk for freshwater and benthic biota was assessed.

2. SAMPLING, SAMPLE ANALYSIS AND RISK ASSESSMENT

In many sampling campaigns performed over the last 15 years, about 150 samples of river water (RW), ~100 samples of ground water (GW) and ~50 sediments (SED) were collected to cover the entire course of the Danube in the RS (~500 km). Samples from the Danube's tributaries – the Tisza, the Sava and the Morava were collected a few km before the confluence with the Danube. At each sampling site, RW samples and several corresponding GW samples (from monitoring or Ranney wells) were taken. The corresponding SEDs were sampled less frequently.

The selection of EPs to be monitored was based on their very frequent use in the RS and suspected ecotoxicological potential, and was complemented with EPs that are most frequently detected in the European Union (EU). It included about 30 pharmaceuticals, 40 pesticides, 20 steroids and 10 artificial sweeteners, compounds with a wide range of physicochemical properties. Since the focus of EP research has changed over the years, from pharmaceuticals and pesticides to steroids and artificial sweeteners, not all selected EPs have been analyzed in all samples taken.

Several analytical methods have been developed and optimized for the identification and quantification of different classes of EPs in water and sediment matrices [3-6]. The most commonly used protocols for the determination of EP traces in complex environmental matrices consist of a water sample preparation by solid-phase extraction (SPE) or ultrasonic extraction (USE) of sediments, followed by extract analysis using liquid chromatography coupled to mass spectrometry (LC-MS). Due to the high selectivity and sensitivity, as well as confirmation possibilities, tandem mass spectrometric detection (MS/MS or MS^2) using an ion trap was chosen for EP determination. The list of EPs detected in RW, GW and SED samples of the DRB in the RS over the last 15 years is presented in Table 1.

Environmental risk assessment of EP levels detected in the samples was performed by calculating risk quotients (RQs). RQs were calculated by dividing the maximum environmental concentration of each EP with the corresponding predicted no-effect concentration for freshwater ($PNEC_{fw}$) or sediment ($PNEC_{sed}$). PNEC values were obtained from the Norman Ecotoxicology Database [7] as the lowest PNECs, preferably based on experimental ecotoxicity data for aquatic or benthic organisms. Environmental risk is classified into four categories: "negligible/no risk" ($RQ < 0.01$), "low risk" ($0.01 < RQ < 0.1$), "moderate/medium risk" ($0.1 < RQ < 1$) and "high risk" ($RQ \geq 1$).

3. RESULTS AND DISCUSSION

3.1 Pharmaceuticals

In the collected samples, pharmaceuticals (~30) from different classes were analysed: antibiotics (penicillins, cephalosporines, sulfonamides, macrolides, tetracyclines), sedatives (benzodiazepines, antiepileptics), analgoantipyretics, antihypertensives (β-blockers, ACE inhibitors, calcium channel blockers), antihyperlipemics (statins), and anticoagulants. Eight pharmaceuticals have been consistently found over the years in samples from the DRB, however, only those most frequently found and showing high risk to aquatic or benthic organisms are discussed.

The antiepileptic carbamazepine was the most frequently detected pharmaceutical, due to its high resistance to biodegradation in the environment, as well as its very low removal rate in wastewater treatment. It passes through natural bank filtration and is found in GW, so it can ultimately reach drinking water as well. According to the $PNEC_{sed}$ value, the highest detected carbamazepine level poses a high risk to benthic organisms. The presence of azithromycin, the most commonly used antibiotic in the RS, in environmental samples is a major problem, especially in GW, as there is a potential for inducing bacterial resistance and reaching the drinking water. The $PNEC_{fw}$ value and calculated RQ (> 1) indicate a high risk to aquatic organisms at the detected levels in both RW and GW. Sulfametoxazole is one of the most frequently found antibiotics in the aquatic environment

worldwide. Although detected in just 1% of RW samples, at a level of low risk to aquatic organisms, the recorded concentrations in sediments are much higher than those expected to have adverse effects on sediment-dwelling organisms [3,8,9].

3.2 Pesticides

About 40 pesticides were investigated in water and sediment samples from the DRB: herbicides, insecticides and fungicides, such as organophosphates, neonicotinoids, carbamates, diacylhydrazines, benzimidazoles, triazines, phenylureas, etc. Over the last 15 years, seven pesticides were commonly found: fungicide carbendazim, insecticides carbofuran, dimethoate, malathion and imidacloprid, as well as herbicides atrazine and propazine. The frequency of their detection is explained by the extensive agricultural use in the RS, as agricultural land covers as much as 66% of the country's total land area. The highest pesticide concentrations were reported for samples from the Morava River, a tributary of the Danube, heavily impacted by agricultural practices.
Based on the very low values of $PNEC_{fw}$ and $PNEC_{sed}$, the levels of detected pesticides in the DRB in the RS, although low, pose a high or medium risk to aquatic and benthic organisms. At the time of sampling, most of these pesticides were approved for use in the RS. With the exception of malathion, all of them are now banned. Considering their high ecotoxicity at trace levels, the current ban is justified. Although atrazine and propazine were banned almost two decades ago, they are still being recorded at high levels in the samples of the DRB, due to their extreme persistence in the environment. Malathion, as a pesticide still approved for application, was found only in sediments, due to its extensive biodegradation and short half-life, as well as its almost complete immobilization in the organic-rich sediment matrix. Its detected concentrations are significantly higher than the levels known to have adverse effects on benthic organisms, so the results suggest that it should be included in the monitoring programs and restricted in use [4,9,10].

3.3 Steroid compounds

In the last ten years, EP research in the DRB has been extended to included 20 steroids: steroid hormones, such as natural estrogens and synthetic hormones, as well as human/animal and plant sterols. Of nine steroid hormones monitored, only mestranol was found in the sediments, at levels of low risk for benthic organisms. Since these compounds are usually present in the environment at very low concentrations, the inability to record them in water samples could be explained by the limited performance of applied analytical method. The investigated sterols were found at considerably higher levels than other detected EPs. Although some steroids occur naturally, they usually enter the environment in large quantities through discharges of raw sewage and treated urban wastewater, as well as via run-off from agricultural land treated with manure or sludge. Due to their highly hydrophobic properties, sterols show a strong preference to bind to solid organic-rich matrices and are found in all analysed SED samples. The human/animal sterol coprostanol was detected at the highest concentrations in RW samples, while cholesterol was the most abundant in the sediments. None of the GW samples tested contained sterol residues, indicating successful elimination by bank filtration. Coprostanol was recognized decades ago as one of the most important chemical markers for human-sourced sewage contamination. It has been proven to be a useful indicator in sterol ratios applied to confirm human faecal pollution and to distinguish between sewage-sourced and non-human biogenic inputs. Although cholesterol is the most abundant sterol in the human body, it is not a specific marker for sewage pollution of the environment, because it is also present in plant material. For many steroid compounds, there is a lack of ecotoxicity data, preventing the assessment of the potential risk to aquatic or sediment-dwelling organisms at detected levels. However, for those for which $PNEC_{fw}$ and $PNEC_{sed}$ are available, a high risk was found in both water and sediment samples. The detrimental impact of steroid compounds on the aquatic ecosystem have been recognized for more than two decades, as many ecotoxicity studies have shown abnormal reproductive function, impaired growth and endocrine disruption of aquatic and benthic organisms at trace amounts of

sterols and steroid hormones. The results have shown that the DRB in the RS is highly contaminated with raw, untreated sewage, leading to a high environmental risk to biota, which indicates the much-needed treatment of municipal wastewater [5,11-13].

3.4 Artificial sweeteners

The decades-long use of sweeteners in food products and medicines has resulted in their ubiquitous environmental occurrence. For this reason, five years ago, the focus of the EP investigation in the DRB in the RS was shifted to artificial sweeteners. The results have shown that acesulfame and sucralose were the most frequently detected, as they were found in all collected RW and GW samples. Their widespread presence in the aquatic environment can be explained by the fact that they are metabolically inert, highly soluble in water and very persistent. The lower detection frequency of saccharin and cyclamate in RW and GW is related to their limited stability and fast biodegradation. In recent years, acesulfame and sucralose are frequently used markers to indicate older sewage pollution, while saccharin and cyclamate are used as indicators of fresh sewage contamination. Aspartame and neotame were the only artificial sweeteners detected in the investigated SED samples. On the other hand, they were not detected in any water samples. The results can be explained by their rapid metabolism, high level of degradation in the environment and high sorption affinity for organic-rich sediment particles. The concentrations of detected artificial sweeteners indicate significant ecotoxicity of aspartame and neotame, leading to a high risk to benthic organisms [6,14].

4. CONCLUDING REMARKS

Levels of pharmaceuticals, pesticides and artificial sweeteners in the DRB in the RS were generally similar or lower than in other European countries with much larger populations and efficient wastewater treatments that significantly reduce concentrations of EPs to levels similar to those in the RS. The concentrations of detected sterols were much higher than those found in the EU, which is consistent with the high anthropogenic burden by untreated municipal wastewater. It is evident from the results that the sediments of the DRB are of greatest concern with regard to detected EPs, as a high or medium level risk to benthic organisms was determined. Given that sediments are considered as a major sink of organic pollutants, they can also act as a secondary source of pollution in case of resuspension. The results also revealed the highest ecotoxicological risk in the two largest cities – the capital Belgrade and Novi Sad, both heavily impacted by untreated sewage and high population density. It was determined that the Danube's tributary Sava in Belgrade is more polluted than the Danube, due to high dilution capacity of the Danube River. The obtained results indicate the improvement of the treatment and management of sewage wastewater and the necessity of including detected EPs with a high environmental risk in routine monitoring programs.

BIODEGRADABLE POLYESTERS – FROM ECOLOGY TO MEDICINE

Marija Nikolić[1], Faculty of Technology and Metallurgy, University of Belgrade

***Abstract**: Polymeric materials, commonly known as plastics, are versatile group of macromolecular organic compounds which properties make them irreplaceable in many aspects of contemporary life. Due to their exceptional (e.g. lightweight, durability) and easily tailorable (e.g. from stiff to flexible, from superhydrophobic to water-soluble) properties they are important in many fields. The increased use of polymeric materials, especially in packaging sector, is associated with high amount of waste which became a serious environmental problem, since the most of this waste ends up in terrestrial and oceanic environment. One of the solutions of environmental impact of polymeric materials is replacement of non-biodegradable with synthetic biodegradable polymers. Aliphatic polyesters are the main class of synthetic biodegradable polymers and some of them can be produced from renewable sources (biomass), which further contribute to the issue of sustainability. Additionally, in the field of medicine, there is also a growing requirement for biodegradable polymers with temporary function and easy elimination from the body. Within the frame of this contribution the research on synthesis of biodegradable (co)polyesters mainly based on poly(butylene succinate) and polycaprolactone, their structure dependent properties, their nanocomposites with naturally occurring fillers like clays and sepiolites as well as their potential application will be presented.*

Keywords: biodegradable, synthetic polymers, polyesters

1. INTRODUCTION

Although the mass production and use of synthetic polymers started around the middle of last century, today's world is not imaginable without these materials. The reason for such high usage lies in their versatility in terms of physical and chemical properties. They are lightweight and durable and their properties span, for instance, from soft elastomers to hard thermosets, form watersoluble to superhydrophobic, just due to the chemical structure of monomeric unit form which they are comprised. Increased usage of conventional, durable polymeric materials, especially for short-term applications, lead to high amount of polymer waste which cannot be assimilated by living organisms in nature and their accumulation presents an environmental challenge. Therefore, the development of biodegradable polymers is of an utmost importance [1]. Biodegradable polymers are also of interest in biomedical filed where they are developed for controlled released systems or in tissue engendering. Among biodegradable polymers, aliphatic polyesters, due to the presence of hydrolysable ester group in their backbone, are the most promising candidates to replace conventional plastic materials like polyethylene, poly(ethylene terphatalate) or polystyrene [2,3]. They can be obtained from fossil based recourses as poly(butylene succinate), PBS, and poly(ε-caprolactone), PCL, or form renewable resources as poly(lactic acid), PLA (Figure1). However, in order to broaden the application window for biodegradable polyesters different approaches are used to render new materials with desired properties. The most versatile approach is copolymerization to yield random, block or star copolymers with new properties. Also, mechanical strength, barrier and thermal properties can be enhanced and tuned by application of nanocomposite approach. The development of nanocomposites with biodegradable polymer matrix is a very

[1]mnikolic@tmf.bg.ac.rs

dynamic filed of current scientific and industrial interest. In this work research on some copolymers, nanocomposites and controlled release systems developed from PBS, PCL and PLA will be presented.

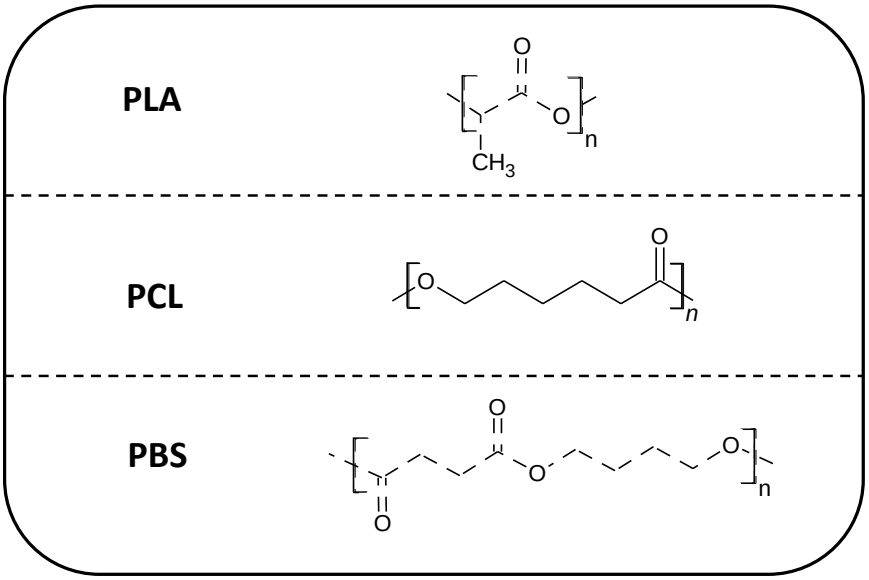

Figure 1. Overview of biodegradable polyesters considered in this work

2. COPOLYMERS OF DIFFERENT BIODEGRADABLE BUILDING BLOCKS.

2.1 Poly(buthylene succinate) based copolymers

Poly(butylene succinate) belongs to the large family of poly(alkylene dicarboxylate) polyesters which are obtained from diacids and diols . The favorable thermo-mechanical properties put apart PBS form other poly(alkylene dycarboxilate)s, since PBS is one of a few polyesters belonging to this family with melting temperature higher than 100 °C. PBS and its copolymers were commercialized in 1994. by Showa Denko (Japan) under trade name Bionolle. They were seen as resins for production of eco-friendly packaging, bottles and mulch films, i.e. as a suitable replacement for low density polyethylene. Fair mechanical properties together with good processability and thermal resistance are in favor of broader use of PBS, nevertheless its low gas-barrier properties are often criticized, especially for the food packaging applications. Hydrolytic degradation of PBS, which is the first step in biodegradation process, is slow, due to its hydrophobic nature and high crystallinity. The degree of crystallinity has a major influence on the degradation rate, since the degradation commences first in the amorphous parts of the polymer. Crystallinity can be tailored through copolymerization, the most effectively for random copolymers. By using transesterification reaction with highly effective titanium based catalyst random copolymers of PBS and poly(butylene adipate), PBA were successfully synthesized [4]. These high molecular weight copolymers were synthesized in order to combine different properties of the parent homopolyesters: high melting point of PBS and higher biodegradability of PBA. Enzymatic degradation test conducted by the use of *Candida cylindracea* lipase showed that all copolymers with high adipate content had an improved biodegradability compared to the homopolymers. By using similar procedure, copolymers of PBS with small amount of unsaturation, arising from fumarate units, were synthesized [5]. The introduction of double bonds into the main chain increased the melting and crystallization temperatures, but a decreasing trend in the crystallinity was observed. Since the biodegradation was not greatly correlated with crystallinity in this case, this study showed that stiffness of the molecular chains and the size of the spherulites are also factors which determined the biodegradation.

Changing the hydrophilicity/hydrophobicity of polymers can be done through copolymerization by the introduction of hydrophilic segments, such as polyethers, into the backbone of the polymer

chains. The introduction of polyether soft segments into polyesters not only change hydrophylicity, but leads to the formation of segmented polymers, the mechanical properties of which can be easily controlled by the type, the weight percent, and the length of these soft segments. Block-copolymers of PBS and two different polyethers of the same molecular weight: poly(tetramethylene oxide), PTMO and poly(ethylene oxide), PEO were synthesized. All prepared copolymers had improved biodegradability compared to PBS homopolymer. Also, copolymers with PEO in the soft segments were more susceptible to hydrolysis than those based on PTMO, which is to be expected from the lower hydrophilicity of PTMO compared to PEO. At the same time mechanical properties were modified and the presence of soft, polyether segments reduced storage modulus in rubbery state compared to PBS homopolymer by one to two decades, as reveled by dynamical mechanical analysis [6,7].

2.2 Poly(ε-caprolactone) based copolymers

Another prominent member of biodegradable aliphatic polyesters' family is poly(ε-caprolactone). PCL is hydrophobic, semicrystalline polymer with a melting point of about 60 °C, and low glass transition temperature of around – 60 °C. PCL is considered as a suitable, environmentally friendly replacement for some non-biodegradable commodity polymers for packaging or in agriculture. PCL exhibits good compatibility and miscibility with other polymers, it is biocompatible, and easily processable polymer. Due to its biocompatibility and slow hydrolytic degradation without the harsh change of pH in the surrounding medium, PCL has been investigated for some long-term medical applications, such as in some prolonged controlled release systems or for different scaffolds, where physical and mechanical properties should be maintained for at least 6 months.

In order to combine properties of PCL and PBS and to maintain high melting temperature of copolymers, multiblock copolymers of these two polymeric units were synthesized. Multiblock copolymers having PBS and PCL as building blocks were synthesized through diisocyanate coupling reaction, demonstrating that this approach yields copolymers with versatile properties [8]. Mechanical strength, deduced from storage modulus in glassy and rubbery state, was a firm function of composition, where softer materials were obtained with introduction of more flexible PCL block into the polymer chains. Biodegradability was investigated in alkaline medium and in soil burial test and it was strongly compositional dependent. The copolymers with higher density of ester linkages (higher content of PBS) were more prone to degradation in alkaline medium. PCL was more susceptible to degradation in soil as well as PCL-rich multiblock copolymers. Furthermore, triblock copolymers with PCL lateral blocks were synthesized, in order to broaden the application window of PCL and to establish correlation between macromolecular structure of block copolymers and their properties. As a central block two different condensation polyesters of a fixed molecular weight were used, poly(butylene succinate), PBS and poly(butylene adipate), PBA, while molecular weight of lateral PCL blocks was varying in the series of copolymers. Melting temperatures of all copolymers were slightly lower compared to PCL, as a consequence of imperfections of formed PCL crystallites, imposed by the presence of second crystallizable component. Conversely, degree of crystallinity of PCL fraction was considerably higher in all of the copolymers indicating a nucleation effect of the present PBS or PBA in the copolymers. Yet, in the hydrolytic degradation tests weight losses were lower in PBS series and higher in PBA series compared to PCL, indicating possibility of tailoring biodegradation kinetics by copolymer composition. The changes in molecular weights during the course of degradation revealed surface erosion mechanism for the both series of triblock copolymers.

Properties of copolymers can also be tailored by the change in the architecture of polymer chain. Through the synthesis and comparison of the properties of diblock and triblock copolymers of PCL and PEO, it was demonstrated that thermal, surface and degradation properties of these polymers depend not only on the chemical composition, but also on the chain architecture, i.e. diblock vs. triblock [9,10].

3. (NANO)COMPOSITES WITH BIODEGARDABLE POLYSTER AS A MATRIX.

3.1 Poly(ε-caprolactone) based (nano)composites

Mechanical, thermal or barrier properties of aliphatic polyesters can be significantly improved with the addition of small amount of nanofiller. A great number of nanofillers were employed in development of nanocomposites with biodegradable polymers, such as natural lamellar clays, carbon nanotubes, metallic nanoparticles, graphene, etc. [11-13]. From the economic viewpoint natural clays are a good choice since they are abundant and easy to exploit. Among natural clays, layered silicates are the most investigated, since they are of high mechanical strength, chemical resistance and well investigated intercalation chemistry which is important for surface modification. The most challenging task in nanocomposite preparation is to achieve good filler dispersion in polymer matrix. Only in the case of a good dispersion, the interface between a filler and matrix dramatically increases, allowing a full contribution of the filler to improve the matrix properties. Therefore, the surface of a filler is usually modified with suitable organic molecules (to yield organoclay) in such way to provide good interaction with polymer matrix. Solution casting was used to prepare PCL/organoclay nanocomposites with two different organically modified montmorillonites, Cloisite®30B and, more hydrophobic, Cloisite®15A. All nanocomposites had improved mechanical properties in terms of dynamic storage modulus. At the same time a trend of decrease in strain at break with increase in the clay loading is observed, similar to the usually found embrittlement effect of the clay [14]. Detailed rheological studies of these nannocomposites in melt and in solid state showed that mechanical properties are mainly influenced by the effective aspect ratio of the clay [15].
Sepiolite is fibrous natural clay, which emerges as a new inorganic nanofiller. Sepiolite fibres are organized in bundles and they can be easily functionalized through reaction with silanol groups at their surface. At the same time sepiolite possesses exchangeable cations, which makes the basis for modification through ion exchange reactions. Modification of sepiolite was performed with the goal to increase its compatibility with PCL hydrophobic matrix. Modification was performed with (3-mercaptopropyl) trimethoxysilane, by covalent attachment and with hexadecylamine by ion exchange reaction. Organomodification of sepiolites promoted the dispersion of nanofiller in PCL matrix and the mechanical performance of nanocomposites was improved. Due to the favorable interactions which could be established with PCL (whose repeating unit has long aliphatic part) the highest reinforcement was achieved for the sepiolites modified with hexadecylamine [16]. Also, barrier properties of nanocomposites' films were investigated on permeability to water vapor. It was found that the barrier properties were improved by addition of modified sepiolite into the PCL matrix.

3.2 Poly(lactide acid) based (nano)composites

The most researched and developed biodegradable aliphatic polyester is certainly poly(lactic acid), primarily because it is a polyester which can be produced from renewable resources. Due to the chiral monomeric unit, PLA can have a range of properties which depend strongly on its optical purity, i.e. content of L- and D-enantiomer. Optically pure PLLA (comprised of only L-enantiomer) is crystalline polyester with melting temperature around 170 °C and glass transition temperature of around 60 °C. PLA is seen as a polymer that can be broadly used for general packaging (compostable tableware and plastics bags), in agriculture (mulch films) and in fiber industry (disposable garments), since it can be easily processed using conventional equipment. However, in order to replace currently used commodity thermoplastics some of its shortcomings as poor barrier properties, brittleness and cost effective production has to be overcome. In the field of packaging application it would be of great importance to improve some functional properties of PLA, such as antibacterial activity. PLA composites with antibacterial activity were obtained by incorporation of silver-enriched zeolite (Ag-Z) in polymer matrix. Antibacterial activity of composites was proven

toward two bacterial strains, Gram-negative *Escherichia coli* DSM 498 and Gram-positive bacteria *Staphylococcus aureus* ATCC 25923 and was slightly pronounced toward *E.coli*. At the same time silver-enriched zeolite had a reinforcement effect on the polymer matrix.

4. BIODEGRADABLE POLYESTERS AS DRUG RELEASE SYSTEMS.

Microencapsulation of active substances is in the focus of current research efforts due to many advantages which these systems have, compared to conventional drug delivery systems. Besides the protection of a drug, microencapsulation offers possibility of controllable and targeted drug delivery. Natural choice for the matrix of microspheres in such systems is biocompatible and biodegradable polymeric material. Biodegradable and biocompatible PCL and its copolymers and blends are very often used as matrix-building material in drug release microspheres' systems, since PCL possesses good permeability for small molecules. The potential of PCL as drug carrier for hydrophobic carbamazepine as well as conditions for microencapsulation of this drug were evaluated. Microspheres in the size range from around 5 μm to around 100 μm could be successfully obtained, with high encapsulation efficiency. It was demonstrated that release of carbamazepine from smaller PCL microspheres was slower, as a consequence of better drug distribution in comparison to the bigger microspheres [17]. By changing the hydrophilicity of PCL microspheres through blending with PEO, release profiles of carbamazepine could also be efficiently modified [18]. Block copolymers of PCL with small amount of PEO block were likewise efficiently applied as drug carriers in microencapsulation of ibuprofene [19].

5. CONCLUSION

Biodegradable aliphatic polyesters are versatile materials which can be applied in different fields. In this work possibility to tailor material properties by copolymerization, nanocomposite preperation and blending approach, using PCL, PBS and PLA polyesters, is described. Also, the potential application of biodegradable polyesters as the matrix for drug release from polymer microspheres is presented. For other biodegradable synthetic polyesters further improvements through development of new building units, synthetic procedures and molecular architecture will certainly promote these materials' application. New achievements are expected particularly in the field of (nano)composites for an easy and efficient modification and tuning of properties. With this advances and growing ecological awareness, it is expected that the market of biodegradable aliphatic polyesters will see a steady growth in the future.

This work was supported by the Ministry of Science, Technological Development and Innovation of the Republic of Serbia [Contract No. 451-03-47/2023-01/200135]

THE *ESPeRT* PROJECT: A "POLYTECHNIC" STRATEGIC PLAN FOCUSED ON SUSTAINABILITY

Alessandro Gasparetto[1], Dipartimento Politecnico di Ingegneria e Architettura, Università degli Studi di Udine, Udine, Italy
Stefano Grimaz[2], Dipartimento Politecnico di Ingegneria e Architettura, Università degli Studi di Udine, Udine, Italy

Abstract: *In this paper, a strategic research project, carried out by the Polytechnic Department of Engineering and Architecture of the University of Udine, and focused on sustainability, is presented. The project, named "ESPeRT", is focused on three interconnected research areas: sustainability of the production processes; energy and green economy; territorial resilience. The project is designed to be functional for the implementation of the UN 2030 Agenda on Sustainable Development, the Next-Generation EU and of the National Recovery and Resilience Plan. The research activities carried out in the framework of the ESPeRT project are complemented by a new teaching offer related to sustainability. Namely, a new Master course on "Industrial Engineering for Sustainable Manufacturing" has been designed and implemented, starting from the academic year 2023-24.*
Keywords: Sustainability, Ecological Transition, Digital Transition, Agenda 2030, UN SDGs

1. INTRODUCTION

In recent years, the issue of sustainable development has become increasingly central to global and local policies. At the same time, the climate changes underway are causing important transformations of the ecosystem and producing increasingly frequent extreme phenomena, with relevant socio-economic impacts. This fact highlighted the urgency of making a transition to a sustainable development, also aimed at reducing the risks of disasters and at mitigating threats, with a substantial reduction of climate-altering emissions and with a transition to clean energy. The sustainable development goals of the UN 2030 Agenda [1], the Paris Agreement [2] and the European Green Deal [3] aim at a progressive decarbonisation and at adopting circular economy solutions, based upon a science-based and risk-informed approach. It is therefore necessary to aim at a greater sustainability of the productive processes, by exploiting innovative technologies and management models capable of combining an efficient production with the needs of environmental protection and of the rational use of resources. The fragility of the territory and the plurality of risks to which it is subject also require improvement of the territorial resilience with a holistic and systemic vision, not only to face disasters and crises *ex-post* but also to anticipate them *ex-ante* and transform them into opportunities for regeneration and development in the recovery phases.
The effects caused by the COVID-19 pandemic are also added to this picture [4]. These effects have led to major changes and have placed new global challenges on the table, highlighting the close interconnection between health, technological and socio-economic aspects, and above all the difficulty of management and governance, due to the high level of complexity that characterizes the era of globalization. The recovery plans - such as the Next Generation EU [5] and the Italian National Recovery and Resilience Plan [6] - intend to promote a robust recovery of the economy under the banner of ecological transition, digitization, competitiveness, training and social, territorial and

[1]alessandro.gasparetto@uniud.it
[2]stefano.grimaz@uniud.it

gender inclusion. The ecological transition, in particular, is focused on themes with a strong polytechnic connotation, such as:

- circular economy;
- energy efficiency and redevelopment of buildings;
- renewable energies, hydrogen, sustainable mobility;
- protection of the territory and of the water resources.

These plans follow the "build back better" principle introduced by the Sendai framework [7]: the goal is not a return to normality aimed at restoring pre-pandemic conditions, but rather a new normality characterized by more advanced standards of quality of life. In other words, the objective of these plans is to seize development and improvement opportunities by introducing among the recovery objectives also those defined by the above mentioned UN Agendas (and among these, primarily those of the UN 2030 Agenda on sustainable development), as well as the protocols on climate change and the Green Deal.
The ultimate goal is to shape the future with the new generations as a point of reference and to start a real process of change, transformation, renewal, regeneration and revitalization. It is a path of recovery and development in which research, first of all, is called to give its concrete contribution in terms of strategies and solutions. Research and technological innovation are among the main drivers of the economic development of a country, but in particularly complex historical moments, such as those of post-pandemic recovery, it is necessary to adopt an interdisciplinary and focused approach.
The Polytechnic Department of Engineering and Architecture, with the *ESPeRT* project, intends to systematize its expertise in a highly interdisciplinary general project, also open to contributions from other departments and institutions, with the aim of giving a concrete contribution of research and innovation in this direction.

2. GOALS AND STRUCTURE OF THE PROJECT

The *ESPeRT* project, coordinated by the Polytechnic Department of Engineering and Architecture of the University of Udine, intends to contribute to the achievement of the objectives of the UN Agendas and the challenges introduced by the recovery plans (such as the Next Generation EU and the Italian National Recovery and Resilience Plan) by operating on three interconnected research areas:

- sustainability of the production processes;
- energy and green economy;
- territorial resilience.

Figure 1 shows the structure of the *ESPeRT* project. Those listed above are three issues that constitute the main components of the ecological transition that is a fundamental part of the sustainability. Their transversal character requires the systemisation of various polytechnic skills in an interdisciplinary logic also open to the synergistic contribution of other disciplines present in other departments and institutions.
The project is designed to be functional for the implementation of the UN 2030 Agenda on Sustainable Development, the Next-Generation EU and of the National Recovery and Resilience Plan and, in particular, pursues the following aims:

1. provide research contributions contextualized and consistent with the recovery and post-pandemic COVID-19 recovery policies defined at the international, national and local level;
2. define a logical framework that allows to be best expressed the potential deriving from an interdisciplinary “polytechnic” approach on current and emerging issues;
3. facilitate the systemisation and capitalization of the experiences and skills present in the University of Udine, in order to proactively contribute to the ongoing change process;
4. make the multi-sectoral contributions more organic, in order to act as a guide and functional support to the reference territory in the process of change, outlining the possible synergies between Universities, Institutions and public and private subjects involved in the process.

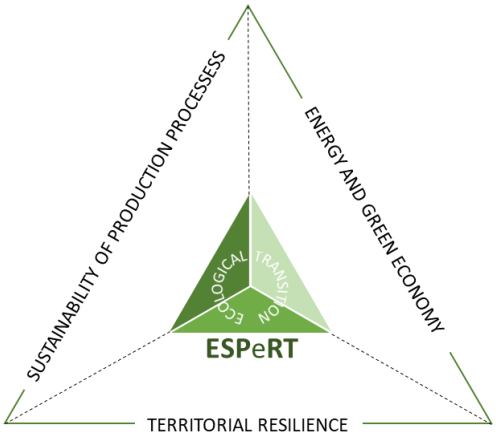

Figure 1. The structure of the *ESPeRT* project for sustainability.

The project is structured in Workpackages, Tasks and Sub-tasks, following a logical and functional framework in which the individual contributions research are nested. The three main WPs are:

- WP S - Sustainability of Production Processes;
- WP E - Energy and Green Economy;
- WP R - Territorial Resilience.

The triangular scheme shown in Figure 1, made up of three converging triangles which, joining together, point to a common goal, highlights the role of interdisciplinary synergy that underlies the project and at the same time constitutes the logical path that links organically the individual research activities.

The structure given to the project is designed to allow a certain degree of dynamism and adaptability over time in order to allow, where deemed appropriate and functional for the purposes of the project, to enrich the various WPs by integrating them by inserting new Tasks, Subtasks and new actions, also on the proposal of scientific representatives of other departments and institutions. The placement of these integrations in this pre-structured scheme ensures the maintenance of the overall logical coherence of the project and the finalization of the various contributions.

In the following subsections of the paper, the three Workpackages, involving a total of more than 100 researchers of different disciplines, will be described.

2.1 WP S – Sustainability of Production Processes

Sustainable development is a form of economic development compatible with the protection of the environment and of the resources for the future generations. It implies the simultaneous pursuit of economic prosperity, environmental quality and social equity.

An increasing number of organizations acknowledge environmental protection and responsibility towards others stakeholders as priorities of the company. Therefore, the design and management of processes cannot be limited to the sole perspective of profit, but must consider the effects on the environment (e.g. in terms of pollution, CO_2 production, creation of waste, etc.) and the effects on society (for example in terms of well-being at the workplace and improvement of the quality of life of the employees and of the society in general).

Consequently, sustainable production is an important driver of sustainable development and requires rethinking and innovating not only the production systems, but also the supply networks, the logistics systems and the characteristics of the products and services. In this sense, research on sustainable production is characterized by a strong interdisciplinarity.

Furthermore, the choices relating to sustainable production can be declined in the three characteristic areas of sustainability - economic, social, environmental - but also at different decision-making levels (strategic-managerial, infrastructural and operational).

The research activities of the WP S are aimed at the transfer and diffusion of technologies, methodologies and knowledge for strengthening the sustainability of production processes in terms of:

a) business models for sustainability (strategic-managerial level);
b) infrastructures for the control and monitoring of industrial plants and products (infrastructural level);
c) process and product prototyping for a sustainable industry (product-process operational level).

The WP S intends to study the innovation of products, processes and infrastructures and their alignment in order to create a business model for sustainability that describes the main strategic decisions and organizational structures that guide the introduction of product/process/infrastructure innovations. The goal is to provide the companies with a support for the improvement of products (for example in terms of functionality, resistance, reliability, duration, etc.) and processes not only in terms of economic and operational performance but also of well-being work and environmental impact.

2.2 WP E – Energy and Green Economy

The energy issue represents an essential element for any program aimed at achieving energy efficiency while respecting the environmental sustainability. Historically, every economic development has been supported by an increase in the energy availability, with clear correlations between the growth of gross national product and energy demand. Relying mainly on limited and non-renewable primary sources (such as fossil sources) leads to a vicious circle of increases in impacts and depletion of resources: reversing this process requires a redesign of the production chains in a broad sense, both in terms of energy production (renewable sources, energy efficiency energy conversion), and in terms of energy demand in the civil, industrial and transport fields (reduction of consumption, integrated systems, innovative distribution networks, waste reduction and circular economy).

This transition involves explicitly energy aspects, referred to in goal n.7 of the UN Agenda 2030 (Clean and accessible energy), while also maintaining the need for equity through the effort to ensure universal access to quality services. But the importance of demand-side optimization links to goals n. 11 and 12 (Sustainable cities and communities, Responsible consumption and production), requires innovation such as referred to in goal n. 9, and supports the fight against climate change (goal n. 13). This imposes important technological challenges, and the development of strategies to manage the transition with different interventions corresponding to the medium and long-term objectives. This project takes advantage of the internal skills of the Polytechnic Department of Engineering and Architecture of the University of Udine to develop suitable models and technologies, in terms of system analysis (with attention to the development of sustainable logistics networks of production and transport), in terms of technological choices (with a focus on the energy efficiency of buildings and plants), in terms of development of key technologies for overcome technological bottlenecks in the short, medium and long term (innovative heat exchange systems, use of carbon-free fuels, material recycling methodologies, innovative solar energy conversion technologies), in terms of numerical modelling and phenomenological analysis to support these objectives.

2.1 WP R – Territorial Resilience

The WP R intends to address, in an interdisciplinary way, the issue of territorial resilience. The UNDRR (United Nations Office for Disaster Risk Reduction) highlights how territorial resilience, in its various components, contributes decisively to the achievement of a large part of the development objectives sustainability defined by the UN Agenda 2030 and the fulfilment of the goals introduced by the Sendai Framework on Disaster Risk Reduction.

The theme of territorial resilience is central for a country like Italy, and in particular for its North-Eastern regions, which are exposed to a variety of natural and man-made hazards. The peculiar

geographical configuration, the economic development and the intensive use of the soil, the abandonment of certain territories and the intensive tourist activity in others, the widespread presence and growth of urban and productive settlements, combined with a multiplicity of interconnected infrastructures, make these territories particularly exposed and vulnerable. Particular attention should be paid to critical infrastructures and essential services (hospitals, lifelines, road infrastructures, schools, etc.). The presence of a heritage to be protected with reference both to its naturalistic-environmental and socio-economic values represents at the same time also a distinctive element for identity, culture, history and therefore with historical-cultural value.

Preventing and countering the hydrogeological instability phenomena, reducing the seismic vulnerability of buildings and making a careful and appropriate land use are actions that cannot be postponed. Interventions aimed at monitoring and prevention, the safety of the territory, the redevelopment of settlements, the adaptation of buildings and the improvement of energy efficiency require new conceptual paradigms. We must leave sectoral logics of action and adopt integrated approaches in order to define transversal strategies which, while acting in the immediate and short term, achieve results in the medium and long term. It is therefore important to act synergistically and according to an overall vision on the fronts of forecasting/foresight, prevention and planning, but also to improve knowledge and skills for emergency management, recovery and post-event regeneration. The disaster management cycle, proposed by the United Nations, is the main reference methodology for this purpose, also because it allows us to give an operational meaning to the term “territorial resilience”, not only in reactive terms, but also and above all in pro-active terms, such as the ability to anticipate and adapt to changes.

Central themes of territorial resilience are also the protection and restoration of ecosystems and the rational use of natural resources and, in particular, water resources. Security of supply and sustainable management of water resources along the entire cycle require action on the governance of the integrated water service and on the improvement of the environmental quality of inland and sea waters.

The theme of territorial resilience is therefore strongly interdisciplinary and requires the adoption of a holistic approach capable of systematizing technical-scientific, managerial, administrative and governance aspects in order to protect environmental, socio-economic, historical-cultural values and, where possible, to enhance them. In order to prevent, anticipate and deal with crises, it is necessary to combine in a synergistic way the most advanced knowledge of different sectors with those deriving from the lessons learned from past experiences, analysed and interpreted from a variety of points of view.

3. NEW TEACHING OFFER RELATED TO SUSTAINABILITY

The *ESPeRT* project yields a new teaching offer, too. Namely, a new Master course on "Industrial Engineering for Sustainable Manufacturing" has been designed and implemented, starting from the academic year 2023-24.

This initiative starts from the consideration that the territory, and in particular the sector of heavy manufacturing industry, has been asking for many years the institution of a high level course on sustainable manufacturing, applied to heavy industries. Several industries of the metal production sector are present in the territory of the Friuli Venezia Giulia region (such as the Danieli group, the Pittini group, the Cividale group, Trametal and the SMS groups). These companies require more specific preparation aimed at their needs, consistent with the innovation process they are undertaking, particularly in the field of digitization and sustainability.

The new didactic proposal foresees a new master's degree titled: "Industrial Engineering for Sustainable Manufacturing". This initiative would be the natural completion of the three-year course recently started in Industrial Engineering for Environmental Sustainability, whose access is also open to three-year graduates in management and mechanical engineering. However, it is believed that it can also present elements of attraction towards foreign students, in particular in the context of

agreements, already partially started, between foreign universities and local companies and therefore the course, once fully operational, will be held in English.
For the detailed planning of the course, a path has been envisaged involving the representatives of companies, not only to define the contents, but also the methods of teaching, such internships and laboratory activities in collaboration with companies, as well as integrated teaching modules with company technical staff.
This teaching initiative will have contents belonging to several fields, which are of uttermost importance for the University, for the territory, for the stakeholders of the project, for the companies involved, as well as for the society as a whole:

- Sustainability: training activities will be provided in the field of energy management, green design, sustainable circular economy, etc.
- Digitization: training activities will be planned in the field of automation and mechatronics and robotics, in the field of virtual prototyping and big data.
- Internationalization: the teaching offer will be in English, with agreements that involve foreign companies and universities.
- Third mission and social impact: the course was born from a request from local companies, it will be built together with these companies that will be involved in the training activity.

4. CONCLUSION

In this paper, a strategic research project, carried out by the Polytechnic Department of Engineering and Architecture of the University of Udine, and focused on sustainability, has been presented. The project, named “ESPeRT“, is focused on three interconnected research areas: sustainability of the production processes; energy and green economy; territorial resilience. The project has been designed so as to be functional for the implementation of the UN 2030 Agenda on Sustainable Development, the Next-Generation EU and of the National Recovery and Resilience Plan. The research activities carried out in the framework of the ESPeRT project have been complemented by a new teaching offer related to sustainability. Namely, a new Master course on "Industrial Engineering for Sustainable Manufacturing" has been designed and implemented, starting from the academic year 2023-24.

This research was supported by funds of the Strategic Plan of the University of Udine (ESPeRT project).

Abstract: *Waste glass is one of the significant environmental problems. Due to its wide application in everyday life, glass, and especially glass packaging of items of general use, represents a large share of communal waste. The production of glass packaging, especially from primary sources, requires a lot of energy. One of the ways to reduce the consumption of energy and natural resources in an efficient way is the application of circular economy principles, i.e. the reuse of waste glass. Waste glass as an effective auxiliary material for ceramic products is widely used depending on its properties and application conditions. In this paper, the physical-chemical characterization of waste glass of general use was carried out in the function of reuse by incorporation into the stable structure of the eco-sintered product.*
Keywords: waste glass, items of general use, environmental protection.

1. INTRODUCTION

Glass as a transparent, amorphous, solid, brittle and chemically stable material, thanks to its physical and chemical properties, is used for the production of packaging in almost all branches of industry. Nowadays, waste glass (glass cullet) represents a major environmental challenge in urban areas. Non-degradable glass waste occupies significant areas of landfills, which leads to serious environmental problems [1]. By reusing glass waste, it is possible to save primary raw materials and also a large amount of energy. The recovery of 100 million glass objects of general use will save: 30 thousand tons of glass sand, 100 thousand tons of soda, 18 thousand MWh of electricity and 76 million m3 of natural gas [2].
According to previous research, waste glass as a raw material or auxiliary material is used in many branches of industry, such as: replacement for concrete aggregate (pozzolanic additive), construction materials (filling layers for the construction of roads and parking lots), raw material in the technological process of making glass, raw material for sandblasting, raw material for the production of glass beads in reflective paint for marking highways, raw material for the production of glass fibers, fractionator for lighting matches,auxiliary material for obtaining sintered ceramic materials, etc[3-9]. Characteristic of the process of obtaining sintered products is the use of waste glass cullet as an auxiliary material due to the optimization of the sintering temperature. As its share in the mixture increases, the melting temperature of the ingredients decreases [10]. Accordingly, in the paper, a physical-chemical analysis of waste glass slag was performed with special reference to its use as an auxiliary material in eco-sintered ceramic products.

2. MATERIALS AND METHODS

The material used in the research is glass cullet obtained from waste glass of general use, and due to the need to homogenize the ingredients and auxiliary materials in the sintering process, it was crushed to a powder form. The glass cullet was examined by FTIR and SEM-EDX analyses. FTIR spectra were recorded in the Spectroscopy Laboratory of the Faculty of Technology in Leskovac. The analysis was performed on a spectrometer BOMEM Michelson Hartman & Braun Series MB in the area 4000-400 cm-1 at a resolution of 2 cm-1. The preparation of the sample was done by the "potassium bromide" process, which involves pulverization and uniform dispersion in KBr (1.5 mg/150 mg KBr), then the mixture was vacuumed and pressed under a pressure of 200 MPa, whereby a suitable lozenge was obtained.
The structure of the glass cullet sample was recorded using the SEM-EDX technique in the Laboratory for Electron Microscopy at the Medical Faculty, University of Niš. The sample was analysed on a JOEL JSM-5300 scanning microscope with a Linx Analytic QX2000 probe.

3. RESULTS AND DISCUSION

The basic raw materials used in the production of glass are: quartz sand (about 56%), soda (about 12%), calcium carbonate (about 12%), resin (about 4%) and additives for colouring, i.e. for removing colour [2]. Consequently, the presence of silicon, sodium and calcium oxides in the largest mass fractions is expected in the waste glass cullet. Table 1 shows the chemical composition of waste glass of general use based on previous research [11-15].

Table 1. Optimum chemical composition of waste glass of general use items

Compound	Concentration [%]
SiO_2	66-88
Al_2O_3	0-7
Fe_2O_3	0-4
CaO	0-15
MgO	0-5
Na_2O	3-18
K_2O	0-6
P_2O_5	0-3
TiO_2	0-1

According to presented chemical composition, it can be seen that the dominant compound in waste glass is silicon dioxide with a mass share of over 60%. The basic oxides from which glass is formed (glass formers) are SiO_2 and Al_2O_3. CaO and MgO oxides are glass stabilizers, while Na_2O is glass modifiers. Researches by Keawthun et al. and Giovani et al. confirm the presence of silicon dioxide in amorphous form in waste glass shards of general use items [12,16].
Figure 1 shows the FTIR spectrum of the reference waste glass, which confirmed the chemical characterization of the waste glass.

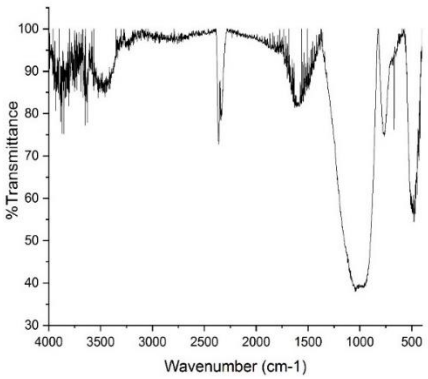

Figure 1. FTIR spectrum of waste glass

The FTIR spectrum of waste glass highlights a broad and intense band at 900-1100 cm^{-1}, which originates from asymmetric stretching vibrations of silicon and oxygen of silicate tetrahedral chains, which is in accordance with the researches of Torres-Carrasco et al. and Kouassi et al. [14, 17]. On the other hand, according to research by Rad et al., FTIR analysis of glass karst indicates specific silicate peaks from 800 to 1300 cm^{-1} and metal ion peaks from 400 to 550 cm^{-1} [18]. Vibrations between 400 and 550 cm^{-1} are due to the presence of metal oxides [18-19]. Figure 2 shows a SEM microphotograph of waste glass and an EDX spectrum.

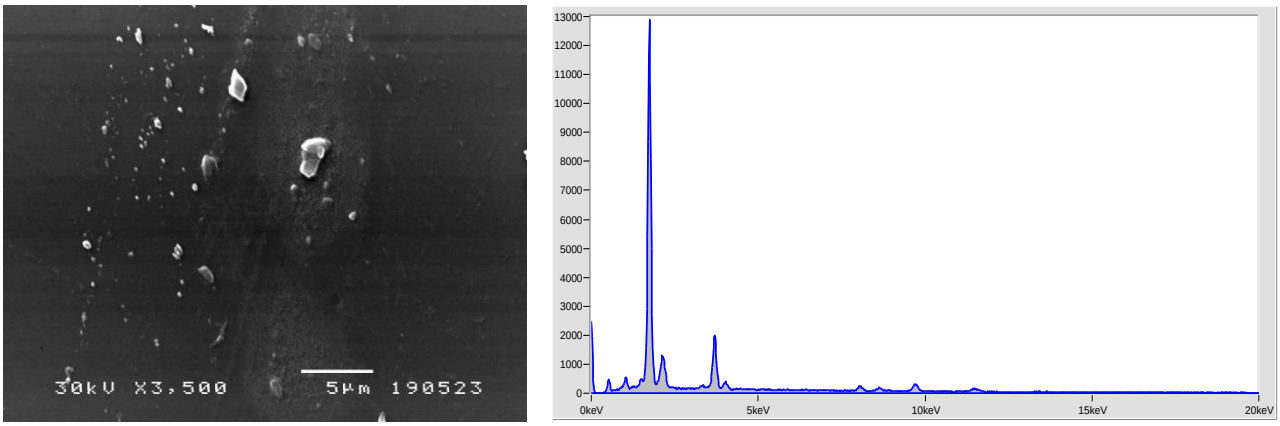

Figure 2. Microphotograph and EDX spectrum of waste glass

A photomicrograph of waste glass indicates relatively few pores unevenly distributed over the surface of the sample, which is in accordance with the research of Vance et al. [20]. Characteristic peaks of oxygen, silicon and calcium can be observed on the EDX spectrum of glass cullet, which confirms the chemical characterization of the glass [21,22].

Based on the characterization of the waste glass cullet, the dominant content of silicon dioxide in the tested sample can be determined. The characteristics of this compound, such as: stability at high temperatures, low-temperature coefficient of linear expansion, optical transparency in the spectral range from infrared to ultraviolet radiation, chemical inertness, hardness, mechanical strength and others, make it suitable for incorporation into sintered ceramic materials [23]. Glass cullet also has extraordinary pozzolanic characteristics, which is another advantage for use in the production of ceramic products.

In order to improve the characteristics of sintered products and increase environmental efficiency, other waste materials (galvanic sludge, ash, slag, cathode glass) are added as ingredients in the sintering process [25]. The obtained sintered product has such a structure that it can have a useful value, reducing and the risk of environmental pollution to its minimum.

4. CONCLUSION

Technological procedures for the reuse of waste glass cullet enable the recuperation of valuable raw material, which can be used for the same or similar purposes. The incorporation of glass cullet into an eco-sintered product has a multiple positive effect on the environment, considering that stable structures of eco-ceramic products are obtained by sintering. On the other hand, the newly obtained material has the possibility of practical application in many branches of industry due to the high mass fraction of glass cullet and good physical-chemical characteristics.

IMPACT OF WASTEWATER ANTIBIOTICS ON RIVER WATER QUALITY IN BELGRADE AREA

Ljiljana Tolić Stojadinović[1], Innovation Centre of the Faculty of Technology and Metallurgy
Svetlana Grujić[2], Faculty of Technology and Metallurgy, University of Belgrade
Nikolina Antić[3], Customs laboratory, Customs Administration of the Republic of Serbia
Tatjana Đurkić[4], Faculty of Technology and Metallurgy, University of Belgrade

Abstract: *Municipal wastewater in the Belgrade area is discharged into the Danube and the Sava Rivers without any treatment. This affects the quality of river water since wastewater is one of the most important sources of environmental pollutants, including pharmaceuticals. To assess the impact of this effect, the presence of three commonly used antibiotics in wastewater and receiving river water was determined. A previously developed liquid chromatography-tandem mass spectrometry method for the analysis of antibiotics in natural water matrices was validated for wastewater and applied in analysis of samples from the Belgrade area. All investigated antibiotics were detected in both wastewater and river water samples. The highest concentration of antibiotics in wastewater was found for sulfamethoxazole, while trimethoprim was detected at the highest level in surface water. The most frequently detected antibiotic in surface water was azithromycin. The environmental risk assessment was performed for surface water biota. Azithromycin was found to pose a high risk to aquatic organisms, while the risk level of sulfamethoxazole was medium or low. In conclusion, the obtained results show the detrimental impact of untreated wastewater discharge on the river water quality in the Belgrade area, emphasizing the need for urban wastewater treatment.*
Keywords: Antibiotic, Urban wastewater, River water, LC-MS/MS, Environmental Risk Assessment

1. INTRODUCTION

Antibiotics have been increasingly produced and used worldwide in human and animal medicine. As a result, significant amounts of antibiotics have been released into the environment through waste from households, hospitals, the pharmaceutical industry, and farms. Antibiotics are frequently detected in surface water samples in concentrations that could be hazardous to aquatic organisms [1, 2]. The increasing presence of antibiotic residues in the water environment is now a matter of great health concern. However, there are no regulations concerning the maximum allowed concentrations of antibiotics in the aquatic environment. The latest update of the Watch list of substances for Union-wide monitoring in the field of water policy [3] includes several antibiotics, which reflects the concern regarding the presence of these contaminants in aqueous media. Wastewater represents one of the most significant sources of pollutants, such as antibiotics, in the environment [1]. Due to the absence of wastewater treatment plants in Belgrade, municipal wastewater is directly discharged untreated into the Danube and Sava Rivers. Consequently, it is necessary to assess the presence of antibiotics in Belgrade's surface water and evaluate their adverse effects on water quality.

[1]ljtolic@tmf.bg.ac.rs
[2]svetlana.grujic@tmf.bg.ac.rs
[3]anticn@carina.rs
[4]tanjav@tmf.bg.ac.rs

The aims of the present study were (a) to validate liquid chromatography-tandem mass spectrometry (LC-MS/MS) method for the determination of selected antibiotics in wastewater; (b) to determine the concentrations of selected antibiotics in wastewater and receiving water in the Belgrade area; and (c) to assess the environmental risks of antibiotics found in river water samples.

2. MATERIALS AND METHODS

2.1 Chemicals and reagents

The pharmaceuticals selected in this study are among the most commonly used antibiotics in Serbia. Analytical standards (purity > 95%) of three chosen antibiotics (trimethoprim, sulfamethoxazole, and azithromycin) were supplied from Hemofarm (STADA Group, Vršac, Serbia). The stock standard solutions of every analyte were prepared in methanol at a concentration of 100 μg mL^{-1}. The working standard solutions were prepared by mixing the stock standard solutions of three drugs and diluting them with methanol. All solutions were preserved at –4 °C. All solvents used were HPLC grade from Sigma-Aldrich (St. Louis, US). Deionized water was obtained by passing the distilled water through a GenPure ultrapure water system (TKA, Niederelbert, Germany).

2.2 LC-MS/MS analysis

A previously developed LC-MS/MS method for the determination of pharmaceuticals was used in this study [4]. A Dionex UltiMate 3000 LC system (Thermo Fisher Scientific, Waltham, MA, US) coupled to a LTQ XL (Thermo Fisher Scientific) linear ion trap as a mass detector was used for LC-MS/MS analysis. A reverse-phase Zorbax Eclipse® XDB-C18 column, 75 mm × 4.6 mm i.d. and 3.5 μm particle size (Agilent Technologies, Santa Clara, US) was used for the separation of the analytes. A pre-column (12.5 mm × 4.6 mm i.d. and 5 μm particle size, Agilent Technologies) was installed in front of the separation column. The mobile phase consisted of methanol (A), deionized water (B), and 10% acetic acid (C). The mobile phase gradient was changing as follows: 0 min, B 33%, C 2%; 12 min, B 98%, C 2%; 15 min, B 98%, C 2%. The initial conditions were then re-established and held for 15 minutes. The flow rate of the mobile phase was 0.5 mL min^{-1}. The electrospray ionization (ESI) technique in the positive ionization mode was used. The optimal source parameters were as follows: source voltage (4.5 kV), sheath gas (25 au, i.e., 25 arbitrary units), and capillary temperature (290 °C). An aliquot of 10 μL of the final extract was injected into the LC system.

2.3 Method validation

Using wastewater samples spiked at two concentration levels (50 and 100 ng L^{-1}), a previously developed procedure for the determination of selected pharmaceuticals in surface water and groundwater [5] was validated. Validation was performed by evaluating recovery, repeatability, sensitivity, and linearity. The repeatability of the method was expressed as the relative standard deviation (RSD). The sensitivity of the method was evaluated by determining the limits of detection (LODs) and quantification (LOQs). LODs and LOQs of the method were obtained as the minimum detectable amount of analyte with a signal-to-noise (S/N) ratio of 3 and 10, respectively. The linearity of the analytical response was studied using the matrix-matched standards prepared at five concentration levels (10–250 ng L^{-1}). The linear regression analysis was performed in order to determine the correlation coefficient (R^2).

2.4 Sample collection and sample preparation

Wastewater and surface water samples were collected in the Belgrade area, around the confluence of the Danube and Sava Rivers (Figure 1). Samples of wastewater were collected at three locations of

municipal wastewater discharge. An automatic sampling device was used to collect samples continuously for 24 hours. Samples of surface water were collected at three locations downstream from wastewater discharge. Surface water samples were collected by direct sampling from a boat in the middle of the river flow at a depth of about 50 cm. Samples were kept at 4 °C until analysis.

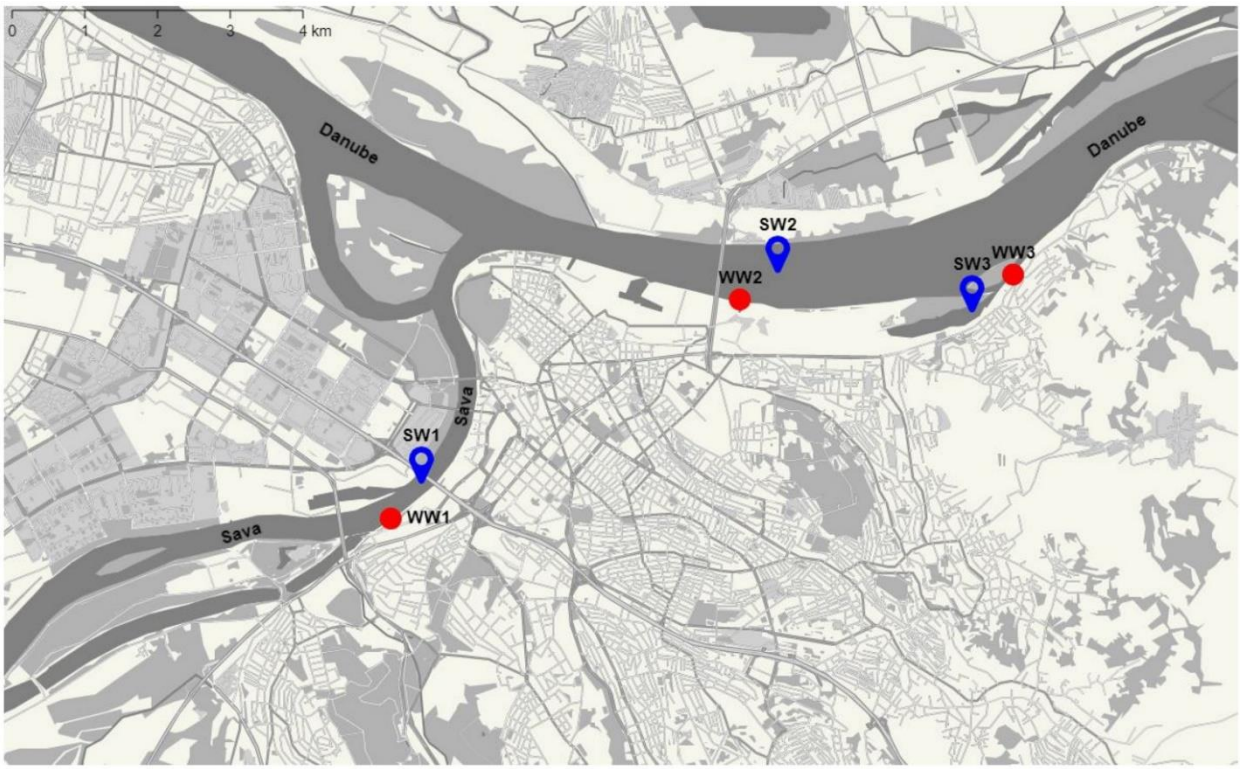

Figure 1. Map of wastewater (WW1–WW3) and river water (SW1–SW3) sampling sites
Source: https://www.stepmap.com/

A previously developed sample preparation method for the determination of pharmaceuticals in different aqueous matrices [5] was used for both wastewater and river water samples. In brief, water samples were prepared using solid-phase extraction: Oasis HLB column (Waters, Milford, MA, US) was preconditioned with 5 mL of a methanol-dichloromethane (1:1) mixture and 10 mL of deionized water. A 100 mL water sample with a pH value adjusted to 6.0 was applied. Then the column was dried for 10 min, and analytes were eluted using 15 mL of a methanol-dichloromethane (1:1) mixture. The obtained extract was evaporated and reconstituted to a volume of 1 mL with methanol. The final extract was filtered through a 0.45 µm polyvinylidene difluoride (PVDF) filter (Roth, Karlsruhe, Germany) and analyzed.

2.5 Environmental risk assessment

To assess the environmental risk of antibiotics detected in surface water, risk quotients (RQ) were calculated using the equation (1):

$$RQ = \frac{MEC}{PNEC} \quad (1)$$

where MEC is the measured environmental concentration and PNEC is the predicted no-effect concentration of the detected analyte [6]. The lowest available PNEC values (trimethoprim 120 µg L^{-1}, sulfamethoxazole 0.6 µg L^{-1}, and azithromycin 0.019 µg L^{-1}) were obtained from the NORMAN database [7]. Environmental risk was classified in three levels: $RQ \geq 1$ high risk, $0.1 \geq RQ > 1$ medium risk and $RQ < 0.1$ low risk [8].

3. RESULTS AND DISCUSSION

3.1 Method validation

The obtained validation parameters are presented in Table 1. The recoveries were in the range of 70–92% for trimethoprim and sulfamethoxazole. For azithromycin, the obtained values of recovery were not in this range, probably due to the pH value of the sample being adjusted to 6.0 which was optimal for other pharmaceuticals. The achieved RSD values were in the range of 5–11%. Low limits of detection (0.02–1.9 ng L^{-1}) and quantification (0.07–6.3 ng L^{-1}) indicate that the method is sensitive and suitable for the determination of trace levels of selected analytes in wastewater samples. Correlation coefficients (R^2) were in the range of 0.993–0.999, which implies that the developed method is linear in the tested concentration range (10–250 ng L^{-1}). Based on the values of the obtained validation parameters, it can be concluded that the applied method is appropriate for the determination of selected antibiotics in wastewater samples.

Table 1. Validation parameters of the analytical method
Source: *original copyright*

Analyte	Recovery, % (RSD, %)		LOD, ng L^{-1}	LOQ, ng L^{-1}	R^2
	50 ng L^{-1}	100 ng L^{-1}			
Trimethoprim	88 (8)	92 (5)	1.9	6.3	0.993
Sulfamethoxazole	83 (5)	70 (8)	0.2	0.7	0.999
Azithromycin	58 (7)	55 (11)	0.02	0.07	0.999

3.2 Sample analysis

Analyzed antibiotics were detected in wastewater in the concentration range from 122 ng L^{-1} (trimethoprim and sulfamethoxazole) to 1184 ng L^{-1} (sulfamethoxazole) (Table 2). All analyzed antibiotics were detected at the sampling site WW1, unlike samples WW2 (two antibiotics detected) and WW3 (none detected), which is likely due to WW1 being the largest wastewater discharge in the Belgrade area. In surface water, antibiotics were detected in the concentration range from 2 ng L^{-1} (azithromycin) to 334 ng L^{-1} (trimethoprim). The most frequently detected antibiotic was azithromycin, which was detected in all three river water samples.

Table 2. Antibiotics detected in Belgrade urban wastewater (WW1–WW3) and corresponding river water (SW1–SW3) samples (n = 2)
Source: *original copyright*

Analyte	Concentration (SD), ng L^{-1}					
	WW1	SW1	WW2	SW2	WW3	SW3
Trimethoprim	122 (12)	–	482 (72)	–	–	334 (54)
Sulfamethoxazole	122 (19)	–	1184 (152)	11 (1)	–	127 (7)
Azithromycin	318 (48)	9 (0)	–	2 (0)	–	58 (1)

In river water samples SW1 and SW2, collected downstream from the corresponding wastewater discharges, antibiotic concentrations were significantly lower than those detected in the wastewater, or analytes could not be detected, probably due to dilution. However, in the case of sampling site SW3, all analytes were detected at relatively high concentrations. SW3 was located in a small bay, away from the river mainstream, with limited water flow, consequently accumulation of contaminants occurs at this sampling site.

3.3 Environmental risk assessment

In order to assess the intensity of the environmental impact of wastewater discharge on aquatic biota, RQs were determined for analytes detected in surface water. It was determined that the presence of trimethoprim was related to a low environmental risk (RQ = 0.003, Figure 2). The risk level for sulfamethoxazole was low (RQ = 0.018) at the sampling site SW2 and medium (RQ = 0.212) at the sampling site SW3. It was determined that azithromycin presents medium environmental risk at sampling sites SW1 and SW2 (RQ = 0.474 and RQ = 0.105, respectively). However, azithromycin posed a high risk to the aquatic organisms at the sampling site SW3 (RQ = 3.053). A high environmental risk for azithromycin was previously reported, such as in the Bay of Biscay in Spain [9]. In addition to the risk to aquatic organisms, the presence of azithromycin in water is highly harmful as it induces microbial resistance [10]. Obtained results indicate that wastewater in the Belgrade area discharged into rivers without treatment negatively impacts the quality of the receiving water.

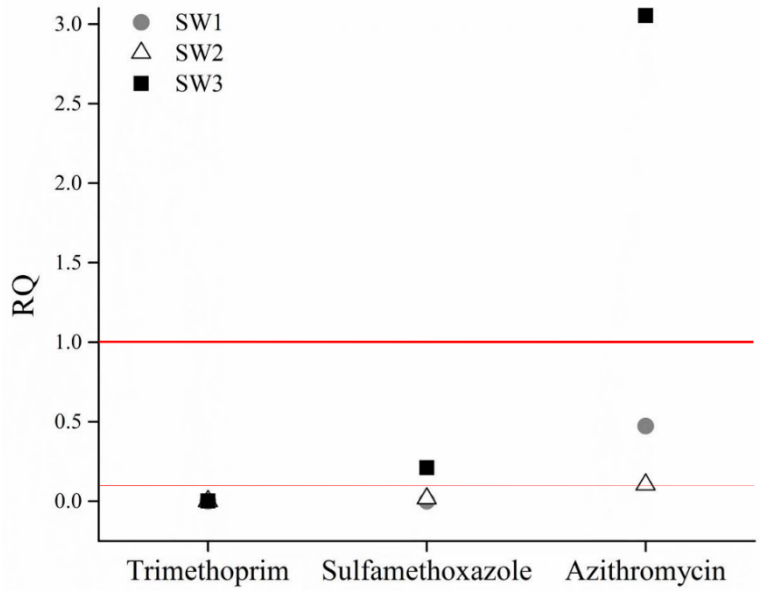

Figure 2. Risk quotients (RQs) calculated for antibiotics detected in river water
Source: original copyright

4. CONCLUSION

In this paper, a previously developed method for the determination of pharmaceuticals in various water matrices was successfully validated for wastewater. The content of selected antibiotics in municipal wastewater and corresponding surface water in the area of Belgrade was determined. Samples were collected at three locations of municipal wastewater discharges and at three locations in the Danube and Sava Rivers downstream from the wastewater discharges. Analyzed antibiotics were detected in both wastewater and surface water samples. Based on the determined RQ values, it was revealed that azithromycin posed a high risk to the aquatic biota. The obtained results demonstrate that the discharge of untreated municipal wastewater has a negative impact on the quality of river water in the area of Belgrade.

Abstract: *Organic and inorganic pollutants, accumulated in the environment, could pose a potential danger to living organisms. Some of these pollutants negatively affect the physiological activities of living organisms, and in certain concentrations, they can be lethal to biotic communities. In addition to the natural sources of emission of these substances in the environment, a large number of anthropogenic activities contribute to a sudden increase in their concentration. The development of new and improving existing ecologically sustainable techniques to prevent or reduce their outflow and retention in the environment is more necessary than ever. Therefore, the focus of this work will be examining the efficiency of environmentally friendly adsorbent based on modified starch and diatomaceous earth for the removal of selected organic and inorganic pollutants from aqueous solutions. The influence of the chemical modification of starch, followed by the addition of diatomaceous earth, on its structural, morphological, and adsorption properties, will be examined. The possibility of using starch-diatomaceous earth adsorbent for the removal of brilliant green dye, pharmaceutical compounds, and lead ions from aqueous solutions will be evaluated through the adsorption efficiency under the given conditions.*
Keywords: Adsorption, Potato Starch, Brilliant Green, Pharmaceutical Compounds, Pb^{2+} ions.

1. INTRODUCTION

Aware that the need for water is increasing, both due to the increase in the world's population and the increased exploitation of water resources, we see that providing sufficient amounts of water is becoming an increasingly demanding challenge [1]. Water surfaces are mostly polluted by anthropogenic activities, through industrial wastewater and municipal wastewater that are discharged directly into rivers, oceans, and other water bodies. These effluents contain different types of organic and inorganic pollutants. Contaminated surface and groundwater can be highly toxic if they enter the food chain for humans and animals [2]. Synthetic organic dyes are considered persistent bioaccumulative toxic substances. Their toxic effects include disruption of the ecological balance and carcinogenicity. They are widely used in the textile industry, as well as in the production of leather, cosmetics, paper, plastic, etc. Depending on the parent dye, its degradation can produce transformation products that can be more toxic than the original compound, or less toxic by-products can be formed instead [3]. Pharmaceuticals and their metabolites although mostly present in residual

[4]risticm@tmf.bg.ac.rs
[5]alexp@tmf.bg.ac.rs
[6]trivunac@tmf.bg.ac.rs

amounts in discharged water may have detrimental effects on living organisms and human health. Pharmaceuticals are developed to be biologically active and persistent to maintain their therapeutic activity in humans and animals. In this sense, the physicochemical properties of pharmaceutical products, such as high polarity, volatility, high lipophilicity, and persistence, can affect their removal efficiency during wastewater treatment [4]. Heavy metals enter wastewater through natural and anthropogenic sources. The former includes soil erosion, volcanic activities, and weathering of rocks and minerals, whereas the latter comprises mineral processing, fuel combustion, street run-offs, landfills, agricultural activities, and industrial activities (mining, printed board manufacturing, metal finishing and plating, semiconductor manufacturing, etc). Due to the high stability, solubility, and migration activity of heavy metals in aqueous media, untreated or inadequately treated metal-contaminated wastewater effluents cause a variety of health and environmental impacts [5,6]. The method for removing these pollutants from wastewater must meet the following conditions: a high percentage of removal, low operating costs, and a relatively fast process, without the creation of side products. As such, adsorption is distinguished, with the use of adsorbents that are available in nature in large quantities.

In this paper, the possibility of using modified starch for the removal of organic dye (brilliant green), pharmaceutical compounds (erythromycin and clopidogrel), and heavy metal ions (lead) was investigated. The starch was first chemically modified with melamine, a nitrogen-rich compound, and then in the second part of the modification, diatomaceous earth was added to investigate its effect on the adsorption properties of the modified starch.

2. EXPERIMENTAL PART

2.1 Materials

The following chemicals were used: potato starch (SuperLab, Serbia), melamine (2,4,6-triamino-1,3,5-triazine; 99 %, Fisher Scientific), diatomaceous earth (SiO_2 95%, Sigma-Aldrich), brilliant green dye (90%, Sigma-Aldrich), pharmaceutical compounds (erythromycin and clopidogrel), Pb^{2+} ions (solution of $Pb(NO_3)_2$).

In all modified samples, the base material is starch that has been chemically modified. The modification was carried out in two steps. In the first stage of modification, gelatinized starch was mixed with melamine at a temperature of 80 °C, while in the second stage of modification, amino-modified starch was mixed with diatomaceous earth at 40 °C. The materials thus obtained were dried in an oven at 50°C overnight and finally ground into powder.

Label of materials: S – native starch, de – diatomaceous earth, SM – starch modified with melamine, Sde – starch modified with diatomaceous earth, SMde – starch modified with melamine and diatomaceous earth.

2.2 Methods

The FTIR technique (Nicolet iS10, Thermo Scientific) was used to examine the type of functional groups on the surface of the adsorbent, while the SEM (FE-SEM, TESCAN Mira3 KSMU) was used to examine the morphological characteristics.

The investigation of pollutant adsorption by modified starch was performed in the batch mixing system, at 150 rpm, at room temperature. Adsorption of dye (brilliant green, BG) and heavy metal ions (Pb^{2+}) was investigated from individual aqueous solutions, and the measured initial pH value of both solutions was around 5. The adsorption experiments were conducted for 180 min, with a constant dose of adsorbent (0.05 g), initial concentration (10 mg dm^{-3}), and the volume of the solution (25 mL). The BG dye concentration in the solution was analyzed using a UV-VIS spectrophotometer for the visible range at 630 nm, while the concentration of Pb^{2+} ions in an aqueous solution was determined using atomic absorption spectroscopy at 283 nm. Adsorption of pharmaceutical compounds (erythromycin and clopidogrel) was investigated at constant adsorbent dosage (0.05 g),

initial concentration (500 mg dm^{-3}), and solution volume (25 mL) for 180 min. The separation of pharmaceutics was conducted using a Dionex UltiMate 3000® LC system (Thermo Scientific, USA). For detection and quantification of pharmaceutics LTQ XL (Thermo Scientific, USA) mass spectrometer was used with electrospray ion source and linear ion trap mass analyzer.
The removal efficiency (%) of selected pollutants from aqueous solutions, R, is calculated according to the equation (1):

$$\%R = \left(\frac{C_0 - C_t}{C_0}\right) \cdot 100 \quad (1)$$

where C_0 and C_t (mg dm^{-3}) are the concentration of pollutant at the initial time and after time t (min), respectively.

3. RESULTS AND DISCUSSION

FTIR is an effective technique to determine and characterize functional groups present in the material. The FTIR spectra of investigated adsorbents are shown in Figure 1., while the wavenumbers of characteristic bands in FTIR spectra are summarized in Table 1.

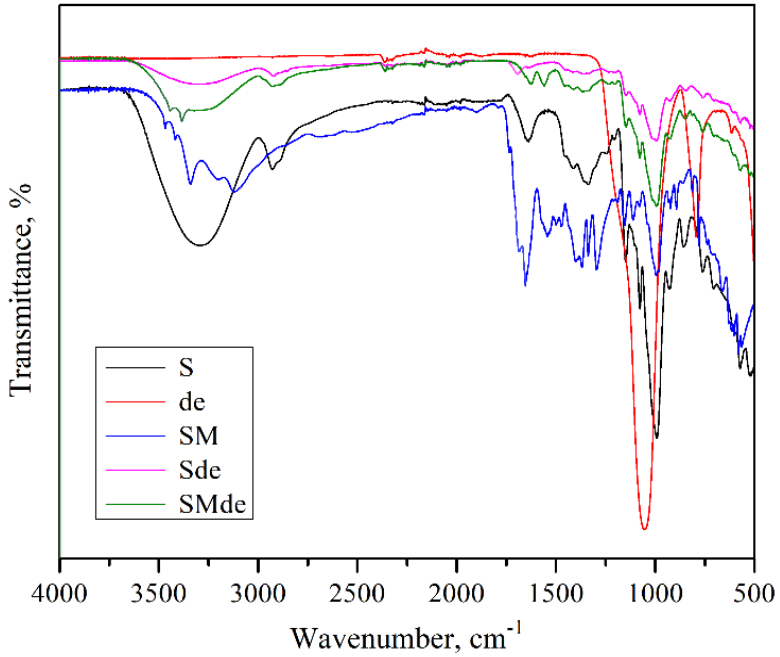

Figure 1. FTIR spectra of adsorbents
Source: original author's

By comparing the FTIR spectra, the presence of additional peaks on the FTIR spectra of modified materials was determined [7-10], which confirmed the successful synthesis of new starch-based adsorbents.

–O–Si–O stretching [10]	-	814	-	816	816
–Si–O–Si stretching [10]	-	705	-	705	706

Through the micrographs obtained by SEM, it was possible to evaluate the morphological changes in modified starch granules. SEM micrographs of adsorbents are shown in Figure 2. The surface of unmodified potato starch granules is smooth, without pores and cracks, and spherical to oval in shape. SEM micrograph of diatomaceous earth (de) reveals a variety of rigid shapes and macropores, i.e. open cavities, which may be responsible for its adsorption properties. It can be noted that after the modification, there was no complete disruption of the starch granule structure (SM/Sde/SMde) compared to natural starch (S). In the case of starch modification with melamine (SM and SMde), particle agglomeration and coating of particles with melamine occur to the greatest extent. For starch modification with melamine and diatomaceous earth (SMde), it is observed that the surface of the starch granules is rougher, with ridges originating from diatomaceous earth. The starch modification with diatomaceous earth (Sde) resulted in the adhesion of diatomaceous earth to the starch surface, with the surface of the granules becoming rough with bumps and holes.

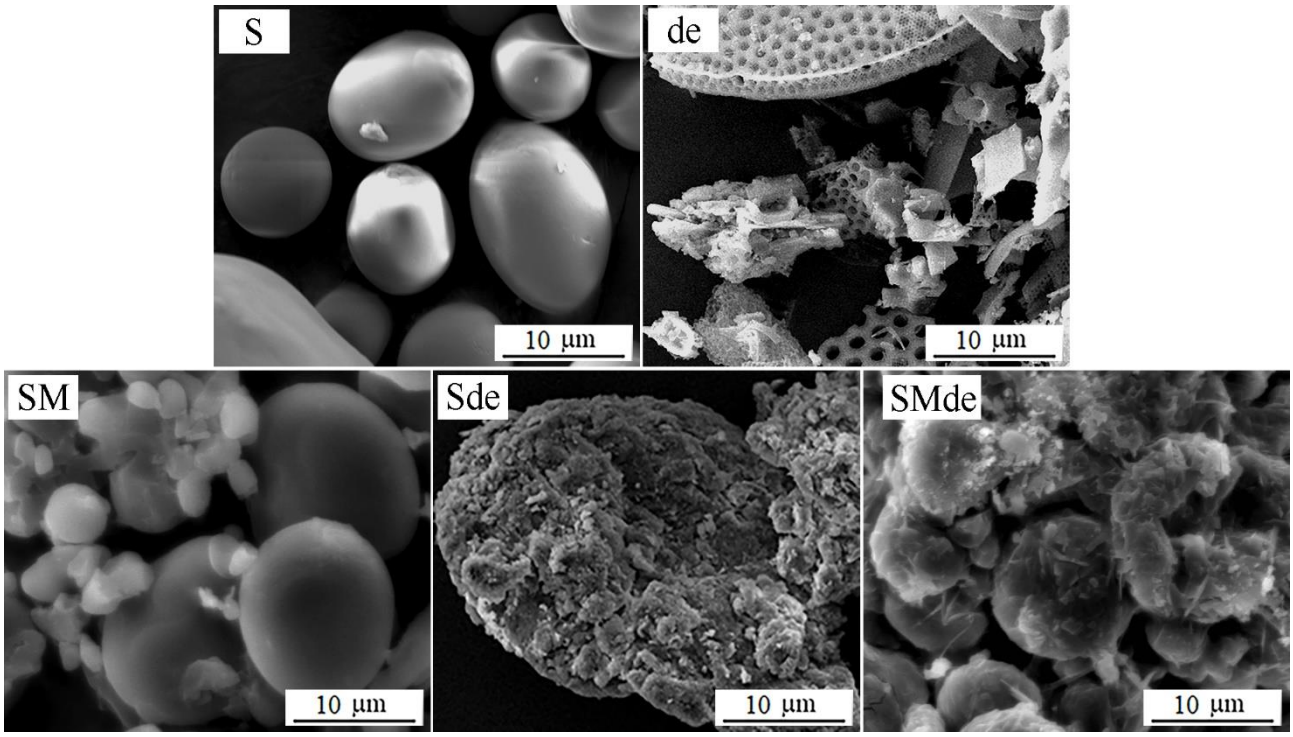

Figure 2. SEM micrographs of adsorbents
Source: original author's

The results of testing the adsorption properties of adsorbents based on modified starch are shown graphically in Figure 3. The results of the comparative analysis show that all examined materials show higher efficiency in removing organic pollutants compared to metal ions. The material SM, i.e. starch modified only with melamine, showed the highest efficiency in the removal of all selected pollutants. This means that the addition of diatomaceous earth after starch modification with melamine (SMde) has no effect on removal efficiency. On the other hand, the adsorbent obtained by modification of native starch with diatomaceous earth (Sde) showed better adsorption efficiency compared to the starting materials, i.e., native starch (S) and diatomaceous earth (de). The results of the adsorption experiments confirmed that the applied modification influenced the surface and morphological properties, contributing to the increase in the efficiency of modified starches to remove organic pollutants and metal ions from water.

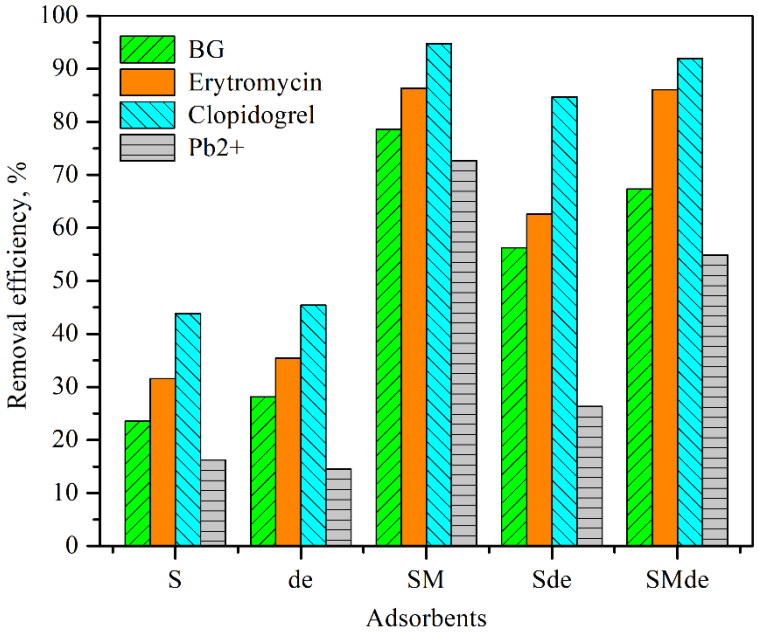

Figure 3. Adsorption efficiency of examined adsorbents toward BG dye, pharmaceuticals (erythromycin and clopidogrel) and Pb^{2+} ions
Source: original author's

4. CONCLUSION

In this study, the possibility of using adsorbents based on natural material, starch, for the removal of brilliant green dye, pharmaceutical compounds (erythromycin and clopidogrel), and Pb^{2+} ions was examined. The results of FTIR and SEM analysis showed the success of the modification process and the presence of melamine and diatomaceous earth in the structure of the new adsorbents, as compounds with which the modification was performed. Higher removal percentages were obtained for organic pollutants, especially pharmaceutical compounds, compared to metal ions. The removal efficiency of the clopidogrel drug was 95.7% for the adsorbent based on modified starch with melamine and 91.6% for modified starch with melamine and diatomaceous earth. It was shown that diatomaceous earth has no effect on the adsorption properties of the material after modification with melamine, which may be a consequence of coating the pores in the diatomaceous earth structure with melamine. As the tested adsorbents, especially the material based on modified starch with melamine, proved to be promising for the removal of organic pollutants from aqueous solutions, it is necessary to conduct more extensive tests of the adsorption properties of these materials with a special focus on the removal of pharmaceutical pollutants from wastewater.

Abstract: *Fly ash (FA) is an industrial waste material generated during coal combustion in thermal power plants. In order to reuse this kind of industrial waste, and at the same time to reduce its quantity, fly ash was used as a cheap material for the preparation of efficient adsorbents for the removal of selected dyes from water. For that purpose, different modification methods were used to obtain alkali-activated fly ash samples. The success of the modification process and characterization of the unmodified and modified materials was monitored by Fourier transform infrared spectroscopy, and scanning electron microscopy/energy dispersive spectroscopy. The adsorption properties of examined samples were studied through the adsorption of methylene blue, crystal violet, alizarin red, and methyl orange. All samples showed the highest adsorption efficiency for crystal violet removal, while the sample modified with a combination of NaOH, Na_2SiO_3, and diatomaceous earth (FA/geopolymer) was the most efficient adsorbent for all selected dyes. Therefore, the influence of initial pH value and contact time on adsorption was examined for the adsorption of crystal violet onto FA/geopolymer. It was found that alkaline modification improves the adsorption characteristics of fly ash making it a promising candidate to solve the problem of colored wastewater.*
Keywords: Fly Ash, Dyes, Alkali Modification, Adsorption.

1. INTRODUCTION

Discharge of water polluted with dyes from different industries leads to several problems in the environment. The presence of dyes in water affects its coloration, the permeability of sunlight, and thus the process of photosynthesis and the food chain, as well. Therefore, their removal from the environment is very important. Among the various methods (membrane filtration, photodegradation, ion exchange), adsorption stands out as a simple and energy-efficient technique [1,2]. The advantage of this method is reflected in the large number of available adsorbents. A significant amount of scientific research is focused on developing methods for repurposing agricultural, municipal, and industrial waste. In this way, waste materials gain a use value, their amount in landfills can be reduced, and thus, the harmful impact on the environment can be reduced as well. Fly ash represents a growing environmental problem, as it is an inevitable by-product of coal combustion. In Serbia, the share of coal in the production of electricity is 65 %. Large amounts of ash end up in landfills, and its

[1]nkaric@tmf.bg.ac.rs

[5]milena.milosevic@ihtm.bg.ac.rs
[6]trivunac@tmf.bg.ac.rs
[7]alexp@tmf.bg.ac.rs

disposal and transport represent a growing environmental problem. Therefore, numerous researches are focused on finding ways to reuse fly ash. One of the most important applications of fly ash is as a construction material, in the production of roads and various types of concrete. Today, fly ash is also used for the rehabilitation of surfaces degraded by mining activities, as a base and covering for sanitary landfills of municipal and other waste, for the production of activated carbon and artificial zeolite, etc. [3]. One idea is to use fly ash as an effective adsorbent for the removal of various pollutants, such as waste gases, heavy metals, dyes, and other organic compounds [4]. The adsorption efficiency of fly ash can be improved by its activation and modification [2,5].
In an attempt to reuse fly ash, in this work, an alkaline and thermal modification was applied to obtain cheap and efficient adsorbents for the removal of selected dyes from water. The influence of the applied modification method on the efficiency of obtained materials to adsorb methylene blue (MB), crystal violet (CV), alizarin red S (ARS) and methyl orange (MO) was examined. The adsorption process was studied through the influence of the initial pH value of the adsorbate solution, and contact time, and obtained experimental data were compared with the kinetic models.

2. EXPERIMENTAL

2.1 Material preparation

The starting fly ash, obtained from the power plant Nikola Tesla A (Obrenovac, Serbia), was sieved and washed with distilled water, and then modified, as it is shown in Table 1. After the modification, all samples were washed with distilled water to a neutral pH and dried overnight at 105 ^{o}C.

Table 1. Modified fly ash samples, labeling, and modification conditions
Source: original author's

Sample	Mass of fly ash	Modification agent	Modification condition
Ash	–	–	–
Ash_{300}	2.0 g	3.2 g NaOH pellets	300 °C, 3 h, electrical furnace
Ash_{ref}	2.0 g	20 ml 2M NaOH	5 h, reflux, boiling temperature
Ash_G	9.8 g	4.2 g diatomaceous earth 10 g of sodium silicate few drops 16 M NaOH	drying, 2 h, 105 °C aging, 7 days, room temperature
Ash_7	2.0 g	6.0 ml 2M NaOH	shaking (120 rpm), 7 days, room temperature

2.2 Material characterization

Scanning electron microscopy (SEM) with energy dispersive spectroscopy was used to examine the changes in surface and morphological characteristics induced by the modification of fly ash.
The presence of functional groups on the surface of unmodified and modified samples was determined by Fourier transform infrared spectroscopy (FTIR).

2.3 Adsorption experiments

All adsorption experiments were performed in a batch system with constant shaking (170 rpm) at room temperature. To determine the adsorption efficiency of unmodified and modified fly ash samples (0.05 g), 20 ml of the selected dyes (MB, CV, MO, ARS) aqueous solution (20 mg/dm^3) was used, and adsorption experiments were performed for 2.5 h. Adsorption of CV onto Ash and Ash_G (0.05 g) was conducted from 20 ml aqueous solution (20 mg/dm^3) with initial pH adjusted at 3, 5, 7, and 10, to reveal the influence of the initial pH value on the adsorption. The influence of contact time on the adsorption capacities of Ash and Ash_G samples (0.25 g) was examined through the adsorption of CV (20 mg/dm^3) from 100 ml of aqueous solution. During this experiment, the concentration of

CV was measured in the specified periods of time (5, 10, 30, 60, 120, and 180 minutes). For measuring the dye concentration visible spectrophotometry was used. Obtained data were examined by pseudo-first [6] and pseudo-second [7] order kinetic models, given by equations 1 and 2, respectively:

$$q_t = q_e \cdot (1 - e^{-k_1 t}) \tag{1}$$

$$q_t = q_e - \left(\frac{1}{q_e} + k_2 t\right)^{-1} \tag{2}$$

3. RESULTS AND DISCUSSION

The surface morphology of fly ash samples was analyzed by scanning electron microscopy/energy dispersive spectroscopy and obtained results are shown in Figure 1a-1e and Table 1. All fly ash samples are characterized by a similar porous surface with visible cavities and cracks. Nevertheless, applied modifications in the presence of NaOH increase surface porosity, whereby the surface of sample Ash_G is the most porous, which can favor the adsorption of dyes. According to the results of EDS analysis, unmodified fly ash does not contain Na, while in modified samples atomic percentage of Na increases with the concentration of NaOH added and with a temperature of modification. A high content of Na in the modified samples can also favor the adsorption when it occurs through the mechanism of ion exchange.

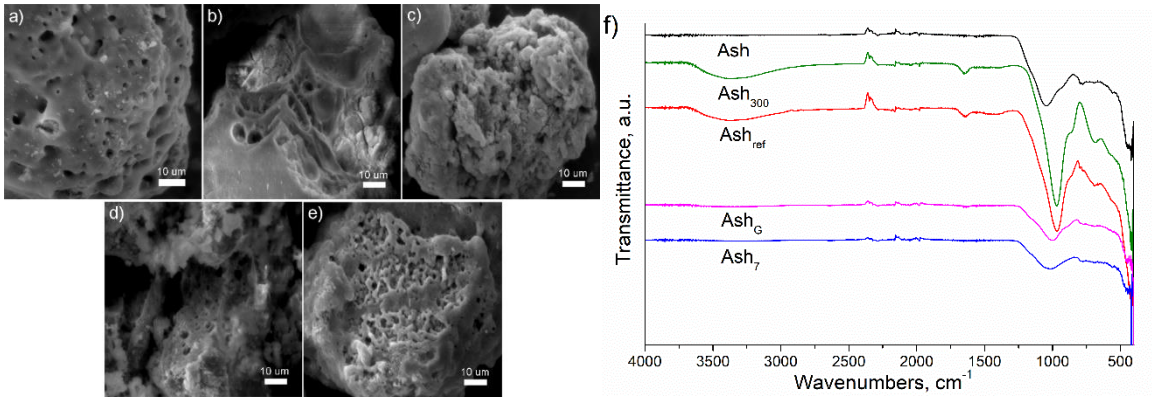

Figure 1. SEM photographs of fly ash samples: a) Ash, b) Ash_{300}, c) Ash_{ref}, d) Ash_G, e) Ash_7 and f) FTIR spectra of examined samples

Source: original author's

Table 2. The atomic percentage of elements obtained by EDS analysis

Source: original author's

Sample	O	Na	Mg	Al	Si	K	Ca	Ti	Fe
	atomic %								
Ash	69.87	-	0.81	9.47	16.43	0.55	1.06	0.19	1.62
Ash_{300}	62.02	5.20	0.87	10.43	18.08	0.28	0.80	-	2.31
Ash_{ref}	59.10	1.92	1.11	13.10	20.82	1.27	0.63	0.15	1.89
Ash_G	61.44	12.71	-	5.48	18.35	0.33	0.35	-	1.33
Ash_7	59.71	0.81	1.19	14.14	18.79	0.50	1.32	0.39	3.15

FTIR spectra of fly ash samples are (Figure 1f) characterized by sharp, distinguish peaks at around 1000 cm^{-1}, and bands of low intensity around 780 cm^{-1}, which originate from the stretching of asymmetric Si - O -Si and symmetric Si - O -Si bond, respectively. The observed shift of the band around 1000 cm^{-1} to the lower wavenumber values is more pronounced for the samples modified at higher temperatures. This small shift, along with the disappearance, or decrease in intensity of peak around 780 cm^{-1} (observed for Ash_{300} and Ash_G, respectively) indicates the formation of alkali-

activated materials. The bands around 3370 and 1630 cm^{-1} can be assigned to the stretching vibration of the O-H bond in hydroxyl groups from the material moisture.

The adsorption efficiency of unmodified and modified fly ash samples to remove cationic (CV and MB) and anionic (ARS and MO) dyes is given in Figure 2. Applied modifications increase adsorption efficiency for cationic dyes, up to 92 % for adsorption of CV onto Ash_G. On the other hand, these alkali treatments have no effect, or even decrease the adsorption efficiency for anionic dyes. Generally, all examined samples show the highest adsorption efficiency for CV, and Ash_G, as the sample with the highest efficiency in CV removal, was selected for further adsorption studies.

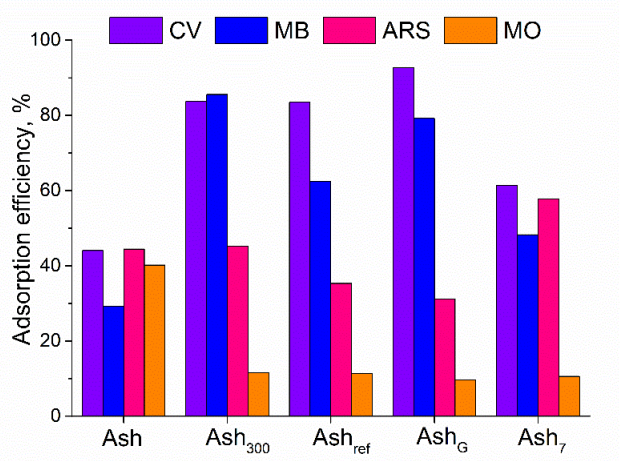

Figure 2. Adsorption efficiency of fly ash samples for removal of selected dyes
Source: original author's

The initial pH value of the dye solution can affect the adsorbent surface, as well as the distribution and the morphology of dye molecules, influencing the adsorption capacities of fly ash samples. The influence of the pH of CV solution on the adsorption capacities of Ash and Ash_G is shown in Figure 3a. Adsorption capacities increase with initial pH value, especially in the case of unmodified fly ash. The influence of contact time between adsorbent and adsorbate solution on adsorption capacities is shown in Figure 3b. The adsorption capacity for both samples increases with the contact time, reaching the equilibrium only for sample Ash.

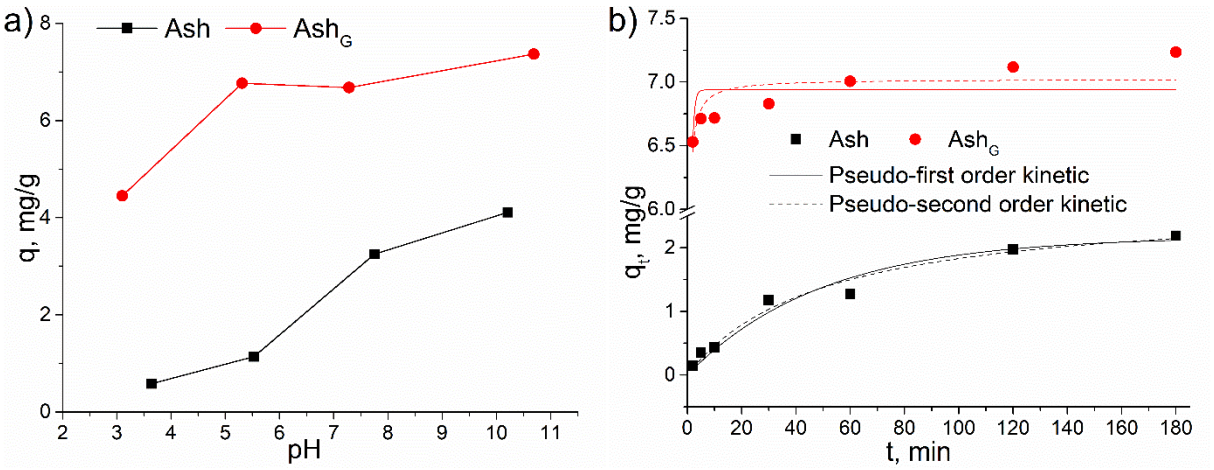

Figure 3. The influence of initial pH value (a) and contact time (b) on adsorption capacities of Ash and Ash_G
Source: original author's

Experimental data are fitted with pseudo-first and pseudo-second kinetic models and also shown in Figure 3b, while obtained kinetic parameters are summarized in Table 3. According to the correlation coefficients (R^2) adsorption of CV onto both samples fits better with pseudo-second order kinetic. However, a better agreement between the experimental adsorption capacity and the one calculated by

the pseudo-first order model, indicates that CV adsorption onto Ash can be better described by this model.

Table 3. Kinetic parameters of CV adsorption onto samples Ash and Ash_G
Source: original author's

Sample	Pseudo-first order			Pseudo-second order			$q_{e,exp}$, mg/g
	$q_{e,cal}$, mg/g	k_1	R^2	$q_{e,cal}$, mg/g	k_2	R^2	
Ash	2.175	0.02014	0.95994	2.735	0.0074	0.97308	2.190
Ash_G	6.938	1.40664	0.25695	7.023	0.8015	0.59680	7.235

4. CONCLUSION

Fly ash, obtained from the power plant Nikola Tesla A, was modified using different alkali treatments and used as an adsorbent for the removal of selected dyes from water. Material characterization showed that applied modifications led to the formation of alkali-activated materials, the increase of the surface porosity, and the atomic percentage of Na. Changes in material structure induced by applied treatments led to an increase in material efficiency in adsorb cationic dyes. All samples showed the highest adsorption efficiency for crystal violet removal, while the sample modified with the combination of NaOH, Na_2SiO_3, and diatomaceous earth (Ash_G) was the most efficient adsorbent for all selected dyes. Adsorption of crystal violet onto unmodified fly ash and Ash_G increases with initial pH value and contact time, following the pseudo-first, and pseudo-second order rate, respectively. It was found that alkaline modification improves the adsorption characteristics of fly ash making it a promising candidate to solve the problem of colored wastewater.

Abstract: *In recent years, there has been a shift in plastics production by replacing conventional fossil-based plastics with bio-based alternatives, in order to reduce their carbon footprint (CF). In this study, an analysis of the CF associated with ten commonly utilized bio-based and recycled polymer families has been conducted. The analysis relies on available reports published from seven major polymer producers.The results have revealed a noteworthy reduction in the carbon footprint of the selected bio-based and recycled materials, with reductions of up to 97%. Furthermore, there is substantial variability both between and within polymer families. This underscores the importance of not only selecting the appropriate base polymer but also making effort in choices of reinforcement fibers and production methods in order to achieve the maximum possible reduction in carbon footprint.*
Keywords: GWP, Bio-based plastics, Recycling, Carbon Capture & Utilization

1. INTRODUCTION

From food packaging, to medical equipment and consumer electronics, plastics have become one of the most used materials globally. In order to allow future generations to enjoy the benefits of these materials, it is necessary to maximize their sustainability. In recent years, there has been a notable shift towards replacing conventional fossil-based plastics with bio-based alternatives, partially or entirely derived from biomass. While currently bio-based and biodegradable plastics make up only about 1% of the total plastic production, the global outlook for bioplastics production capacity indicates significant growth, with projections rising to 7.6 million tonnes by 2026, thereby more than tripling the current capacity.
Plastics have had a substantial environmental impact, contributing with estimated 1.7-2 gigatons of CO_2-equivalent emissions (4.5% of global carbon emissions) throughout their lifecycle in 2015, and this figure is expected to quadruple by 2050 if existing systems are not improved [1]. Mechanical recycling, chemical recycling, bio-recycling (enzymatic degradation) of biodegradable plastic, burying in landfills or incineration are currently the most commonly used methods for managing polymer waste [2]. To ensure sustainable and circular plastics production, recycling methods must be more pronounced in future years as the main approach for the reduction of raw material consumption and carbon emissions. Hence, this paper is focused on global warming potential (GWP) of commercially available bio-based and recycled plastics grades and on benchmark of their environmental performance with the fossil fuels made grades.

2. BIO-BASED AND RECYCLED PLASTIC PRODUCTION

The production of bio-based and recycled plastics is essential for reducing the environmental impact of plastics. Bio-based plastics are made from renewable resources like plant-based materials, while recycled plastics are derived from plastic waste, both contributing to a more sustainable and circular plastics economy, which is depicted in Figure 1. Through mechanical recycling, end-of-life products are used as raw materials, therefore this is the most effective method for reducing plastic waste and virgin feedstock consumption [3]. Mechanical recycling does not change the chemical structure of the material, which permits multiple re-use/recycling of polymeric materials, creating a closed loop. For plastics that cannot be recycled mechanically, chemical recycling is applied, which breaks down the polymer waste into its constituents or directly transforms it into other useful materials for direct repolymerization or other applications [4]. Furthermore, the fossil feedstock used in polymer production is substituted with the bio-based feedstock, whereby the production of biodegradable materials ensures that those will be decomposed by composting, effectively reducing plastic waste. Another step in reducing carbon footprint (CF) of plastic production is the carbon capture and utilization (CCU) technology to remove CO_2 from the flue gas and recycle it in the polycarbonate manufacturing process [5]. This directly reduces greenhouse gases emissions and create a circular system where all by-products are recycled [6].

3. MATERIALS AND METHODS

In order to evaluate the environmental impacts of a plastic production and use, Life Cycle Assessment (LCA) methodology was utilised. LCA assessment considers all stages of plastic's life, from raw materials and production through transportation, use, and ultimately disposal or recycling. The primary purpose of LCA is to quantify and analyze various environmental factors and their effects, such as energy consumption, greenhouse gas emissions, water usage, resource depletion, and other ecological impacts [7]. The key components and steps of LCA include [8]:

1. Goal and Scope Definition -the first step in LCA involves defining the objectives of the assessment and specifying the boundaries of what will be studied.
2. Life Cycle Inventory (LCI) - involves collecting data on all relevant inputs (e.g., materials, energy, water) and outputs (e.g., emissions, waste) associated with the product or process at each life cycle stage.
3. Life Cycle Impact Assessment (LCIA) - where environmental indicators and characterization factors are applied to the data collected in the LCI phase. This step helps quantify the potential environmental impacts, such as global warming potential, acidification, eutrophication, and more.

4. Interpretation - the results of the LCA are analyzed and interpreted to draw conclusions and make recommendations.

In practice, performing LCA is associated with a lot of challenges and issues, where main five are:

1. Data Quality and Availability – data is often limited, outdated, or dependent on geographical location or production methods.
2. System Boundaries – decisions about which life cycle stages and environmental impacts to include can significantly impact the results and interpretation of the assessment.
3. Allocation – refers to the process of assigning environmental burdens to multiple products or co-products within a system.
4. Temporal and Geographical Variability – environmental impacts can vary over time and in different geographic regions.
5. Selecting Impact Categories and Indicators – the choice of indicators can affect the outcome of the assessment and may not capture all relevant impacts.

There are also various LCIA methods, such as ReCiPe, EDIP, CML, EPS, TRACI, that provide the mathematical and computational framework for assessing the specific environmental impacts within various categories. In order to compare two products from different producers we need to have same boundaries (e.g. cradle to gate), to use the single LCI source and the same indicator from single LCIA method. All of this makes crosschecking of LCIA values obtained from various producers almost impossible, and imposes the external evaluation of reported values. In this paper, the evaluation of producers reported GWP values was made using Total Materia Green Line LCA (Figure 2) which performs LCIA calculations according to five methods for 41 indicators in total, whereby single source of LCI data is used, namely Ecoinvent [9,10]. For the current carbon footprint assessment it was used environmental reports from 7 major producers (Acro-Plastics, DOMO, EMS-GRIVORY, Evonik, Ineos, LG-Chem and MOCOM). Those reports were supplemented with Climate change (GWP 100) according to IPCC 2021 no LT obtained using Total Materia Green Line LCA.

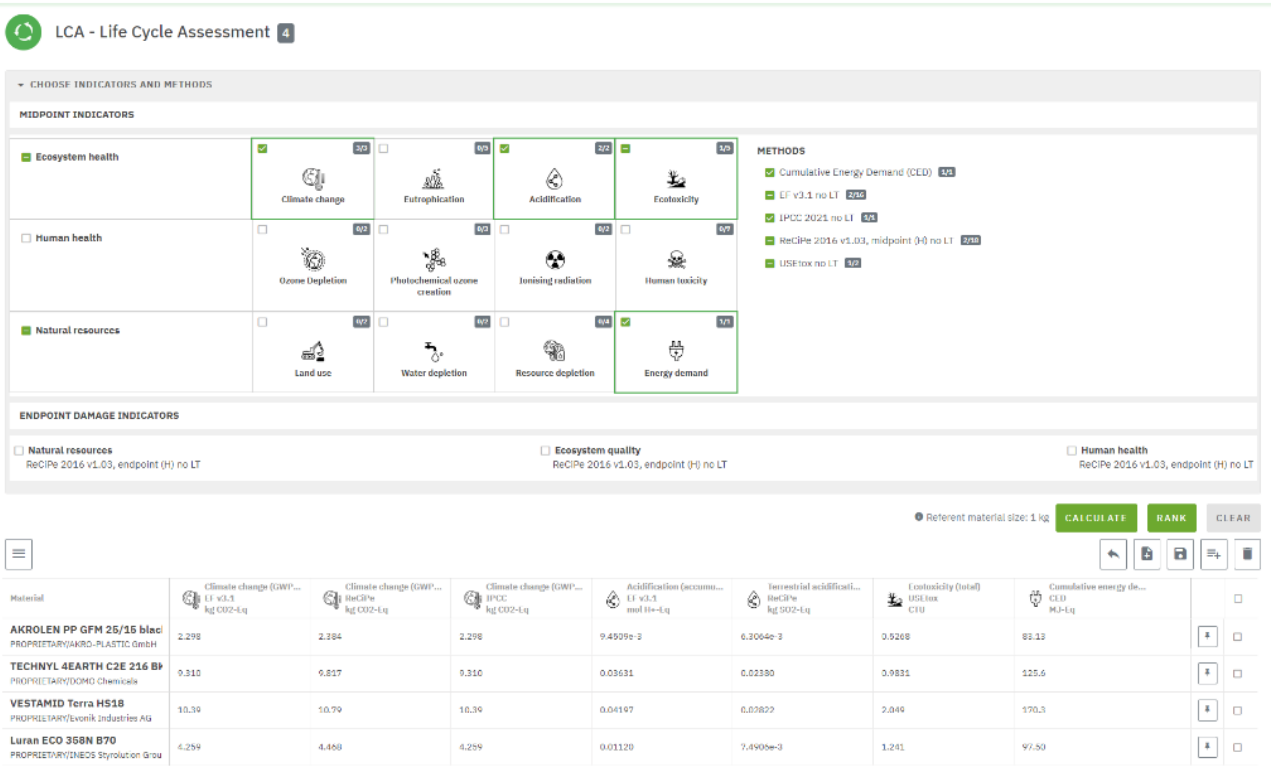

Figure 2. Total Materia Green Line LCA

Source: https://www.totalmateria.com/page.aspx?ID=GreenLine&LN=EN

4. RESULTS AND DISCUSSION

The carbon footprint for 10 commonly used bio-based and recycled polymer families along with the reduction rate based on comparison with conventional grades is summarised in Table 1. Those values are obtained using producers reports for grades given in Table 2. As can be observed in Table 2, only two producers (Acro-Plastics and EMS-GRIVORY) have provided all data needed for the analysis, while in the case of other producers the reduction rate or the actual GWP value were estimated using Total Materia Green Line LCA.

The results demonstrate a great range in the reduction within the same family, e.g. in the case of PA1010 the reduction range from 48% to 77%, as well between studied families, i.e. PA1012 showed a moderate reduction rate of 35%, while PA66 can be produced with reduced CF up to 97%. In absolute numbers, bio-based and recycled polymer materials have CF from 0.25 kg CO_2-Eq to up to 5.8 kg CO_2-Eq, with significant dependence on the polymer family. Also, within the same family CF can vary significantly, e.g. for PA66 CF from 0.25 to 1.95 kg CO_2-Eq, which implies that added fibres and additives, as well as the production method with applied CCU technology to remove CO_2 can make a significant difference.

Table 1. Carbon footprint for bio-based and recycled plastics and the reduction rate

Polymer family	CF (kg CO_2-Eq)	Reduction (%)
ABS	2.68	41
PA1010	1.56 – 4.6	48 – 77
PA1012	5.2 – 5.8	35 – 50
PA6	0.33 – 0.99	87 – 96
PA610	2.1 – 5.1	43 – 66
PA66	0.25 – 1.95	70 – 97
PC	0.69	88
PP	0.51	70
PPS	0.81	88
SAN	0.30	93

Further analysis based on the carbon footprint calculation (cradle to gate) for a 30% glass fibre reinforced PA6.6 compound shows, that the polymer has by far the highest impact on the carbon footprint, followed by the filler content, while everything else can contribute to up to 10% (Figure 3a). Therefore, since polymer families can differ in carbon footprint up to 4 times (Figure 3b), the appropriate selection of base polymers and filler to preserve mechanical and physical properties, is the key point in the quest for more sustainable plastic materials.

5. CONCLUSION

Is this paper, the carbon footprint for 10 commonly used bio-based and recycled polymer families has been analysed using available reports obtained from 7 major polymer producers. Since 5 out of 7 producers haven't provided sufficient data to perform the analysis, estimations have been made using Total Materia Green Line LCA.

The performed analysis has demonstrated a significant decrease of carbon footprint for the selected bio-based and recycled materials, with the reduction up to 97%. Also, there are significant variations between and within polymer families, suggesting that the proper selection of base polymer must be followed, together with the appropriate selection of reinforcement and production method, in order to achieve the maximum reduction of carbon footprint.

Abstract: *In order to protect and improve the environment, promote sustainability, and enhance the quality of life, environmental science relies on simulation and modelling tools. Due to the complexity and non-linear behavior of parameters used to describe quality of the environment, artificial intelligence, i.e. machine learning, models became popular in recent years. In this paper, the application of probabilistic neural network for air pollution prediction regarding ozone exceedances of 120 µg/m³ more than 25 times a year in European urban centers in four countries (Germany, Poland, Romania and Switzerland) is presented. Available ozone data, along with climate data (temperature, solar radiation and precipitation) for the period 2006-2012 were used as inputs. The created classification model has made predictions with satisfactory accuracy (>75%) and precision (>60%). Performed scenario analysis revealed that an increase of temperature for 2°C pronounce climate conditions that favors ozone exceeding of 120 µg/m, whereby probability of such event rise to more than 90%.*
Keywords: Ozone, Probabilistic ANN, scenario analysis, modelling

1. INTRODUCTION

Environmental science aim to protect the environment, enhance sustainability, and improve the well-being of both current and future generations, and therefore modelling and analysis of pollutant concentrations is of immense importance in order to gain insights on environmental quality parameters needed to generate sustainable environmental policies [1]. In recent years, there has been a significant increase in the interest and utilization of artificial neural networks (ANNs) for the forecasting of ambient air pollution [2]. This heightened focus on ANNs stems from the growing recognition of the severe health consequences associated with poor air quality in urban areas. Such detrimental effects include the development of chronic diseases and premature deaths, particularly among vulnerable individuals within the population [3]. Urban population exposure to tropospheric ozone is consider as serious health concern in Europe countries [4]. Hence, ozone levels are monitored regularly, and the European target value for the protection of human health is based on the daily maximum 8-hour mean ozone concentration. Averaged over 3 years, this daily maximum 8-hour mean should not exceed 120 µg/m³ more than 25 times a year.
This paper is focused on air pollution modelling and simulation of ozone concentration in European urban areas, including scenarios based on climate change effects onto the weather patterns. The model aims to predict the frequency of the event of 25 times exceedance of 120 µg/m³, using the classification of main climate factors.

2. LITERATURE REVIEW

The process of ozone formation in the lower layers of the atmosphere is nonlinear, which makes ANNs a very suitable method for modelling. By using ANNs, it is possible to capture all the nonlinearities that exist between the ozone formation and other atmospheric variables, which traditional statistical techniques may not be able to provide. Therefore, among other methods, ANNs have been extensively used for the predicting of ozone concentrations:

1. In Zagreb, Croatia, a study has used neural networks to predict ozone concentrations in urban areas [5],
2. In Bilbao, Spain, ozone prediction was carried out using neural networks at six locations eight hours in advance, using traffic data and meteorological parameters. The results were unsatisfactory (R^2=0.15) compared to other pollutants (e.g., R^2=0.88 for NO_2), indicating the complexity of ozone prediction [6],
3. Narasimhan and colleagues predicted ozone concentrations using meteorological parameters. The most significant input variables were found to be nitrogen dioxide, temperature, relative humidity, and solar radiation (sunshine). The agreement between measured and predicted values was R^2=0.88 [7],
4. Radial Basic Function models were applied to predict ozone in the city of Arosa, Switzerland, with a relative error below 12% [8],
5. Goulier et al. focused on predicting ozone focusing on the impact of traffic, demonstrating that traffic significantly influences ozone concentration in urban areas [9],
6. Maximum daily ozone concentrations have also been predicted using artificial neural networks, which outperformed other statistical regression models [10].

3. METHODOLOGY

Probabilistic neural networks (PNNs) were introduced by Donald Specht in the late 1980s [11]. PNNs are particularly well-suited for pattern recognition and classification tasks. These networks belong to the family of radial basis function networks and use different approach compared to traditional feedforward neural networks, i.e. instead of sigmoid activation functions, PNNs use radial basis functions for processing. PNNs consist of 4 layers that provide a probabilistic output by calculating the probability that the input data belongs to each class, based on the similarity scores calculated by the radial basis functions. They are trained using competitive learning algorithm, which adjusts the prototype vectors for each class using the training data. During training, the network learns to adapt its radial basis functions to better represent the input data distribution.
They have several notable advantages, including their ability to handle non-linearly separable data, simple architecture, and fast training. They are particularly useful for pattern recognition tasks, such as classification and clustering yielding applications in various fields: image recognition, speech recognition, medical diagnosis, and financial modelling. More details can be found in relevant literature [12].

4. RESULTS AND DISCUSSION

4.1 Ozone data

Ozone data expressed as the number of days where the ozone concentrations had exceeded 120 µg/m³ were collected from Eurostat [13] for four EU countries for the period 2006-2012, which is presented in Figure 1. Since the major impact on the concentration of ozone is made by temperature, solar radiation and precipitation, the parameters that quantify their changes in the atmosphere were selected as the model inputs (Table 1). Data for the selected countries and parameters were obtained from Eurostat [13] and their descriptive statistic is provided in Table 2.

Figure 1. Study scope

Table 1. Links between selected climate factors, ozone formation and model inputs [14]

Climate factor	Factor effect	Ozone concentration	Model input	Unit
Temperature increase	Faster chemistry Increase of precursors emission	Increase	Average temperature of warmest month (T_w)	°C
			Average temperature of coldest month (T_c)	°C
Solar radiation increase	Faster photochemistry	Increases (high NOx) Decreases (low NOx)	Total number of hours of sunshine per day (S)	h/day
Precipitation increase	Scavenging of soluble precursors	Decrease	Rainfall (P)	mm

Table 2. Descriptive statistic of ozone data

Criteria	Total	Germany	Poland	Romania	Switzerland
>25 days having O_3>120 µg/m³	112	76	5	15	16
<25 days having O_3>120 µg/m³	432	270	35	106	21
Share of cases with exceed O_3 (%)	21	22	13	12	43

Descriptive statistics of selected model inputs (Table 3) shows that there are no significant differences in the number of sunny hours per day throughout the year, with and without ozone exceedances. However, in the years when temperature exceedances occurred in the hottest month, it was higher by 1.6°C, while in the coldest months, it was only 0.1°C higher compared to years without exceedances. Additionally, in the years when there were ozone concentration exceedances >120 µg/m³, higher precipitation amounts of about 10% were also observed compared to the years without exceedances. The values of the observed parameters also indicate the influence of heatwaves on the ozone formation, which ultimately leads to exceedances in the number of days throughout the year.

Table 3. Descriptive statistic of selected model inputs

Criteria	Value	*S (h/day)*	T_w *(°C)*	T_c *(°C)*	*P (mm)*
>25 days having O_3>120 µg/m³	Mean	5.07	21.92	-0.60	766.34
	Min.	3.98	17.40	-5.90	352.70
	Max.	6.90	27.20	4.30	2,188.60
<25 days having O_3>120 µg/m³	Mean	5.05	20.33	-0.71	708.73
	Min.	3.70	16.70	-10.10	324.10
	Max.	7.30	29.00	4.20	1,380.60

4.2 Model performance

PNN model was created with 4 neurons in the input layer, 358 neurons in hidden layer, 3 in summation layer, and 2 neurons in the output layer. It was trained with 358 datapoints (65% of available data), validated with 107 datapoints (20%) and tested 82 datapoints (15%). Its performance

is given in Table 4, and can be noted that during the training, the model achieved an accuracy rate of over 90% for correctly predicted cases. However, during the validation, the accuracy dropped to a range between 75-90%, but it remained stable during the model testing. This is an indicator that the model is well-trained. The same trend was observed in the terms of precision for this model.

Table 4. PNN model performance

Criteria	Dataset	*Total*	*Predicted*	*Accurate predictions*	*Accuracy (%)*	*Precision (%)*
>25 days having O_3>120 μg/m³	Training	72	95	72	100	76
	Validation	25	27	19	76	70
	Test	17	21	13	76	62
<25 days having O_3>120 μg/m³	Training	286	263	263	92	100
	Validation	85	83	77	91	93
	Test	65	61	57	88	93

It is also noticeable that both accuracy and precision are higher when predicting cases where there are no exceedances (accuracy at 88%, precision at 93%) compared to cases with ozone concentration exceedances. In cases of exceedances, the accuracy during model testing was 76%, and precision was 62%. These results can be attributed to the significantly larger number of cases without exceedances compared to those with exceedances, which increases the model's ability to accurately predict non-exceedance cases of ozone concentration.
PNN model also allows estimation of the significance of particular input to the model prediction by analysing the values of individual smoothing factors (ISFs). The value of ISFs are unique to each network having value up to 3, whereby the larger value indicates that the particular input is more important to the model [15]. The values for the particular model (Table 5) indicate that the temperature of the coldest month in the year and the average number of sunny hours in the year significantly contribute to ozone formation, while the temperature of the hottest month and the amount of precipitation have a proportionally lower impact.

Table 5. Selected ozone data descriptive statistic

Model input	T_c	S	T_w	P
ISF value	2.45	2.28	1.36	0.75

4.3 Scenario analysis

Climate change is expected to affect ozone concentrations in the future, due to changes in meteorological conditions, as well as due to increased emissions of specific ozone precursors (e.g. increased isoprene from vegetation on higher temperatures) and/or emissions from wildfires that can increase under the periods of extensive drought [11]. By understanding the significance of individual model inputs from the previous section, favourable and unfavourable meteorological conditions for the formation of ozone can be defined. For example, a series of high temperatures during the hottest months and lower precipitation levels reduce the likelihood of ozone formation. Considering global climate changes, one can expect a change in these two parameters in an unfavourable direction.
Two scenarios can be defined:

a) favourable meteorological conditions: T_w=20°C and precipitation of 710 mm,
b) unfavourable meteorological conditions: increased temperature (T_w=22°C) and increased precipitation of 770 *mm,*

where remaining two inputs have kept their typical observed range.

The probability of ozone exceedance for each of described scenario is provided in Figure 2., with the probability of exceeding >25 days having O_3>120 μg/m, where the weather conditions favourable for exceedance are shown in light and dark red colour (probability >50%).

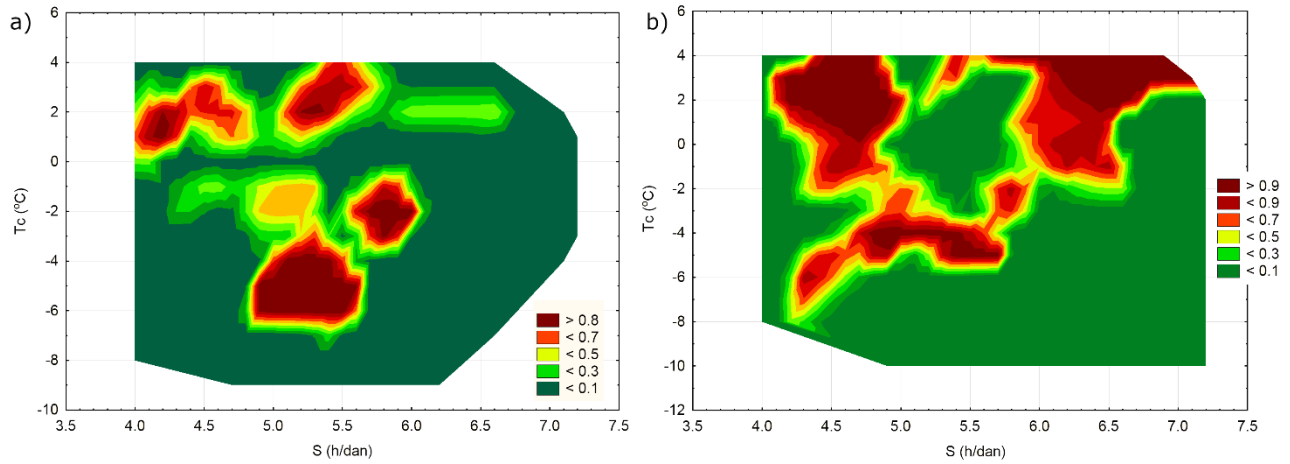

Figure 2. Probability of ozone exceedance for scenario:
a) favourable and b) unfavourable meteorological conditions

It can be observed that the areas with a probability >50% for exceeding the number of days with ozone concentration >120 µg/m³ are more pronounced compared to the favourable scenario. Additionally, there are conditions where the probability of exceeding the number of days with ozone concentration greater than 120 µg/m³ is greater than 90%.

5. CONCLUSION

Is this paper, ANN approach was used for the forecasting of the exceedance of ozone concentration, for cities located in 4 European countries (EU Members), using available climate data (temperature, solar radiation and precipitation) recorded from 2006 to 2012. The obtained model has shown satisfactory accuracy (>75%) and precision, which makes it suitable for the analysis of scenarios.
The performed scenario analysis has demonstrated a significant increase of the probability (>90%) of exceeding the ozone concentration if temperature of warmer months increases for the expected 2°C, followed with increased precipitation, comparing to the initial scenario (T_w=20°C and precipitation of 710 mm).

Abstract: *Air quality in urban areas has a greater impact on the health than other environmental factors, and one of the main pollutants are suspended particles PM_{10} and $PM_{2.5}$. In this paper air quality was monitored in terms of the concentration of $PM_{2.5}$ and PM_{10}, for 09/04/2023, 09/05/2023. and 09/06/2023. in the territory of the city of Belgrade. This period of year was taken due to the assumption that increased air pollution was caused in large connection with the heating season and presence of a large number of individual combustion plants. The Environmental Protection Agency monitors air quality, defined by the CAQI index (The Common Air Quality Index) in real time. Data indicates that the air can most often be characterized as* ***exellent*** *values for $PM_{2.5}$(0 µg/m3 - 15 µg/m^3), and for PM_{10} (0 µg/m^3 – 25 µg/m^3). In a small number of cases, for $PM_{2.5}$ particles (15.01 µg/m^3 - 30 µg/m^3), for PM_{10} particles (25.01 µg/m^3 - 50 µg/m^3), which is characterized as* ***good*** *air quality. From 29 measurement points in Belgrade, the air quality was not characterized as* ***acceptable*** *($PM_{2.5}$: 30.01 µg/m^3 - 55 µg/m^3, or for PM_{10}: 50.01 µg/m^3 - 90 µg/m^3, neither* ***polluted*** *($PM_{2.5}$ 5.01 - 110 µg/m^3; PM_{10} 90.01-180 µg/m^3), nor* ***highly polluted*** *($PM_{2,5}$ above 110.01µg/m^3 ; PM_{10} above 180.01 µg/m^3). Exposure to PM particles has a very bad effect on the respiratory, cardiovascular and nervous systems, including carcinogenic risk.*
Keywords: air pollution, particulate matter, $PM_{2.5}$, PM_{10}, health, air quality

1. INTRODUCTION

It is considered that air quality in urban areas has a greater impact on the health of the population than other environmental factors, and that ambient air pollutants represent one of the most significant causes of health problems in general [1]. A pollutant is any substance present in the air that can have a harmful effect on human health and the environment [2] (4). Air quality is determined not only by the concentration, but also by the type of pollutants [3,4] . One of the main air pollutants are Particulate Matter, PM_{10} and $PM_{2.5}$. $PM_{2.5}$ and PM_{10} particles are suspended particles whose dimensions are less than 2.5 µm and 10 µm, respectively. The most important sources of PM particle can be volcanic eruptions, forest fires, industrial use and burning of coal and oil for the production of electricity and heating, then fuel burning in aviation, car and ship traffic, burning of industrial and communal waste, as well as various agricultural activities.

2. PARTICULATE MATTER ($PM_{2.5}$; PM_{10})

2.1 Chemical composition of suspended particles

The chemical composition of PM particles has a very significant role in terms of impact on human health and air quality. The typical chemical composition of $PM_{2.5}$ particles in urban areas includes: elemental (EC) and organic carbon (OC), sulfates (SO_4^{2-}), nitrates (NO_3^-), ammonium (NH_4^+) ion, chlorides (Cl^-), dust elements and substances of biological origin. The analysis of the composition of $PM_{2.5}$ particles in a large number of studies showed that the largest share in the total mass of particles has OC and water-soluble ions, NO_3^- and SO_4^{2-} [5] . PM_{10} represent a mixture of smoke, soot, dust, salt and acid, along with heavy metals such as lead, cadmium, nickel and arsenic, and are created as a result of the combined impact of heating, traffic and industry.

2.2 Impact of suspended PM particles on human health

The pathogenic properties of PM particles are determined by the size, chemical composition, solubility, source and other characteristics of PM particles (shape, surface area, number). Effects on health as a result of inhalation of PM particles also depend on the way of breathing, the volume of inhaled air, the presence of respiratory diseases, physical activity and age. After inhalation of PM particles, the immune response begins in respiratory macrophages, within the bronchioles. Activated macrophages produce interleukin IL-6, IL-1, tumor necrosis factor alpha, and other proinflammatory cytokines [6], resulting in local inflammation. Induced cell death is another mechanism for causing respiratory diseases caused by PM particles. Oxidative stress, a cascade of inflammatory mediators, and deoxyribonucleic acid (DNA) damage are thought to be involved in PM-induced cell death. Research shows that the mechanism of promoting carcinogenesis by PM particles is based on causing DNA damage and genomic instability [7] . A strong link between PM particles and cardiovascular disease deaths has been established, and several pathways have been identified that explain the link between PM particles and cardiovascular disease. The direct pathway involves the absorption of PM particles into the bloodstream and distant target organs. Systemic inflammation is a well-known risk factor for the progression of atherosclerosis, and proinflammatory mediators are associated with increased blood coagulation and endothelial dysfunction, which can worsen myocardial ischemia [8] . Local inflammation of lung tissue, followed by systemic inflammation, can also lead to disruption of the blood-brain barrier and transfer of PM particles to brain structures. In vitro studies show that certain chemical constituents of PM particles are also neurotoxic.

3. AIR QUALITY MONITORING IN THE REPUBLIC OF SERBIA

In accordance with the Law on Air Protection ("Official Gazette of the RS" No. 36/09 and 10/13) [9] (11), the Serbian Environmental Protection Agency (SEPA) has jurisdiction over the state network for air quality monitoring in Republic of Serbia [10] . Quality monitoring is carried out by applying automatic reference methods in accordance with the Decree on determining the air quality control program in the state network ("Official Gazette of RS" No. 58/11) [11] and the Decree on conditions for air quality monitoring and requirements ("Official Gazette of RS " No. 11/10, 75/10 and 63/13) [12] . Air monitoring is defined by the CAQI index (*The Common Air Quality Index*), developed within the European Commission project. SEPA presents the results of automatic air quality monitoring in real time.

Preliminary, unverified values of air quality parameters within each hour are presented. Verified values and assessment of air quality in agglomerations and zones are given in the Annual report on the state of air quality in the Republic of Serbia [10] . As part of writing this paper, the air quality in the territory of the city of Belgrade was monitored in terms of the concentration of $PM_{2.5}$ and PM_{10} particles, for the beginning of September 2023, for three dates: September 4, 2023, September 5, 2023. and September 6, 2023 (Table 1,2), which is presented in tabular form on the SEPA website.

Analyzing the data, it can be seen that the air in terms of the concentration of PM particles can most often and in the largest number of measurement be characterized as ***excellent***, values for $PM_{2.5}$ particles in concentrations: 0 $\mu g/m^3$ - 15 $\mu g/m^3$, and for PM_{10} particles in concentrations: 0 $\mu g/m^3$ - 25 $\mu g/m^3$. Only September 5th, a smaller number of measurement cases include concentrations for $PM_{2.5}$ particles: 15 $\mu g/m^3$ - 30 $\mu g/m^3$, and for PM_{10} particles 25 $\mu g/m^3$ - 50 $\mu g/m^3$, which can be characterized as ***good*** air quality. Out of 29 measurement points for these three dates, in different municipalities on the territory of the city of Belgrade, the air quality was not characterized as ***acceptable***, neither ***polluted***, nor ***highly polluted*** in any measurement..

Table 3. Air quality index CAQI (The Common Air Quality Index) according to the Environmental Protection Agency of Serbia

Source:[10]

Pollutant	Time	EXCELLENT	GOOD	ACCEPTABLE	POLLUTED	HIGHLY POLLUTED
$PM_{2.5}$	1h	0μg/m^3 - 15μg/m^3	15.01μg/m^3 - 30μg/m^3	30.01μg/m^3 - 55μg/m^3	55.01μg/m^3 - 110μg/m^3	Above 110.01μg/m^3
PM_{10}	1h	0μg/m3 - 25μg/m^3	25.01μg/m^3 - 50μg/m^3	50.01μg/m^3 - 90μg/m^3	90.01μg/m^3 - 180μg/m^3	Above 180.01μg/m^3

In September 2021, the World Health Organization (WHO) issued new recommended values for all major pollutants, so the new recommended value for $PM_{2.5}$ on an annual basis is 5 μg/m^3, while for a period of 24 hours it is 15 μg/m^3. Similarly, recommendations are given for PM_{10}: 15 μg/m3 and

45 μg/m^3 for annual and 24-hour average values, respectively. This change represents a significant tightening of the criteria even in relation to EU standards, which in a short period of time caused the announcement of changes in the corresponding regulation by the European Commission [13] . According to the currently available data on the European Commission's website, the air quality in terms of the concentration of $PM_{2.5}$ particles is categorized as [14]:

- good for levels of fine particles that do not exceed the annual reference value of the World Health Organization of 5 μg/m^3,
- acceptable for levels above 5 and not exceeding 10 μg/m^3
- medium for levels above 10 and not exceeding 15 μg/m^3
- bad for levels above 15 and not above 25 μg/m^3; and
- very poor for levels of and above 25 μg/m^3.

Although according to the data available on the SEPA website, air quality can most often be described as ***excellent***, the measurement of the air quality index - CAQI (Common Air Quality Index) on the national air quality portal, in comparison with European regulations (EEA_European Environmental Agency) and WHO recommendations shows significant deviations.

4. CONCLUSION

In June 2021, the European Environment Agency published a list of 323 cities in the EU where concentrations of $PM_{2.5}$ suspended particles were measured. The city of Belgrade with an average concentration of 21.8 μg/m^3 (5 stations) is the most polluted multi-million city compared to similar cities in the EU. The concentration of suspended PM particles is the main cause of excessive air pollution, and Belgrade generally records the duration of elevated average daily concentrations of PM_{10} [13] . Bad air quality is explained by intensive traffic and a large number of cars older than 12 years and without catalytic converters, the presence of a large number of individual combustion plants, as well as unfavorable meteorological conditions (low temperatures and few days where there was no strong wind). Systematic solution to the problem of air pollution requires long-term planning, cooperation of a wide range of different actors - state institutions, public companies, health system, economy, science, civil society organizations and citizens.In order to reduce pollution and improve air quality in the territory of the city of Belgrade and the entire RS, it would be necessary to harmonize the Limit values prescribed by the Law of the RS, with the values prescribed by the legislation of the European Union, the European Air Quality Index (EU AQI) created by the European Environment Agency, that is, WHO recommendations.

Abstract: *One of the most significant sources of drinking water is groundwater. Therefore, it is crucial to assess groundwater quality and ascertain potential causes of contamination to address pollution and provide people with clean drinking water. In this paper, groundwater in the Morava River plain is investigated and analyzed for 14 physicochemical parameters, such as pH, EC, HCO_3^-, NO_3^-, PO_4^{3-}, Cl^-, SO_4^{2-}, Na^+, K^+, Mg^{2+}, Ca^{2+}, Fe, Mn, and As. To determine groundwater facies and sources of pollution, three multivariate statistical analysis techniques were applied. Hierarchical Cluster Analysis (HCA) was used to group groundwater samples based on their similar chemical characteristics and to determine the dominant hydrochemical groundwater type. According to HCA results, groundwater samples were clustered into three groups, including Cluster 1 (72.3%), Cluster 2 (19.7%), and Cluster 3 (7.9%), and the main groundwater type was Ca-HCO_3 type. Factor Analysis (FA) incorporated with Pearson correlation analysis was conducted to determine the main sources of pollution. Water-rock interactions and agricultural practices were identified as primary pollution sources in the investigated area.*

Keywords: Pearson correlation, Hierarchical cluster analysis, Factor analysis, rock weathering, water pollution

1. INTRODUCTION

Globally, groundwater pollution has emerged as an environmental concern. Generally, groundwater quality depends on the dissolution of minerals, including processes such as water-rock interactions, rock weathering, and ion exchange. These processes represent natural sources of groundwater pollution. On the other hand, groundwater quality has recently been more affected by anthropogenic activities. Excessive use of pesticides and chemical fertilizers, industrial and municipal wastewater discharge, and traffic are anthropogenic activities that influence groundwater quality. These activities represent artificial groundwater contamination sources. Groundwater is used for numerous purposes, including domestic, industrial, irrigation, and drinking [1]. Due to the constant rise in population numbers, the demand for clean water is expanding. In addition, using polluted water for domestic purposes is responsible for over 80% of health problems and illnesses in the world [2]. Therefore, it

is of great importance to assess the quality of groundwater, detect potential pollution sources, and take appropriate measures to prevent pollution. Multivariate techniques are commonly applied to determine groundwater characteristics and pollution sources [3–7]. They involve determining the interaction between chemical parameters, grouping groundwater samples based on their chemical properties, grouping groundwater parameters according to their similar origin, ascertaining groundwater facies, as well as finding the main sources of contamination. This study aims to determine groundwater facies and main factors impacting groundwater quality, combining three multivariate analyses, including Pearson correlation, hierarchical cluster analysis, and factor analysis.

2. MATERIALS AND METHODS

2.1 Study area

The study area (Figure 1) consists of three river plains: the South Morava, the West Morava, and the Great Morava river plain. Together, they form the Morava River plain. Zapadna Morava is formed in Western Serbia by joining the Golijska Moravica and Djetinja rivers. It flows 184 km from west to east, joining the South Morava near Stalać to form Velika Morava. South Morava is formed by the merging of Binačka Morava and Preševska Moravica near Bujanovac, South Serbia. It flows from south to north for 246 km as the longer headwater of Velika Morava. Velika Morava is 185 km long and represents Danube's tributary. The investigated area experiences a moderate continental climate.

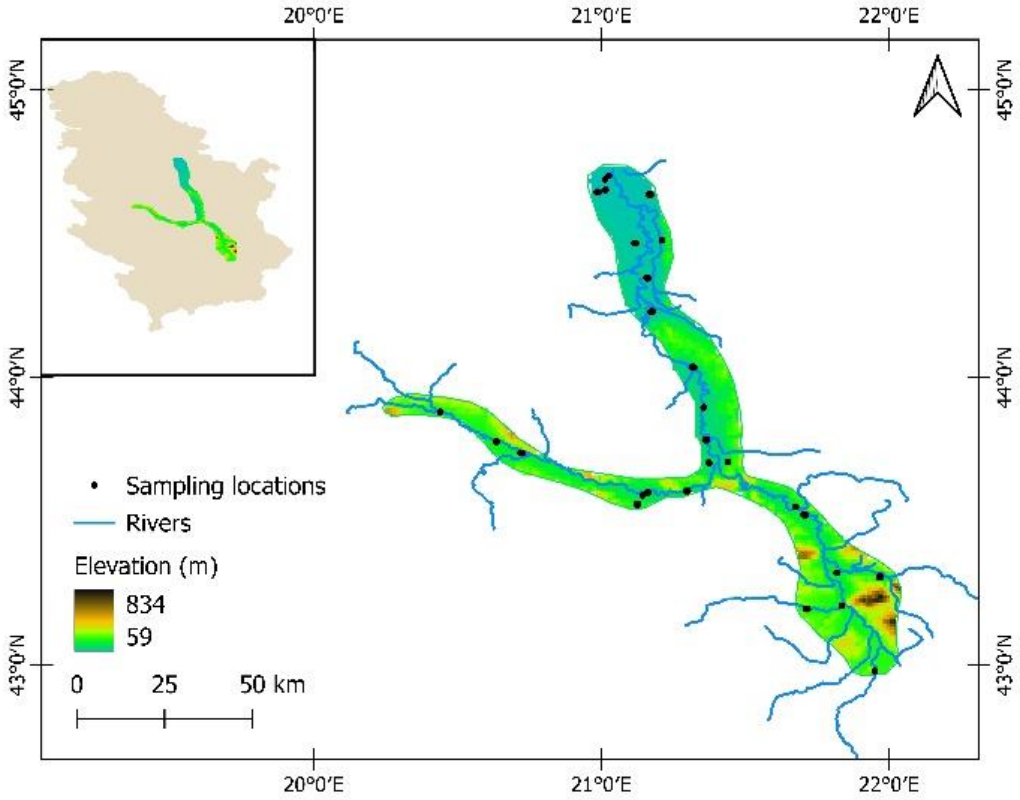

Figure 1. The study area

2.2 Sampling and chemical analysis

In the investigated area, 177 groundwater samples were collected and analyzed for 14 physicochemical parameters, including pH, EC, HCO_3^-, NO_3^-, PO_4^{3-}, Cl^-, SO_4^{2-}, Na^+, K^+, Mg^{2+}, Ca^{2+}, Fe, Mn, and As. High-density polypropylene bottles of 500 mL volume were used for sampling. EC and pH were measured *in situ* using a portable multimeter (YSI 556 MPS, YSI, USA), while HCO_3^- was determined by titrimetry. Before laboratory analyses samples were kept at 4 °C. Major ions (Na^+,

K^+, Mg^{2+}, Ca^{2+}, NO_3^-, PO_4^{3-}, Cl^-, SO_4^{2-}) were determined using ion chromatography (DX-500, Dionex, USA). Inductively coupled plasma optical emission spectrometry (ICP-OES, iCAP 6500, Thermo Scientific, USA) was used to measure Fe and Mn, and As were determined using inductively coupled plasma mass spectrometry (ICP-MS, iCAP Qc, Thermo Scientific, USA).

2.3 Pearson correlation analysis

Pearson correlation analysis is used to determine the interaction between chemical parameters through the calculation of Pearson correlation coefficient (r) [5]. Prior to calculation, data was normalized. Pearson correlation coefficient is calculated as follows.

$$r = \frac{\sum_i^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_i^n (x_i - \bar{x})^2} \sqrt{\sum_i^n (y_i - \bar{y})^2}} \quad (1)$$

Where n is the number of samples; x_i and y_i are chemical parameters; and $\bar{x}$ and $\bar{y}$ are their mean values. Pearson correlation coefficient ranges from -1 to 1. If $0<r<1$, that means a positive correlation between two variables, whereas $-1<r<0$ indicates a negative correlation. In addition, the correlation is stronger if the absolute value of r is higher. Furthermore, the correlation is strong if $|r|>0.7$, moderate if $0.5<|r|<0.7$, and weak if $|r|<0.5$ [6, 7].

2.4 Hierarchical cluster analysis

Hierarchical cluster analysis (HCA) is employed to group groundwater samples into similar groups, called clusters. Samples within the same cluster experience similar chemical characteristics, while being different from the other clusters. Ward linkage and Euclidean distance were used to determine the distance between clusters and the distance between water samples, respectively. A graphical representation of the HCA results is called a dendrogram [8].

2.5 Factor analysis

Factor analysis (FA) is a commonly used multivariate statistics technique in which data dimensions are reduced without losing any of the data's information. FA converts the dataset into parameters called factors, where the first factor accounts for the majority of the variance in the dataset, with other factors accounting for the remainder. In order to maximize factor loadings, Varimax rotation was utilized. In this work, FA was employed to determine sources that control groundwater chemistry and their impact on groundwater quality.

3. RESULTS

3.1 Correlation analysis

Table 1 presents the Pearson correlation matrix for the 14 selected chemical parameters. For further interpretation, only parameters showing moderate correlation ($0.4<r<0.7$) or strong correlation ($0.7<r<1$) are selected and in bold.

EC showed strong positive correlation with HCO_3^-, Cl^-, SO_4^{2-}, Ca^{2+}, and Mg^{2+}, and moderate correlation with Na^+ and K^+. Strong positive correlations were also observed between HCO_3^- Ca^{2+}, and Mg^{2+}, while moderate correlation was present between HCO_3^- and Na^+, Cl^-, and SO_4^{2-}. There was also a moderate positive correlation between Mg^{2+}, Na^+, and Ca^{2+}. These findings suggest that rock-water interaction plays an important role in controlling groundwater chemistry. NO_3^- was moderately correlated with PO_4^{3-} and K^+. SO_4^{2-} also showed a moderate correlation with Mg^{2+}. These indicate the influence of agricultural activities.

Table 1. Pearson correlation analysis of the physicochemical parameters

	pH	EC	HCO_3^-	NO_3^-	PO_4^{3-}	Cl^-	SO_4^{2-}	Na^+	K^+	Ca^{2+}	Mg^{2+}	Fe	Mn	As

Fe	0.02	0.17	0.13	-0.16	-0.04	0.18	0.23	0.24	0.05	0.17	0.13	1		
Mn	-0.05	-0.11	-0.07	-0.2	-0.05	-0.08	-0.11	0.04	-0.07	-0.07	-0.05	0.07	1	
As	0.01	-0.05	-0.04	-0.1	0.14	-0.12	-0.05	-0.01	-0.02	-0.12	0.01	0.32	0.07	1

3.2 Cluster analysis

Hierarchical cluster analysis was applied in order to classify groundwater samples according to their similar chemical properties. To create a dendrogram of groundwater samples, Ward linkage incorporated with Euclidean distance is used (Figure 1). Results show that groundwater samples were classified into three clusters: Cluster 1 (72.9%), Cluster 2 (19.7%), and Cluster 3 (7.9%). All three clusters are characterized by dominance of Ca^{2+} cation and HCO_3^- anion. Therefore, groundwater in the investigated area shows a dominance of Ca-HCO_3 hydrochemical type. Cluster 1 characterizes the highest average values of NO_3^- and PO_4^{3-} concentrations, suggesting that anthropogenic activities, such as agricultural practices, highly influence these samples. Cluster 2 showed the highest average concentrations of HCO_3^-, Cl^-, Na^+, Ca^{2+}, Fe, and As, indicating that these samples are highly influenced by natural or geogenic sources, such as water-rock interactions and rock weathering [9]. Considering average concentrations of examined chemical parameters in Cluster 3, this cluster shows the impact of both natural and anthropogenic sources.

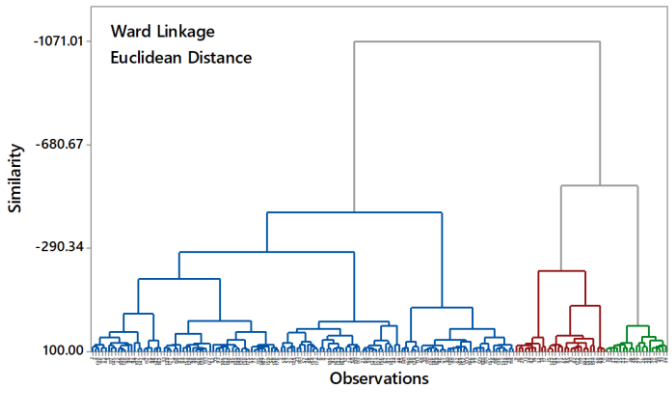

Figure 2. Dendrogram of the groundwater samples

3.3 Factor analysis

Factor analysis was conducted to identify the main pollution sources of groundwater. Varimax rotation was applied, and 14 factors were obtained. Furthermore, only factors with eigenvalues greater than one are extracted (Figure 2a), accounting for 59.50% of the total variance. Extracted factors with

their loadings are presented in Table 2. Parameter values greater than 0.7 are considered significant and are in bold. Factor 1 explains 35.10% of the total variance, with high loadings of EC, HCO_3^-, Cl^-, SO_4^{2-}, Na^+, Ca^{2+}, and Mg^{2+}. Major cations and anions mainly reach groundwater due to water-rock interactions, weathering of rocks, or ion exchange processes. Therefore, Factor 1 can represent the influence of natural sources on groundwater contamination. Factor 2 comprised 14.40% of the total variance, showing high loadings of NO_3^- and PO_4^{3-}. Nitrates and phosphates may originate from anthropogenic sources, such as agricultural practices, wastewater disposal, or sewage intrusion. The investigated area is known for its fertile land. In addition, large amounts of fertilizers are used in order to increase the yield of cultivated crops. Therefore, Factor 2 demonstrates the influence of agricultural practices on groundwater contamination. Factor 3 showed high loadings of Fe and As, explaining 10.0% of the total variance. Contents of Fe and As in groundwater are usually controlled by geomorphology. Thus, Factor 3 represents a geogenic source. Loading plot of Factor 1 vs. Factor 2 is shown in Figure 2b.

Table 2. Extracted factors after Varimax rotation

Parameter	Factor 1	Factor 2	Factor 3
pH	-0.322	-0.164	0.073
EC	**0.918**	-0.313	0.025
HCO_3^-	**0.860**	-0.112	-0.019
NO_3^-	0.152	**-0.806**	-0.185
PO_4^{3-}	0.144	**-0.721**	0.172
Cl^-	**0.801**	-0.247	0.003

4. CONCLUSION

This work uses three multivariate statistical techniques to examine groundwater in the Morava River Plain, Serbia. HCA clustered groundwater samples into three groups, with Ca-HCO_3 being the prevailing hydrochemical type in all groups. HCA also revealed that both natural and anthropogenic factors impact groundwater chemistry. Pearson correlation matrix and FA results were consistent with the HCA results. FA extracted three factors, accounting for 59.50% of the total variance. Water-rock interactions, geogenic sources, and agricultural activities were identified as the main sources of pollution.

Abstract: *Artificial sweeteners are high-priority emerging contaminants that are widespread in surface waters worldwide as a result of municipal wastewater discharges into the aquatic environment. Given that these substances can cause toxic effects on aquatic organisms, they represent a potential risk for the river ecosystem as a whole. Although sediments have not often been the subject of scientific research on pollution with artificial sweeteners, there is a possibility that these substances pose a risk to sediment-dwelling organisms. Aspartame and neotame are sweeteners that have a high sorption affinity for organic-rich particles and partition to sediment in the water-sediment system. In order to determine the possible risk for benthic biota, an ecological risk assessment of detected aspartame and neotame in sediments from five rivers in Serbia was performed. In addition to the risk assessment of individual sweeteners, "the cocktail effect" of their mixture was also estimated. Detected levels were compared with the lowest predicted no-effect concentration (PNEC) values for sediment organisms from the Norman Ecotoxicology Database, based on experimental ecotoxicity data and QSAR model predictions for aquatic organisms.*
Keywords: Artificial Sweeteners, Ecological Risk Assessment, River Sediments, Benthic Organisms

1. INTRODUCTION

Artificial sweeteners are metabolically inert, calorie-free sugar substitutes widely used in food and pharmaceutical products [1]. These substances enter the environment in unchanged form through sewage system and their presence in natural waters has been documented worldwide [2,3]. Some ecotoxicological research has shown that artificial sweeteners can cause toxic effects on aquatic organisms, affecting the growth, behaviour and metabolism [4,5]. For this reason and their unknown long-term environmental fate, they belong to a new class of high-priority emerging contaminants [2]. In scientific literature, ecological risk assessment based on the detected levels of these compounds in river ecosystems has been evaluated only for water organisms [3]. Since sediments represent a functional part of aquatic ecosystems, determination of toxicological risk on benthic biota is a necessary step in a comprehensive overview of river ecosystem contamination with artificial sweeteners.

In this paper, ecological risk of aspartame and neotame was estimated to sediment-dwelling organisms in five rivers in Serbia (the Sava, the Danube, the Tisza, the Morava and the Veliki Lug). These sweeteners were selected for analysis based on their specific physical and chemical properties (high log K_{ow} and log K_{oc} values and low water solubility) [6], with a high sorption affinity for organic-rich particles and partitioning to sediment in the water-sediment system. Detected

[1]egvozdic@tmf.bg.ac.rs
[2]imatic@atssb.edu.rs
[3]tanjav@tmf.bg.ac.rs
[4]svetlana.grujic@tmf.bg.ac.rs

concentrations were compared with the lowest predicted no-effect concentration (PNEC) values for sediment organisms obtained from the Norman Ecotoxicology Database, based on experimental ecotoxicity data and QSAR model predictions for aquatic organisms [7]. In addition to the risk assessment of individual sweeteners, "the cocktail effect" of their mixture was also evaluated. The instrumental analysis of the prepared extracts was performed using liquid chromatography with tandem mass spectrometry (LC–MS/MS), as sensitive and reliable method for the detection of traces of artificial sweeteners in complex environmental matrices.

2. EXPERIMENTAL PART

2.1 Chemicals and reagents

Aspartame and neotame, as high purity (≥ 98%) analytical standards, were purchased from Sigma-Aldrich (Buchs, Switzerland). These sweeteners are approved for use as food additives in the Republic of Serbia (Regulation No. 53/2018) [8]. The solvent methanol (HPLC grade) was obtained from J.T. Baker (Gliwice, Poland). Ammonium acetate was of analytical grade.

2.2 Sampling and sample preparation

Five sediments samples were collected from the following rivers in Serbia: the Sava (SED1), the Danube (SED2), the Tisza (SED3), the Morava (SED4) and the Veliki Lug (SED5). Approximately 1 kg of the sediments was collected in plastic containers and kept in a freezer. After defrosting, the sediment samples were air-dried at room temperature, for several days, in the dark. Samples were then homogenized and sieved through 500 μm pore size sieve. Sediments were prepared for analysis using optimized ultrasonic extraction (USE) method with methanol as extraction solvent. The detailed preparation procedure is shown in a previous study of Gvozdić et al. 2020 [6].

2.3 LC–MS/MS analysis

LC analysis was performed using a Dionex UltiMate 3000 HPLC system (Thermo Fisher Scientific, Waltham, USA). Chromatographic separation of analytes was carried out on a Luna® C8 reverse-phase column, 150 mm × 3.0 mm i.d. and 3 μm particle size (Phenomenex, Torrance, USA). The mobile phase consisted of deionized water, methanol, and 0.1 mol L^{-1} aqueous solution of ammonium acetate. MS/MS analysis was performed using LTQ XL (Thermo Fisher Scientific) linear ion trap mass spectrometer, coupled with a HPLC system. Electrospray ionization (ESI) in negative mode was used as the ionization technique. LC–MS/MS operating parameters for the determination of aspartame and neotame were developed and optimized in a previous study [6].

2.4 Ecological risk assessment

Ecological risk to benthic organisms was evaluated based on risk quotients (RQs) calculated by dividing the measured environmental concentration (MEC) of selected sweetener with the corresponding predicted no-effect concentration (PNEC) for sediment organisms [3]. The PNEC values used in the study were obtained from the Norman Ecotoxicology Database as the lowest PNECs, based on experimental ecotoxicity data or predicted by QSAR (quantitative structure–activity relationship) analysis for freshwater organisms [7]. The lowest PNECs for sediment organisms ($PNEC_{sed}$) were calculated using the following equation (Eq. (1)):

$$PNEC_{sed} = PNEC_{freshwater} \times 2.6 \times (0.615 + 0.019 \times K_{oc}) \quad (1)$$

Ecological risk to benthic organisms is classified into four categories: "negligible/no risk" (RQ < 0.01), "low risk" (0.01 < RQ < 0.1), "moderate/medium risk" (0.1 < RQ < 1), and "high risk" (RQ ≥

1) [3,9]. In order to evaluate "cocktail effect" of the mixture of artificial sweeteners detected in each sediment sample, the RQ_{mix} was calculated, based on the concentration-addition method for risk assessment of mixtures, as the sum of the RQ values obtained from the individual sweetener concentrations (Eq. (2), [9]):

$$RQ_{mix} = \sum_{i=1}^{n} RQ_i \quad (2)$$

3. RESULTS AND DISCUSSION

Aspartame and neotame were found in all river sediment samples. The high detected levels of aspartame (Table 1) reflect high consumption of this sweetener in the human diet in Serbia. The highest concentrations of aspartame detected in rivers the Sava (sample SED1, 568 ng/g) and small river the Veliki Lug (sample SED5, 355 ng/g) point to their high contamination by municipal wastewater. On the other hand, neotame was recorded at significantly lower levels which can be explained by the lower use in food and beverages of this relatively new artificial sweetener. Neotame was found at the highest concentrations in the Veliki Lug River (sample SED5, 56 ng/g) and the Danube (sample SED2, 48 ng/g) indicating high sewage input in these water bodies. In predominantly agricultural regions of sampling sites on rivers the Tisza and the Morava (samples SED3 and SED4), levels of neotame were significantly lower (2 and 6 ng/g, respectively).

Table 1. Ecological risk assessment of aspartame and neotame for sediment-dwelling organisms detected in sediment samples of five rivers in Serbia

River	Sample	Aspartame (ng/g)	RQ*	Ecological risk	Neotame (ng/g)	RQ*	Ecological risk
Sava	SED1	568 ± 71	1.47	high risk	12 ± 3	0.57	medium risk
Danube	SED2	117 ± 20	0.30	medium risk	48 ± 9	2.30	high risk
Tisza	SED3	210 ± 31	0.54	medium risk	2 ± 0	0.09	low risk
Morava	SED4	184 ± 16	0.47	medium risk	6 ± 1	0.29	medium risk
Veliki Lug	SED5	355 ± 42	0.92	medium risk	56 ± 10	2.68	high risk

*$PNEC_{sed}$ values (385 μg/kg for aspartame and 20.9 μg/kg for neotame)

Ecological risk assessment based on the detected levels of aspartame and neotame in five rivers in Serbia indicates low (0.01< RQ < 0.1) to a high risk (RQ ≥ 1) for sediment-dwelling organisms. According to the $PNEC_{sed}$ value for aspartame (385 μg/kg), noticeably high environmental risk (RQ ≥ 1) was recorded in the Sava River (sample SED1). The RQ values for aspartame in other investigated rivers in Serbia were ranging from 0.30 to 0.92, implying medium risk (0.1 < RQ < 1) for benthic biota.

As for neotame, taking into account its $PNEC_{sed}$ value (20.9 μg/kg), high ecotoxicological risk was observed in rivers the Veliki Lug and the Danube, while detected levels in the Sava and the Morava pointed to medium ecological risk. Low risk was determined for sediment from the Tisza, probably as a consequence of lower wastewater burden. In addition, according to the mixture risk approach, calculated RQ_{mix} have shown that the "cocktail effect" of detected sweeteners should be taken into account when assessing the risk to environment. The most pronounced "cocktail effect" was observed for the rivers the Veliki Lug (RQ_{mix} = 3.60) and the Danube (RQ_{mix} = 2.60), both heavily impacted by untreated municipal wastewater (Figure 1).

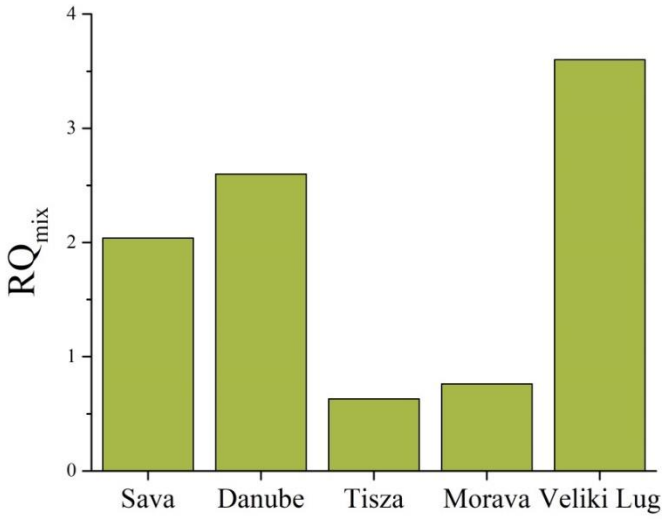

Figure 1. The risk quotients for a mixture (RQ_{mix}) of artificial sweeteners detected in sediments of five rivers in Serbia

The obtained results clearly show that sediments of river ecosystems in Serbia are of great concern in terms of detected artificial sweeteners. Because sediments are a major sink of organic pollutants, they can be a secondary source of pollution in the case of resuspension. Since wastewater treatment in Serbia is generally rare, continuous accumulation of these contaminants in sediments is inevitable. Therefore, investments in the construction of municipal wastewater treatment plants and introduction of new treatment processes, as well as stricter control of sewage pollution in Serbia are necessary.

4. CONCLUSION

The levels of aspartame and neotame detected in rivers the Sava, the Danube, the Tisza, the Morava and the Veliki Lug indicate a significant ecological risk for benthic organisms. The highest ecotoxicological risk was recorded in the Veliki Lug, the Danube and the Sava, as a result of extensive municipal wastewater discharges. This was determined according to risk quotients of the mixture of the two detected artificial sweeteners. The ecological risk was less pronounced in the agricultural regions of the Tisza and the Morava Rivers. The results presented in this study clearly show that untreated wastewater discharges in Serbia affect the quality of river ecosystems and threaten the benthic biota. The estimated high risk to the aquatic environment requires the improvement of municipal wastewater treatment and management and the inclusion of artificial sweeteners in routine monitoring programs.

IMPACT OF URBAN HEAT ISLAND ON BUTTERFLY-BUSH (*BUDDLEJA DAVIDII* FRANCH.)

Mirjana Ocokoljić[1], Faculty of Forestry, University of Belgrade
Djurdja Petrov[2], Faculty of Forestry, University of Belgrade

Abstract: *Urban vegetation serves multiple functions beyond aesthetics, including a pivotal role in shaping the microclimate of modern cities. The ongoing climate change and extreme temperature variations affect the growth and development of plants. As a result, investigating the adaptive potential of plant species to temperature variations within urban environments is gaining critical importance. While researchers worldwide have delved into the influence of biotic and abiotic factors on plants, the variability of plant organisms within urban ecosystems remains unexplored. Therefore, this paper seeks to assess the impact of the urban heat island (UHI) within a humid continental climate (Belgrade, Serbia) on Buddleja davidii Franch. A comparative analysis of interpolated temperatures sourced from meteorological stations in urban, sub-urban and rural zones for all four seasons was undertaken. The causal relationship was confirmed: not only the influence of vegetation on temperatures but also the impact of UHI on the presence and sustenance of vegetation. Namely, a substantial increase in temperature affects the seasonal changes of the butterfly-bush, particularly during extreme climatic events. The obtained results provide an essential foundation for planning and design of urban landscapes that should be adapted to the changed dynamics to ensure the ecosystem services provided by urban shrubs.*
Keywords: Urban Heat Island, Urban Meteorology, Climate Change, Benefits of Plants, Urban Shrubs

1. INTRODUCTION

While investigating the urban climate of 19th century London, Howard [1] became the pioneer in analysing the Urban Heat Island (UHI) effect. These "heat islands" remain relatively stable over time, creating warm air domes above buildings, roads, and other impermeable surfaces. These surfaces enhance the absorption of short-wave radiation, reduce energy loss through the emission of long-wave radiation, and diminish evapotranspiration compared to the natural land cover of the surrounding rural areas. Thermal homogeneity can be disrupted or altered by the presence of green and water surfaces, as noted by Walker et al. [2].

Although urban areas constitute a small portion of local and global ecological systems, their impact on these ecosystems is considerable. Conversely, urban vegetation plays a crucial role in mitigating local temperatures through shading and transpiration. Furthermore, it offers valuable ecosystem services, including carbon sequestration and the provision of habitats for various flora and fauna [3] . Given that phenology, specifically the annual cycle of leafing, leaf development, and senescence, is tightly regulated by temperature in numerous ecosystems, extensive research efforts are directed towards analysing the effects of climate change on these ecosystems [4].

UHI effects have the potential to alter the seasonal vegetation changes in urban areas, particularly affecting exotic and ornamental shrubs [5]. Therefore, our study examines the impact of UHI on the spatial complexity of butterfly bush phenology. We achieved this by recording phenological patterns

[1] mirjana.ocokoljic@sfb.bg.ac.rs
[2] djurdja.stojicic@sfb.bg.ac.rs

across urban, suburban, and rural zones. Within this general framework, our study aimed to quantitatively assess and define the nature of UHI and its influence on phenological patterns. The final goal was to address the challenges of urban design and the utilisation of ornamental shrubs, such as the butterfly-bush.

2. MATERIALS AND METHODS

The research encompasses an area of 446 km^2 within the city of Belgrade, Serbia (Figures 1 and 2). The sites selected for the study of the variability of *Buddleia davidii* Franch. seasonal changes were chosen to represent the broader environment, with a focus on varying degrees of urbanisation and coverage of urban, suburban, and rural settings.

To achieve the objectives of this study, three specific sites were examined in the following municipalities: (1) Vračar (Karadjordjev Park, adjacent to Bulevar Oslobođenja), (2) Surčin (alongside the M266 highway), and (3) Čukarica (Ostružnica, alongside the M19 highway). Each site had 3 to 5 shrubs registered. A more detailed description of the research sites can be found in Table1.

Table 1. Research area description

Location	Latitude φ	Longitude λ	Altitude H (m)	Aspect	Slope*
1.	44º 47' 39.07 " N	20º 27' 57.94" EGr	108	SW	5.2°
2.	44º 49' 49.94" N	20º 16' 47.31" EGr	93	N	0.8°
3.	44º 43' 06.58" N	20º 18' 43.15" EGr	97	W	4.5°

* Slope angles: 0-1° (flat terrain), 3-5° (slightly inclined terrain) and 5-8° (fairly inclined terrain)

An analysis of the impact of the urban heat island on this species was conducted utilising climatological data for the thirty-year period from 1991 to 2020, as well as the autumn of 2022 and the winter of 2022/2023. The data were sourced from the Main Meteorological Stations (MMS) at three locations: Belgrade (44º47' 54.44" N; 20º27' 53.35" EGr; altitude: 132m), Surčin Airport (44º49'27.37" N; 20º17'27.82" EGr; altitude: 99m), and Košutnjak (44º46'15.57" N; 20º25'27.75" EGr; altitude: 203m) [6].

The assessment of temperature normality and diurnal temperature trends followed the methodology proposed by Fries et al. [7], according to which the final interpolation included a digital elevation model and the temperature data from the stations. The interpolation process was executed using ArcGIS/ArcMap 10. To assess the impact of UHI on this ornamental shrub, phenological patterns and events were monitored from 2012 to the summer of 2023 across three distinct locations: (1) an urban (2) a rural and (3) a suburban zone. The BBCH scale [8] was employed for phenological observations over a span of 10 consecutive years. The date of End of Leaf-Fall (ELF) was noted at intervals ranging from 2 to 4 days.

Throughout the autumn, winter, and spring of 2022/2023, the growth and development of twigs and leaves were recorded in the cold part of the year (19 January 2023) and in the first half of the growing season (May 2023). Shoot Length (SL) marking the beginning of shoot growth, Shoot Final Length (SFL) when shoots reach approximately 90% of their final length, Leaf Length (LL) and Leaf Width (LW) were measured. The material was collected during field research, with an aim to obtain 50 leaf and 10 shoot samples for quantitative analysis from each individual within Site 1. Consequently, the cumulative sample encompassed 250 leaves and 50 shoots. For the purpose of morphological structure assessment, herbarium specimens were employed to measure attributes such as shoot length, leaf length, and maximum leaf width using the UTHSCSA Image Tool. Quantitative parameters were processed using descriptive statistics and a one-way Analysis of Variance (ANOVA) analysis. The analysis was conducted using the Statgraphics Centurion 19 software package.

3. RESULTS AND DISCUSSION

By utilising interpolated mean daily air temperatures from the thirty-year reference period, the average seasonal air temperatures were determined for each site, as follows:
Autumn: Site 1: 13.37°C, Site 2: 12.74°C, and Site 3: 12.93°C.
Winter: Site 1: 2.89°C, Site 2: 2.04°C, and Site 3: 2.29°C.
Spring: Site 1: 13.44°C, Site 2: 12.71°C, and Site 3: 12.75°C.
Summer: Site 1: 23.24°C, Site 2: 22.65°C, and Site 3: 22.64°C (Figure 1).

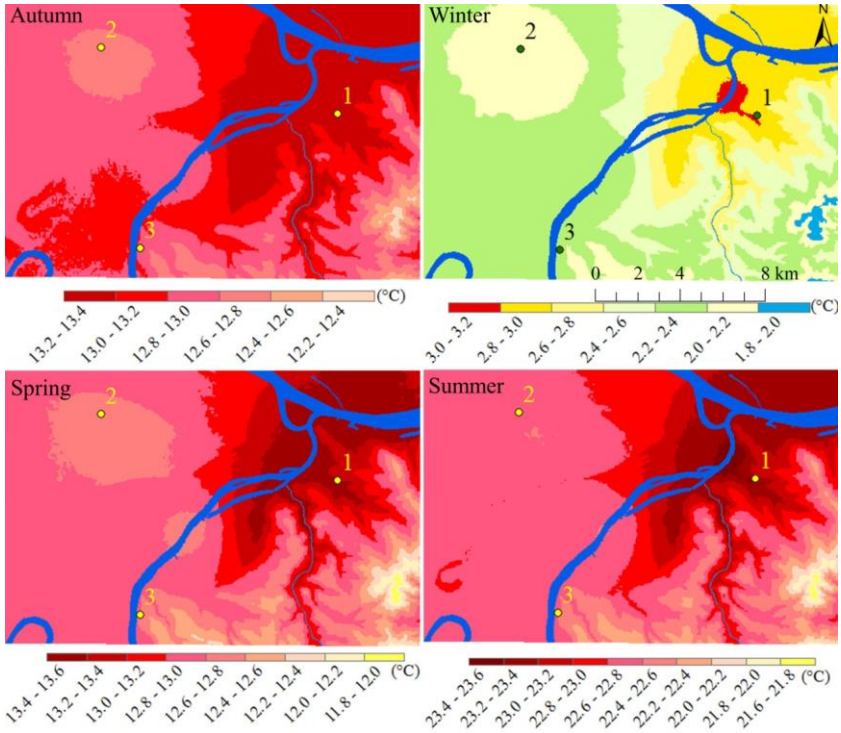

Figure 1. Spatial distribution of mean seasonal air temperatures (ºC) in the research area for the reference period 1991-2020

The research area had the following mean seasonal air temperatures by site for the autumn of 2022: Site 1: 14.32°C, Site 2: 13.55°C, and Site 3: 13.75°C. During the subsequent winter of 2022/2023, the mean seasonal air temperatures were: Site 1: 5.89°C, Site 2: 5.24°C, and Site 3: 5.39°C (Figure 2). Deviations from the normal (1991-2020) for the mean seasonal air temperatures during the autumn of 2022 and winter 2022/2023 were positive. This indicates that temperatures were higher than the normal means. Specifically, for the autumn period, temperature deviations by site were as follows: Site 1: 1.42°C, Site 2: 0.81°C, and Site 3: 0.82°C. Similarly, during the winter period, deviations were as follows: Site 1: 3.00°C, Site 2: 3.20°C, and Site 3: 3.10°C.
The findings of the research support the conclusion that the autumn of 2022 was warm, including a heat wave occurring in late October and early November. The winter in Belgrade was the second warmest since 1888, and it was marked by a record low number of frost days. Applying the percentile method, the mean seasonal temperature for the winter in Belgrade fell into the extremely warm category, as classified by RHMS. Several periods of warm weather were observed, with air temperatures exceeding the multi-year average. These warm intervals included the end of the first decade, the middle and the third decade of December, as well as the first decade, the end of the second decade of January, and the end of the second and the beginning of the third decade of February. Conversely, cold periods, characterised by temperatures below the multi-year average, occurred in mid-December, and at the end of the first and the beginning of the second decade of February [9]

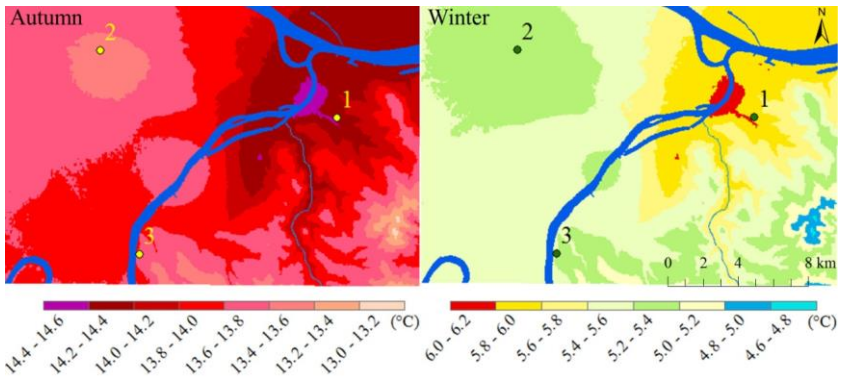

Figure 2. Spatial distribution of mean seasonal air temperatures (ºC) in the research area for autumn of 2022 and winter of 2022/2023

The research conducted in these three locations revealed that between 2012 and 2021, all specimens of the butterfly-bush exhibited deciduous habit in urban, sub-urban, and rural areas. The phenophase of early leaf fall (ELF) during this ten-year period occurred from 2 December to 28 December. Each site had butterfly-bush specimens whose characteristics and clustering tendencies were typical of the plant aged between 17 to 23 years. Studies by Kunick [10] and Ocokoljić & Petrov [11] suggest that these plants can live up to 40 years. However, an evergreen growth mode was recorded for the first time in the autumn and winter of 2022/2023, but only at Site 1. This specific site clearly identified as an Urban Heat Island (UHI) based on temperature data from the reference period and the last year (Figures 1 and 2). The butterfly-bush is recognised as capable of developing both as a deciduous and an evergreen shrub [12]. However, the evergreen form was observed for the first time in the Belgrade urban environment within the UHI zone. In contrast, specimens within sub-urban and rural zones remained deciduous, with the ELF phase registered at Sites 2 and 3 from 4 December to 27 December 2022.

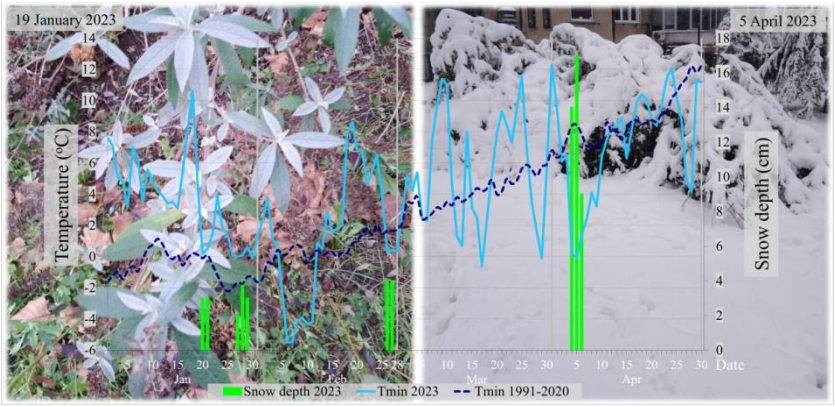

Figure 3. Butterfly-bush at Site 1 with an overview of snow depth, minimum daily air temperatures from 1 January to 30 April 2023 and their normals for the reference period 1991-2020

Taking into consideration species' application, it is stressed that the most notable plant responses to climate change are seasonal variations, including a prolonged growing season, an earlier onset of spring, and delayed autumn phenophases [13]. The findings of the conducted research confirm that the effects of the UHI led to an evergreen mode of growth and shoot development in December and January at Site 1. These findings align with the observations made by Denny et al. [14], who emphasised that phenology exhibits variations in response to local climate conditions. Low temperatures and snowfall during the winter and spring of 2023 did not lead to leaf fall (Figure 3).

A comparative analysis of winter and spring growth reveals the distinctive traits and general characteristics of the species. Statistically significant differences were determined for all three traits through a one-way ANOVA test, yielding p-values below 0.0001 and F-values of 224.426 (shoot length), 39.855 (leaf width), and 21.250 (leaf length). These findings were substantiated by low

standard deviation values and coefficients of variation for all variables. Figure 4 presents the key elements of descriptive statistics. This research unveiled that for the first time in eleven consecutive years of study, the UHI effect brought about the evergreen nature of the butterfly-bush and triggered an early onset of the growing season (growth and leafing) in 2023.

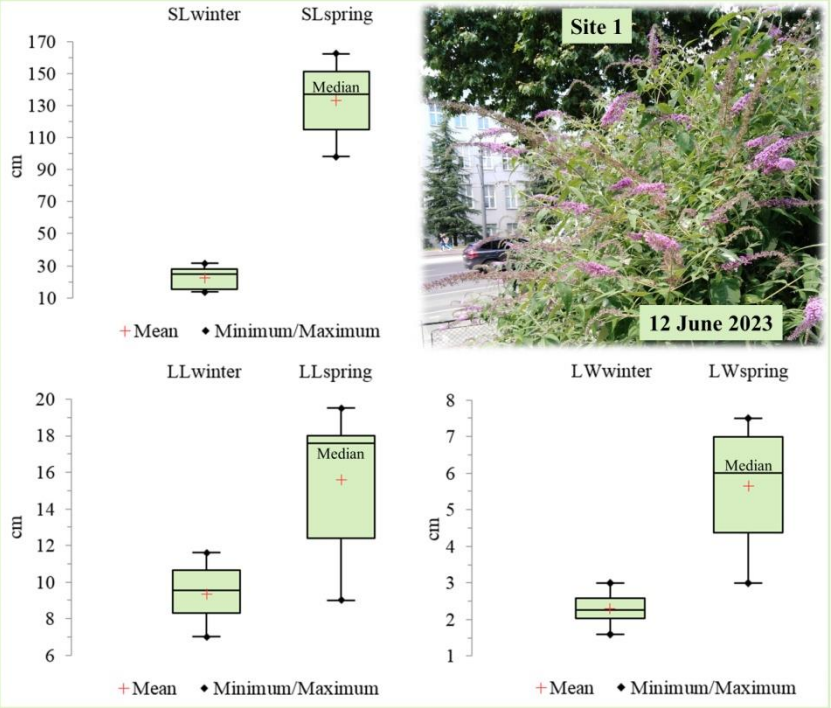

Figure 4. Morphological and metric characteristics: shoot length (SL), leaf length (LL) and leaf width (LW) of butterfly-bush for winter (winter, 19 January 2023) and spring (spring, 25 May 2023) for Site 1

The obtained results form the foundation for the operationalisation of landscape design that plays a pivotal role in the management of local landscapes and the assurance of environmental sustainability [15]. The novelty in this study lies in evaluating the response of the butterfly-bush to heat, particularly in regions affected by the Urban Heat Island (UHI) effect. This assessment holds promise for its potential application in the redesign of urban landscapes since the butterfly-bush serves as a significant nectar source, attracting butterflies during its flowering phase, while also providing sustenance for birds during cold months.

4. CONCLUSIONS

Based on research conducted in urban, suburban, and rural zones in Belgrade, it was confirmed that the UHI has an impact on the phenology of the butterfly-bush. Considering the anticipated widespread effects of climate change in urban areas, it is imperative that further research be undertaken in the upcoming period. While the exact implications of these changes remain unclear, the ongoing reality of global warming underscores the increasing responsiveness of urban areas to climate change. Consequently, urban ecosystems are certain to undergo significant functional and structural transformations. The results of this study stress the potential of the butterfly-bush to yield significant social benefits within cities not only through the reduction of UHI intensity but also through the provision of ecosystem services of urban shrubs.

This research, conducted at the University of Belgrade - Faculty of Forestry in 2023, was supported by the Ministry of Education, Science, and Technological Development of the Republic of Serbia [451-03-47/2023-01/20016]

EFFECTS OF URBANISATION ON *SIMPHORICARPOS ORBICULATUS* MOENCH IN THE GREEN INFRASTRUCTURE OF BELGRADE

Mirjana Ocokoljić[1], Faculty of Forestry, University of Belgrade
Djurdja Petrov[2], Faculty of Forestry, University of Belgrade
Dragan Vujičić3[3], Faculty of Forestry, University of Belgrade

Abstract: *Despite the well-documented intra-urban variability of Urban Heat Island (UHI) effects, little is known regarding the spatial and temporal variability in coralberry's response to UHI. The beginning and conclusion of the growing season were determined using hourly and daily climate data sourced from the Republic Hydrometeorological Service of Serbia (RHMS). This study deals with the impact of urbanisation on coralberry phenology in Belgrade from 2007 to 2023. Among various components of green infrastructure, we analysed urban parks and a city cemetery. Urban parks exhibited a less pronounced change in the duration of their growing seasons, owing to the interaction between the UHI and the cooling effect within parks. These research findings address two crucial gaps in urban phenological studies: the influence of urban composition on phenology and the role of micrometeorological observations in shaping coralberry phenological patterns. Furthermore, they shed light on shifts in coralberry's phenological patterns under the influence of urbanisation, a matter of significance due to its impact on biodiversity, ecosystem services, and implications of land use, management, restoration, and landscape planning and design.*
Keywords: Urban Ecology, Temperature, Urban Green Spaces, Phenology, Sustainability

1. INTRODUCTION

The conversion of natural and agricultural land into urban areas is on the rise every year. Projections for urbanisation in 2030 indicate that it will reach 81% of the total population, compared to 1960, when it stood at just 34% and 2014, when it increased to 54%. This rapid urbanisation, driven by the high demand for land use change, has detrimental effects on the environment, particularly on the urban climate, giving rise to Urban Heat Islands (UHIs) that increase temperatures within urban centers [2]. However, green spaces or green infrastructure (GI) can help ameliorate these adverse impacts by reducing both the maximum temperatures and temperature fluctuations in cities. Previous research primarily relied on on-site observations and focused on measuring air temperatures to quantify the cooling effects of specific structures and types of green spaces. It's worth noting that the degree of cooling is affected by the type, structure, and size of green spaces. For instance, diverse types and compositions of green spaces in urban areas tend to have more pronounced cooling effects than green spaces with simple, less intricate structures [3]. However, the effect of UHIs on specific plant species, particularly shrubs, continues to pose a challenge. To address the gaps in the existing research literature, this study aims to identify and classify heat-resistant coralberry individuals within GI in the context of intensive urbanisation in Belgrade. Furthermore, it aims to analyse how UHI affects coralberry plants growing in various types and structures of green areas located within the UHI zone of Belgrade, with varying degrees of urbanisation. The findings of this research will

[1] mirjana.ocokoljic@sfb.bg.ac.rs
[2] djurdja.stojicic@sfb.bg.ac.rs
[3] dragan.vujicic@sfb.bg.ac.rs

contribute to the planning and designing of GI elements, optimising their size and distribution to develop the most adequate coralberry compositions.

2. MATERIAL AND METHODS

The research was conducted in the territory of Belgrade, Serbia (Figure 1), specifically in the municipalities of Savski Venac (Site 1: Milutin Milanković Park and Site 2: Three Keys Park (*Ser. Park tri ključa*)) and Palilula – (Site 3: New Cemetery (*Ser. Novo groblje*)). The sites were selected based on cartographic material, urbanisation degrees, and on-site investigations. The primary criterion for choosing these sites was the presence of coralberry, aiming to determine its adaptability, which positions it as a potentially valuable addition to the urban GI. Furthermore, the study examined various approaches to its implementation, including solitary, group, and linear arrangements, with the aim of ensuring balanced and harmonious spatial development from the perspectives of landscape architecture, ecology, and art [4].

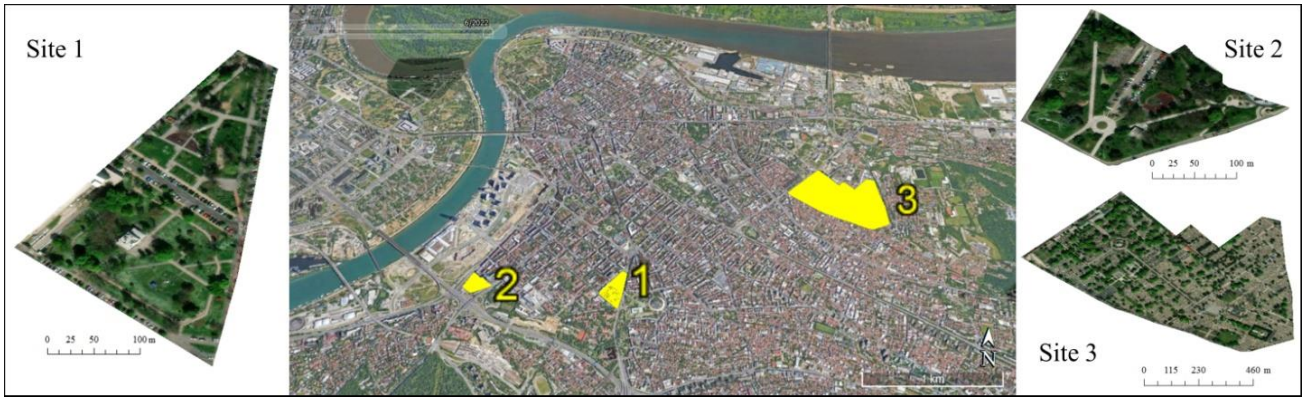

Figure 1. Research area

Site 1, spanning an area of 33.376 m^2, lies in the GI of Belgrade commonly known as Western Vračar (*Ser. Zapadni Vračar*). It is situated between Tiršova Street, Pasterova Street, and the Boulevard of Liberty (*Ser. Bulevar oslobođenja*). The park hosts 14 coralberry plants, all belonging to a 20-year-old group planting. It encircles the First Serbian Meteorological Observatory and underwent reconstruction in 2010 (source: JKP Zelenilo Beograd, https://www.zelenilo.rs/publikacije/zeleni-informator). Site 2, with a total area of 21.394 m^2, is in proximity to the E75 road, Kneza Miloša Street and some local roads. This area is within the Three Keys Park, formerly known as Beautiful Appearance (*Ser. Lep izgled*), which underwent reconstruction in 2022. Within this park, a solitary, mature coralberry plant, aged 23 years, has been recorded. Site 3, boasting an area of 310.102 m^2, is the New Cemetery situated on Ruzveltova Street. This cemetery, established in 1886, was the first planned and regulated burial ground in Belgrade. It is protected as an immovable cultural asset of Belgrade [5]. A line of 16 coralberry specimens, aged 27 was recorded. The total sample counts 31 selected plants which all remained healthy and undamaged throughout the 17-year research period, during which they were pruned in the cold part of the year before the growing season.

Phenological data spanning from 2007 to 2023 were obtained through visual observations conducted twice a week on the same day at all sites, using the extended *BBCH* scale, as defined by Meier [6]. The following dates were determined: the day of bud break (BB), i.e. flower bud scale opening in 2023, the beginning of flowering (BF), i.e. the day with more than 10% of the flowers open, the end of flowering (EF), marking the day when the flowering process was completed, and fruit abscission (FA) for the period spanning 2007 to 2023. Using the digital messaging system introduced by Koch et al. [7], these dates were converted into days of the year (DOY), with 31 January corresponding to 31 DOY. The calculation of the required number of cold hours (CH) for flower bud scale opening was based on the methodology of Cosmulescu & Ionescu [8], which entailed summing the hours when temperatures were below 7°C and above 0°C. This calculation began on 1 November, as the stated authors suggest that temperatures before this date are too high to contribute to the accumulation

of cold hours in a humid continental climate. We calculated the growing degree days (GDD) for the period after the bud break in 2023 and from 1 January to the beginning of flowering (BF) for 2007-2022. We followed the methodology outlined by Lalić et al. [9] and used a temperature threshold of 5°C, as recommended by the World Meteorological Organization (WMO) [10]. For the years 2007 to 2022, BF and EF were expressed as mean values determined based on data collected from the observed sites. The data obtained from phenological observations were statistically analysed employing descriptive statistics and the relationships between temperature and phenological events were examined using Spearman's correlation coefficient (ρ).

In addition, the fruit analysis comprised two diameters (R_1 and R_2), the length and width of the fruit clusters (LC), and the number of fruits in each cluster (№F). Fruits for analysis were handpicked in early autumn from the southern part of the canopy at the time when they had reached full maturity. To maintain the fruit moisture content, they were packed carefully in appropriate containers designed to prevent them from heating up. Each individual yielded a sample of 100 fruits whose diameters were measured using a Starrett 727 series digital calliper (Athol, NE, USA). The total number of sampled fruits stood at 3,100.

Quantitative data underwent statistical analysis, which included descriptive statistics, Spearman's correlation coefficient (ρ), one-way ANOVA, and cluster analysis. These statistical procedures were carried out using IBM SPSS Statistics 21, XLSTAT 2020, and ArcGIS/ArcMap 10.3. Meteorological data for the reference period of 1991-2020 and 2021/23 were sourced from the Main Meteorological Station in Belgrade (44º 47' 54.44"N; 20º 27' 53.35"EGr). This data was retrieved from RHMS (Republic Hydrometeorological Service of Serbia) on June 30, 2023.

3. RESULTS AND DISCUSSION

Green Infrastructure (GI), and its relationships with urban fabric patterns in highly urbanised environments, play a significant role in the planning and design of urban green spaces. Examination of GI within central Belgrade reveals its fragmented nature (Figure 1). Moreover, this densely built-up area is characterised by the limited number and size of green spaces. The urban vegetation predominantly comprises trees and lawns, with a relatively lower presence of shrubs such as coralberry in the overall composition.

Based on 16 years of records, it was determined that the lowest GDD for coralberry BF occurred in 2022 (530.3°C), while the highest was recorded in 2018 (876.1°C). In the case of EF, the lowest GDD was observed in 2011 (1825.8°C) and the highest in 2022 (3699.8°C). The mean GDD value for BF over the 16-year period was 714.2°C, while it was 2307.8°C for EF (Figure 2). Regarding BF, the lowest average DOY was 125 in 2022, while the highest was 147 in 2021. In the case of EF, the lowest DOY was recorded in 2011 (201), and the highest was in 2022 (325). The mean DOY value for BF over the 16-year period was 133, while it was 224 for EF (Figure 2). Linear trends and Spearman's correlation coefficient (0.930) indicate that over 16 consecutive years, there was a direct correlation between DOY and GDD for BF. Furthermore, the low values of standard deviation and variation coefficients suggest that there were no statistically significant differences between the research years. The obtained results align with Réaumur's findings [11], indicating that plant growth and development are more closely linked to the accumulation of heat units (GDD) than to daily air temperatures during phenophases. Linear trends for EF indicate growth in both DOY and GDD. However, Spearman's correlation coefficient of 0.141 suggests a relatively weak correlation. EF GDD exhibits substantial standard deviations alongside a low coefficient of variation. There is clear evidence of an increase in mean annual temperatures during the phenophases, which affects their duration [12]. Furthermore, these results affirm the impact of extreme climatic events and climate changes on the prolongation of phenophases [10].

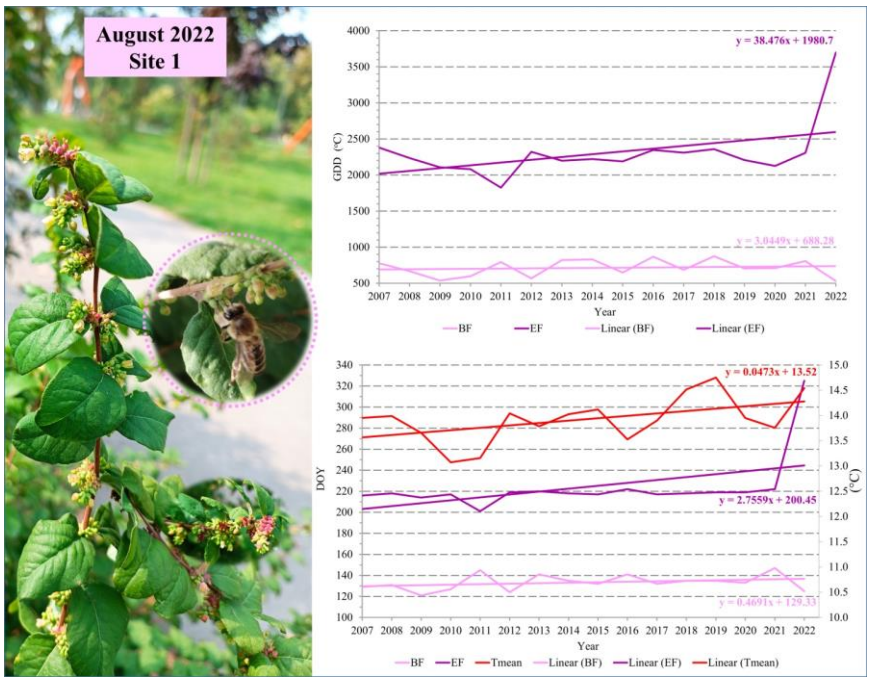

Figure 2. Coralberry Phenogram – DOY and GDD for BF and EF parameters from 2007 to 2022 at research sites, mean annual air temperatures, and linear trends

Given that 2022 marked the second-warmest year in Belgrade since 1888 (RHMS), the research in 2023 was conducted on the sites whose number of accumulated cold hours (CH) between 1 November 2022 and the bud break in 2023 varied from 1763 hours at Site 1 to 1776 hours at Sites 2 and 3. It should be noted that bud break varies with individual plants and locations, as well as the requirement for growing degree days (GDD) after dormancy [13]. The lowest value for BF was recorded at Site 1 (10.5°C), followed by Site 3 (17.5°C), and Site 2 (28.5°C). Spearman's correlation coefficients computed for BF, with a probability of $p<0.05$, confirmed the statistically significant positive correlation between CH and the number of days from 1 November. However, no other correlations were found to be significant. These findings provide a crucial foundation for the planning and sustainability of green infrastructures that include coralberry as a species whose flowers serve as a source of nectar for bees, wasps, and flies (Figure 2). The fruits, displaying hues of purple, pinkish-purple, and coral-pink, ripened successively. Their dispersion (FA) started in late autumn, primarily due to consumption by birds. Throughout all the years of our research, they persisted until the summer of the following year. These findings contrast with the conclusions presented in Link [14] and Hidayati et al. [15] that the fruits typically endure until spring, which may be indicative of the impact of urbanisation or the Urban Heat Island (UHI) effect across all research sites. Our study aligns with the hypothesis that fruits of red hues represent an evolutionary trait associated with bird preferences for these specific colours [16].

The research has provided insights into the morphological traits of fruits and their clusters, contributing to our understanding of the acclimatisation of the coralberry, a non-native species introduced from North America, in the GI of Belgrade [13]. Since the fruits of the coralberry persist through the winter, a period when a small number of species in GI Belgrade bear fruits, we investigated the metric and morphological features of these fruits and their clusters.

The minimum R_1 ranged from 2 mm (Site 2) to 6 mm (Site 3), while R_2 ranged from 1 mm (Sites 1 and 2) to 5 mm (Site 3). Conversely, the maximum R_1 was between 9 mm (Sites 2 and 3) and 10 mm (at Site 1), while R_2 ranged from 7 mm (Site 2) to 8 mm (Sites 1 and 3). Both diameters exhibited low standard deviations and correlation coefficients, indicating low variability within the study sites. Compared to the results reported by Link [14] and Hidayati et al. [15] that the diameter variation typically ranges from 4 mm to 4.5 mm, the recorded mean diameters were larger at all sites, ranging from 5.4 mm to 7.6 mm. One-way ANOVA test, with a p-value of <0.0001, and F-values of 8.070 for R_1 and 5.325 for R_2 confirmed the lack of statistical significance between the sites. Moreover, the

dimensions of fruit clusters and the number of fruits per cluster had not been previously studied. Our research revealed that the average length of the clusters ranged from 22.74 mm (Site 3) to 25.26 mm (Site 1), while the width ranged from 14.04 mm (Site 3) to 17.59 mm (Site 1). Statistical insignificance was confirmed by the small values of the standard deviation, correlation coefficients, as well as the values of the F of the one-way ANOVA test ($p<0.0001$) of 1.292, and 11.098, respectively. The mean number of fruits per cluster ranged from 11.370 (Site 3) to 19.22 (Site 1). The small values of standard deviation and coefficient of variation suggest approximately the same number of fruits per cluster within each location. Furthermore, the F-test of one-way ANOVA yielded a value of 17.641, indicating relatively low significance in the differences between the study sites. Spearman's correlation coefficients (0.653, 0.718, and 0.719) indicate a significant correlation between the length of the cluster and the number of fruits per cluster in 2022, as expected. However, for the other parameters, Spearman's correlation coefficients were either insignificant or of very low significance.

According to Reyers et al. [17], it is essential to adapt to the local context and apply an approach that includes mutual relations. To achieve this goal, and to determine the extent of additional services of GI ecosystems with coralberry, a cluster analysis was conducted using the morphometric characteristics of clusters and fruits (Figure 3). Based on the morphometric characteristics of coralberry fruits and their clusters, Sites 1 and 2 were identified as a closely related pair. Both sites are parks within the municipality of Savski Venac, where the urbanisation rate stands at 91.89%. In contrast, Site 3 – the New Cemetery in the municipality of Palilula, with an urbanisation rate of 10.33%, exhibits significant differences regarding the analysed characteristics (https://land.copernicus.eu/local/urban-atlas/urban-atlas-2018).

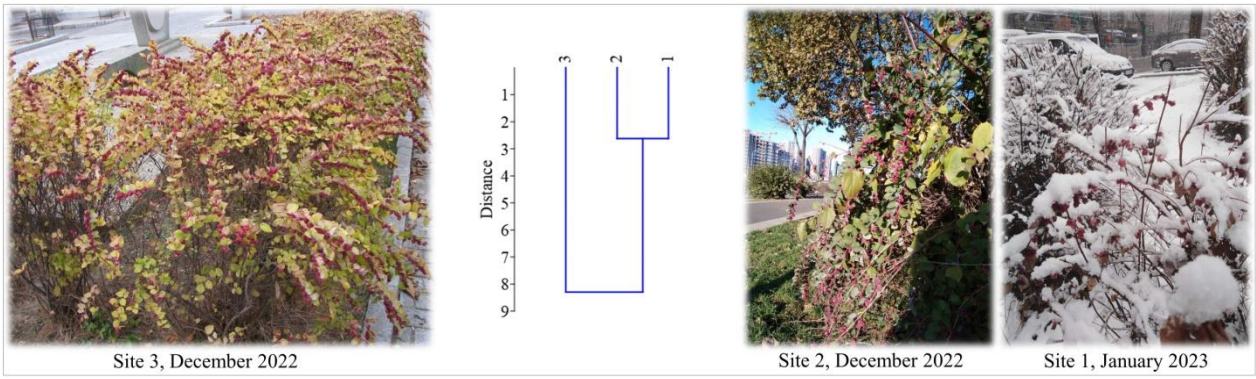

Figure 3. Cluster analysis conducted using morphometric traits of fruits and clusters with accompanying personal photographic material from the studied GI elements in Belgrade

4. CONCLUSION

The obtained results confirm the significance of coralberry as a component of GI in highly urbanised areas. It enables the creation of vibrant and cascading visual effects (with its arched branches) during autumn and winter and its fruits serve as a valuable food source for birds and small mammals. This research contributes to our expanding understanding of coralberry's interactions with the environment and its impact on ecosystem services. The findings suggest that when selecting plant species for GI in UHI areas, fruit colour should be taken into consideration. This applies to both new elements and the reconstruction of existing ones, as it can expedite the ecological succession process and optimise additional ecosystem services.

This research was supported by the Ministry of Education, Science, and Technological Development of the Republic of Serbia [451-03-47/2023-01/20016]

CHEMICAL VARIABILITY OF PERSONAL CARE AND COSMETIC PRODUCTS

Anja Bubik[1], Faculty of Environmental Protection, Slovenia
Katrin Školnik Škrabe[2], Faculty of Environmental Protection, Slovenia

Abstract: *Personal care and cosmetic products (PCCPs) are diverse group of products designed to maintain a good personal hygiene and health, enhance the appearance, and promote overall well-being. Today, the cosmetic industry is offering a vast number of PCCPs, but although the field is regulated and constantly evolving, it is necessary to be aware of various chemical ingredients. Based on the EU Cosmetic Regulation 1223/2009, around 26,000 common ingredients are present in PCCPs and approx. 1,300 substances are currently prohibited in the EU.*
Within the Erasmus+ project GreenGate, which addresses the safety use and healthy choice of cosmetics, we studied the chemical variability of commercially available PCCPs. The number of chemicals was quantified using the data from ingredient lists, and a detailed analysis was performed based on the categorization of PCCPs into seven groups according to their intended use. The average number of ingredients among 458 PCCPs was 19. Decorative cosmetic products were the most diverse and variable group of PCCPs based on the chemical composition. On the other hand, hair care products possessed the highest average number of ingredients (22) with a maximum of 51. Through a brief survey, the unawareness of the average cosmetics users was highlighted.
Keywords: Personal Care and Cosmetic Products, Chemicals, Ingredient List, Survey, Awareness

1. INTRODUCTION

The skin is more than just another simple biological barrier membrane. It is a selectively permeable barrier which encounters various substances and agents from the environment daily and serves several vital functions that are crucial for our overall health and well-being. Additionally, it is the most visible aspect of the human phenotype and the largest organ of the human body [1,2]. It comes in direct contact with various of chemicals daily and can acts as a gateway through which these chemicals may infiltrate our bloodstream.
Personal care and cosmetic products (PCCPs) are also such kind of products, produced and applied in a huge amount worldwide. For some, cosmetic products may seem like a recent invention because of their mass production, availability, and consumers' growing demands. However, discoveries and benefits of their use go back thousands of years. Throughout history, civilizations have used cosmetics for different purposes. Today, there are many different PCCPs, with thousands of brand names and chemical compositions. These chemical mixtures can be derived from natural or synthetic sources. In accordance with Art. 2 of Regulation (EC) No 1223/2009 on cosmetic products, a 'cosmetic product' means *"any substance or mixture intended to be placed in contact with the external parts of the human body (epidermis, hair system, nails, lips and external genital organs) or with the teeth and the mucous membranes of the oral cavity with a view exclusively or mainly to cleaning them, perfuming them, changing their appearance, protecting them, keeping them in good condition or correcting body odours"* [3, 4]. The key difference between cosmetics and personal care products is that cosmetics are chemical compounds used for the enhancement of the appearance of a person, whereas personal care products are chemical compounds that are used to maintain good personal

[1]anja.bubik@fvo.si
[2]katrin.skolnik@gmail.com

hygiene and health as well the enhancement of appearance. So, cosmetics are also a type of personal care products [4].
In recent years, the PCCP industry has been booming in Europe as more and more consumers become increasingly aware of the importance of their health. According to the Cosmetics Europe association data, 60 % of people believe that cosmetics have a positive impact on their life, and as many as 88 % find it difficult to imagine life without cosmetics [5]. Within the European cosmetics market, Germany consumed the largest number of cosmetics in 2021, followed by France and Italy, the three countries together valued at approx. 40 billion euros. Among all, skin care is still the dominant force in the cosmetic industry in Europe, capturing more than 27 % of the European cosmetics market in 2019 [5].
There are a vast number of PCCPs on the market with numerous brands, offering a diverse selection of products for different preferences, needs and trends. The cosmetic industry is also very dynamic and is evolving constantly, since new products are introduced regularly, reflecting advancements in formulation technologies, emerging beauty trends, and consumer demands. But being aware of chemicals in cosmetics is very important for several reasons, from personal health and safety to environmental risks. Cosmetics typically contain a variety of chemical compounds that serve different purposes, such as preserving the product, enhancing its texture, providing colour, or delivering specific skincare benefits. These chemicals can include preservatives, emulsifiers, fragrances, colorants, antioxidants, and active ingredients, among others. While cosmetics can be beneficial for skin health and aesthetics, it's essential for individuals to be aware of the ingredients in the products they use, as well as any potential sensitivities or allergies, to ensure that cosmetics are used safely and effectively. Based on EU Cosmetic Regulation (No. 1223/2009) there are around 26,000 common ingredient names for PCCPs and only approx. 1,300 substances are currently prohibited in cosmetic products in the EU [3]. In terms of numbers, there is still considerable room for improvement in terms of chemical safety and possible healthier alternatives. Additionally, since PCCPs can be consumed only for external usage, they are more likely to enter the environment in large quantities due to human activities and can cause more damage to different ecosystems. No matter the type, leave-on or rinsed-off products, these products enter the environment depending on the ability and efficiency of the sewage treatment plants to remove them [6]. Some chemicals used in cosmetics have also the potential to cause adverse effects on our health.
The main objective of the research was to quantitatively highlight the presence of chemicals in our everyday care and raise the awareness on safety use and healthy choice of cosmetics among the adults.

2. METHODOLOGY

The research was partly conducted within the international project entitled *"GreenGate - Towards responsible choice and healthy use of cosmetic products"*, founded by the EU Erasmus+ Programme. It addresses the problem of insufficient education and awareness of adults of harmful substances in cosmetics, cleaning and washing products and is in line with the *"EU's chemicals strategy for sustainability towards a toxic-free environment"* that is a part of the EU's zero pollution ambitions, a key commitment of the EU Green Deal [7]. By educating adults through innovative learning content and related tools, project aims to prevent the use of harmful cosmetic products, positively impact their health, and protect the environment. The consequences of insufficient solving of this issue lead to increase in allergies, diseases, and consumer hypersensitivity to certain substances in products and increased environmental pollution due to the use of products containing harmful substances. As an upgrade of the project activities the determination and evaluation of the chemical variability in randomly selected PCCPs was performed. From all of 500 collected products, cleaning products were eliminated, and the remaining 458 products were analysed for chemical composition based on the ingredient list. 34,4 % of products were of Slovenian origin. Due to the large number of data, products were categorized into 7 groups based on their characteristics and use:

- ✓ **Category 1: SKIN CARE** (Facial creams, Body lotions, Hand & Foot creams, Moisturisers, Eye creams, Toners, Hydrating & anti-aging creams, Serums, Sun Protection products)
- ✓ **Category 2: BODY CARE** (Shower gels, Body washes, Soaps, Oils)
- ✓ **Category 3: HAIR CARE** (Shampoos, Conditioners, Serums, Hair colourants and Lotions)
- ✓ **Category 4: DEODORANTS**
- ✓ **Category 5: PEELING & CLEANING** (Facial masks, Cleansing lotions, Scrubs, Exfoliators)
- ✓ **Category 6: ORAL CARE** (Toothpastes, Mouthwashes)
- ✓ **Category 7: DECORATIVE COSMETICS** (Lip & eyeliner, Lipstick & glosses, Foundations, Powders, Eye shadows, Mascaras, Blushes, Nail varnishes)

Among all, the "Skin care" category was the most represented with 36,2 % of products, while the representation of remaining categories varied between 5,7 and 14,8 % (Figure 1). After grouping products, we quantified the number of chemicals using the ingredient lists and determined the variability, diversity, and frequency of chemicals in each category. Additionally, short survey about the public awareness was performed to check their opinion and raise their awareness on the topic. 207 people of different age groups collaborated in the online survey and two thirds of respondents were women. All data were analyzed using Microsoft Excel 2011.

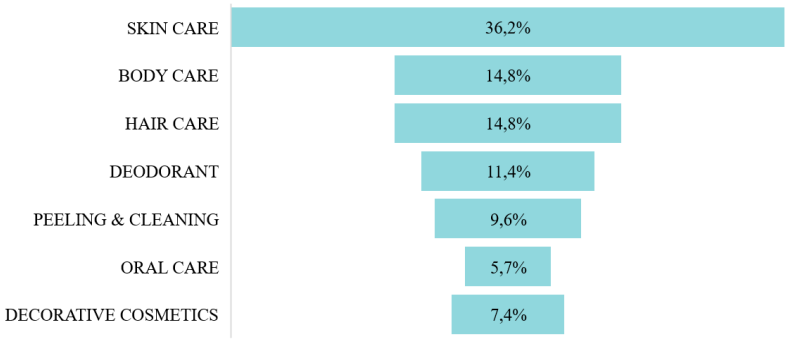

Figure 1. PCCPs categories included in the analysis of chemical variability
Source: A. Bubik

3. RESULTS

The average number of ingredients among 458 of randomly selected PCCPs was 19. Hair care products possess the highest average number of ingredients (22) with a maximum of 51 (Table 1). Skin care products also contain 22 chemical ingredients on average with a bit lower maximum value (48) compared to hair care products. The category of oral care product contained the fewest chemicals on average – 13. Chemical diversity was the highest among the skin care products (Table 1*).

Table 1. Chemical diversity and variability within the PCCPs categories
Source: *A. Bubik*

		Chemical Diversity/Variability		No of Chemicals/product		
				AVERAGE	MIN	MAX
1	**SKIN CARE**	**663***	4,0	22	1	48
2	**BODY CARE**	316	4,6	19	10	33
3	**HAIR CARE**	438	6,4	**22**	9	**51**
4	**DEODORANTS**	225	4,3	18	6	28
5	**PEELING & CLEANING**	330	7,5	20	5	40
6	**ORAL CARE**	127	4,9	13	2	24
7	**DECORATIVE COSMETICS**	264	**7,8****	20	4	48

As this category is composed of various products for the skin care and is also the dominant force in the cosmetic industry in Europe, the results were expected. The variability of chemicals was the

highest in the category “Decorative cosmetics”, as it was calculated that almost 8 different ingredients are used in each product on average (Table 1**).
Among the ingredients five the most commonly presents chemicals of each category were collected and are listed in the Table 2. As expected, water (“Aqua”) is the most commonly present ingredients in PCCPs. Regardless the category of “Deodorants”, water is presents in majority of products; in the category “Peeling & skin cleaning products” even in 95,5% of products. Second the most found ingredients is “Parfum”. In oral care products parfums were not found. It is just a speculation, that those products are free of parfums. It is very well known that the term "parfum" or "perfume" in cosmetics typically refers to a mixture of fragrant essential oils and aroma compounds, along with solvents and fixatives. Cosmetic companies often list "parfum" or "perfume" as an ingredient on product labels to protect their proprietary fragrance blends, which are considered trade secrets. This means that the exact composition of the fragrance mixture is not disclosed to consumers. This information is of a sensitive nature and necessitates a careful costumer approach. If a costumer possesses specific concerns about allergies or sensitivities to fragrance ingredients in cosmetics, it's advisable to choose products that are free of fragrance. Limonene (citrus scent) and linalool (lavender scent) are among the most common fragrance terpenes used in multiple household products and PCCPs. They both oxidize upon contact with air forming hydroperoxides as primary oxidation products, and these have been recognized as important contact allergens [8]. On interesting founding was CI 77499 as the 5th most common component in decorative cosmetics. CI 77499 or a black iron oxide is a colouring agent in cosmetic products, which typically offer enduring colour with no frequent reapplication once applied.
Using short survey in the last part of the research we confirmed, people are unaware of the real extent of the chemical ingredients in PCCPs. Survey was focused on the categories, which showed the highest numbers regarding ingredients in the 1st part of the research, like hair care product. Results showed that almost all respondents (94%) of our survey agree, that commercial shampoos contain a lot of chemicals, but majority of them (79,3%) meant, that they possess less than 20 ingredients (Figure 2). Our research revealed opposite; hair care products contain 22 different chemicals on average (Table 1).

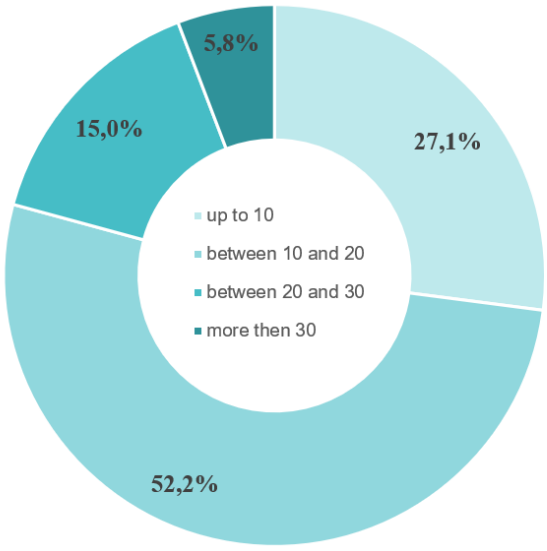

Figure 2. Survey respondent opinion about the number of chemicals presents in our shampoos

4	Phenoxyethanol	Glycerin	Linalool	Citral	Citric Acid	Limonene	Limonene
	44,6%	72,1%	60,3%	65,4%	50,0%	57,7%	47,1%
5	Cetearyl Alcohol	Cocamidopropyl Betaine	Limonene	**Aqua**	Sodium Hydroxide	Sodium Saccharin	CI 77499
	42,2%	70,6%	52,9%	**59,6%**	45,5%	50,0%	44,1%

4. CONCLUSION

It's important to note that commercial cosmetic products contain a variety of synthetic chemicals, which can have various effects on our skin, overall health, and the environment. But it is also crucial to emphasize that not all chemicals in cosmetics are harmful, and many have been thoroughly tested for safety. However, the safety of cosmetic chemicals is a key concern, and regulatory agencies in many countries establish guidelines and regulations to ensure that cosmetics are safe for consumer use. Additionally, consumers should be proactive in researching and understanding the ingredients in the products they use, especially if they have specific skin sensitivities or allergies. To stay informed about chemicals in cosmetics, individuals can read ingredient labels, research specific ingredients or product formulations, and refer to resources such as databases or guides provided by regulatory authorities or trusted organizations focused on consumer safety and health. Many companies are now also offering products with natural and organic ingredients, catering to individuals seeking alternatives to synthetic chemicals. Moreover, by creating homemade products, individuals can have full control over the ingredients used, ensuring that they are natural and safe.
Ultimately, the choices we make as consumers can play a significant role in shaping the cosmetic industry, encouraging transparency, safety, and sustainability. Being informed and conscious consumers can lead to healthier choices for ourselves and the environment.

This research was partially supported by EU Erasmus+ Programme [grant number 2021-1-CZ01-KA2020-ADU-000026171].

TECHNICAL-TECHNOLOGICAL DISASTERS, RISK ASSESSMENT AND ENVIRONMENTAL SECURITY

Miloš Tošović[1], Faculty of security studies, University of Belgrade

Abstract: *Modern complex production systems are based on newer technologies, technologically advanced production machines and plants, and modern monitoring and surveillance systems. Oversights occasionally occur in work and functioning, which result in minor or major malfunctions, sometimes breakdowns, which are followed by accident situations that lead to technical-technological disasters. In the modern concept of security for the timely prevention of tragic consequences for people and material goods or their reduction to a minimum, an appropriate risk assessment is carried out, in order to implement risk management and more secure and more efficient production in practice. On the basis of risk indicators, modern risk management standards, integrated risk management and production processes management is applied. In the analysis of the accompanying security aspects, a particularly important place holds the analysis of the conditions and ways of achieving the required level of environmental security, especially in the part related to the working and living environment, including plant and animal life and environmental media.*
Keywords: technical-technological disasters, risk assessment, security, environmental security.

1. INTRODUCTION

The current human needs for certain materials and products, in the conditions of a growing market, increasingly require the realization of various technical-technological complex production processes. Such modern business conditions are accompanied by certain security risks, which must be identified, analyzed and assessed in a timely manner [1].
Disaster risk, until the 1970s, was perceived as a direct consequence of natural hazards [2], and then it began to be understood as caused by the intersection of hazards, exposure and vulnerability of influential elements. After several decades of research on various mega-disasters, scientists have introduced the social dimension of disaster risk, with the understanding that disasters are a human construct [3], which requires risk assessment and appropriate handlling [4] through risk management and the integration of risk management and processes [5]. In the multidimensional risk assessment associated with anthropological disasters, different components of risk (hazard, exposure, vulnerability and resilience) are considered, which are observed in the combined natural and socio-economic causation in the disaster risk assessment model.
Various natural and especially anthropogenic disasters, depending on the environment, accompanying processes and conditions of origin and development, are accompanied by different types of risk of consequences for material resources, housing and other objects, human lives and environmental consequences. In parallel with achieving the goals of sustainable development, there is a need to promote sustainability, inclusive and sustainable economic growth, full employment and dignified work [6]. On the other hand, there is a need for development that is more secure for people while promoting a better quality environment. Accordingly, various influential factors, including technical-technological disasters, must not cause harmful consequences for people and the environment [7]; from the point of view of security [8] this is especially covered by environmental

[1] milostosovic79@gmail.com

security. The main goal of this paper is to point out the functional connection that exists between technical-technological disasters, the necessary risk assessment and the realization of the necessary level of environmental security in the living and working environment.

2. TECHNICAL-TECHNOLOGICAL DISASTERS AS A SECURITY PROBLEM

In the third decade of the 21st century, the increasingly numerous human population has become significantly more technical-technological advanced, while facing numerous security risks brought by new technological solutions and applications of new advanced technologies, modern monitoring and surveillance systems. In addition to natural disasters, such as floods, earthquakes, droughts, etc., which affect the economy and the population, in environmental security, the manifestation of security aspects of technical-technological disasters is particularly specific [1]. In the conditions of current social and economic development, environmental and other disasters have become an integral part of the functioning of modern society, with the direct or indirect influence of man on their occurrence and consequences.

The 2009 United Nations International Strategy for Disaster Reduction [9] defines a disaster as a serious disruption in the functioning of a community or society, with widespread human, material, economic and environmental losses and impacts, which exceed the ability of the affected community or society to cope using own resources.

Contemporary socio-economic development, accompanied by an irresponsible attitude towards nature, due to man's desire for an excessive increase in material wealth, has led to a dangerous situation of real and serious anxiety of humanity for its future perspective, quality of life and survival on Earth [10]. On this basis, there has been a development of social awareness about the necessity of rational and moderate exploitation and use of natural resources and of bringing economic development into harmony with the real possibilities of the natural environment, which includes a very important aspect of environmental sustainability.

Man's relationship with the environment, which for decades has been more destructive than constructive [11], has led to a number of different global, regional and local environmental problems. These environmental problems culminated in numerous examples in the emergence of various environmental crises and disasters. Due to the pronounced influence of negative human action on the environment [12], in recent decades there has been an increase in natural and technological disasters in the world.

Various forms of threats to humans and ecosystems dictate the need to improve the conditions of survival and sustainability of current and future generations. Solving this issue requires implications on policies based on activities, which will contribute to sustainable development by investigating the effects of various factors on economic growth [13] and the effects of new technologies on the prevention of technical-technological disasters and their consequences. There exists a kind of paradox between human progress and an increased sense of insecurity [14]. The disaster risk arises when the hazards come into contact with physical, social and environmental threats. According to Vlahos [15], environmental disasters caused by anthropogenic factors include the following: (a) industrial accidents with chemical and radioactive environmental pollution; (b) pollution of river courses; (v) degradation of natural resources; and (g) environmental-political upheavals (eg wars, revolutions, etc.).

Various technologies, especially technologies for processing certain raw materials and creating by-products, have become potentially dangerous for man and his immediate and distant environment, due to the following [1]: (a) inappropriate management of technologies; (b) inadequate choice of location; (v) low-quality technological solutions; and (g) irresponsible behavior of people, society and individuals. As a result, accidents occur, sometimes with catastrophic long-term and unforeseeable consequences for people and environmental security. Contemporary scientific and technological development of society has led to the growth of standards, but also to the increase of security problems and various types of risks in different areas of human activity, including economic, social and environmental aspects of sustainability, accompanying risks and security [1].

3. DISASTER RISK ASSESSMENT

Effective, long-term disaster risk reduction requires taking into account the dynamics of each of the influencing components and the mode of population, economic and climate change, as well as appropriate policies and decisions. It is especially important to apply the appropriate methodology to include these factors within research scenarios designed for smaller losses in disasters. The developed scenarios and their subsequent analysis combine the knowledge and insight of stakeholders and experts as well as the use of simulation modeling in risk assessment and in contributing to strategic risk reduction [16].

The impact of disasters on a global scale is increasing, and existing projections of economic and population growth, together with the impacts of climate change, show that the associated losses will increase in the future [17]. Hence, disaster risk reduction is necessary as an ongoing activity, which includes active efforts to reduce the impact of anthropogenic disasters, but also includes accompanying actions and measures. Planners of disaster risk reduction strategies face difficult decisions regarding resource allocation, scheduling, and planning priorities. Effective disaster risk reduction requires consideration of long-term changes, along with sources of uncertainty for integrated responses to disaster threats.

The disaster risk reduction process inherently exhibits factors of complexity. Designing, testing and implementing risk reduction strategies requires the collection, processing and interpretation of a large amount of data and information from a number of different natural, engineering and social disciplines, among which security is one of the most important. There is a need to incorporate numerous aspects from the local to the international level in the planning and implementation of disaster risk reduction to prevent unwanted outcomes related to various anthropogenic disasters.

Uncertainty in factors affecting disaster risk is also significant, affecting trends in risk components such as economic, population and climate change, urbanization rates, the impact of new technologies and political factors. Disaster risk reduction therefore needs to consider and integrate these uncertainties, especially in risk reduction investment plans and decisions. Determining certain weak points in technical-technological systems in terms of risk should be followed by appropriate improvements in production processes, through redesigning and reengineering processes in order to minimize the perceived risks.

Disaster risk reduction efforts are based on risk assessments and identification of management actions for risk reduction. Such risk assessments in earlier development periods mostly had a static approach taking into account the current risk, which is insufficient to include the mentioned complexities and uncertainties [18]. Their inclusion by risk assessment can be achieved through scenario analysis, with relevant assumptions of tomorrow for a range of stakeholders and expected circumstances, together with the dynamics of disaster risk factors. Therefore, there is a need for an adequate approach in risk assessment, which can include all these elements in risk assessment scenarios [16].

4. RELEVANCE OF ENVIRONMENTAL SECURITY IN CONTEMPORARY CONDITIONS

The contemporary trend of ecology, environmental analyses and environmental problems dictate the inevitable need for a comprehensive perception of environmental security problems. This kind of perception has gained particular importance if the connections and contradictions in the relation between nature, society and the economy are taken into account, which are manifested through environmental security issues [10]. The redefinition of the concept of security begins after the relaxation of the bloc tension of the Eastern and Western bloc countries. In the early 1980s, environmental factors were integrated into the concept of security [19]. In the 1990s, the concept of security was expanded to use the concepts of environmental security, food security, health security, energy security and income security [20].

In the last decade, an increasing number of authors on the international scene use the term environmental security implying the concept of sustainable development, which is at the core of environmental security, while in Serbia the term environmental security is mostly used, which includes the concept of sustainable development, but also the threat to political stability [20]. Environmental security, without which there is no social and economic progress, requires taking the necessary measures to reduce political and ethnic conflicts and prevent the further implementation of environmental crime [21].

The topicality of environmental security stems from the fact that at a time of increasing importance of ecology in all production and social activities, environmental security is becoming part of the security policy of most countries in the world. At the same time, one cannot talk about a complete concept of security [10, 20] if the issues of environmental degradation and protection, scarcity of resources, water and food security, energy, population problems, destruction of ecosystems, migration, natural or human-caused disasters, climate change, environmental crime, environmental terrorism or violence related to environmental degradation are not considered.

The contemporary security approach mandates the obligation to define and assess the risk of technical-technological disasters for the purpose of: (a) preventive action; and (b) ensuring effective action according to the principles of crisis management in the event of an eventual manifestation. A broader analysis of security aspects according to the analytical research carried out in this paper especially includes the relational connections of these disasters with the binding concept of sustainable development and, within that, the particularly significant and current issue of environmental sustainability [1].

5. THE RELATION OF TECHNICAL-TECHNOLOGICAL DISASTERS, RISK ASSESSMENT AND ENVIRONMENTAL SECURITY

The functional consideration of the issue of technical-technological disasters has a wider analytical triangular framework, on the one hand there is the security analysis of potential technical-technological disasters, on the other hand the required level of disaster risk assessment, and on the third hand the achievement of the required level of environmental security, which will be manifested at the local, regional and wider area. In the subject consideration, for the needs of the research-analytical procedure, it is possible to single out dual interconnection relations, which connect pairs of individually separated analytical elements.

The relation of technical-technological disasters - risk assessment is a starting point, because it fits into the concept of risk assessment in a broader sense in the domain of disasters and especially in a narrower sense in the part that refers to technical-technological disasters in various material, energy, economic and other production systems. Undertaking measures aimed at eliminating the causes of occurrence and/or minimizing the effects of a risky event in the case of various technical-technological systems, as well as measures to ensure minimal losses and eliminate the consequences if risky events occur, is, according to the general approach [22], the starting point of risk management of technical-technological disasters.

The relation of technical-technological disasters - environmental security is related to the consequences of security violations due to the occurrence of these types of disasters, especially in the part of the environmental aspects of the impact on the environment, that is, from the point of view of security, it is related to a partial part of environmental security. According to the general approach [22], the field of action of hazard factors of technical-technological disasters does not only include the immediate environment of these production systems, but also often covers a wider territory, including the territories of other countries. In this way, the number of potentially endangered people and material resources, as well as the territory of possible endangerment of the environment, i.e. violation of environmental security, directly increases. Analyzing potential environmental hazards and possible environmental impacts is particularly important in order to achieve the required level of environmental security.

The relation of risk assessment - environmental security is particularly important because of the necessary frameworks, policies, responsibilities and resources for risk management of technical-technological disasters, including the partial environmental aspect. The basic framework for risk management is defined by international standards ISO 31000 [23], which helps organizations to effectively manage risks through processes at various organizational levels. The focus is on environmental aspects, according to which it is necessary to prepare appropriate risk information, derived from the characteristics of technical-technological processes, in order to achieve the required security level of development of the process itself and the security level of people in the process, as well as the security level of the environment.

6. CONCLUSION

The current conditions of the dominant importance of ecology and the environmental trend in economic and human activities of different types and scope, especially in technical-technological complex systems, reflect the special need to expand consideration to various environmental aspects. Among them, the following can be singled out as particularly interesting and functionally significant: technical-technological disasters, risk assessment and environmental security.

The impact of disasters at the global level is increasing, especially in terms of insured losses, that is, various costs of their consequences, and further projections of economic and population growth indicate a trend of their increase in the future. Hence, anthropogenic disaster risk reduction is necessary as a permanent activity, which includes active efforts to reduce the corresponding impacts and hazards, along with technical-technological improvements. The topicality of environmental security in conditions of increasing importance of ecology in production and social activities, conditions the professional obligation of special integrated security analyses according to the comprehensive concept of security.

The functional consideration of the issue of technical-technological disasters has a wider analytical triangular framework, in which through the research-analytical procedure, it is possible to single out dual interconnection relations, which connect pairs of individually separated analytical elements, namely: (i) the relation of technical-technological disasters - risk assessment; (ii) the relation of technical-technological disasters - environmental security; and (iii) the relation of risk assessment - environmental security.

Integrated viewed in a broader environmental and security consideration and approach, the triple relation of technical-technological disasters - risk assessment - environmental security is procedurally, security-wise and functionally very important in the contemporary conditions of the current environmental trend and the need to ensure environmental security for people, objects, material goods and environment media. The same is particularly important in order to achieve integrated risk management, which should be incorporated into the organizational management system with an appropriate level of performance of the production process and managerial, economic and more secure business.

ECONOMIC CONSIDERATIONS OF THE RELATIONSHIP OF NATIONAL INCOME, MINERAL RESERVES AND ENVIRONMENTAL ACCOUNTING

Radule Tošović[1], Faculty of Mining and Geology, University of Belgrade

Abstract: *In current economic considerations for standards of economic progress, the measurement of economic activity at the country level is particularly important. In that domain, gross national product (GNP) and gross domestic product (GDP) are successfully used as standard measures of economic development. The question of their definition and monitoring relies to a significant extent on the available natural resources, a very significant part of which includes mineral resources and mineral reserves. At the same time, basic mineral production represents the initial production link for many economic branches and many forms of accompanying production, which could not be realized if there were no mineral raw materials produced, that is, if there are no different mineral components. Consideration of the national income and the direction of further economic development policy start from the existing capital funds, namely: (a) produced capital; (b) human capital; and (c) natural capital. Accounting for natural resources and particularly significant mineral resources and mineral reserves occupies a particularly important place in the essential economic analysis. As an integral part of the modern comprehensive analytical approach, environmental aspects are also taken into account, with the inclusion of analytical elements of environmental accounting and the connection with economically significant mineral reserves.*
Key words: economy, national income, mineral reserves, accounting, environment.

1. INTRODUCTION

Both world and national economic trends have a direct and very significant connection with the mineral economy and the mineral sector at the observed level of economic analysis. The developments in question are partly related to the complex market of mineral raw materials, partly to the prices of mineral raw materials, and partly to the contribution of the mineral sector to the national income, that is, to the social and economic development of the country. It is a fact that in the modern conditions of modern material production, certain mineral raw materials are of strategic importance and are considered at the European and world level through the so-called critical mineral raw materials. In countries with developed mineral economies, strategies for securing them are very current, both from the natural point of view of the quantity and quality of mineral reserves, and from the economic point of view of the contribution to the national income and economic development [1].

Contemporary consideration of the conditions and methods of achieving national income is linked to complex analyzes of the realization of newly created value from various economic branches, especially the strategically and economically sensitive mineral sector, but also the analysis of the relevant relationship to the natural resources of the environment, especially mineral resources as basic economic elements of material production. The individual economic development plans of a large number of countries are based precisely on initial analyzes of availability, conditions and ways of using mineral reserves of metallic, non-metallic and energy mineral raw materials. Certain development projections in certain countries show a direct dependence on certain mineral raw

[1] radule.tosovic@rgf.bg.ac.rs , toshovic@yahoo.com

materials, so that the plans for achieving the national income directly depend on their price, supply and demand, the possibility of placement in terms of quantity and quality, but also on the action of special strategic and non-economic factors [2].
As part of the comprehensive consideration of social development issues, especially the part based on mineral raw materials, especially in domestic conditions in Serbia, it is very important to consider the relationship regarding the environment, issues of ecological economics and environmental accounting. In addition to the issue of securing the required amount of mineral raw materials, the issue of environmental costs of their material production, issues of pollution prevention, costs of environmental protection and costs of elimination of environmental impact is unavoidable. On the other hand, the cost burden of a unit of mineral reserves is analyzed analytically against the question of market price, profit rate and profitability rate, all in accordance with the principles of economic geology and the economics of mineral resources [3].
Consideration of the interrelationship between national income - mineral reserves - environment in the mineral sector is very significant, especially in the part with an overview of the importance in the economy of the company [4, 5, 6], business policy and strategy [7, 8] and management in the company [9]. The main goal of this research and analytical work is to, in accordance with the modern level of the subject matter [10-23], indicate the operational importance of considering mineral reserves according to driving economic activities and direct participation in the national income, but especially according to the ecological aspect and accounting elements of the economy environment.

2. ENVIRONMENTAL CONSIDERATION ITEMS OF NATIONAL INCOME

The realization of the national income is related to various analytical aspects of its acquisition as well as the realization of the final results, in which mineral resources also take part. Initial economic consideration [10] is related to the prior definition of the type of standard measures of gross national product (GNP) or gross domestic product (GDP), which are most often used to measure the level of economic activity and progress in the country's development. Almost all statistics used in macroeconomic analysis are based on these measures, as standards of economic progress.
In practical application, GNP/GDP can give a wrong impression of economic development, due to the existence of inconsistencies, such as failure to account for unpaid work, production for domestic consumption and the value of leisure time. Since GNP/GDP measures only goods exchanged in the market, they leave out labor in the household sector, do not include indicators of health, life expectancy or education level, nor reflect income inequality. Countries with extreme inequality may have higher GDP per capita than countries where income is distributed more equally, even though the average resident in the other country is wealthier. In addition, from the analytical point of view of the issues of this paper, it is particularly important to emphasize that GNP/GDP do not account for environmental degradation and resource depletion. [11]. The subject matter is very important for developing countries, which rely heavily on natural resources, especially mineral resources. If a country clears its forests, digs up mineral reserves, reduces soil fertility and pollutes water sources, it certainly impoverishes the nation. A particular problem is that mineral resources are exhaustible and non-renewable [2]. In such circumstances, the economic policy makers of the development of the economy and the nation can view them quite unrealistically, until the effects of environmental damage become visible, which can sometimes take decades.
Economic growth by itself does not necessarily represent real economic development and can reduce human well-being if it is accompanied by growing inequality and environmental degradation. Therefore, in the analysis of national income, it is very important to take into account the factors of resources, especially mineral resources and the environment. One of the approaches to the revision of the national income budget is to estimate the economic value of depreciation of natural capital and subtract that estimated value from the standard measures of GDP/GNP [10]. In standard national income accounting, the depreciation of anthropological capital, such as buildings and equipment, is subtracted, which is extended to the calculation of the depreciation value of

natural resources, which is also subtracted from GNP/GDP. A comparison of adjusted net domestic product calculations show significant deviations from standard benchmarks.
From an analytical point of view, the modified GDP model with ecological-economic-accounting correction has a particularly pronounced impact on net investments. The standard measure of net investment corrects gross investment by subtracting depreciation of produced capital. Based on the calculation of depreciation of natural capital, a large number of developing countries show much lower or even negative net investment. This significantly affects the development strategy, because investments are the most important economic determinant of long-term growth. By not taking into account the depreciation of resources, including mineral resources, as well as the environment, the real values of investments are systematically overestimated [12].
A very important step in the integration of the analysis of economic policy, environmental policy and social policy was the development of the measure of true savings, which includes depreciation of natural capital and borrowing abroad [13, 14]. That measure tends to determine how much national income is being saved for the future, taking into account both the depletion of natural resources, especially mineral resources as part of them, as well as additions to capital funds. The analysis of true savings, especially suitable for developing countries, indicates that an apparently successful development opportunity may hide a serious depletion of natural capital, which includes especially economically significant mineral resources, and in some cases may even produce a negative amount of net real savings.

3. ASSESSMENT OF ECONOMICLY SUSTAINABLE WELFARE

In the modern conditions of economic analyses, the assessment of depreciation of resources, including mineral resources, through which the ecological component of environmental analysis is viewed, is included in the items of national income. The approach with the so-called defensive costs [10], which are associated with the removal of the consequences of pollution, that is, attempts to repair or compensate for damage to the environment. According to standard accounting, these costs are included in GDP, which is why items of national income can influence the overestimation of national economic success.
As an illustrative example of defensive costs, the expenditures of the US Superfund state fund intended for the cleaning of toxic waste dumps, which are counted as a contribution to GDP [10], can be cited. Medical costs of treating diseases caused by water or air pollution are similarly added to GDP. If homeowners or businesses in a coastal area suffer property damage from an oil spill and file a claim for compensation, legal and cleanup costs are also added to GDP. According to this logic, if the damage from pollution is greater and the costs of removing the consequences of pollution are higher, the country is richer, which is a rather irrational attitude.
To show defense costs and environmental damage, an Index of Sustainable Economic Welfare (ISEW) was proposed for the USA [15]. Later, this concept was partly revised by creating the Genuine Progress Indicator (GPI) for the USA. The GPI adjusts for economic output by starting with a measure of consumption, which is adjusted for income inequality, then adds the value of unpaid labor and subtracts estimates of defense spending. Rather than measuring the total amount spent on consumer durables (eg refrigerators), the GPI measures the services provided by those goods. This favors more efficient and durable capital, which requires less frequent consumption but provides more services. Along with correcting the level of depletion of natural, especially mineral resources and long-term damage to the environment, the GPI shows a much slower economic development compared to the GDP indicator, which is constantly increasing.
Long-term damage to natural, especially mineral resources and the environment, such as the destruction of the ozone layer and the accumulation of gases, which intensify the greenhouse effect, are responsible for a large part of the differences between GDP and GPI [16, 17]. If long-term and cumulative environmental impacts are excluded, the resulting measure is closer to GDP, but still shows a much lower profit e.g. for the USA in the period after 1975. Measures of sustainable economic well-being similar to the GPI, calculated for European countries and Australia, show a

similar pattern. Namely, measures of the GPI type grow more or less parallel to GDP in the period from 1950-1970, but after that they grow at a slower pace or even decline [16].

4. ENVIRONMENTAL SERVICES AND GREEN ACCOUNTING

The third analytical-accounting approach to correcting items of national income for environmental damage includes defining the environment as a production sector, which provides services to the economy, many of which remain unrecorded, because at first glance they are free [18, 19, 20]. Examples include providing clean air and water, removing carbon dioxide from the atmosphere with the help of trees, health and recreational benefits provided by natural areas, etc.

If environmental services are impaired, e.g. by draining wetlands, the estimated costs of replicating those services must be subtracted from national output. Because wetlands perform important functions that include water purification, nutrient recycling, flood control, and providing habitat for wildlife, the estimated values can be very high. According to current standard accounting methods, wetlands do not contribute to output at all, but a shopping center built on a drained wetland would therefore contribute to output, both through the construction of the shopping center itself and through the annual sales of materials, goods and services.

The mentioned approaches of modifying the GNP/GDP items have their advantages, but it is rather difficult to determine a single criterion of modification. Some analyzes reject the single measure of ecological greening of GDP/GNP. Instead, it is proposed to use accompanying items, which in a physical sense measure the funds and functions of the environment, without necessarily attempting to value them [21]. Accompanying items can provide a detailed picture of the natural resource base and environmental condition by measuring variables such as forest cover, mineral resources, water supplies and noting their changes over time. Input/output analysis can show the likely impacts of various economic policies on resource stocks, including economically very important mineral resources. Economic valuation methods can also convert physical measures into monetary measures to estimate adjusted NNP/NDP. The United Nations has published a guide to integrated economic and environmental accounting using the accompanying items approach [22]. In the economic, accounting and environmental practices so far, no system of revision of items of national income for the impact on resources, including mineral resources, as well as the environment has been generally accepted and as a single present in application. In practice, most economic analyzes still rely on standard measures of GDP or NDP. It is obvious that such circumstances require a special correction of economic theories, in order to influence the new measurements of the national product and income. In the current analytical approach, the implications of the environmental accounting or green accounting approach can be specifically explored.

Directing the policy of sustainable development with the evaluation of the national income is economically and accountingly connected with the funds of total fixed assets, which remain the same or increase over time. These capital stocks include manufactured capital, human capital (skills and education) and natural capital. In doing so, different types of natural capital are distinguished, which can be replaced to a certain extent, the so-called. non-critical natural capital, but special attention should be paid to critical natural capital, i.e. resources such as water supplies for which there are no adequate substitutes [10, 22]. The same category can also include economically very important and currently irreplaceable, exhaustible and non-renewable mineral resources.

National income accounting must take into account any changes in the capital categories shown. Investments in capital are an integral part of standard GNP/GDP, and depreciation of produced capital should be subtracted from GDP to obtain NDP (net domestic product). According to existing analytical views, human capital is not amortized, provided that spending on education is adequate. Hence, the main analytical issue in resource and environmental accounting relates to the estimation and subtraction of depreciation of natural capital in order to obtain the adjusted net national product of NNP. The above requires certain specialist and detailed expert analyzes of the depreciation of natural resources, among which the specific issue of mineral resources, considering their characteristics and especially economic, social and development importance.

5. CONCLUSION

Contemporary world and national economic trends have a direct and significant connection with the mineral economy and the mineral sector at the observed level of economic analysis. Consideration of conditions and ways of achieving national income is linked to complex analyzes of the relationship to natural resources, especially mineral resources as basic production elements.

Realization of national income is related to various analytical aspects of acquisition, including starting mineral resources, with expression through standard measures of gross national product or gross domestic product, which are used in macroeconomic analysis and standards of economic progress. In the analysis of national income, it is important to take into account the factors of resources, especially mineral resources and the environment, along with assessing the economic value of depreciation of natural capital and subtracting its value from standard measures of GDP/GNP.

Analytically, the modified GDP model with ecological-economic-accounting correction has a particularly pronounced impact on net investments, which are needed for geological research and exploitation of mineral reserves, as well as the construction of mineral processing capacities. The assessment of depreciation of resources, including mineral resources, through which the ecological component of environmental analysis is viewed, is included in the items of national income and affects investments, so that they are not overestimated.

A special analytical and accounting approach to correcting items of national income for environmental damage includes defining the environment as a production sector, which provides the economy with a number of seemingly free services. In the same way, the direction of the policy of sustainable development with the evaluation of the national income is economically and accountingly connected with the funds of total fixed assets, which increase in development conditions. The main practical and analytical issue in accounting for mineral and other resources and the environment is related to the specific assessment and deduction of depreciation of natural capital. In the mineral sector and the mineral economy of the country, the above requires specialist and detailed expert analyzes of the depreciation of mineral resources, considering their specificities, but also their production and strategic importance in further economic and social development.

QUALITY OF SWIMMING POOL WATER AND HYGIENE

Slavica Krsmanović[1], Academy of Vocational Studies Belgrade
Danijela Pecarski[2], Academy of Vocational Studies Belgrade
Jasmina Bašić[3], Academy of Vocational Studies Belgrade

Abstract: *Without water there is no life. Today, more than ever, water resources in nature are threatened and it is necessary to preserve them and maintain their quality at a satisfactory level. This primarily applies to drinking water, but water for other purposes such as pool water should not be neglected either. It is pool water that can play a major role in preserving and improving an individual's health, but only if it is safe. In addition to adequate maintenance and disinfection, a prerequisite for safe pool water is the hygienic behavior of the users themselves. Any lack of hygienic behavior can lead to a microbiological risk. Any microbiological contamination carries a risk for users, especially fecal contamination. One of the most basic hygiene measures when using the pool is to shower before entering the pool. Applying this hygiene measure removes all substances that are on the body and can be potential pollutants. Based on the results of numerous studies, it is observed that users neglect hygienic behavior, which can lead to health risks. Research has shown that risky behavior is not related to socio-demographic characteristics and that adequate education is the best way to increase awareness of the importance of hygiene.*
Keywords: Hygienic behavior, Microorganisms, Swimming pool, Water

1. INTRODUCTION

Today, there is a clear need not to endanger the environment, and on the other hand, to satisfy growing human needs. The quality of the environment is the result of the action of various external factors, often negative, which is especially pronounced in the domain of lack of drinking water and often appropriate sanitary conditions. The very decision of the United Nations General Assembly to mark March 22 as World Water Day speaks of the importance of water protection and highlights the fact that every person has the right toa sufficient amount of safe water for drinking, personal hygiene, domestic use, sports, recreation andother needs.

The World Health Organization estimates that about 2 billion people in the world do not have hygienic drinking water in their homes [1], and that almost 50% of the population does not have safe sanitary conditions [2]. Lack of hygienically correct water is one of the main causes of death from infectious diseases, primarily from diarrhea.

Water resources are under great pressure, the number of pollutants is increasing as a consequence and result of industrial and technological development. Water resources are not inexhaustible and it is necessary to preserve them. It is of great importance to maintain water quality at a satisfactory level, above all when talking aboutdrinking water, but also about water for other purposes. It is known that the quality of surface water is threatened by numerous harmful agents, but the quality of water in swimming pools also requires attention.

Using the pool contributes to healthy physical activity and has a stimulating effect on the whole organism. It is recommended for all population groups, and is especially suitable for obese, physically

[1]slavica.krsmanovic5@gmail.com
[2]danipecarski@gmail.com
[3]basic.jasmina23@gmail.com

inactive,elderly people, as well as for cardiovascular patients. Physical activity contributes to weight control and reduces the risk of cardiovascular diseases, diabetes and other diseases. Swimming is recognizedas one of the most beneficial forms of exercise and is also recognized as a rehabilitation therapy.
Water activity has great potential for health, both preventively and therapeutically.
The safety of pool water is achieved by adequate disinfection and is a prerequisite for improving and preserving health. However, the fact is that adequate disinfection and adequate maintenance of the pool facility will not ensure the safety of the pool water if there is no hygienic behavior of the users themselves.

2. QUALITY OF SWIMMING POOL WATER

Maintenance of all pool facilities as well as regular monitoring of pool water quality is an obligation, but also a task of the responsible persons. Safety, as a goal of public health, implies the reduction of the risk of injuries, the transmission of infectious diseases and the appearance of disinfection byproducts. Most of the challenges that can lead to health risks in the pool can be solved by adequate water treatment, which includes filtration and appropriate disinfection. One of the important moments in maintaining the quality of pool water is the addition of fresh water, in order to dilute substances that cannot be removed from the water by treatment.
Pool water is exposed to pollution risks, primarily microbiological and chemical. Microbiological risk occurs as a result of the presence of microorganisms in the pool water and has the highest probability of occurrence, even in well-maintained pools, especially where the hygienic behavior of the users is absent.

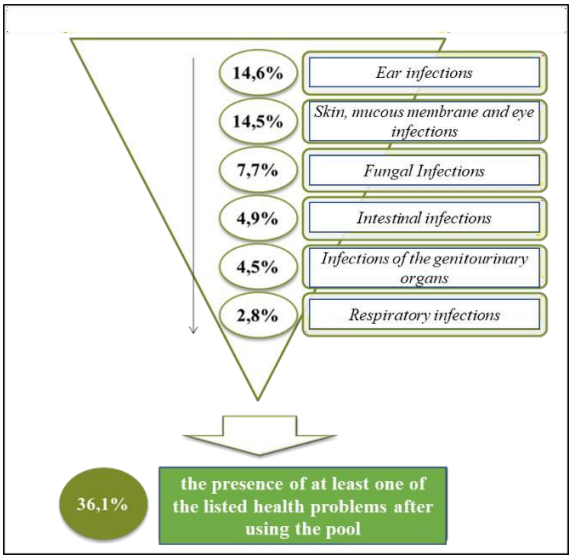

Figure1. The percentage of respondents aged 18 to 25 with the presence of a health problem after using the pool

Source: Krsmanović, S.: Istraživanje i analiza higijenskih navika dece i omladine korisnika bazenskih objekata u Srbiji. Doctoral thesis, The European Center for Peace and Development, University for Peace estalished by UN, (2018).

A large number of microorganisms of non-fecal, as well as fecal, origin can lead to contamination of pool water, and potential sources for this are human body secretions, feces, saliva, urine, sweat or vomited contents. Microbiologically contaminated pool water can lead to the appearance of various types of infections that find their way through natural body openings, as well as present skin damage. As a result of the unhygienic behavior of users of swimming pool facilities, the most common infections that can occur are skin, mucous membrane or eye infections, respiratory infections, ear infections, genitourinary infections, fungal infections and intestinal infections.

The World Health Organization also warns us about the danger of bacterial infections, which has provided a list of 12 bacteria that represent the greatest threat. Among them, Pseudomonas aeruginosa, Enterobacteriaceae and Acinetobacter baumannii stand out.
Looking at the dangers that threaten us from bacteria indicates that the regular application of hygiene measures is a prerequisite for reducing the microbiological risk in pool water. Research has been done on the topic of how much the users are really aware of what the absence of hygienic behavior brings. The results of a study in Italy show that 46.4% of respondents believe thatthey cannot get sick from pool water [3].
The safety of bathers primarily depends on hygienic behavior. The user's hygienic behavior reduces the risk of infections and thus makes all other maintenance techniques easier.

3. HYGIENIC BEHAVIOR

Showering before entering the pool is one of the most basic hygiene measures that can reduce the risk of microbiological contamination of the water. Applying this hygiene measure removes traces of sweat, urine, fecal matter, cosmetics and all other potential water pollutants, but also facilitates disinfection with a reduced amount of disinfectant, which makes the water more pleasant to use.
That hygienic behavior is important, we also notice from the warnings, advice and rules of behavior highlighted within each swimming pool facility. However, the fact is that the rules are not always followed, which is confirmed by numerous studies in the world, as well as in our country.
Based on an Italian study, it can be noted that 41.7% of bathers never read the rules of conduct displayed in swimming pool facilities [3], while another study shows that even 60.9% of respondents are not sufficiently familiar with the house rules of the swimming pool. of the object they use [4]. The data of a study conducted in our country show that less than one third of the respondents (30.2%), who use swimming pool facilities, read the warnings, advice and rules of conduct highlighted within the swimming pool facility, while more than half of them (58.3%) notices, but does not attach importance to them, which is worrying [5].
All substances found on the skin are introduced into the water, which reduces the amount of chlorine in the pool and increases the risk of infection, as well as allergic effects of disinfection byproducts on the respiratory organs and skin [6].
Based on the results of numerous studies over the past ten years, we can conclude that there is a presence of risky behavior on the part of users of swimming pool facilities, both in the past and today. A large Italian study on the behavior of users of swimming pools, which included five cities and more than 4,000 respondents, shows that only two-thirds of respondents always take a shower before entering the pool [7]. In another Italian study, the results showed that 69.2% of users use showers before entering the pool [8]. Bearing in mind the danger of various types of infections that can arise as a result of risky behavior, the percentage of users who regularly shower before entering the pool should be significantly higher.
Research conducted in our country shows that 70.7% of respondents consider that using showers before entering the pool is a very important hygiene measure, but only every other respondent (50.2%) applies this hygiene measure always, i.e. they take a shower regularly before entering the pool [9]. It is concluded that there is a high percentage of respondents who do not attach importance to this hygiene measure, but also a certain percentage of them who have developed hygiene awareness, but do not have developed hygienic behavior. Of interest for future activities, the reasons for this behavior were also important. In addition to hygiene, which is cited as the most common reason for taking a regular shower before entering the pool (86.0%), every tenth respondent also mentions getting used to the temperature of the pool water. Based on this result, it is concluded that there are respondents who have hygienic behavior, but for the wrong reason, which leads to the conclusion about necessary education. On the other hand, respondents who sometimes or never use the showers before entering the pool state that they come to the pool having already showered from home as the most common reason. This reason does not represent adequate hygienic behavior because users ignore the fact that they can be exposed to impurities on the way from home to the pool.

Health culture is part of the general culture of every individual, regardless of gender, age and education. User education on the topic of applying hygiene measures and their importance in reducing health risks is an important segment of public health. Education needs to be carried out continuously in order to achieve the best possible results and to motivate users of swimming pool facilities who have no interest in changing their behavior.
Back in 2010, the Center for Disease Control and Prevention (CDC) created the "Triple A's of Healthy Swimming" program, which encourages hygienic behavior among users of swimming pool facilities through 3 pillars: awareness, action and advocacy [10]. In the framework of awareness, the emphasis is on hygiene, in the framework of action, on the interest of users in water quality, and advocacy means encouraging and educating others on the importance of hygienic behavior and proper maintenance of the swimming pool facility.
The fact is that even in developed countries there are failures in the application of hygiene measures, which is confirmed by the data of a large number of studies, which indicates the comfortable behavior of people, regardless of the standard and living conditions.

4. CONCLUSION

The health risk for users of pool water can occur primarily as a result of inadequate hygienic behavior and insufficiently high awareness of the importance of applying hygiene measures when using pool facilities. The fact is that safe bathing primarily depends on self-discipline and the level of culture. Behavior, as a pattern of actions, can be influenced. Adequate education of all population groups and consideration of risks can point out the importance of hygienic behavior in every domain, which is a safe way to safe use of swimming pools.
Unhygienic behavior, as socially acceptable, represents a public health problem and requires positive changes. It is counterproductive that places that serve for recreation, relaxation and health promotion are actually places that can endanger us. That is more than enough reason to constantly work on strengthening awareness of the importance of hygiene.

Antonije E. Onjia[4], Faculty of Technology and Metallurgy, University of Belgrade

Abstract: *Fly ash is a by-product of coal combustion in thermal power plants. Heavy metal(loid)s (HMs) are the most recognized among the many dangerous compounds in fly ash. These substances may contaminate the environment and can pose a threat to human health. Various analytical techniques are used to analyze HMs in leachate. To investigate the possibility of contamination of the environment, heavy metals and metalloids (Pb, Zn, Mn, Fe, As, Ba, Be, Cu, Cr, Co, Cd, Sb, Se, and V) were leached from fly ash using a toxicity characteristic leaching procedure (TCLP). The fly ash samples used in this work were obtained from four thermal power plants (Kostolac, Kolubara, Tent B, and Morava). Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES) technique was used to determine the concentration of these elements in the leachate. Accurate elemental analysis was achieved with this technique. Among all analyzed metal(loid)s, Fe, Mn, Zn, and As were the most abundant.*
Keywords: ICP-OES, TCLP, trace elements, power plant, coal combustion

1. INTRODUCTION

Coal combustion in coal-fired boilers produces several different types of ashes, including fly ash, bottom ash, boiler slag, flue gas desulfurization materials, and other fluidized bed combustion ash, cenospheres, and scrubber residues, amongst other things [1]. Coal fly ash and bottom ash are the two main industrial by-products generated during the combustion of coal [2]. Due to the enrichment of heavy metals and metalloids (heavy metal(loid)s, HMs) in the ash particles, the disposal of these solid residues is considered a potential source of soil and groundwater pollution. The concentration of HMs in the ashes depends on several factors, including the type of coal feed, coal source, the occurrence of significant elements and their association with the organic and inorganic components of the coal, combustion conditions, volatilization-condensation mechanisms, and the particle size of the ash [3],[4]. During the transport and disposal of the residues from coal combustion, they are exposed to the leaching effects of rain. It is imperative to predict the leaching behavior of residues to prevent the environmental effects [5],[6].
Inductively Coupled Plasma Optical Emission Spectroscopy (ICP-OES) is a powerful analytical technique widely employed in environmental and materials analysis to determine HMs in various matrices. It has several characteristics, such as the ability to simultaneously analyze multiple HMs, wide dynamic range, high sensitivity, and low interference from matrix effects, which make it an indispensable tool in environmental monitoring, where HMs play a critical role.

[1]jlukic@tmf.bg.ac.rs
[2]latinka@anahem.org
[3]trivunac@tmf.bg.ac.rs
[4] onjia@tmf.bg.ac.rs

The aim of this study was to develop an ICP-OES method for analyzing HMs in the coal ash leachate and to investigate coal ash leaching behavior in order to analyze the potential for their reuse.

2. MATERIALS AND METHODS

2.1 Chemicals and Reagents

Coal fly ash and bottom ash samples were collected from four thermal power plants in Serbia that combust coal. Leaching of various HMs was carried out by applying batch Extraction Procedure (EP) and toxicity characteristic leaching procedure (TCLP). The TCLP extraction fluid (pH = 2.88) was prepared by diluting glacial acetic acid, while the EP extraction solution was deionized water (18.2 MΩ·cm). Deionized water was prepared using a Simplicity ultrapure water system (Millipore, Bedford, MA, USA). Acetic acid was supplied from Sigma Aldrich (Buchs, Switzerland). Standard solutions were purchased from AccuStandard (New Haven, USA).

2.2 Sample preparation

In a polyethylene bottle, 50 mL of EP or TCLP leaching fluid was mixed with 1.0 g of sample (20÷1 solid-to-liquid ratio), and the mixture was stirred at room temperature for 24 hours. The leachate was centrifuged at 6000 rpm for 10 minutes. The obtained supernatants were used for the analysis of HMs. Triplicate leaching tests were performed using the same weight of the sample and the same volume of the leaching solvent.

2.3 ICP-OES Measurements

The concentrations of HMS were determined by the ICP-OES instruments (Thermo Scientific model iCAP 6500 duo). To control the ICP-OES system, Thermo Scientific™ Qtegra™ software was employed.

3. RESULTS AND DISCUSSION

The first step was to optimize the ICP-OES parameters to enhance the analytical performance and achieve better results in HM analysis in coal fly ash leachate. The simplex method [7] was used to get optimal conditions for this analysis (Table 1).

Table 1. ICP-OES instrumental operating conditions

Parameter	Setting
RF Power	1150 W
Nebulizer gas flow	0.6 L/min
Auxiliary gas flow	0.5 L/min
Cooling gas flow	12 L/min
Exposure time	Axial/Radial
Low (UV)	15 secs
High (Visible)	5 secs
Peristaltic pump speed	50 rpm

Next, the linearity, detection limits (LOD), recoveries, and precision of the method have been investigated. To determine the linearity of the method, a calibration curve was constructed by analyzing a series of standard solutions with known concentrations of the HMs. The response of the instrument is plotted against the concentration of each HM, and the linearity is evaluated by calculating the correlation coefficient (R^2) of the calibration curve. The LOD was estimated by analyzing a series of blank samples and calculating the standard deviation of the blank measurements

and then calculated as three times the standard deviation of the blank measurements. A known amount of HM is spiked into a sample matrix, and the recovery is calculated as the ratio of the measured concentration to the spiked concentration. Finally, the precision of the method was determined by analyzing a series of replicate samples and calculating the relative standard deviation (RSD) of the ICP-OES measurements. Table 2 shows the wavelengths (λ) of the analyzed elements as well as the interferants, LODs, RSDs, and recoveries.

Table 2. Analytical parameters for ICP-OES determination of HMs in fly ash leachate

No.	HM	λ (nm)	Interferant	LOD (ppb)	Spiked conc. (ppm)	Recovery (EP) (%)	Recovery (TCLP) (%)	RSD (%)
1	As	189.042	Al, Co, Fe, V, Ni	2.91	0.3528	103	105	4.1
2	Ba	493.409	None	1.23	0.2601	101	103	3.4
3	Be	313.042	Ce, V	0.97	0.0025	102	102	2.7
4	Cd	228.082 214.438	Ce, Ni, Fe, Ti	0.42	0.0035	98	94	1.9
5	Co	228.616	Ba, Ce, Cd, Cr, Ni, Ti, Mo	0.97	0.0270	104	99	1.8
6	Cr	283.563 267.716	Ni, Mo, Be	1.72	0.0728	103	104	2.0
7	Cu	324.754	Mo, Ti	0.94	0.0447	101	98	1.6
8	Fe	259.940 239.562	None	4.28	3.7163	93	96	4.8
9	Mn	257.610 279.482	Ce	0.87	1.2607	94	97	4.5
10	Sb	206.833	Al, Ce, Cr, Co, Fe, Ni, Ti,	0.54	0.0204	105	96	4.3
11	Se	196.090	Fe	2.33	0.0552	104	98	4.1
12	V	282.402	Ce, Cr, Fe, Ti, Mo	0.91	0.0480	95	92	3.2
13	Zn	202.548	Cu, Fe, Ni	0.18	0.1964	102	97	2.1

The lowest value of the detection limit is 0.18 ppb for Zn, while the highest LOD is 4.28 ppb for Fe. The recovery ranges from 93 to 105%. A good linearity was observed for all HMs (R^2>0.999), and RSD is within ±5%. There are no notable differences between TCLP and EP recoveries.
The chemical constituents of fly ash and bottom ash are very similar, with the main difference being particle shape and size. Bottom ash is larger in size and very irregular, containing pores and cavities [8]. Ground to a suitable fineness, bottom ash can have a similar purpose as fly ash (e.g., production of building materials).

3.1 Leaching of heavy metal(loid)s from fly ash with EP leaching solution

The HM concentrations in the EP leachate are shown in Figure 1. Arsenic is the most prevalent (1.49 ppm) HM in the fly ash sample originating from the Kolubara thermal power plant. Arsenic (As) is markedly toxic and carcinogenic, and it is one of the most important HMs that cause both ecological and human health problems [9]. Concentrations of other HMs do not exceed 0.6 ppm.

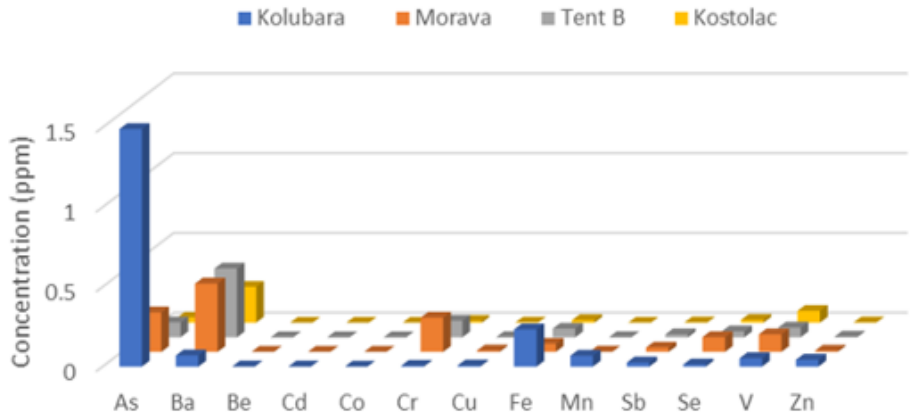

Figure 1. Concentrations of heavy metal(loid)s in fly ash leachate (EP leachate)

3.2 Leaching of heavy metal(loid)s from fly ash with TCLP leaching solution.

Figure 2 shows the results of fly ash leaching using the TCLP leaching solution. Concentrations of HMs are significantly higher in TCLP leachate compared to EP leachate. This is because metal solubility generally decreases with increasing pH. The most abundant HMs in fly ash leachate were As, Fe, and Mn, which were found in the range of 0.03–1.49 ppm, 0.02–0.23 ppm, 0.0005–0.07 ppm and 0.05–1.41 ppm, 1.28–24.38 ppm, 2.24–3.04 ppm, for EP and TCLP leachate, respectively. The ash sample from the Tent B thermal power plant contained the highest concentration of these elements.

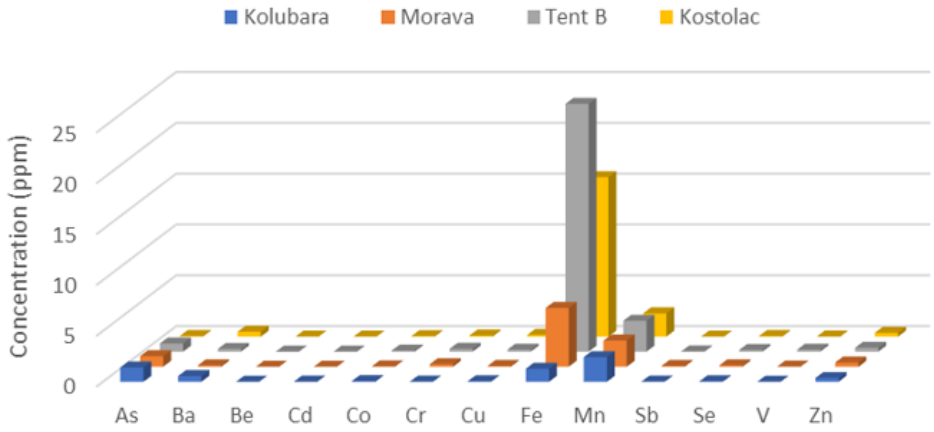

Figure 2. Concentrations of heavy metal(loid)s in fly ash leachate (TCLP leachate)

3.3 Leaching of heavy metal(loids)s from bottom ash with EP leaching solution.

The levels of HMs in the bottom ash leachate are shown in Figure 3. Compared to fly ash samples, less arsenic was leached into deionized water in this instance. Similar to fly ash, the most prevalent metals in this leachate were Fe, Mn, Zn, As, and Ba, though in smaller quantities.

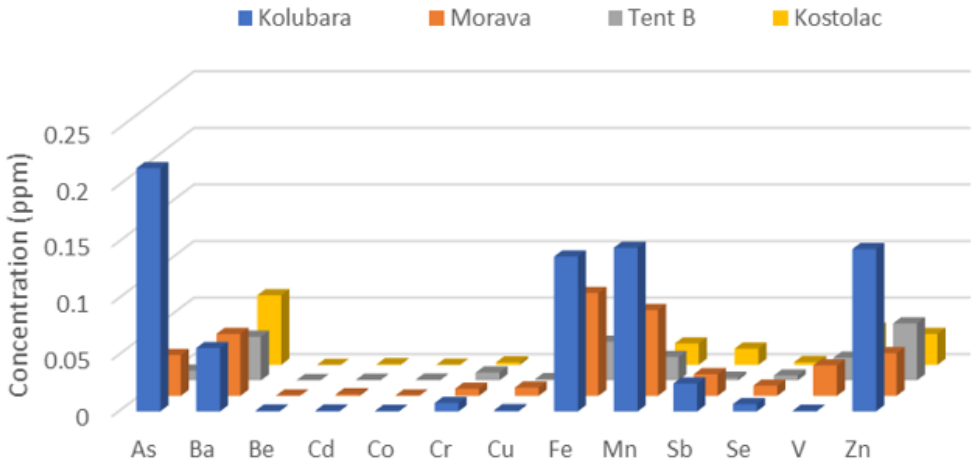

Figure 3. Concentrations of heavy metal(loid)s in bottom ash leachate (EP leachate)

These results can be explained by the similar composition of these two ashes but the different sizes of the particles, which is one of the important factors affecting the amount of leached HMs.

3.4 Leaching of heavy metal(loids)s from bottom ash with EP leaching solution.

The concentrations of the heavy metals(loids) that were leached out with TCLP solvent are shown in Figure 4. Similar to the fly ash samples (Figure 2), the most abundant HMs in the bottom ash TCLP leachate were Fe, Mn, As, and Ba.

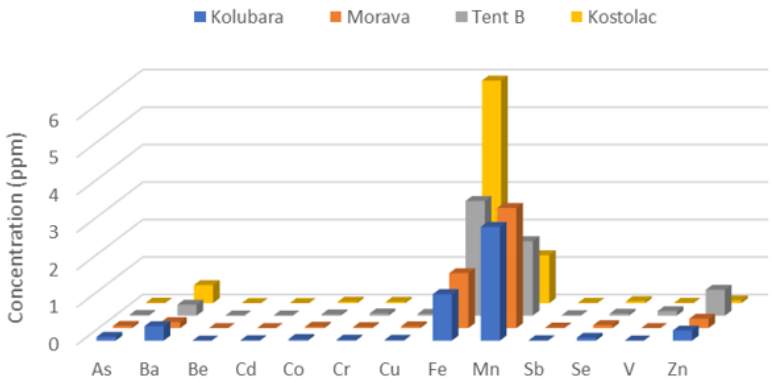

Figure 4. Concentrations of heavy metal(loid)s in bottom ash leachate (TCLP leachate)

4. CONCLUSION

In general, ICP-OES is a reliable and robust technique, offering good linearity, recovery, and precision, making it suitable for analyzing HMs in coal ash leachate. According to the leaching tests, coal fly ash and bottom ash from various locations have similar leaching characteristics. Higher concentrations of heavy metals (loids) were leached during the TCLP leaching test, which can be explained by the lower pH value affecting the mobility of heavy metals. Among all analyzed metal(loid)s, Fe, Mn, Zn, and As were the most abundant in the ash samples.

ANALYSIS OF CARBON MONOXIDE IN AMBIENT AIR USING PASSIVE SENSORS

Andrijana Miletić[1], Faculty of Technology and Metallurgy, University of Belgrade
Antonije Onjia[2], Faculty of Technology and Metallurgy, University of Belgrade

Abstract: *Air quality monitoring is necessary due to various pollutants that can have a harmful effect on human health. Carbon monoxide (CO) is a pollutant of concern because it is very toxic at low concentrations. It is an odorless and colorless gas that is very difficult to detect. In recent years, passive sensors have been widely used to analyze CO in ambient air. The CO sensor for commercial use must be stable during operation and have a linear and reproducible output over a long period. Hence, developing CO gas sensors with high sensitivity, selectivity, and stability is essential. This study compared three types of CO gas sensors: electrochemical, metal-oxide semiconductors, and colorimetric. Each of these sensors is characterized by specific advantages and disadvantages; therefore, their comparative analysis is presented, and their most important characteristics are emphasized.*
Keywords: air quality, electrochemical sensors, metal-oxide semiconductors, colorimetric sensors

1. INTRODUCTION

Rapid industrial development leads to the endangerment of the basic components of the environment: air, water, and soil. This type of pollution has a severe impact on people; therefore, the existence of environmental pollution control is of great importance [1]. Air pollution is a big problem worldwide, especially in cities with developed industries. Harmful substances come directly from anthropogenic or natural activities and can be formed later in the atmosphere through mutual interaction. Gases and particles that pollute the air can be hazardous and associated with various diseases. Air pollutants include CO, NO_2, NO, SO_2, NH_3, and many others [2]. Carbon monoxide (CO) is one of the most poisonous gases and is also called the silent killer because it is very toxic to humans [3]. It is colorless and odorless and can be produced from both natural and anthropogenic sources. This most often includes incomplete combustion of fossil fuels and exhaust gases from vehicles, as well as volcanic activity and wildfires [4]. Depending on the concentration of CO to which people are exposed, the health consequences can be minimal or even fatal [5]. By increasing the concentration of CO in the body, the amount of oxygen decreases because human blood has a much greater affinity for CO than for oxygen [1]. CO binds to hemoglobin in the blood and prevents it from transporting oxygen through the body. Some characteristic symptoms are headache, dizziness, and nausea, which occur at low concentrations of CO. At high concentrations, more serious organ damage occurs, and in fatal cases, even death [4]. Because the content of pollutants in the air directly affects people's health, it is extremely important to monitor air quality. Air monitoring is necessary to determine the source of pollution, assess exposure, and form a plan for air quality management to protect people from the harmful effects of polluting gases [6]. Monitoring the amount of dangerous gases in the air has drawn more attention recently as a way to control the environment, not only in industrial environments but also in workplaces and residences. Most researchers study pollutants such as CO, CO_2, NH_3, VOCs, SO_2, and others [1].

[1]amiletic@tmf.bg.ac.rs
[2]onjia@tmf.bg.ac.rs

In the last few decades, various chemical sensors have been developed to detect various types of pollutants in various media [7,8]. Several types of popular sensors are piezoelectric [9], electrochemical [2], metal-oxide semiconductors [1], and colorimetric sensors [10]. For the analysis of pollutants in the air, various types of gas sensors that work on various principles have been developed to obtain fast but high-quality results [11]. Gas sensors are widely used for monitoring air quality in the environment, workplaces, living places, and industries [3]. Recently, gas sensors have been increasingly improved and developed to improve human safety and air quality. The main parameters of the gas sensor are sensor response, selectivity, sensitivity, limit of detection, energy consumption, operating temperature, and, of course, production costs [1]. Various devices are available for measuring CO concentration, but fast, portable, and selective sensors are still being developed [12]. So far, electrochemical sensors, metal-oxide semiconductors, and colorimetric sensors have been widely used [10]. The main goal of this study was to compare three various types of CO gas sensors. In recent years, using these sensors to analyze CO in ambient air has become a real challenge. Therefore, their comparative analysis is presented, and their most important characteristics are singled out.

2. PASSIVE SENSORS

2.1 Electrochemical sensors

Electrochemical sensors work on the principle of converting the concentration or partial pressure of the target gas into an electrical signal. These sensors can differ depending on what type of electrolyte they use: liquid, gel, or solid. However, using electrochemical sensors with a liquid electrolyte is increasingly common in practice. An electrochemical sensor consists of several parts: a working electrode, a counter electrode, a reference electrode, and an electrolyte. Figure 1 shows a schematic diagram of the electrochemical sensor. Electrodes can be made of various materials. The walls of the sensor housing must be made of a hydrophobic membrane that is permeable to gases and impermeable to liquids. This way, the amount of gas reaching the electrodes is controlled [4,13].
Determining CO is based on measuring the potential change when oxidation and reduction processes occur concurrently on the working and counter electrodes. Oxidation occurs when gases collide with the working electrode:

$$CO + H_2O \Rightarrow CO_2 + 2H^+ + 2e^- \quad (1)$$

The process of oxygen reduction takes place on the counter electrode:

$$O_2 + 4H^+ + 4e^- \Rightarrow 2H_2O \quad (2)$$

These two reactions lead to the flow of current. The generated current is related to the number of molecules that have been reduced, i.e., oxidized [4,13].

The measured value of electrochemical sensors can be affected by other substances in the air, and this phenomenon is called the crossing effect. During the crossing effect, the reduction/oxidation potential of undesirable substances is measured, and the result obtained in this way is not accurate. When the measured values are higher than the actual values, it is positive interference, while negative interference occurs when the read values are lower than the actual values. The operation of electrochemical sensors can be affected by the conditions under which the measurements are made [13]. Electrochemical sensors have a relatively fast response, low energy consumption, and are lightweight [11].

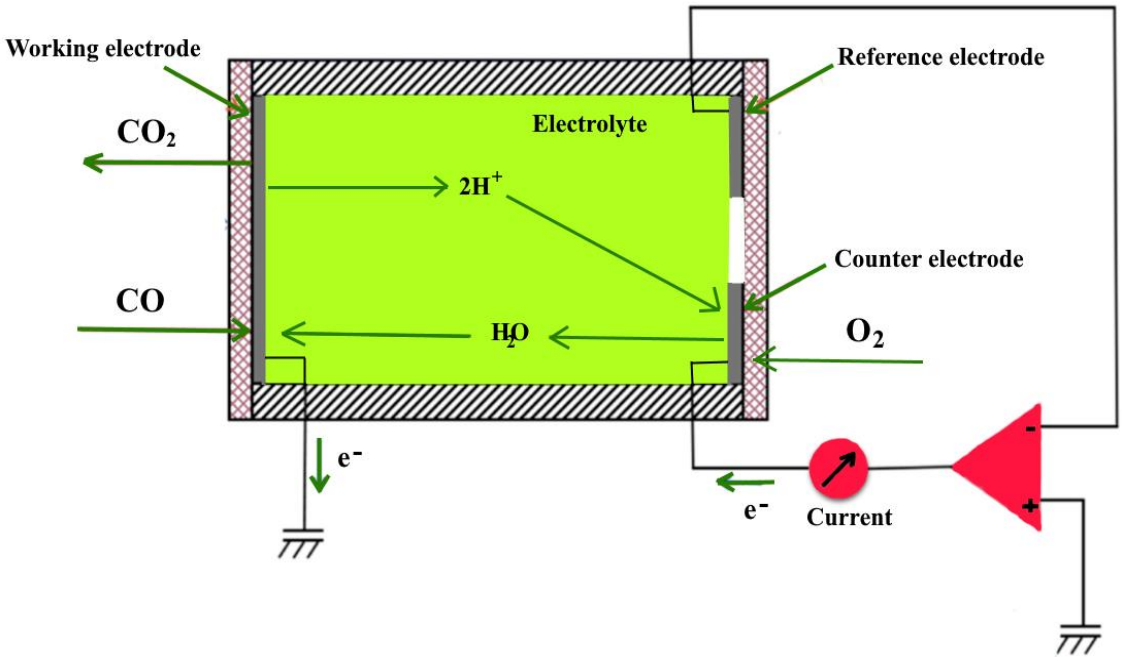

Figure 1. Schematic diagram of the electrochemical sensor

2.2 Metal-oxide semiconductors

When carbon monoxide comes into contact with a metal oxide semiconductor (MOS) gas sensor, a change in electrical conductivity or resistivity occurs. Based on that change, the target gas concentration is determined. Two types of MOS sensors used for CO detection, the n-type and the p-type, are shown in Table 1. Since not all oxides have the same properties, there are differences between semiconductors. Oxides such as SnO_2, ZnO, and TiO_2 are the most widely used because they have a good crystal structure, density, and lattice parameter, and they are the most studied for use in CO detection [1]. In addition to these three n-type conductors, Co_3O_4, the p-type semiconductor, gives good results in the determination of CO because it has a very high catalytic activity towards the oxidation of CO [14]. Metal oxides can be synthesized by various techniques such as hydrothermal, electrospinning, RF and DC sputtering, chemical vapor deposition (CVD), anodization, sol-gel, vapor phase transport, UV lithography, and many others [1].

Table 1. Various types of semiconductors for CO sensing

Metal-oxide	Type of the semiconductor	Reference
TiO_2	n-type	[3]
SnO_2	n-type	[15]
ZnO	n-type	[16]
Fe_2O_3 or Fe_3O_4	n-type	[17]
In_2O_3	n-type	[18]
WO_3	n-type	[19]
CuO	p-type	[1]
Cr_2O_3	p-type	[20]
Co_3O_4	p-type	[14]
NiO	p-type	[21]

MOS sensors detect CO based on the redox reaction between the determined gas and the sensing material. First, oxygen is adsorbed on the surface of metal oxides, creating a surface layer depleted of electrons. Depending on the types of MOS, there will be an electron-depletion layer in the n-type and a hole accumulation layer in the p-type. In the n-type, electrons are charge carriers, and in the p-type, holes are charge carriers. Therefore, due to the adsorption of oxygen molecules, the resistance

in the n-type is high and low in the p-type. Under the influence of the reducing gas, oxygen atoms are removed, and the trapped electron is transferred back to the sensing material, resulting in a decrease in the resistance in the n-type and an increase in the resistance in the p-type. Based on changes in resistance, MOS sensors detect CO gas [1,3]. MOS sensors are characterized by low cost, simplicity, high sensitivity, and low response time. The disadvantages are the high operating temperature, poor selectivity towards gases of the same type, and the fact that they are susceptible to environmental conditions. Currently, SnO_2 is the most efficient MOS material because it has excellent CO detection capabilities, especially at low concentrations [1,4].

2.3 Colorimetric sensors

The colorimetric determination of CO attracts attention due to its high sensitivity, simplicity, and selectivity. The reaction between the tested gas and the sensing probe is crucial when using colorimetric sensors. As a result of this reaction, a color change occurs. These sensing probes are a vital part of the sensor, and the operation of the CO sensor depends on these sensing probes. Chemicals in the probes act as catalysts for the reaction but also cause a color change. There are various types of sensing probes for CO determination. Most current colorimetric CO sensors are based on organic probes such as rhodium, iridium, and ruthenium complexes. Organic complexes of Pd are also used, and one example of a sensing probe contains palladium salts as a catalyst and molybdenum compounds as indicators. Although these probes have a fast response, high specificity, and high sensitivity for CO detection, their synthesis is complex [6,22].
Colorimetric sensors are characterized by their simplicity, rapid response, and low costs. However, their main disadvantage is the impossibility of continuously using a single sensor, especially when the resulting reaction is irreversible [23]. There are various attempts to overcome this shortcoming of colorimetric sensors. Lin et al. (2018) worked on a gradient-based colorimetric sensor, while Mo et al. (2023) developed a repeatable colorimetric system. The system is set to register changes in the colorimetric sensor signal, prevent the sensor from reaching saturation, and allow the sensor to fully regenerate before the subsequent measurement.

3. CONCLUSION

Air pollution from various contaminants is a problem worldwide, particularly in cities and urban areas where industry has grown. There must be enough monitoring to track the amount of contaminants in the air because air quality can significantly impact human health. Due to its unique characteristics and high toxicity, CO differs from other contaminants, making early identification and detection in ambient air crucial. As a result, carbon monoxide sensors aid in preventing excessive CO exposure; therefore, it is crucial to design CO gas sensors with high sensitivity, stability, and selectivity. There are several types of CO gas sensors, but the three most common types are electrochemical, metal-oxide semiconductor, and colorimetric sensors. These sensors have certain advantages regarding CO detection but also several drawbacks. Hence, researchers from all over the world are trying to overcome these disadvantages in order to enhance their performance. By comparing these three sensors, which are frequently used in the analysis of ambient air, their operating principles, advantages, and challenges associated with using them are highlighted. In this way, their comparative analysis was carried out. When synthesizing CO gas sensors, the main interests of researchers are in enhancing sensitivity, response time, selectivity and recovery time. Since the performance of the gas sensor depends on improving these key features, many researchers base their research on this. In addition, modern systems should undoubtedly be quick and affordable for the analysis of the target gas.

Abstract: *One of the most BTEX (benzene, toluene, ethyl benzene and a mixture of o-, m- and p-xylenes) compounds are prominent environmental pollutants commonly found in discharges and petroleum products. These volatile aromatic compounds (VOCs) are severely toxic to living organisms if contact is maintained. They originate from incomplete combustion of organic matter, and their major sources to the urban environment include vehicular emissions (mobile source), gasoline evaporation, coal burning and residential heating, and waste incineration (stationary sources). Water sediments are not well known as a source of BTEX. However, it is crucial to consider that they can act as a source, as well as sink, of organic compounds, especially in a water body located in an urban city exposed excessively to the above-mentioned sources of BTEX. In this study, we aimed to identify and quantitatively analyze VOCs compounds in sediment by using purge-and-trap (P&T) gas Chromatography-Mass Spectrometry (GC-MS).*
Keywords: VOCs; sediment analysis; GC-MS; toxicity

1. INTRODUCTION

With the rapid development of urbanization and industrialization during the last two decades, the number of pollutants has increased significantly, which can lead to severe environmental pollution in water bodies. Considering that pollutants, such as BTEX (benzene, toluene, ethyl benzene, o-, m-, p-xylenes), pose a high accumulation property in the body due to heavy exposure, they can cause various adverse health effects. In this regard, BTEX are discharged to aquatic environments from natural or anthropogenic sources and distributed between the aqueous phase and the sediments during their transport. Hence, investigating sediment contamination in terms of ecological and health risks of trace pollutants is crucial in predicting aquatic ecosystem risks [1,2].
BTEX are widely employed as degreasers and intermediates in chemical synthesis, fuels, and fuel additives. The presence of solvents in the environment, especially in water, has become a significant health concern for over three decades due to their potential carcinogenicity [3,4]. It is reported that BTEX in urban environments have harmful effects on the central nervous system, and benzene is classified by the International Agency for Research on Cancer (IARC) as a human carcinogen with pending assessment updates [5]. All the BTEX chemicals can produce neurological impairment, and exposure to benzene can additionally cause hematological effects including aplastic anemia and acute myelogenous leukemia. The critical nature of the neurotoxicity is reflected by the use of neurological

[1]trajkovic@ihtm.bg.ac.rs
[2]milica.sentic@ihtm.bg.ac.rs
[3]slobodan.cvetkovic@ihtm.bg.ac.rs
[4]amiletic@tmf.bg.ac.rs
[5]onjia@tmf.bg.ac.rs

impairment as the basis for 9 of 13 maximum residue levels (MRL) for BTEX chemicals [5]. The carcinogenic (leukemogenic) potential of benzene is well established, as indicated by its consensus classification as a human carcinogen by the National Toxicology Program (NTP 2001), U.S. Environmental Protection Agency (EPA) (IRIS 2001) [6], and International Agency for Research on Cancer (IARC).

BTEX predominantly originated from a wide array of products such as cleaning supplies, pesticides, building materials, office equipment, and craft materials, including glues and adhesives, photographic solutions, and tires. They are usually included in the composition of paints and lacquers, varnishes, and fuels and serve as precursors for producing other compounds. Aromatic hydrocarbons can be divided into monoaromatic hydrocarbons and polyaromatic hydrocarbons, whereas BTEX belongs to the group of monoaromatics with unique properties due to the delocalized electron density in benzene, including additional stabilization. BTEX are commonly found in crude oil and are used in geochemical investigations as direct indicators of the presence of oil and gas; they are easily volatile and can be degraded by microorganisms, which affect their precise measurement seriously.

Within this work, a procedure of gas chromatography-mass spectrometry (GC-MS), including purge and trap extraction (P&T), is used for the quantification of BTEX compounds in sediment samples [7,8]. The modification of several EPA standard methods for BTEX determination was made. Continuous monitoring of various parameters that may affect the performance of the method is necessary for ensuring an appropriate result quality. This primarily refers to specificity and selectivity, linearity, detection limit, precision, accuracy, and measurement uncertainty. It is emphasized how important it is to reflect the pollution status of BTEX comprehensively and evaluate the potential ecological risk of these analytes for water management in future studies.

2. MATERIAL AND METHODS

2.1 Reagents and laboratory supplies

The QA/QC of the analysis with scientifically acceptable results was ensured using the certified reference material (CRM) (Internal/Surrogate Standard Mix M-8260A-B-IS-SS-10X) for QC of VOCs analyses. CRM and all the reagent blanks were prepared by carrying out the entire analytical procedure and included as quality control samples. Concentrations were obtained as the average of three random measurements, whereas the analytical quality was evaluated by analysis of replicate. Methanol used for sediment sample preparation was of chromatographic grade. The solvent chromatogram showed no BTEX interfering peaks. The stock standard solutions were prepared in the appropriate solvent and stored in vials with Teflon-lined stoppers in the refrigerator. Intermediate mix standard solutions were prepared by diluting the stock standard solutions. Calibration standard solutions were prepared by diluting the intermediate standard solution. Since the exposure to BTEXs was to be minimized, pure standard materials and stock standard solutions were handled in a hood.

Sample containers of 40 ml t screw cap vials were used, each equipped with a Teflon-faced silicone septum. It was essential to wash vials and septa with detergent and rinse with tap and distilled water. The vials and septa were air-dried at room temperature, placed in an oven at 105^{o}C for 1 h, and cooled in a place free from organics.

2.2 Purge-and-Trap Gas Chromatography-Mass Spectrometry

Purge-and-Trap (P&T) Gas Chromatography-Mass Spectrometry (GC-MS) is the most widely used method in BTEX analysis [7]. A purge-and-trap system (Teledyne Tekmar ATOM XYZ) coupled with GC-MS (Agilent GC 7820A with MS 5977B) was used to analyze BTEX in sediment samples. After purging and cooling the trap with ultra-high-purity N_2, the samples were purged, trapped, and then introduced into GC-MS to measure BTEX [8,9].

2.2.1 P&T sampler method conditions

Purge: Prepurge 0.00 min; flow: 0 mL/min, Preheat Mix Speed: slow, sample preheat time: 0 min, Presweep time: 0.25 min, water vol: 10.0 mL, Sweep water time 0.25 min, Sweep water flow: 100 mL/min, Sparge vessel heather: off; Purge mix speed: Medium; purge time: 11.0 min, Purge flow: 40 ml/min, Purge and MCS Purge T = 20 °C; Dry Purge Time: 1.00 min, Dry Purge flow: 100 mL/min; Dry Purge T = 20 °C.
Desorb: Methanol Needle Rinse: Off; (V=0 mL); water Needle Rinse V = 7 mL; Sweep Needle time: 0.25 min; Desorb preheat T = 245 °C; GC Start Signal: Begin Desorb; Desorb time: 2.00 min; Drain flow: 300 mL/min, Desorb T = 250 °C.

2.2.2 GC-MS instrument method conditions

Column: Agilent DB-VRX, 20 m × 0.18 mm, 1 μm film, helium – 1 mL/min; oven profile: 35 °C, 4 min, 15 °C/min to 85 °C, 30 °C/min to 225 °C, 2 min hold, Run 14.0 min; Inlet: 180 °C, 120:1 Split, 19.752 psi; temperature: transfer line 225 °C; Source 230 °C; Quad 150 °C: scan: Range 35 m/z to 260 m/z, solvent delay: 0.5 min, normal scanning; gain: gain factor 10.00, autotune.

2.3 Interferences

Major potential contaminant sources in this kind of analysis are volatile materials in the laboratory and impurities in the inert purging gas and the sorbent trap. Using Teflon tubing, Teflon thread sealants, or flow controllers with rubber components in the purging device is avoided since such materials out-gas organic compounds, which will be concentrated in the trap during the purge operation. Interfering contamination may occur when a sample containing a low concentration of BTEX is analyzed immediately after a sample with high BTEX concentrations. Preventive action of thorough rinsing of the purging apparatus and sample syringes with two water portions was conducted, as well as one or more reagent blanks were analyzed to check for cross-contamination [9]. Another potential source of contamination from traces comes from organic solvents (i.e., the highest purity methanol), which was assessed before the standard preparation in methanol.

3. RESULTS AND DISCUSSION

The specificity and selectivity of the method were determined based on the retention times of peaks and ion characteristics for each analyte (quantifier and qualifier ions).

Table 1. Retention times and selected ions of the target analytes
(Masses for P&T GC-MS VOC and ISTD)

No.	Analyte	RT	Quantifier	Qualifier	Qualifier	Qualifier
1.	Benzene	5.632	78	52	39	77
2.	Toluene	7.827	91	65	39	92
3.	Ethyl benzene	9.003	91	106	65	51
4.	m – xylene**	9.134	91	106	77	51
5.	p – xylene*	9.134	91	106	77	51
6.	o - xylene	9.363	91	106	77	51

** m- and p-xylene (the same RT, as one peak), so the result is given as a total result for m, p-xylene*

Linearity was tested in a range of different concentrations for each analyte individually on a series of standard solutions prepared according to a standard procedure. Linearity is confirmed because the correlation coefficient (R^2) is greater than 0.999.

Table 2. Linearity with and the corresponding values of the coefficient correlation R^2

Analyte	y= Ax+B	R^2
Benzene	y = 212005.8 x + 2802.4	0.9996
Toluene	y = 292823.9 x + 4918.1	0.9994
Ethyl benzene	y = 104198.1 x + 3631.2	0.9992
m,p - xylene	y = 174957.8 x + 6926.3	0.9992
o - xylene	y = 86776.6 x + 3243.8	0.9991

The values of the correlation coefficient R^2 exceed the value of 0.99, so they can be considered sufficiently close to 1.0; therefore, the dependence can be considered linear. The detection limits were determined from seven repetitions of the concentration standard of 1.0 µg/l and based on the equation: MDL = S*t(n-1,1-alpha = 0.99) where: t(n-1,1-alpha = 0.99) – Student's t value for 99% confidence level and n-1 degrees of freedom, S – standard deviation of repeated analysis.

Table 3. Values of standard deviation and limit of detection (t=3.143 for n-1=6)

Analyte	STDEV	MDL
Benzene	0.012	0.04
Toluene	0.010	0.03
Ethyl benzene	0.012	0.04
m,p - xylene	0.013	0.04
o - Xylene	0.010	0.03

Precision and accuracy were determined by running 6 spiked samples at 0.1 µg/kg. Accuracy is determined by calculating the standard deviations and relative standard deviations.

Table 4. Parameters of precision and accuracy at the level of 0.1 µg/kg

Analyte	Mean	STDEV	RSD (%)	Bias	Bias (%)	Recovery (%)
Benzene	1.082	0.0823	7.6	0.082	8.2	108.2
Toluene	0.995	0.0938	9.4	-0.005	-0.5	99.5
Ethyl benzene	0.98	0.0901	9.2	-0.02	-2.0	98.0
m,p - xylene	0.947	0.0641	6.8	-0.053	-5.3	94.7
o - xylene	1.067	0.0963	9.0	0.067	6.7	106.7

The obtained results show that the requirements of the EPA are fulfilled because recoveries were in the range of 80-120%, and the relative standard deviations were less than 20%.

Table 5. Values of measurement uncertainties at the level of 0.1 µg/kg

Analyte	u(Rw), %	u(bias), %	u (%)	U (%)
Benzene	7.6	8.9	11.7	23.4
Toluene	9.4	4.0	10.3	20.5
Ethyl benzene	9.2	4.4	10.2	20.3
m,p - xylene	6.8	6.1	9.1	18.2
o - xylene	9.0	7.8	11.9	23.9

*where *u is the total (combined) measurement uncertainty, while the extended measurement uncertainty is U = u* 2*

There are no specified special EPA requirements for measurement uncertainty, but considering that it is determined based on accuracy and precision that meet the prescribed criteria, it can be considered that the values of measurement uncertainties are also satisfactory.

Table 6. Calibration, Accuracy, and Precision Data

Compound	Calibration			Accuracy and precision (n = 7, 0.1 µg/kg)[1]		
	Linearity RF (%RSD)	MDL (ppb)	Avg. RF	Avg. Conc. (ppb)	Accuracy (%)	Precision (%RSD)
Benzene	5.48	0.12	1.510	0.85	87	4.51
Toluene	3.39	0.13	1.24	0.95	95	4.44
Ethylbenzene	5.48	0.22	1.50	0.88	90	7.91
m-, p-xylene	9.22	0.43	1.15	1.7	89	7.51
o-xylene	6.57	0.20	1.17	0.89	88	7.03

Data from the seven 0.1 µg/kg samples

4. CONCLUSION

This study confirmed the capability of the use of the P&T system for the determination of BTEX concentrations in the sediment samples with a developed method by a GC-MS. The %RSD of the calibration curve passed all method requirements. Furthermore, MDL, precision, and accuracy showed no interference from excessive water. The procedure of method verification showed that the obtained values are satisfactory and that the applied method can be used to analyze BTEX in sediment samples.

This research was supported by the Ministry of Science, Technological Development and Innovation of the Republic of Serbia (Contracts No.: 451-03-47/2023-01/200026 and No.: 451-03-47/2023-01/200135).

ECONOMIC INSTRUMENTS IN THE FUNCTION OF ENVIRONMENTAL PROTECTION

Saša Marković[1], The Academy of Applied Technical Studies Belgrade
Darja Žarković[2], The Academy of Applied Technical Studies Belgrade

Abstract: *Economic instruments influence the trends of those economic activities that present a danger to the environment and are a suitable and efficient way of reducing environmental costs to the expense of companies (polluters). This is called "internalization of externalities", which means that companies that pollute the environment in any way (externally) take on themselves (internally) the payment of that type of costs. The existence of the costs of degradation of the ecological balance is a very strong reason for the establishment of economic instruments through which companies are charged the price of degradation of the ecological balance. There are many economic instruments that serve to protect the environment and in this paper only those that have the greatest application and importance will be listed: environmental taxes; environmental compensations; transferable pollution permits; deposit refund system; subsidies. The basic purpose of introducing various economic instruments is to force polluters to make a choice. The result of this will have ecological, but also economic consequences of rational behaviour. The main reasons or motives for the significant use of economic instruments in environmental policy are: establishment of efficient and economical environmental policy, administration reform, fiscal reform, and gaining of new sources of public revenue.*
Keywords: internalization of externalities, economic instruments, environmental protection, costs, environmental taxes

1. INTRODUCTION

Environmental pollution is a term that was accepted in the time after the sixties of the last century. In the economic sense, it represents a category that the great economist Marshall called "external effects" for producers and consumers. When deciding on alternative levels of production, consumption, investment, etc., economic entities calculate the costs and benefits of each of the different alternatives. Inputs from the environment and/or outputs of economic processes are not specifically included in the costs and benefits borne by the polluter.
In market economy conditions, companies will try in every possible way to ignore elements of social costs of the environment even if they are aware of their existence. Even more if there are no sanctions for such behaviour. The market mechanism will encourage individual economic participants to transfer social costs to other actors or to postpone them for some future time. This, in turn, means that the existence of social costs of the environment is an argument for the formation of social institutions that will take care of the preservation of the environment.

[1] smarkovic@atssb.edu.rs
[2] dzarkovic@atssb.edu.rs

What are the instruments through which certain institutions approach the realization of this goal? The classic approach of economic theorists is the one that reckons with the "internalization" of these externalities. In some cases, costs related to externalities cannot be expressed because the ownership of goods or services is not precisely defined [1].
In deciding on different alternative levels of production, consumption, investment and the like, economic subjects are forced to take into account the costs and results, only for themselves, of each of the different alternatives they intend to undertake. Ecological inputs and/or outputs of economic processes, and especially their possible social consequences, as a rule, are not included in the costs and results. Hence, they do not have adequate influence on individual economic entities when making business and investment decisions. Under competitive pressure, the market mechanism is powerless to account for the social cost borne by certain participants, especially in the future. In other words, the existence of social costs of the ecological balance disturbance is a very strong reason for the incorporation of social instruments through which economic actors (enterprises) are charged the "price" of the ecological balance disturbance [8].
There are numerous economic instruments that are used to "internalize" these externalities. Their common feature is that, unlike legal and technical instruments, they leave the participants free to respond in the way that suits them best. Economic instruments affect the costs and benefits of those activities that pose a danger to the environment and are an appropriate and efficient way of reducing environmental costs to the burden of companies (polluters). Terminologically, this is called "internalization of externalities", which means that companies that pollute the environment in any way (externally), take upon themselves (internally) the payment of that type of costs, which can be reflected in fees to state or local authorities, taxes, fines and similar [2].

2. CHARACTERISTICS OF ECONOMIC INSTRUMENTS

Before listing and briefly describing the basic economic instruments, it is necessary to get acquainted with their basic characteristics [3]:

- Transparency - The environmental goals of the green tax reform must be realistic, believable and precisely determined, and the interested public must be timely and thoroughly informed.
- Precision - Environmental taxes should be introduced gradually, with an appropriate dose of caution, while taking into account economic, ecological, demographic, bio-regional, ethno-cultural, psycho-social and political trends. Because any ill-measured and ill-advised action with a bad intention can cause very serious problems, ranging from the loss of competitive advantages on the integrated world market and job losses, all the way to the decline of state authority.
- Equality - Environmental taxes must be compensated by tax breaks in other areas, in accordance with the principle of fiscal neutrality, so as not to stifle production. Where environmental taxes act regressively, the application of compensatory measures is necessary. Predictable social injustices can be alleviated by increasing the non-taxable part of income (subsistence minimum) or lowering the rates of already introduced indirect taxes (sales tax, value added tax). In principle, any system of monetary valuation that is not corrected by fiscal redistribution and conflict arbitration works only in favour of the rich.
- Simplicity - Environmental taxes must be easy to understand so that employees in financial services can simply apply them.

- Stability - The possibility of tax evasion (avoidance of paying taxes) is also relevant for the scope of incomes, therefore it should be taken into account that the obligation to pay them cannot be easily avoided.
- Adaptability - An important element of any environmental protection strategy is its adaptability, both to the overall economic dynamics and the pace of environmental changes. One should always strive to achieve the desired directing power with as few adverse consequences as possible, whenever possible.
- Credibility - Determining the optimal level of the environmental tax and the appropriate choice of the taxpayer is a very sensitive issue. The amount of environmental taxes must not be determined arbitrarily or under lobbying pressure. The very assessment of the justification and possibility of introducing environmental taxes, as well as the procedure for determining their optimal level, requires great financial effort (a large number of public officials, a wide circle of experts, representatives of non-governmental organizations, lobbyists of various interest groups are involved).
- Solidarity - Successful green tax reform cannot be done in one country and there must be an appropriate degree of international alignment. Protecting their own environmental well-being, hyper-industrialized countries are introducing an increasing number of standards, regulations and economic instruments for the internalization of environmental costs, and the accelerated transfer of external economies from countries with higher standards of environmental protection and a stronger compulsion to internalize environmental costs to those with a lower degree of regulation feeds the justified fear that ecological progress could (p)remain a monopoly of rich countries. It would be neither fair nor economically justifiable to force developing countries to immediately bear the full costs of adapting to strict international environmental standards at a time when they are faced with the high social costs of the neoliberal transition.
- Expediency - The full benefit from the introduction of environmental taxes will only be realized when the revenues thus obtained are directed to concrete projects of environmental research and development (to make the technology as reliable, safe and high-quality as possible).
- Responsibility - Despite great faith in science, the final decision is still (and almost always) political.

3. ECONOMIC INSTRUMENTS IN THE FUNCTION OF ENVIRONMENTAL PROTECTION

There are many economic instruments that serve to protect the environment (over 150 in the European Union), and only those that have the greatest application and importance will be listed here (5).

3.1. Environmental (ecological) taxes

Establishing tax burdens that take into account the limitation of non-renewable resources means going to meet green tax reforms, with the ultimate clear goal: desirable environmental action should be made economically profitable as well. Green taxes should cover certain emissions (carbon dioxide, sulfur dioxide, nitrogen oxides), municipal waste, nuclear energy, gasoline, fossil fuels (for heating), certain chemicals containing cadmium, mercury, chlorine, soil concreting and others. activities.

Environmental taxes, as a supplementary source of public revenue, are becoming a social reality. In a number of OECD countries, the instruments of the fiscal system are increasingly being used for the realization of environmental goals. The end of the twentieth century, in

most OECD member countries, was marked by the process of the so-called "greening of tax systems", starting with the introduction of individual environmental taxes (on artificial fertilizers, packaging materials, batteries) and ending with comprehensive environmental tax reforms [4].
The key reason for the introduction of environmental tax in the tax system lies in the need to amortize the impact of pollution on the environment. The goal of environmental taxes is to sanction harmful emissions (air pollution, waste water).
Fiscal burdens, which are built into the price of the product, should force the producer or the consumer to take into account the costs of environmental pollution, as well as other external costs (eg increased noise near the airport), when making economic decisions. Both polluters and consumers should be stimulated to produce or use those products that are more ecologically sound, and the producer should reduce pollution to a level where the marginal cost of implementing a measure to prevent pollution is equal to the prescribed tax rate. In all situations, the polluter has a choice: either to pay the full amount of tax, or to introduce new equipment and technology to reduce pollution, thereby reducing his tax liability. There are three basic categories of environmental taxes [5]:

- Tax on energy products - tax on mineral oils and motor fuels, tax on gasoline, diesel, heating oil, kerosene, kerosene, natural gas and electricity consumption;
- Transport tax - tax for the registration and use of motor vehicles, on the import and sale of motor vehicles, on the use of roads and highways, on insurance of luxury yachts and on air passengers;
- Tax on pollution and natural sources - Tax on pesticides and artificial fertilizers, on packaging and packaging of metal, plastic, glass, ceramics, on waste, on air pollution, on batteries, tires, available containers, on waste water, on plastic bags, on water pollution, on ozone pollutants and on nuclear energy.

In the last decade of the 20th century, income taxes were significantly reduced, by around 10%, in order to be able to introduce environmental taxes into the tax system through tax reforms, in which the Scandinavian countries are particularly at the forefront. Finland and Denmark applied a compensatory measure with tax reforms, by reducing income taxes and increasing bills for energy from non-renewable sources. Energy taxes were introduced with the aim of optimizing energy types and preserving non-renewable resource potentials. Energy taxes also fulfil ecological functions, given that tax "impositions" achieve a higher degree of use and the necessary economy in the disposal of resources. Taxes on energy products were introduced into the EU legislation in accordance with several very important legal principles: prohibition of discriminatory application of domestic costs; prohibition of the application of state measures, such as subsidies; banning the application of quantitative import and export restrictions and other measures with the same effects; and the obligation of member states not to temporarily introduce energy taxation.
The green tax reform, in the member states of the European Union, has been implemented with varying success, and the leaders are Denmark, Finland, Germany, the Netherlands, Sweden and Great Britain. A common feature of the tax reforms in these countries is that they implemented a compensatory measure of income/personal income tax cuts, with the aim of increasing employment [6].

3.2. Pollution charges

The basic purpose of pollution fees is to internalize the cost of damage caused by pollution, by determining the price for activities that pollute the environment, according to the "polluter pays" principle. The classic form of internalization of negative externalities is the

determination of fees for products that pollute the environment, in the form of a unit tax (per unit of pollution). The intention of the legislator is to encourage the polluter to internalize externalities, bearing in mind his marginal external costs. This is achieved by imposing a unit tax, which contains an unrealistic assumption that the reduction in pollution will come from a reduction in production. To overcome this difficulty, fees are introduced for actual pollution emissions [7]. In these situations, the polluter considers the damage caused to the environment as his production cost and the company can continue to pay compensation or will invest in new technologies with the aim of reducing pollution emissions to the permitted level.

3.3. Subsidies

Subsidies, as alternative market approaches to reducing environmental damage, are influenced by subsidizing pollution reduction equipment or subsidizing pollution costs. Subsidies for equipment are intended to reduce the costs of technology in the form of donations or loans with favourable conditions (interest, repayment term, write-off of receivables).

3.4. Deposit and refund systems

The economic instrument of the deposit and refund system discourages illegal dumping of pollutants. A deposit is determined for possible damage, which is equal to the difference between the social and private cost of waste disposal, it is mainly applied for packaging waste and a refund guarantee is issued in all cases if no damage is caused. This instrument combines the pollution compensation and the procedure for the supervision of monitoring costs [7].
The deposit has the same function as the pollution fee, but the main difference is that the potential polluter has an incentive to properly dispose of or process the waste, if it is cost-effective considering the quantity, because that is the only way he will be able to return his deposit. The advantage of this economic instrument is that it does not impose additional monitoring and enforcement costs, and that it promotes the recycling/reuse of raw materials.

3.5. Tradable permits/trading system for pollution permits

In the system of exchangeable permits, the state determines the total allowed amount of pollution, and the market determines the price of pollution. When the information is precise and complete, the tradable permit system achieves the same results as the pollution charge, because it starts from a known variable - the socially permissible/permissible level of pollution. There is a type of tradable permit based on credits that a polluter can acquire if its emissions are below the level and "permits" to pollute, which are marketable and available to polluters depending on new technologies. The state determines the trading conditions for exchangeable permits. Polluters whose total emissions are below the limit values enter the market and sell "permits" for pollution, polluters in a certain region, whose emissions are above the target amount, buy them. In this way, the market of "rights to pollute" is developing [7]. The system of exchangeable permits and the trading of permits/quotas is an effective mechanism for monitoring pollution in the region, and individual polluters are beyond its power. The problem is how to establish a balance between different types of pollution, because in one region probably not all polluters emit the same substances, while depending on climatologically, hydrological and other circumstances, for a given area, certain types of pollution may be disproportionately more dangerous than others.

4. CONCLUSION

Linking economic and environmental policies and their effective integration implies the development and more consistent use of economic instruments. In OECD member countries, in the last two decades, around 150 different economic instruments, including subsidies, have been identified, and of that number, more than 80 are various environmental fiscal taxes. Economic instruments are used as a supplement to regulatory instruments, because their application is an effective form of environmental protection. The basic meaning of the introduction of various economic instruments is to force polluters to make a choice, the result of which has ecological and economic consequences of rational behaviour. The tendency to shift the centre of gravity of environmental protection policy from regulatory to economic instruments of environmental protection is motivated by the gradual dominance of the so-called preventive ecology. The modern concept of environmental protection implies a high degree of compatibility between fiscal policy and environmental policy goals. From an economic point of view, the primary goal of environmental policy is to ensure that the external costs of pollution are borne entirely by emitters. The state must intervene to reduce the costs that the polluter creates for other members of society, and it is quite certain that the polluter would not take such costs into account.

OVERVIEW OF AIR POLLUTION IN THE CITY OF BOR DURING THE PERIOD OF 2020–2022

Jelena Milosavljević[1], Technical Faculty in Bor, University of Belgrade
Snežana Šerbula[2], Technical Faculty in Bor, University of Belgrade
Tanja Kalinović[3], Technical Faculty in Bor, University of Belgrade
Jelena Kalinović[4], Technical Faculty in Bor, University of Belgrade
Ana Radojević[5], Technical Faculty in Bor, University of Belgrade

Abstract: *The annual levels of SO_2, PM_{10}, as well as As, Pb, Cd and Ni in PM_{10} were assessed in the City of Bor, as an environmental hotspot, from 2020 to 2022. The given period included the data when copper smelting activities were not performed due to the enlargement of the production capacities. The data were compared to the air quality in the study area before 2020 and to the current air quality status in the Republic of Serbia and Europe. The defined annual limit values were exceeded for SO_2, PM_{10}, and Pb concentrations in PM_{10}, while the annual target values were exceeded for As and Cd content in PM_{10}. Among the measuring sites, the poorest air quality was observed at the site Jugopetrol, located in the prevailing NW wind direction. The standstill in the copper smelting activities was perceived in the reduction of the annual levels of SO_2, As, Pb, Cd and Ni in PM_{10}. Compared to the current data for the Republic of Serbia and Europe, the air quality in the City of Bor was poor.*
Keywords: air pollution, SO_2, PM_{10}, toxic elements, copper smelter

1. INTRODUCTION

Air pollution originates from natural and anthropogenic emission sources, whereby the latter ones are considered dominant in the areas endangered by different industrial activities. Air pollutants such as: sulphur dioxide (SO_2), particulate matter (PM), ozone (O_3), nitrogen dioxide (NO_2), and carbon monoxide (CO) are recognised by the World Health Organization (WHO) as crucial environmental threats to the human health on the global level [1] based on their association with numerous negative health conditions. Both inhalation and dermal contact with SO_2 could lead to respiratory problems, lung damage, skin burn or irritation etc. PM, as a major component of air pollutants, are classified as carcinogenic [2]. PM exposure is associated with increased rate of hospitalization, lung cancer, as well as respiratory and cardiovascular diseases. It should be emphasised that toxic elements present in PM are associated with carcinogenic and non-carcinogenic health risks [3]. Environmental impacts of air pollutants could be observed through the damages of ecosystems, acid rain, soil acidification, ozone depletion, deforestation, climate change etc. [2,4,5].
Mining and metallurgical activities in the City of Bor have contributed to the significant environmental pollution, whereby extreme air pollution was denoted in previous decades [6,7,8,9]. Thus, modernization of the copper production was performed and pyrometallurgical copper production was replaced with the flash smelting technology (FST) with higher productivity and

[1]jmilosavljevic@tfbor.bg.ac.rs
[2]ssherbula@tfbor.bg.ac.rs
[3]tkalinovic@tfbor.bg.ac.rs
[4]jkalinovic@tfbor.bg.ac.rs
[5]aradojevic@tfbor.bg.ac.rs

smaller negative environmental impact, as the main advantages. However, the data for the period after the FTS implementation indicated that the City of Bor is still a hotspot concerning air pollution with As and SO_2 [10]. Thus, the continuous monitoring of the air pollution in the City of Bor still represents one of the most important issues in terms of protection of human health and the environment.

This paper summarizes the annual concentrations of SO_2, PM_{10}, as well as As, Pb, Cd and Ni in PM_{10} for the period 2020–2022, aiming at comparing the periods before and after the FST implementation, regarding the current air quality status in the Republic of Serbia and Europe as well. The given 3-year period includes the air pollution data when copper smelting was out of order due to the enlargement of the copper production capacities.

2. METHODOLOGY

Mining in Bor started 120 years ago with the discovery of copper rich ore deposits, which were afterwards exploited and processed. The pyrometallurgical copper production from sulphide ores (chalcopyrite – $CuFeS_2$, chalcosine – Cu_2S, coveline – CuS and arsenopyrite – FeAsS) was the main pollution source of SO_2 and particulate matter, along with the copper mining activities. The outdated technology was replaced with the FST as an advanced and energy-efficient production method, during 2016 [9,10].

Monitoring of the air pollution levels in the City of Bor is performed by Mining and Metallurgy Institute Bor. In the given period (2020–2022), polluting substances (SO_2, PM_{10}, as well as As, Pb, Cd and Ni in PM_{10}) were measured at seven sites (Table 1) which were part of the local and the national Air Quality Monitoring network. The air pollution levels are given in the annual reports by Mining and Metallurgy Institute Bor [11,12,13].

The analysed period also included the data when the smelting was fully stopped, due to the enlargement of the copper production capacities from April 2022 till the end of the year 2022.

Table 1. Description of the measuring sites for monitoring of the air pollutants in the City of Bor
Source: MMI reports [11,12,13]

Measuring sites	Zone	Coordinates	Location*	Measured parameters

3. ANALYSIS OF AIR POLLUTING SUBSTANCES LEVELS

3.1 The levels of SO_2

The annual levels of SO_2 for the study period are given in Figure 1. Annual SO_2 concentrations have exceeded the defined limit value (LV, 50 μg m^{-3}) [16,17] at the sites TF (during 2020 and 2021), TP (2020) and JP (in the period 2020–2022). Considering the 3-year period, it can be seen that SO_2 levels decreased at all the measuring sites, with the highest levels in 2020 and the lowest in 2022. This could be attributed to the fact that smelting activities were not performed since April 2022. Among the measuring sites, the highest levels of SO_2 were observed at the site JP. This site was also characterised by the poorest air quality, regarding SO_2 levels, in the previous years [7,8,9,10]. This can be attributed to the location of this measuring site, which is located in the prevailing NW wind direction.
Although the levels of SO_2 were not as high as in the previous decades [7,8,9,10], in the Serbian Environmental Protection Agency reports [18,19], during 2020 and 2021, the air quality in the study area was of the third category (*i.e.* over-polluted air). The City of Bor was the only agglomeration in this category due to the high SO_2 levels. During 2020 and 2021 the levels of SO_2 were measured in the Republic of Serbia at 44 and 39 stations (excluding stations in Bor), respectively, and the annual limit value was not exceeded at any of these stations [18,19]. The SO_2 annual levels have been decreasing across the European countries from 2009 to 2018, with the highest decrease noted at the stations in suburban, and the lowest at the stations in urban areas [2].

3.2 The levels of PM_{10}

The levels of PM_{10} were above the defined LV (40 μg m^{-3}) [16,17] only at the site JP (2022) (Figure 2). The exceedances of the annual LV were not pronounced as in the period after the implementation of FST [10].
High levels of PM_{10}, along with the levels of SO_2, have contributed to the fact that the air in the City of Bor was overly polluted (III category) during 2021 [19]. During 2020 and 2021, the annual LV was exceeded at 18 and 15 stations, respectively, which makes PM_{10} the dominant polluting substance in the Republic of Serbia [18]. In Europe, during 2018, PM_{10} levels above the annual LV were noted at 6% out of more than 3000 stations [2].

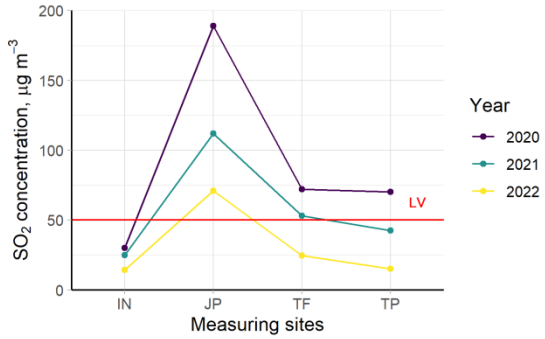

Figure 1. SO_2 concentrations at the measuring sites in the City of Bor (horizontal line represents annual limit value – LV)

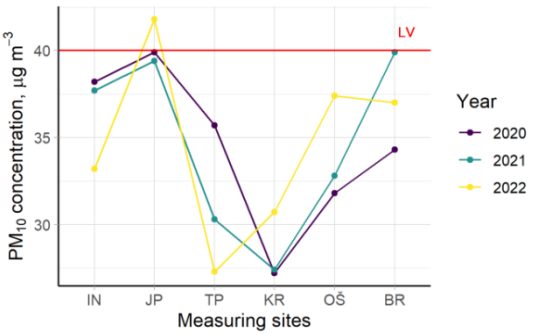

Figure 2. PM_{10} concentrations at the measuring sites in the City of Bor (horizontal line represents annual limit value – LV)

3.3 The levels of As, Pb, Cd and Ni in PM_{10}

Arsenic concentrations have exceeded the annual target value (TV, 6 ng m^{-3}) [16,20] at all the sites, during the analysed period, except at the site KR (2022) (Figure 3a). Compared to the As levels in 2020, during 2021 and 2022, the concentrations were lower, which could be attributed to the standstill in the copper smelting activities. The annual As concentrations were lower compared to the period

after the implementation of FST (2016–2019) [10]. The measuring site with the highest levels of As was the JP, which is located in the prevailing NW winds [10]. The high levels of this toxic element in PM_{10} were also noted during 2022, when smelting was not performed, which indicated that As could also have originated from other anthropogenic activities, such as resuspension of dust from the flotation tailings, as well as handling of the copper concentrates during transportation.
In Serbia, As levels on an annual basis were far below the TV during 2020 and 2021 [18,19]. During 2018, As levels above the annual TV were recorded at 6 out of more than 650 stations in Europe [2].

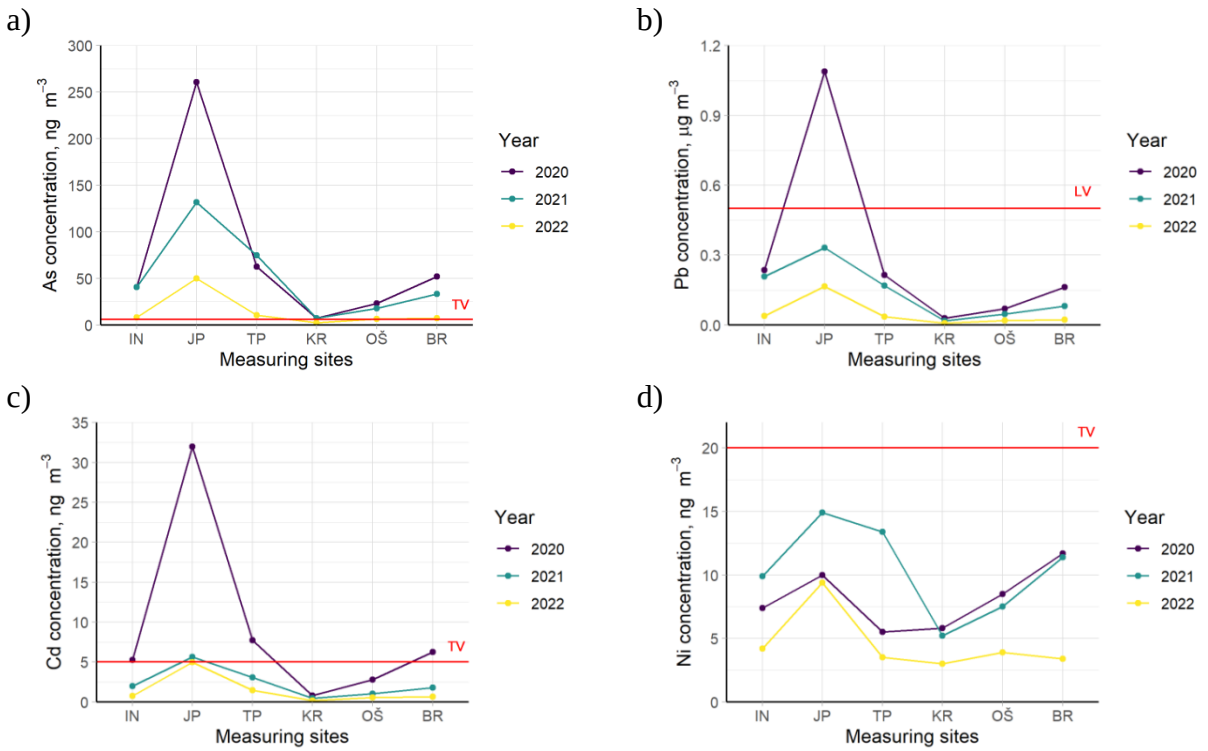

Figure 3. Toxic elements concentrations (a) As, (b) Pb, (c) Cd and (d) Ni in PM_{10} at the measuring sites in the City of Bor (horizontal line represents annual target value – TV for As, Cd and Ni, and limit value – LV for Pb)

Pb levels were above the defined annual LV (0.5 µg m^{-3}) [16,17] at the site JP (2020) (Figure 3b). Compared to the Pb concentrations during 2020, the concentrations of this toxic element were lower during 2021 and the lowest during 2022 when smelting activities were stopped. However, the JP stands out with the highest levels of Pb, due to its location on the prevailing wind directions, resuspension of dust from the flotation tailings, as well as handling of copper concentrates during transportation. The levels of Pb at the site JP frequently exceeded annual LV in the periods before and after implementation of FST [9,10].
In Serbia, during 2020 and 2021, the levels of Pb in PM_{10} did not exceed the LV, both at the stations where fixed and indicative measurements were done [18,19]. The Pb levels above the annual LV were recorded only at one out of nearly 700 stations across Europe during 2018 [2].
From Figure 3c it can be seen that concentrations of Cd were above the defined TV (5 ng m^{-3}) [16,20] at the sites IN (2020), JP (2020 and 2021), TP (2020), and BR (2020). Since 2020, the levels of Cd decreased on an annual basis, with the lowest ones during 2022 when smelting was not performed. The measuring site JP stands out with the highest levels of Cd, due to the dust resuspension from the flotation tailings, as well as copper concentrate handling during transportation. At the site JP the exceedings of the defined TV were observed in the periods before and after the implementation of FST [9,10].
In Serbia, the Cd levels on an annual basis were far below the TV during 2020 and 2021 [18,19]. In Europe, concentrations above the annual TV for Cd were not recorded during 2018 [2].

The Ni levels were below the defined annual TV (20 ng m^{-3}) [16,20] (Figure 3d). Among the measuring sites, the highest levels of Ni were observed at the site JP during 2021 and 2022, and the site BR during 2020. The lowest levels of Ni were noted for all the sites in the period when smelting activities were not performed, which could indicate its dominant anthropogenic origin. The annual levels of Ni did not exceed the defined TV in the period after FST implementation [10].
The levels of Ni on an annual level were below the defined TV during 2020 and 2021 in Serbia [18,19]. The concentrations of Ni were above the annual TV at 3 out of nearly 700 stations in Europe during 2018 [2].

4. CONCLUSION

The aim of this study was to analyse the concentrations of the air pollutants monitored at the measuring sites in the City of Bor, which is recognised as one of the most polluted region in the Republic of Serbia and beyond, due to the copper mining and smelting activities. The annual levels of SO_2, PM_{10}, as well as As, Pb, Cd and Ni in PM_{10} from 2020 to 2022 were compared to the defined limit and target values, as well as the current air quality in the Republic of Serbia and Europe. The data were also compared to the air quality in the study area before the analysed period. The exceedances of the defined annual LVs were observed for SO_2, PM_{10}, and Pb concentrations, and the annual TVs for As and Cd. Regarding the measuring sites, the site Jugopetrol located in the prevailing NW wind direction was characterised by the poorest air quality. The standstill in the smelting activities, due to the reconstruction of the copper smelter, was noted for the lower content of SO_2, As, Pb and Cd during 2022. Considering the air quality in the study area in previous years, the concentrations of the given pollutants were generally lower. However, the air quality in the City of Bor, for the given period, was poor, regarding the air quality in the Republic of Serbia and Europe, as well.

This research was supported by the Ministry of Science, Technological development and Innovation of the Republic of Serbia for financial support, within the funding of the scientific research work at the University of Belgrade, Technical Faculty in Bor, according to the contract with registration number 451-03-47/2023-01/200131. Our thanks also go to English language teacher Mara Z. Manzalovic from the University of Belgrade, Technical Faculty in Bor, for providing language assistance.

MINING SOLID WASTE AROUND BOR, YESTERDAY, TODAY, TOMORROW

Milan Trumić[1], Technical Faculty in Bor, University of Belgrade
Vladimir Nikolić[1], Technical Faculty in Bor, University of Belgrade
Mirjana Marić[2], Zijin Copper Bor
Jelena Janković[3], ProAkta, Beograd

Abstract: *Intensive exploitation and processing of copper ore in the area of Bor District has led to the degradation of large areas of land and the deposition of large amounts of solid waste (mining overburden and waste dumps, flotation tailings, smelter slag). The characteristic of these wastes is that they contain significant amounts of copper and other elements, but also permanently lead to soil, water and air pollution. The paper shows photos of the evolution of the appearance of mine solid waste landfills and provides data on sanation and recultivation and a plan for further activities. Conceptual solutions for sanation degraded areas created by hundred years of mining in Bor were also given.*
Keywords: Overburden, Flotation Tailings, Environment

1. INTRODUCTION

In the modern practice of producing non-ferrous, rare and precious metals, more and more attention is paid to the possibility of treating raw materials with low metal content, considering that they have disappeared, or the reserves of rich ores are very limited. At the same time, the intensive development of technology in the world leads to a higher consumption of metals, which results in a multiple increase in the price of metals in recent years [1]. The development of technological processes for recov ering the low-percentage copper ore and complex raw materials, demands the massive production, which has got a strong negative effect on the environment, especially when such ore is mined in the open-pit mines. The harmful influence of mining operations has been reflected in the degradation of vast areas of soil (open-pit mines), then, damping large volumes of solid wastes (mining overburden, waste rock dump and flotation tailing) as well as the occurance of acid mining waters. During the metallurgical processes of polymetalic ores and concetrates, besides obtaining the basic metals, there have also been formed middlings (slag, dust, and mud-slurry) [2].
Some research has shown that today there are 3,500 active overburden dumps in the world and that 100 billion tons of mining waste are deposited there annually [3]. In the countries of the European Union, more than 5 billion tons of mining waste are disposed of, most often in Finland, Greece, Ireland, Portugal , Spain, Sweden and Great Britain [1].
In 2020, the equivalent of 4.8 tons of waste was produced per EU resident. This figure includes 3,080 kg of coarse mineral waste and 1,735 kg of waste from other sources. In other words, 64 percent of waste in the EU comes from mining. Figure 1 shows data on waste generation by individual countries in Europe [4].

2. BOR YESTERDAY

Formerly RTB-Bor and today Zijin Copper represents one of the most important mining and metallurgical complexes in the Western Balkans. Mining production in Bor began in 1903, with underground exploitation. Surface mining in Bor began in 1912 and lasted until 1986. The two largest open-pit mines are Veliki Krivelj (opened in 1979) and Cerovo (opened in 1990).

Until 2001, the following were deposited on the territory of the municipality of Bor: 450 Mt of overburden, 207 Mt of flotation tailings and 23 Mt of smelter slag [5,6]. This waste represents a total of 99.95% of the total waste deposited on the territory of the municipality of Bor. Approximate quantities of deposited material in the vicinity of Bor are shown in Figure 2, and a schematic representation in Figure 3.

Mining has degraded 1198 ha of agricultural land, i.e. 0.02 ha per inhabitant. As a result of the discharge of wastewater from flotation and flotation tailings, 2,500 ha of land was destroyed, i.e. 0.4 ha per inhabitant [5,6]. The total area of the RTH tailings pond is 86.4 ha, and the area of the inactive "Visoki planir" mine disposal site is 302 ha with 177 ha of flat areas and 125 ha of sloping areas.

From the creation of the mining waste disposal site until 2019, technical and biological recultivation of degraded areas was carried out on several occasions. For example, in just one action in 1992, 190,000 acacia seedlings were planted on the flotation tailings of Bor and Veliki Krivelj, and 74 ha of degraded soil was filled with humus and grass was sown [7].

3. BOR TODAY

Serbia Zijin Copper DOO is a company operating within the Zijin Mining Group. It was founded on December 18, 2018, on the day when Zijin and the Government of the Republic of Serbia signed the final documents, i.e. the contract on the acquisition of 63 percent of ownership in RTB Bor. Serbia Zijin Copper is committed to reducing the adverse impact on the environment and since taking over RTB Bor has invested considerable funds, among other things, in reculturing degraded areas. Table 1 shows data on recultivated areas and planted seedlings by location [7].

Table 1. The area that has been recultivated and the number of seedlings planted

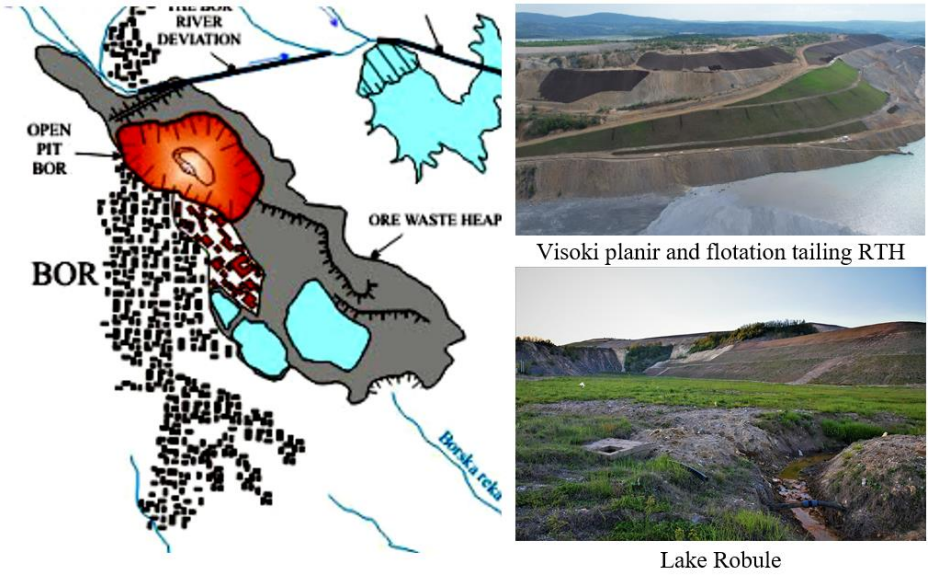

Figure 4. An example of recultivation (Bor today)
Suorce: [8]

4. BOR TOMMOROW

In the future, the company Serbia Zijin Copper DOO plans to continue activities on the recultivation and remediation of degraded areas, as well as the preparation of project documentation and the construction of solar power plants, which would meet part of the electricity needs from renewable sources. The use of renewable energy sources will significantly relieve the electricity grid of Serbia. The construction of solar power plants will be carried out in three phases, over the next 10 years, with the ultimate goal that in 2033 the production of electricity will be around 100 megawatts, while simultaneously reducing carbon emissions by 175,000 tons per year. The plan is that after the implementation of the project, the surroundings of Bor will look like the photos in Figure 5.

Figure 5. Forecasting the appearance of the around Bor in the future
Suorce: [8]

5. CONCLUSION

The constantly increasing development of human society is based on the development of industrial production and energetics imposing thus the necessity for larger exploitation of mining resources, that is, mineral raw materials. A long-term exploitation in Bor and its vicinity had a great influence on the environment through the degradation of large areas of soil (open-pit mines), then, the deposition of huge volumes of solid wastes (overburden and waste rock), next, forming waste waters and air pollution. How it was yesterday, how it is today, and how it will be tomorrow for the citizens of Bor, we leave it to the readers to answer for themselves, and we only give a couple of photos in Figure 6.

Yesterday Today Tomorrow

THE SOLUTION FOR REUSING NON-RECYCLABLE PLASTIC-BASED MATERIALS

Danijela M. Jašin [1], Technical College of Applied Sciences, Zrenjanin
Ljubica Lazić Vulićević [2], Technical College of Applied Sciences, Zrenjanin
Valentina Mladenović [3], Technical College of Applied Sciences, Zrenjanin
Aleksandar Rajić [4], Technical College of Applied Sciences, Zrenjanin

Abstract: *In this paper, an innovative technology for recycling materials that cannot be recycled using conventional methods is presented, such as composite plastics, for example. The result is an eco-friendly material with good mechanical properties that can replace wood, metal, and other plastic materials. The production and application of this eco-material are in complete accordance with environmental principles.*
Keywords: Recycling, Innovative Technology, Non-recyclable Materials, Mechanical Properties

1. INTRODUCTION

From the 1950s to the present day, plastic production has been steadily increasing. This is entirely understandable when considering the widespread use of plastic materials in various sectors.The worldwide production of plastics reached a staggering 390.7 million tons in 2021 [1]. The packaging industry undoubtedly takes the lead. Plastic bottles for bottled water and soft drinks, as well as a whole range of other types of packaging in the food and other industries, as well as the automotive, electrical, and construction materials industries, are practically inconceivable without the use of plastic. Only 9% of the mentioned quantity of plastic produced after use is recycled, so it is clear that plastic waste represents a global problem [2].
It is expected that the amount of plastic waste will exceed one billion tons by 2050 [2], which necessitates a serious approach to recycling, as well as innovation in this field and the development of new types of materials.

2. PREVIOUS EXPERIENCES IN PLASTIC RECYCLING

Existing known plastic recycling processes require very careful and detailed sorting of waste materials by type, which is by no means simple and requires prior knowledge to properly separate and sort them after collection. In fact, existing recycling technologies can only process homogeneous plastic materials. Sorting plastic materials, especially when dealing with large quantities, is challenging because plastic materials often appear almost identical at first glance, and the markings for plastic type are sometimes hard to spot.
In practice, it often happens that improper sorting in the primary selection phase, as well as in the primary recycling phase, which involves mechanical shredding of plastic waste, leads to the mixing of various plastics. From contacts with larger plastic recycling centers in the country and the region, we have information that during one business year, between 5-10% of the amount of plastic waste

[1]danijelajasin@gmail.com
[2]lazic.ljubica@yahoo.com
[3]valentina.mladenovic@vts-zr.edu.rs
[4] aleksandarrajic@yahoo.com

processed through primary recycling cannot be further processed with known technology. It is also common for plastic pieces to be sent for recycling that consist of multiple parts made of different types of plastic. The costs of separating such parts far exceed the upper limit of profitability, and they need to be manually separated using various tools. Unfortunately, even such an approach is not a guarantee of achieving complete separation [3, 4]. In such cases, all parts are shredded together and pose a problem for further recycling.

Currently, there is no known technology for recycling, processing, and reusing composite and mixed plastics with glass. Such waste materials are mostly incinerated or deposited in landfills. One of the recycling ideas for composite and mixed plastics is presented in this paper. The result is a new, innovative technology that successfully recycles 80% of previously non-recyclable, non-hazardous composite and mixed plastics and glass, with only 20% consisting of selected plastic materials. The resulting eco-material possesses exceptional properties, as demonstrated in the following chapters of this paper. First, however, we will present the fundamentals of the innovative technology for recycling composite, mixed plastics, and glass.

3. INNOVATIVE RECYCLING TECHNOLOGY AND PRODUCTION OF INNOVATIVE ECO MATERIALS

The innovative recycling technology (Fig. 1), i.e., processing and reusing various types of composite and mixed plastics, which are mostly not recyclable, along with glass, is based on a special process for preparing the initial plastic waste.

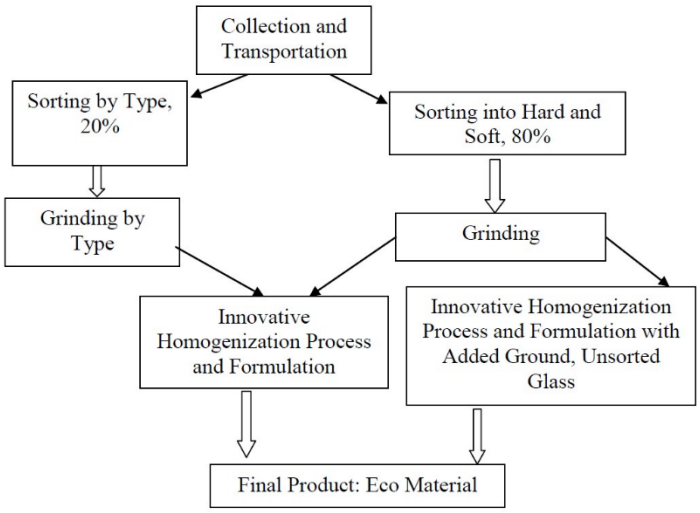

Figure 1. Diagram of Innovative Recycling Technology

The core of innovation is in a specific type of homogenization of the starting material with changes in the sequence of operations in the recycling process. The formulation and recipe design that combine waste materials are also a form of innovation, requiring a significant number of hours for experimentation and trials.

By comparing the processes of conventional recycling and innovative recycling, the innovative technology offers the following solutions:

- Processing, recycling, and reusing various types of waste mixtures, plastic composites, and glass.
- Sorting by type (polypropylene, polyethylene, polyvinyl chloride, etc.) is minimized or can even be eliminated because our formulation includes only 20% of selected plastic, as mentioned earlier. Therefore, there is a clear saving in time, labor, and storage containers.
- The elimination of the need to further process sorted plastic separately and in separate lines (washing, drying, granulation) or to wait for one type to be processed before the next.
- Reducing the number of mechanical processing operations of waste plastic that precedes the production of the finished product.

- A specific process and formulation for mixing waste plastic to homogenize it in a straightforward manner.
- A new process and formulation for mixing waste plastic to obtain a widely applicable material for various finished products.

Through the injection molding and extrusion process from regranulate a new product is obtained with a clear limitation that, depending on the type of initial waste plastic, a recycled product of the same type with known characteristics and limited applications is produced. In our case, the resulting eco-material has entirely new properties, significantly improved compared to the raw materials, and thus a wide range of possibilities for a broad spectrum of finishing products.
The aforementioned observations lead to the conclusion that this innovative technology presents a solution for the reutilization of a significant quantity of mixed waste plastics, composites, and glass. It demonstrates energy efficiency and yields a product with a broad spectrum of applications. It serves as a noteworthy illustration of sustainable development and the circular economy, both of which are global aspirations.
Upon reviewing the literature and closely following developments in this field, it appears that there are seemingly analogous concepts related to recycling composites and mixed plastic waste. However, these concepts are typically confined to specific combinations of plastic and composite mixtures. A notable distinction from our solution lies in the considerably more intricate and extensive mechanical treatment of the initial material they employ. Additionally, these concepts lack in the homogenization process, where high temperatures are utilized, resulting in unavoidably higher energy expenditures and, consequently, escalated recycling costs.

4. A PRODUCT MADE FROM MATERIALS OBTAINED THROUGH NEW TECHNOLOGY

From materials obtained in this way, various products can be made, and the paper examines filled or hollow plastic profiles - eco column, which can serve as a replacement for traditional columns made of wood, concrete, metal, etc.
For this patent, an intellectual property protection certificate number 57664 was obtained in Serbia. In future research, it is necessary to conduct a life cycle assessment of the eco-product using the appropriate methodology [5], as this would further position this eco-material. It is important to note that this innovative technology falls within the recycling sector, which is certainly one of the priority areas for development and investment worldwide, in accordance with the principles of Agenda 2030 [6]. Considering that, until now, there hasn't been a cost-effective and beneficial solution for waste materials such as composite plastics, various plastic mixtures combined with waste glass, etc., the market for this innovative technology, eco-material, and its related products is substantial.

5. THE TYPE OF WASTE PROCESSED USING INNOVATIVE RECYCLING TECHNOLOGY

The formulation of innovative technology involves the following types of waste materials:
- Soft PVC - Index number according to the waste catalog:150201 [7]. After grinding, this mass is homogenized with glass and other non-recyclable plastics, and it is used as a filler for profiles. It is rarely recycled, even though recycling is possible, and is typically subjected to incineration.
- Rigid PVC - Waste index number: 1501002 [7]. It is used as a filler in a certain percentage or for manufacturing profiles.
- Multi-layer HDPE plastic bags with an addition of 10-15% PA or PET are used as a component for filling material. Waste index number: 150102 [7].
- Ground packaging glass, waste index number 150107 [7]. The potential for recycling is significant, but it has almost become inactive in our region. [8].

Manufacturing products from non-hazardous waste plastics that have not been suitable for recycling until now, occurs in several stages.

- The extrusion process for creating elongated hollow profiles from recycled plastic,
- Filling hollow profiles with a composite filler made from non-recyclable plastic-based materials, with the addition of ground glass or fabric. The filled profiles are called eco-columns.

6. MECHANICAL PROPERTIES OF THE ECO-MATERIAL AND THE FINISHED PRODUCT

In order to obtain certain mechanical properties of the eco-columns, tests were conducted on hollow and filled plastic profiles. Prior to that, the properties of the materials for manufacturing the profiles and the filler material were evaluated. The tests were conducted in laboratory at the Faculty of Civil Engineering in Subotica.

6.1 Testing plastic material for profiles

The mechanical characteristics testing of the plastic profile material was conducted on 9 samples. The test specimens were rotationally symmetrical in the cylinder shape with a length of 50 cm, and a diameter of 30 mm. The obtained average values of the results are:

- mass per volume: m = 1.414 g/cm3,
- tensile strength: σ = 33.24 MPa,
- recovery of strain after tensile failure: δ_E = 98.6 %.

6.2 Testing composite filler material

The mechanical characteristics testing of the composite filler material based on hydraulic binder was conducted on 9 samples in the form of a prism with dimensions of 4x4x16 cm. The reported results represent the mean values and pertain to a water-saturated state:

- mass per volume: m = 1.471 g/cm3,
- bending tensile strength: σ = 2.68 MPa,
- compressive strength: σ = 6.22 MPa.

6.3 The compression testing of short columns untill failure

These tests were conducted on samples that were cut out of the columns (hollow and filled) and prepared in a way to avoid slenderness efects during compression testing. The tests were performed on three samples of hollow and three samples of filled columns. The columns had square cross-section dimensions of 75x75mm, an average wall thickness of 7.2 mm, and a composite recycled mixture as the filler, while the height of the samples was 260 mm [9]. Samples during testing are shawn on Figure 2 and obtained diagrams on Figure 3 and Figure 4. The diagrams are interesting because they show the difference in the load-bearing capacity between a hollow and a filled column, and this is in favor of the filled column, as expected. Nonetheless, it's evident what the maximum compressive load capacity is for both column types, hollow and filled.

Figure 2. Samples during testing
Source: [9]

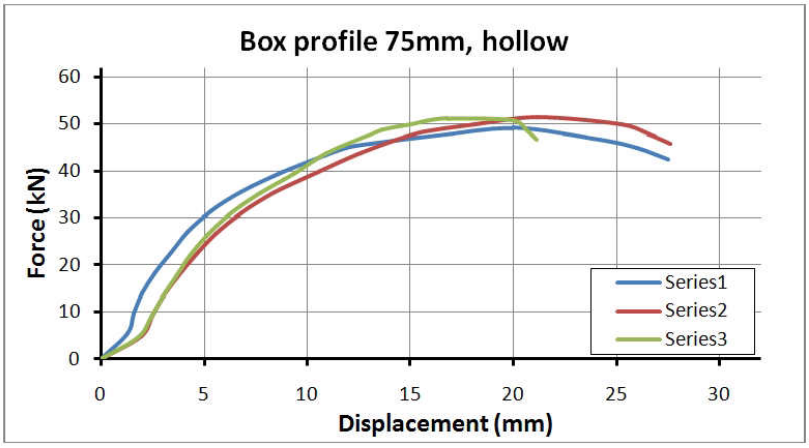

Figure 3. The compression testing untill failure data of hollow profiles
Source: [9]

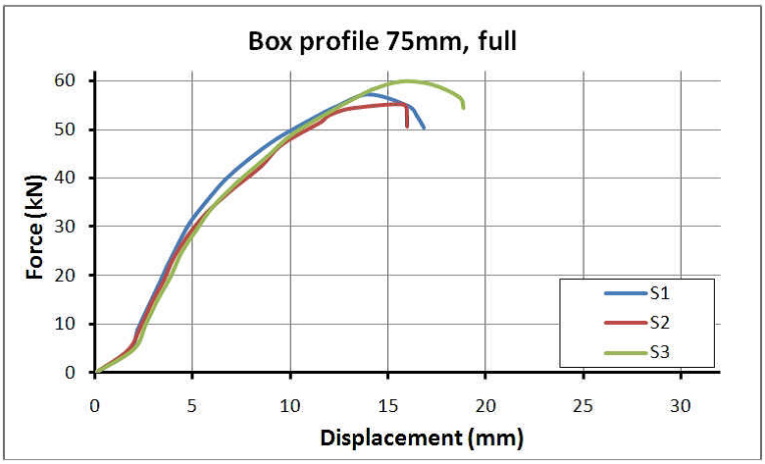

Figure 4. The compression testing untill failure data of filled profiles
Source: [9]

- The maximum achieved compressive force at the point of failure for a filled column: F = 57.87 kN.
- The maximum achieved compressive force at the point of failure for a hollow column: F = 50.89 kN.
- The maximum deformations (shortening) - filled column: Δl = 17.21 mm,
- The maximum deformations (shortening) - hollow column: Δl = 25.42 mm.

7. CONCLUSION

In this paper, the potential of materials resulting from research in the development of innovative technology for recycling composite plastics is presented. This eco-material is functional and comes with numerous advantages, including:

- It can replace traditional materials (metal, concrete, wood, etc.) in the production of widely applicable products in construction, agriculture, transportation, etc.
- It doesn't require additional protection in terms of impregnation or painting.
- Green manufacturing technology.
- Environmental protection,
- Savings and conservation of natural resources - waste materials that were previously incinerated or deposited in landfills are used instead of primary raw materials.
- The products can be recycled again using the same technology.

- The products can be aesthetically attractive, they can be colored during the manufacturing process, and their surface appearance can be customized to mimic the look of wood or any other desired structure.

The points highlighted in this paper undeniably lead to the conclusion that this innovative technology, and we can confidently add the label 'green technology' to it, as a solution for reusing a wide range of waste plastic mixtures, composites, and glass, is energy-efficient and results in a product with a broad range of applications. It can serve as an example of sustainable development and the circular economy that is pursued on a global scale

ELEMENTAL ANALYSIS OF RARE EARTH ELEMENTS IN COAL FLY ASH FROM THERMAL POWER PLANTS IN THE REPUBLIC OF SERBIA

Filip Živković[1], Faculty of Technology and Metallurgy, University of Belgrade
Milica Stojković[2], Faculty of Technology and Metallurgy, University of Belgrade
Maja Đolić[3], Faculty of Technology and Metallurgy, University of Belgrade
Mirjana Ćujić[4], Vinča Institute of Nuclear Sciences, University of Belgrade

Abstract: *Today, coal is widely used as an energy source in thermal power plants, but the process of combustion results in emissions of many air-pollution substances, as well as producing large amounts of bottom ash, fly (electrophilic) ash, and slag. In most cases, these materials are disposed of in landfills where they have a negative impact on the environment and human health. This paper focuses on exploring the possibility of extraction of rare earth elements from fly ash collected from different thermal power plants in the Republic of Serbia (Thermal power plant „Nikola Tesla" TENT A and thermal power plant „Kolubara"), by analyzing the concentrations of those elements in collected samples. Rare earth elements are a group of 17 chemical elements: Sc, Y, La, Ce, Pr, Nd, Pm, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb and Lu. The samples were acid-digested with a mix of concentrated mineral acids (nitric acid, hydrofluoric acid, and boric acid), in order to determine the elements of interest from the sample matrix. Determination of the content of rare earth elements was done by the ICP-MS.*
Keywords: coal fly ash, rare earth elements, microwave digestion, extraction

1. INTRODUCTION

After the process of coal combustion in thermal power plants (TPP), waste materials such as bottom ash, fly (electrophilic) ash, and slag are left behind. In the Republic of Serbia, those waste materials are, in most cases, disposed of in landfills where they have a negative impact on the environment and human health. The reason for this negative effect is due to a high content of various toxic substances, which can pollute different environmental mediums (air, soil, and water) [1]. However, due to the complex composition of fly ash, it is proven that this waste material can be used for various purposes and not disposed of in landfills. It can be used in the construction industry, for producing ceramics, for soil stabilization, in the production of catalysts, as a filler in the tire industry, and its potential use as a sorbent as well as raw material for extraction of useful elements (such are rare earth elements) is widely examined [2]. Because of technological development, increasingly strict regulations in the field of environmental protection as well as economic benefits, interest in fly ash as an alternative raw material for obtaining useful products is higher than ever. In this paper, the possibility of obtaining rare earth elements from fly coal ash was examined.
Rare earth elements (REE) are a group of 17 chemical elements in the periodic table with very similar chemical properties, including scandium, yttrium, and 15 lanthanides (lanthanum, cerium, praseodymium, neodymium, promethium, samarium, europium, gadolinium, terbium, dysprosium, holmium, erbium, thulium, ytterbium and lutetium) [3]. Rare earth elements have been subdivided

[1]zivkovicfilip25@gmail.com
[2]mstojkovic@tmf.bg.ac.rs
[3]mdjolic@tmf.bg.ac.rs
[4]cujicm@vinca.rs

into two groups, i.e., light rare earth elements (LREEs) and heavy rare earth elements (HREEs), according to their atomic weight. LREEs include elements from scandium (atomic weight 44.96), yttrium (atomic weight 88.91), lanthanum (atomic weight 138.91) through europium (atomic weight 151.96) while HREEs include elements from gadolinium (atomic weight 157.25) through lutetium (atomic weight 174.97) [4]. REEs are not found in nature as pure metals, they are extracted from different minerals, which do not often occur in easily exploitable deposits. These elements do not occur individually in nature because of their chemical similarity. There are around 200 rare earth elements containing minerals, but out of those only bastnaesite, monazite, xenotime, and ion-adsorbed clays are mined for commercial REE production [5]. Today, rare earth elements are very used in different industries. Some of them include the high-tech industry and a variety of consumer goods such as computers, cell phones, fluorescent lighting, permanent magnets, medical devices, and advanced defense technology [6]. Catalysts, ceramics and glass, metallurgical use, and alloy manufacturing as well as polishing are the major industries that consume thousands of tons of rare earth elements [4].
In order to extract REEs from coal fly ash samples, nitric, hydrofluoric, and boric acids were used. The main purpose of using those acids is to free the elements of interest from the sample matrix so that the analysis of the content of those elements in collected samples can be done.

2. MATERIALS AND METHODS

Representative samples of electrophilic, and landfill fly ash were collected from the thermal power plants "Nikola Tesla" TENT A and "Kolubara", six samples in total. The first step was to weigh 0.5 g of each sample on an analytical scale and then transfer those to closed tubes specially designed for microwave digestion. The extraction procedure was done in two steps. Firstly, after the samples were weighed, 3 ml of concentrated nitric acid (HNO_3) and 2 ml of concentrated hydrofluoric acid (HF) were added. The microwave digestor was set to work with a power of 800 W and a pressure of 80 psi for the first 10 minutes, and then at a pressure of 120 psi for the next 15 minutes. The second step of the procedure involved the addition of 20 mL of pure distilled water and 10 mL of 5% boric acid (H_3BO_3). Tubes were put back in the microwave digestor and the parameters were set at the pressure of 80 psi for the first 10 minutes, and then at the pressure of 120 psi for the next 10 minutes. After the digestion was done, tubes with samples were put aside to cool. Cooled samples were filtered using syringes and microfilters and preserved. Such samples were further diluted so that the analysis of the content of rare earth elements could be done by ICP-MS. The content of the following elements was determined: Sc, Y, La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb and Lu. The software program Qtegra was used for analysis of the obtained data.

3. RESULTS AND DISCUSSION

Figure 1 and Table 2 show the obtained results, expressed in unit mg of element per kg of sample. Samples T1 and T2 are samples collected from the TPP "Nikola Tesla" TENT A, and samples K1, and K2 are samples collected from the TPP "Kolubara". Samples T1 and K1 are electrophilic fly ash, and samples T2 and K2 are fly ash collected from landfills.
Analyzing the presented results, it was concluded that the overage content of REE was higher in the samples of fly ash originating from TPP „Kolubara" (samples K1, and K2) compared to the ones from TTP „Nikola Tesla" (samples T1, and T2) (Table 1). The highest content of REE in fly ash from both TPPs was sampled directly from landfills and has a content of 309.65 mg/kg (sample T2) and 434.89 mg/kg (sample K2). This corresponds to the information that the average content of REE on a global scale in fly ash is around 404.00 mg/kg [7]. Taking into consideration that the American Ministry of Energetics proposed that a concentration of REE in fly ash over 300.00 mg/kg is favorable for the extraction process and further metal-recovery application, those fly ashes are estimated to be suitable for this kind of utilization [8].

Regarding the content of critical elements (Nd, Eu, Tb, Dy, Y, Er, expressed in mg/kg), as the most valuable material source, they were measured in all selected samples. The overage content of critical elements was also higher in the K samples – 98.00 mg/kg, compared to the T samples – 83.6 mg/kg, respectively (Table 1).

Table 1. Content of all elements in collected samples

Samples	**T1**	**T2**	**K1**	**K2**
The total content, mg/kg	266.16	309.65	230.19	434.89
Overage content, mg/kg	288.00		332.54	
The total content of critical elements (Nd, Eu, Tb, Dy, Y, Er), mg/kg	76.57	90.63	65.4	130.59
Overage content of critical elements (Nd, Eu, Tb, Dy, Y, Er), mg/kg	83.6		98.00	

In the analyzed samples, the content of cerium (Ce) was the highest of all individual REE (in samples K2, and T2 concentration was 138.63 mg/kg, and 100.12 mg/kg, respectively), which is in accordance with the natural appearance of this element in Earth crust (Figure 1). The descending order of the significant concentration of the elements (in terms of their quantification) was the following: cerium (Ce, in the range of 40.92 – 138.63 mg/kg), scandium (Sc, in the range of 20.09 – 41.05 mg/kg), and lanthanum (La, in the range of 40.92 – 73.99 mg/kg). Respecting the critical elements, only the neodymium (Nd, in the range 34.26 – 62.58 mg/kg), and yttrium (Y, 22.33 – 50.29 mg/kg), have shown significant content in all analyzed samples. The less significant concentrations were measured for the following elements: praseodymium (Pr), samarium (Sm), gadolinium (Gd), and, dysprosium (Dy), in the range of 4.21 – 16.81 mg/kg. The other elements: europium (Eu), terbium (Tb), holmium (Ho), erbium (Er), thulium (Tm), ytterbium (Yb), and lutetium (Lu) have not shown significant values.

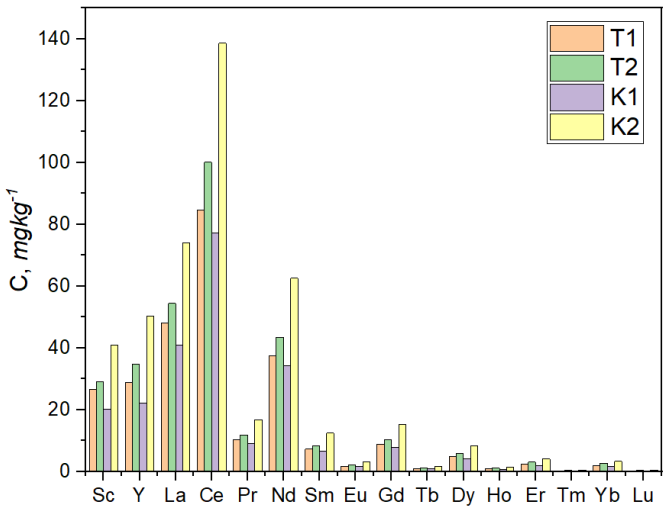

Figure 1. Content of elements in collected samples

Comparing the selected sample sites, it was determined that fly ash collected from landfills has a higher content of REE compared to electrophilic ash (Table 1, Figure 1), which is probably due to the synergetic effects of weather conditions and other (organic/inorganic) compounds present at the landfills. This means that disposal of industrial fly ash is the less acceptable approach, respecting to the waste management hierarchy [9].

The extraction procedure demonstrated in this research (the combination of concentrated mineral acids: HNO_3, HF, and 5% H_3BO_3), has shown an efficient analytical approach for the qualitative and quantitative analyses of REE. The results proved that this method is feasible for the metal-recovery application. Further investigation should be directed toward the environmental impact assessment related to the optimization of three main process parameters: greenness, efficiency, and economy.

3. CONCLUSION

Large amounts of fly ash are being disposed of in landfills which has a negative impact on the environment and human health. Within this work, the content of the REE was examined with the aim of proving that coal fly ash can be used as a material from which those elements could be extracted. The samples were treated with a mix of mineral acids in a microwave digestor. Elements of interest were extracted and their content was analysed using ICP-MS.

Based on the data obtained, the following conclusions were made: (i) The content of REE is higher in the samples of fly ash originating from TPP „Kolubara“ (K1, and K2) than TPP „Nikola Tesla“ (samples T1, and T2); (ii) All four samples of fly ash have the content of all REE that is higher than 200 ppm; (iii) Sample K2 has a content of rare earth elements equal to 434.89 mg/kg which is a bit higher than the global average concentration of those elements in fly ash. Based on that, it can be concluded that fly ash has the potential to be used as a material from which REE could be extracted, but it is necessary to develop appropriate methods for that extraction so the process can also be economically profitable, besides the fact that it would have a less harmful impact on the environment and human health.

The authors gratefully acknowledge the financial support of the Science Fund of the Republic of Serbia, IDEAS call, grant no. 7743343, project SIW4SE which conducts research in the field of innovative solutions for the use of electrophilic ash originating from thermal power plants and waste from the textile industry.

SUSTAINABLE PRODUCTION IN CARDBOARD INDUSTRY

Darja Žarković [1], The Academy of Applied Technical Studies Belgrade
Saša Marković [2], The Academy of Applied Technical Studies Belgrade

Abstract: *Many aspects of sustainable cardboard industry are not related only to production itself (product quality and its market price, production process, supply of raw materials and its costs), but also to nus products, energy and water consumption, equipment service time, occupational health, and environmental issue. Thus, successful companies in cardboard production are driven by the basic principles of sustainable development and implementation of good manufacturing practice and cleaner production principles. These companies continuously invest in environmental protection – establishing the hierarchy of waste management (waste minimization and waste separation at the source), reduction of raw materials consumption, more efficient fresh water and energy usability, replacement of traditional raw materials with more environmentally friendly (eco – friendly) raw materials where it is possible. Positive effects of these actions are measurable and visible in preserving environment for future generations, by means of minimization of negative impacts on the environment (quantity and quality of wastewater, waste gases, noise and vibrations and solid waste). Implementation of 3R principle (Reduce – Reuse – Recycle) in cardboard industry also brings benefits in its economical aspect. This paper describes one Serbian cardboard mill, with documented certification of the ISO 14001 and successfully implemented principles of cleaner production.*
Keywords: Cardboard industry, sustainability, environment protection, economy, cleaner production

1. SUSTAINABLE PRODUCTION AND ITS IMPORTANCE

One of the most used definitions of sustainable production is the one that defines it as a production of goods and services in a manner that is socially beneficial, economically viable and environmentally benign over whole life cycle [1]. Besides the high quality of final product and its competitiveness at market, the aim of sustainable cardboard production is also to ensure conservation of resources and preserves the regenerative capacity of the environment, as well as to obtain social benefits for employees and associated companies. In practice, sustainable production is based on optimized balance between inputs (raw materials, water, energy, human resources etc.) and production outputs (main products, nus-products and effluents). The environmental aspect of sustainable production presents the implementation of the basic principles of cleaner production in the production process and service activities: automation and digitization of processes, prevention of pollution and minimization of waste generation (e.g. reducing the emission of harmful substances at the point of origin and reducing the amount of generated waste through the 3R principle: Reduce-Reuse-Recycle), then more efficient use of energy, water and resources, application of environmentally friendly products, provision of "green" services and achievement of a more competitive price for the final product [2]. Sustainable production implies the integration of ecological, social, and economic aspects, because it leads the management to think that investment in cleaner production, humanity and effectiveness of resource usage presents a long-term profitable strategy. It results in saving resources, thereby reducing business costs and the price of the final product, with no compromise in its quality. This paper presents one successful cardboard mill in Serbia, as an example of good

[1] dzarkovic@atssb.edu.rs
[2] smarkovic@atssb.edu.rs

manufacturing practice, especially concerning environmental issue of sustainable cardboard production – minimization of emissions to water, air and soil, economic usage of resources, waste management (Reduce - Reuse - Recycle principle), energy efficiency, and all of them in accordance with legal regulations. The special part in sustainable cardboard production presents the positive impact of described mill on the circular economy principles – recycling cardboard and waste reuse, as well as minimizing generation of solid waste and its characterization if needed. This cardboard mill promotes new and efficient technologies for waste recycling.

2. GOOD MANUFACTURING PRACTICE IN CARDBOARD PRODUCTION

Until the mid-nineties of the last century, the global paper and cardboard industry presented a serious polluter of the environment, especially concerning amounts of spent water and the pollution level of wastewater. Beside such environmental impact, released wastewater contained significant quantities of spent fibers, fillers, and additives. In that way, a certain part of raw materials and additives were permanently lost with released wastewater, instead to be returned to the production process and usefully spent. That problem was partially solved by implementing cleaner production measures (non-obligatory) and obtaining Integrated Pollution Prevention and Control (IPPC) permission (legal instrument in Europe and in Serbia from recently). Beside significant environmental benefits, cleaner production brings economic improvement too – decreased consumption of raw materials, fresh water, and energy, and finally – decrease of production costs. The central idea in the IPPC directive is the application of the best available techniques (BAT) with technically and economically viable measures on pollution prevention, pollution control technologies, efficient resource and energy consumption, prevention of accidents and disturbances, without negative effects on the final product quality [3]. Although there is a wide variety of paper products and production technologies, almost all types of paper- and board-making processes have the following basic units: stock preparation, approach flow system, paper and board machine and additional process units (calendars, coaters, a coating color kitchen…) [3]. This paper presents good manufacturing practice at the example of one successful Serbian cardboard mill, which has implemented the standard for the management in the field of environmental protection (ISO 14000), and has also successfully participated in the UNIDO Cleaner Production Programme (environmental protection and rationalization of resources and energy consumption) [3]. By obtaining IPPC certificate, this mill verified that it has permitted impact on environment, which brings, among all, the direct access to the European Union market.

2.1. About the mill

Described mill is a cardboard factory – recycled cardboard manufacturer near Belgrade, located at the right bank of the Sava River. The mill produces recycled cardboard ("white-lined chipboard") in several quality types (with different layer content and different number of layers) and in different grammage - from 230 g/m^2 up to 450 g/m^2. Total annual production capacity is 160.000 tones/year. With the last reconstruction of the paper machine in 2021, this mill expanded its production portfolio with thinner cardboards - grammage 160 g/m^2, 180 g/m^2 and 210 g/m^2 [4]. During this phase of the investment cycle, with a total value of 30 million euros, significant changes and improvements were made to paper machine, the most significant of which are [4]:

- reconstruction of the former section (installation of the completely new fourdrinier forming section),
- reconstruction of the press section (installation of Jumbo press),
- reconstruction of the coating section (installation of Curtain coater)
- installation of new winder.

Recycled cardboard which is produced in the mill has a wide range of applications in the food and beverage, confectionary, pharmaceutical, chemical, tobacco and spare parts industry, as well as for lamination in the production of transport packaging [4]. Depending on the customer's request, the mill produces cardboard in sheets or reels, and the width of the cardboard machine is 3,2 m. The

reconstruction of drying sections in the mill is successfully completed in September 2023, and expected annual production is 190.000 tons with improvement in product quality [4]. During this phase of the investment cycle, significant improvements were made to the cardboard machine [4]:

- the entire drying section with steam and condensate system was replaced (61 steel cylinder with a diameter of 1.83 m)
- the entire air system with recuperation was reconstructed.

New investments and further modernization of the mill will be continued in next years, with the construction of a new mass preparation line (construction of a new plant and installation of state-of-the-art mass preparation equipment), as well as a new biological wastewater treatment plant [4].

2.2. Environmental issue in cardboard production

Production of cardboard in the described cardboard mill is based completely and only on recycled paper fibers as the main raw material (from year 2005. onwards). Nowadays this mill is the largest recycler of wastepaper in Serbia, with the usage of 120.000 tons of recycled paper per year (for production of 90.000 tons/year of cardboard). In this manner, described mill significantly participate in the green agenda - sustainable development through circular economy, solid waste minimization and toward resource conservation and nature preservation. By recycling paper and cardboard, firstly we save the forests, secondly the energy savings for production is up to 40% and thirdly there is no production of methane. By recycling one ton of wastepaper and cardboard, 17 trees are saved, and 1 ton of office paper as many as 24 trees, thereby saving water, electricity, fuel and not cutting down new trees. Concerning environmental impact connected to paper manufacture, several aspects should be analysed [3]: consumption of raw materials and water, use of additives, energy consumption, wastewater emissions (quantity and quality), solid waste generation (such as waste sludge from effluent treatment plant (ETP) and other types of solid waste), air emissions from paper machines and from energy generation, odour from vapours and from wastewater treatment plant (local) and the noise from paper machines (local). The Reference Document on the Best Available Techniques in the Pulp and Paper Industry commits producers to decrease freshwater consumption, which should be realized by water recirculation and system closure [5]. Paper and cardboard mills in Serbia are faced with more stringent effluent permits, requested by the European norms. Described mill operates in accordance with the postulates of the circular economy, with the application of the principle of reducing resource consumption through the reuse of waste, increasing energy efficiency and, consequently, reducing the emission of gases with the greenhouse effect [7]. Active participation in environmental actions, good cooperation with the local government and relevant ministries, continuous work and investment in the latest equipment and technology in the field of environmental protection using best available techniques (BAT), exchange experience with foreign partners, constant investment in education and training of its staff, this mill builds a safe path towards fulfilling its vision of having good business practice and sustainable production [4].

Prevention of air pollution from the mill is based on special air protection measures which were carried out: partial reconstruction of the boiler facilities and more efficient supply of natural gas. Both measures contribute to the reduction of energy consumption and, therefore, the emission of harmful substances to the air [4].

Protection of water resources (dominantly the nearby Sava River) is based on the existing Wastewater treatment Plant (WWTP) for purifying technological water, which operates in the structure of the described cardboard mill. The WWTP was significantly improved by the realization of investments from 1997/98. in the part of the reconstruction of paper pulp preparation. The next phase of investments foresees investments in the complete closure of the process water flow and investment in the modernization of WWTP, with the recirculation of usable materials from WWTP back to the production process. Only in the first phase of the plant's reconstruction, in 2010, nearly a million EUR have been invested in equipment that enabled an additional reduction in freshwater

consumption, as well as a significantly increased level of wastewater treatment. That was done by the rehabilitation of the existing wastewater treatment system: improvement of the chemical dosing system, waste dewatering presses were installed, a device for additional water purification of the internal water circuit was installed, as well as an additional float unit in internal water cycle. All of this was done with the aim of as much water recirculation as possible, within the production process itself, thus making the wastewater treatment system work as efficiently as possible and decrease the impact on the Sava River. The next phase of the water improvement project toward the highest standards of water protection would be implementation of the biological treatment of wastewater.

Waste management in the mill is based on three main technical measures, respecting the hierarchy of waste management: separation of waste at the point of origin, reduced consumption of raw materials and energy and replacement of raw materials with more environmentally friendly raw materials in the process where possible. All of this results in the minimization of negative impacts on the environment and preservation of the environment for future generations. What significantly distinguishes this cardboard mill from other factories and makes it a friend of the environment is the fact that it uses only wastepaper as the basic raw material to produce European-quality cardboard. For production purposes, about 120,000 tons of wastepaper are collected and processed annually, which would have ended up in municipal landfills.

Operating problems in wastepaper (as raw material) purchasing present significant items in cardboard production across entire country. The first problem relates to individual, non-organized and non-systematic collection of wastepaper, done by persons from vulnerable social groups. That army of people earn money for living by "collecting" certain quantities of wastepaper from the garbage and dump areas near urban sites, sometimes from landfills, and bring it to recycling centers, where they get some refund in cash. The public communal enterprises dealing with solid waste (including wastepaper) cannot employ those people because of the increase of total operating costs, so these people had to work on the streets, as individuals, contributing in unpopular "gray economy." As a result of that non-systematic collection of wastepaper, only small quantities of it can be collected from household waste, so the level of paper recycling is insufficient compared to the paper mills need. Missing recycled fibers are purchased from importing wastepaper from the surrounding countries and region. The second problem in wastepaper purchasing for the mill relates to the quality of collected wastepaper. Very often, wastepaper from household waste is disposed together with other biodegradable waste, especially wet waste. It causes decontamination of wastepaper with other waste, water, and other liquids, predicting processes of decomposition of wastepaper, with occurrence of odor and bacteria, enabling the usage of such a wastepaper as a raw material for producing cardboard for food industry packaging. And the last, but not the least problem in wastepaper purchasing is related to registration of some companies from surround countries to have a status of "recyclers", so the wastepaper generated in Serbia (as a valuable raw material for cardboard mills) is exported to surrounding countries and not used in Serbian paper and cardboard mills. So, it is obvious that all these problems decrease the level of possible usage of wastepaper as raw material.

3. CONCLUSION

According to the presented environmental demands, results, and achievements in sustainable cardboard production, based on described cardboard mill, several conclusions can be made. Firstly, the described mill constantly works and invests in environmental protection, guided by the basic principles of sustainable development and local business guidelines (good manufacturing practice for example). Secondly, this mill uses only wastepaper as the basic raw material to produce European-quality cardboard, what significantly distinguishes this cardboard mill from other factories and makes it a friend of the environment. Thirdly, significant investment in implementing the biological treatment of wastewater is planned in this mill as the next phase of the water improvement project toward the highest standards of water protection. Described mill has the status of "recycler in the field

of wastepaper and cardboard", and all amounts of waste packaging paper and cardboard that are processed in the mill count towards the achievement of national goals in sustainable development and circular economy. By preventing air pollution, protection of water resources and solid waste management, this mill builds a safe path towards fulfilling its vision of having environmentally - friendly and sustainable production.

SENSORS FOR AMMONIA DETECTION BASED ON CARBON NANOFILLER

Marija Prosheva[1], Faculty of Technology and Metallurgy, Ss. Cyril and Methodius University in Skopje
Jadranka Blazhevska Gilev[2], Faculty of Technology and Metallurgy, Ss. Cyril and Methodius University in Skopje

Abstract: *Quartz crystal microbalances (QCM) toxic gas sensors were fabricated using waterborne polymer composites as sensing material. The polymer matrix was reinforced with 1 wt% of graphene/ multiwalled carbon nanotube hybrid (G/MWCNT) prepared in different ratios. The composites were obtained by emulsion mixing. In all composites, the incorporation of G/MWCNT hybrid led to* electrical *conductivity and the Young's modulus. The gas sensing measurements towards different concentrations of ammonia revealed that the sensor reinforced with 1:10 G/MWCNT hybrid had the best response at room temperature compared to the other samples.*
Keywords: Sensors, G/MWCNT, waterborne composites

1. INTRODUCTION

The protection of the living organisms from the harmful influence of the toxic gases is in close connection with their fast detection. Therefore, the development of sensors that can operate ~~at~~ ambient conditions, have simple design, lower production costs and higher efficiency ~~is from~~ great importance.
Quartz crystal microbalances or QCM sensors can detect mass change in nanograms in addition to the good stability [1,2]. The main advantages of these sensors are: the fast response, ability to work at room temperature, chemical inertness of the substrates and low cost. Since the sensor response of the QCM sensors is based on the mass change, the size of this sensor can be changed without compromising the sensitivity [3-5]. Thus, these sensors can be fabricated in smaller dimensions and incorporated into different devices (smartphones, watches, GPS navigation devices, etc.). In this way continuous monitoring of the air and real-time information about the air quality can be achieved. Consequently, this will lead to a rapid reaction of those affected in case of presence of toxic gases [6,7].
Owning to their remarkable chemical, molecular and physical properties, carbon nanomaterials are widely used for fabrication of sensor devices [1-5,8-12]. Disadvantages of carbon nanomaterials are ~~is~~ that the method of their synthesis strongly affects their performance, working with them can be quite complicated [2,3,8,9]. To improve their processability, carbon nanomaterials are incorporated in polymer matrixes. Development of polymer/carbon nanomaterial composites offer additional advantages, such as improved thermal stability, durability and electrical properties [13-17].
In this work polymer composites based on graphene/multiwalled carbon nanotubes hybrid filler were prepared via emulsion mixing. The sensitivity of the obtained composites was investigated towards different concentrations of ammonia gas.

2. EXPERIMENATL PART

2.1 Materials

For the preparation of the graphene/multiwalled carbon nanotubes hybrid filler graphene nanopowder (G, 8 nm flakes) from Graphene Supermarket (USA) and multiwalled carbon nanotubes (MWCNT, length = 5-15 μm; diameter = 10-30 nm) from Sigma Aldrich were used. For preparing G/MWCNT water dispersions sodium dodecyl sulphate (SDS) with 98% purity from Sigma Aldrich was used. For synthesis of the polymer matrix methyl methacrylate (MMA) with 99% purity from Qumidroga, buthyl acrylate (BA) with 99% purity from Qumidroga and 2-Hydroxyethyl methacrylate (HEMA) with 99% purity from Sigma-Aldrich were used. Dowfax 2A1 45% solution (alkyldiphenyloxidedisulfonate) from Dow chemical company as costabilizer and potassium persulphate (KPS) with 99% purity from Sigma-Aldrich as initiator were used. Throughout the experimental work distillated water was used.

2.2 Methods

The G/MWCNT hybrids were prepared in five different weight ratios, i.e. G:MWCNT = 10:1, 5:1, 1:1, 1:5, and 1:10. The hybrids were prepared by sonicating (UP200Ht, Hielscher Ultrasonics GmbH, Germany) appropriate amounts of G and MWCNT in air medium with constant stirring at 200 rpm in ice bath. The sonication parameters were: amplitude of 70% and 50% duty cycle for 90 min efficient time. Later the hybrids were dispersed in 50g water using SDS surfactant. The ratio SDS:hybrid was 1:1. The dispersion was sonicated for 10 min following the previously mentioned parameters.

The polymer matrix was synthetised by emulsion polymerisation using MMA, BA and HEMA as monomer system. The MMA:BA:HEMA ratio was 49.5:49.5:1. The synthesis started by preparation of seed containing 10 wt% MMA/BA (ratio 1:1). The monomers were dispersed in water using Dowfax 2A1 (2 wt% based on the monomers). The mixture was heated in reactor equipped with nitrogen inlet and it was continuously stirred. When the temperature of the mixture reached 70°C KPS initiator (0.5 wt% based on monomers) was added and the polymerization continued in batch mode for 3h.

The final polymer dispersion was prepared with seeded semicontinuous emulsion polymerization. In a reactor equipped with nitrogen inlet seed (30g) and water (100g) were stirred and heated to 70^{o}C. When this temperature was reached the KPS initiator (0.5 wt% based on monomers) was added and the feeding of the MMA/BA/HEMA monomer system dispersed in water with Dowfax 2A1 (2 wt% based on the monomers) started with rate of 4.2 g/min. The polymerisation was performed in nitrogen atmosphere for 3h in semi-batch and 2h in batch mode. The solid content of the polymer dispersion was 50 wt%.

The nanocomposites were prepared by emulsion mixing. An appropriate amount of G/MWCNT water dispersions were added into appropriate amount of polymer dispersion drop-by-drop during continuous mixture. The concentration of hybrids with respect to the polymer was 1 wt%. In order to obtain free-standing films, the dispersions were casted in silicon moulds and let to dry at 25°C and 55% humidity for five days.

2.3 Characterization

The electrical conductivity of the free-standing samples was measured by Jandel RM3000 four-point probe resistivity instrument.

The tensile tests were performed with SHIMADZU 25T type AGX universal/tensile tester. For this purpose, the free-standing films of the composites and the neat polymer were cut in appropriate tensile test specimens. The length between the grips was 50 mm and the with a constant strain velocity was 20 mm/min. The Young's modulus was calculated with Microsoft Excel functions.

The sensor properties were investigated using Quartz Crystal Microbalance (QCM- 3000 manufactured by MicroVacuum Ltd. of Budapest, Hungary). The composites and the polymer were drop casted onto crystal (Au 5-MHz AT-cut) and let to dry. Before the tests started the thickness of the samples was determined using Biosense software in order to normalize the sensor response. Standard NH_3 and nitrogen gas were used during the measurements. The ammonia gas was diluted with nitrogen by adjusting the flow rates of the gas mixing and regulating system (manufactured by MicroVacuum Ltd. of Budapest, Hungary). The total flow rate of the gas was 50.2 mL/min, and the concentration of ammonia was 100 ppm, 250 ppm, 500 ppm, 750 ppm and 1000 ppm. The measurements were performed ~~at~~ ambient conditions.

3. RESULTS AND DISCUSSION

In this study G/MWCNT/Polymer composites were prepared by emulsion mixing method. The concentration of the G/MWCNT hybrid with respect to the polymer was 1 wt%.
In Table 1 are presented the electrical conductivity values of the samples as average of five measurements. The best electrical conductivity have the samples filled with 1 wt% 10:1 and 5:1 G/MWCNT hybrid. In these samples the electrical conductivity is in the range of 10^{-2} S/m. Slightly lower electrical conductivity in the other samples might be from poorer dispersion of the hybrid throughout the polymer matrix.

Table 1. Electrical conductivity of the G/MWCNT/polymer composites

Sample	Electrical conductivity (S/m)
10:1 G/MWCNT	$1.86*10^{-2}$
5:1 G/MWCNT	$6.03*10^{-2}$
1:1 G/MWCNT	$1.36*10^{-3}$
1:5 G/MWCNT	$1.23*10^{-3}$
1:10 G/MWCNT	$2.89*10^{-5}$

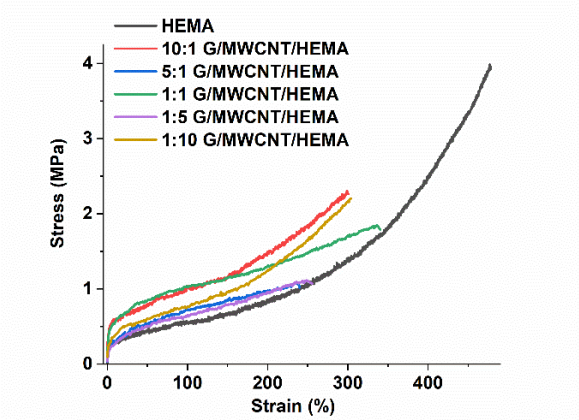

Figure 1. Stress-strain behaviour of the neat polymer (marked as HEMA) and G/MWCNT/polymer composites (marked as: 10:1 G/MWCNT/HEMA, 5:1 G/MWCNT/HEMA, 1:1 G/MWCNT/HEMA, 1:5 G/MWCNT/HEMA and 1:10 G/MWCNT/HEMA)

In Figure 1, the stress-strain curves of the neat polymer (marked as HEMA) and G/MWCNT/polymer composites (marked as: 10:1 G/MWCNT/HEMA, 5:1 G/MWCNT/HEMA, 1:1 G/MWCNT/HEMA, 1:5 G/MWCNT/HEMA and 1:10 G/MWCNT/HEMA) are presented.
In Table 2 are presented the elongation at break, stress at break and the Young's modulus of the samples as average of three measurements. With the incorporation of hybrid filler, the elongation of the nanocomposites decreased and the Young's modulus increased, especially for the 1:10 sample which turned out to have Young's modulus almost 6 times higher than the neat polymer.

Table 2. Elongation at break, stress at break and the Young's modulus of the samples

Samples	Elongation at break (%)	Stress at break (MPa)	Young's modulus (MPa)
HEMA	474	3.46	0.11
10:1 G/MWCNT/HEMA	307	2.16	0.33
5:1 G/MWCNT/HEMA	288	1.28	0.14
1:1 G/MWCNT/HEMA	326	2.27	0.35
1:5G/MWCNT/HEMA	252	0.99	0.11
1:10 G/MWCNT/HEMA	272	1.54	0.63

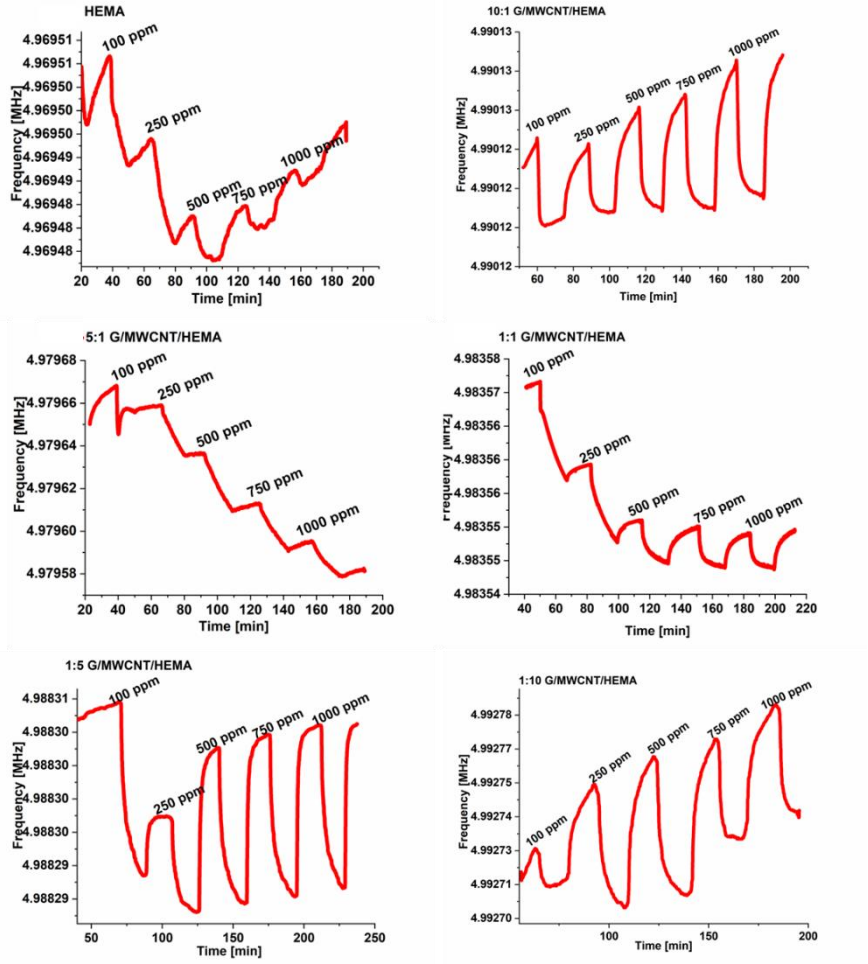

Figure 2. Frequency – time responses of the neat polymer (HEMA) and the composites 10:1 G/MWCNT/HEMA, 5:1 G/MWCNT/HEMA, 1:1 G/MWCNT/HEMA, 1:5 G/MWCNT/HEMA and 1:10 G/MWCNT/HEMA

Figure 2 shows the typical time responses in terms of frequency shift for G/MWCNT/polymer based QCM sensors. The quartz crystals coated with the different composites were employed for detection of different concentration of ammonia gas.

After each exposure to toxic gas, the chamber was evacuated to return the sensor to its initial state. The measurements were carried out at room temperature. In order to evaluate the sensor activity of the material, the frequency change due the mass change as a result from the adsorption of gas molecules on the surface of the material was followed.

In order to compare the obtained results for each sample the frequency change was normalized by dividing the frequency change and the thickness of each sample. In Figure 3 are given the normalized sensor responses.

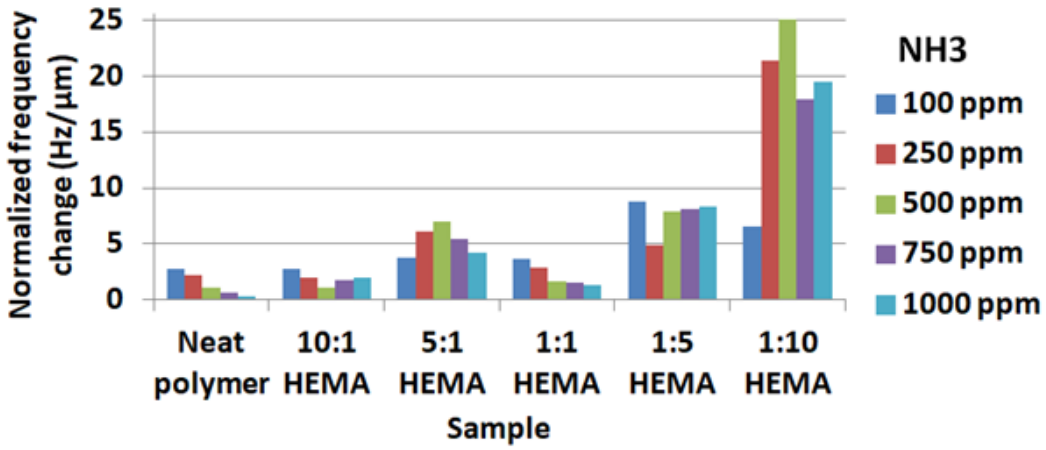

Figure 3. Normalized sensor responses of the neat polymer and composites

From the normalized frequency changes can be observed that the neat polymer, 10:1 G/MWCNT/HEMA and 1:1 G/MWCNT/HEMA composites have sensor responses at the same range, below 5 Hz. The sensor responses of the composites 5:1 G/MWCNT/HEMA and 1:5 G/MWCNT/HEMA are slightly higher, between 5 Hz/μm and 10 Hz/μm. On the other hand, 1:10 G/MWCNT/HEMA presented the best sensor response. The sensor response increased with increment of the gas concentration up to 500 ppm. With further increment of the ammonia concentration the frequency change did not increase, most likely due to saturation of the composite surface with ammonia molecules.

4. CONCLUSION

G/MWCNT/polymer composites were successfully prepared via emulsion mixing method. The incorporation of G/MWCNT lead to electrical conductivity of the composites up to the order of 10^{-2} S/m. The investigation of the mechanical properties showed that the incorporation of hybrid filler led to increase of the Young's modulus of the samples, especially to the 1:10G/MWCNT composite. In addition, this sample presented the best sensing activity towards ammonia which demonstrates its potential to be used as a sensing material.

INVESTIGATION OF THE UV STABILITY OF LIGNIN/POLYMER COMPOSITES

Marija Prosheva[1], Faculty of Technology and Metallurgy, Ss. Cyril and Methodius University, Skopje
Jadranka Blazhevska Gilev[2], Faculty of Technology and Metallurgy, Ss. Cyril and Methodius University, Skopje

Abstract: *In the scope of this research polymer/lignin composites were synthesized via in-situ miniemulsion polymerization. The monomer system was containing methyl methacrylate and butyl acrylate in equal amounts. Whether, the concentration of lignin was 1 wt.%, 2 wt.% and 3 wt.% with respect to the monomers. The successful incorporation of lignin within the polymer matrix was confirmed by infrared spectroscopy. The UV and visible light absorptive properties of the composites were investigated using UV-visible spectroscopy. To investigate the UV stability of the polymer/lignin composites, the samples were exposed to UV irradiation (366 nm) for 90 h. The progress of the degradation was followed using infrared spectroscopy. The obtained results indicated that the samples with 2 wt.% and 3 wt.% lignin suffered minor chemical changes after UV irradiation.*
Keywords: Lignin, Waterborne composites, UV stability

1. INTRODUCTION

Lignin is a complex natural polymer that is the building block of plants. This natural polymer has an aromatic structure that can vary depending on the source from which it is isolated [1,2]. Lignin possesses a wide range of properties that contribute to its wide application [3]. Due to its phenolic structure lignin possesses strong antioxidative properties, so with incorporation of lignin into a polymer matrix is expected that the photo-oxidative degradation of the matrix will be supressed [2].
The preparation of lignin-based polymer composites is usually through melt or solution blending [4-11]. The main disadvantages of these methods are the processing of the composites at higher temperatures (160-210°C) [4,5,7,8,11] or the use of toxic organic solvents such as tetrahydrofuran [6], chloroform [12] or dioxane [9]. However, these two methods do not always offer a uniform dispersion of the filler throughout the polymer matrix [13]. This can be an important drawback considering the high tendency of lignin to agglomerate due to its complex chemical structure [10]. The poor dispersion of the filler through the polymer matrix can negatively affect the final properties of the composite. The in-situ synthesis of polymer composites represents a suitable solution to overcome the problems with the dispersion of the filler. During in-situ polymerization the filler is distributed between the polymer chains. In this way, agglomeration of the filler is prevented, which improves its dispersion [14].
In the scope of this research lignin-based polymer composites were synthetised by in-situ miniemulsion polymerization. Emulsion polymerization in which water is used as a polymerization medium is not only an environmentally acceptable method, given that the use of volatile organic components is reduced, but it is also economically viable. The resulting composites were exposed to UV irradiation to investigate their stability towards photo-oxidative degradation.

[2] jadranka@tmf.ukim.edu.mk

2. EXPERIMENATL PART

2.1 Materials

Kraft lignin from Aldrich and sodium dodecyl sulphate (SDS) with 98% purity from Sigma – Aldrich were used for preparation of lignin water dispersion. The neat copolymer and composites were prepared using methyl methacrylate (MMA) with 99% purity and butyl acrylate with 99% purity from Aldrich. Stearyl acrylate (SA) with 97% purity from Aldrich and Dowfax 2A1 45% solution (alkyldiphenyloxide disulfonate) from Dow chemical company were used as costabilizer and surfactant, respectively. Potassium persulphate (KPS) with 99% purity from Sigma – Aldrich was used s initiator. During the experiments distillated water was used.

2.2 Methods

In the first step of the synthesis, lignin water dispersions were prepared. Namely, appropriate amount of SDS surfactant was dissolved in water by stirring with a magnetic stirrer for 30 minutes. Once the SDS was dissolved, an appropriate amount of lignin was added. The lignin:SDS ratio was 1:1. The dispersion was sonicated using a tip sonicator (UP200Ht, Hielscher Ultrasonics GmbH, Germany) the sonication parameters were: 70% amplitude, 50% duty cycle and 10 minutes effective time, while mixing with a magnetic stirrer at 200 rpm.
The composites were synthetised by in-situ miniemulsion. The miniemulsion was prepared by mixing aqueous phase that consisted of lignin water dispersion and Dowfax 2A1 surfactant (2 wt.% based on monomers) and oil phase that consisted of MMA and BA (mass ratio of 50:50) and SA costabilizer (6 wt.% based on the monomers). The intended solid content of the polymer dispersions was 20 wt%. The two phases were sonicated together for 15 minutes effective time following the parameters: 70% amplitude, 50% duty cycle, under continuous mixing at 200 rpm. The miniemulsion was transferred to a 250 mL reactor equipped with a stirrer and a nitrogen inlet. The reactor was heated using a water bath. When the temperature of the mixture in the reactor reached 70°C, KPS initiator (0.5 wt.% based on monomers) dissolved in water was added to it. Then the emulsion was polymerized for 60 minutes at 70°C.The neat copolymer was prepared using the previously described procedure, with the aqueous phase consisting only of water and surfactant.
The monomer conversion was followed gravimetrically, the conversion was 60 %.
To perform the characterization of the samples, the copolymer/composite dispersion was casted in silicon moulds and the free-standing film was obtained by water evaporation under controlled conditions (25°C and 55% humidity) within five days.

2.3 Characterization

The samples were characterized by Fourier transform infrared spectroscopy (FTIR) equipped with an attenuating total reflection (ATR) (Perkin Elmer Spectrum 100) operating at 20 scans. The scanning area was from 4000 to 650 cm^{-1}. The obtained spectra were analysed with OMNIC software.
The effect that the lignin has over the photostability of the polymer matrix was investigated by exposure of the samples to 366 nm UV radiation at ambient conditions (25°C and 55% relative humidity) for 90 hours. The progress of the photodegradation was evaluated by analysing the samples with the FTIR-ATR spectrometer. With the OMNIC software, the surfaces of the spectral bands related to the following functional groups were determined: carbonyl, hydroxyl and ether group. In order to quantitatively monitor the changes, the ratios between the surfaces of the carbonyl and hydroxyl groups and the ether and hydroxyl groups were determined.
To evaluate how the incorporation of lignin into a polymer matrix influenced the absorption in the ultraviolet and visible region, the composites were analysed by ultraviolet-visible spectroscopy

(UV-VIS) (UV-Mini 1240 Shimadzu). The obtained spectra were analysed with UVProbe 2.42 software.

3. RESULTS AND DISCUSSION

Within this research lignin/polymer composites were synthetised via in-situ miniemulsion polymerization. The concentration of the lignin was 1 wt.%, 2 wt.% and 3 wt.% based on the monomers. Figure 1 shows the FTIR spectra of lignin (L), P(MMA/BA) and L/P(MMA/BA) composites.

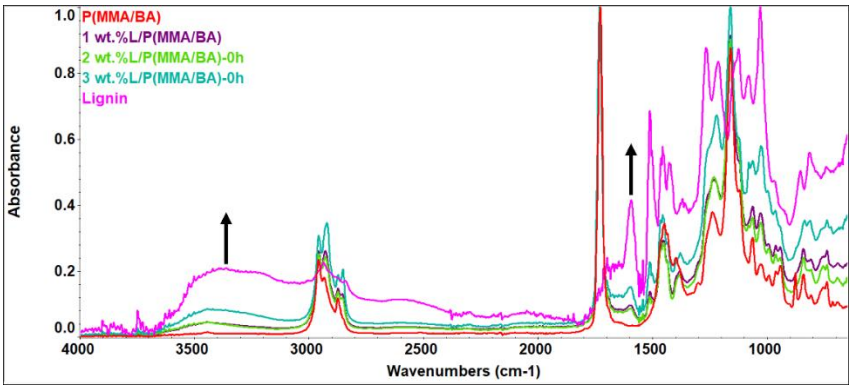

Figure 1. FTIR spectra of lignin (L), P(MMA/BA) and L/P(MMA/BA) composites

The characteristic bands originating from the hydroxyl group (OH – 3700 – 3100 cm^{-1}), the skeletal vibrations of the aromatic C=C bonds (1600 – 1400 cm^{-1}) and the ether group (C – O – C –1300 – 1000 cm^{-1}) can be observed on the spectrum of lignin. Spectral bands characteristic for the carbonyl group (C=O – 1730 cm^{-1}) and the C – O – C from the ester group (1160 cm^{-1}) can be observed in the spectrum of the copolymer. When examining the spectra of the composites, the characteristic bands for the copolymer can be noticed. Moreover, the appearance of the characteristic bands for the hydroxyl group (3700 – 3100 cm^{-1}), as well as bands originating from the skeletal vibrations of the aromatic C=C bonds (1600 – 1400 cm^{-1}) can be seen, which indicates a successful incorporation of lignin into the polymer matrix.

The UV and visible light absorption capability of the samples was investigated using UV-Vis spectroscopy. In Figure 2 are shown the UV-Vis spectra of the samples.

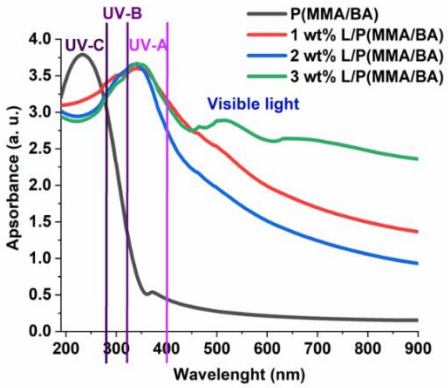

Figure 2. UV-Vis spectra of the copolymer and the composites

Due to its phenolic structure, lignin has a high absorption power in the area of UV-B (280 – 315 nm) and UV-A (315 – 400 nm) light. Therefore, the absorption maximum of the composites is shifted to a higher wavelength compared to the copolymer. It can also be noted that the absorption of visible light is significantly higher for the composites compared to the copolymer. This indicates that the lignin-based composites would be efficient UV blockers and would offer good protection against UV-Vis radiation.

The progress of the UV aging process was followed by infrared spectroscopy. The areas of the characteristic bands that suffered significant change were calculated, i.e.hydroxyl group (OH – 3700 – 3100 cm^{-1}), carbonyl group (C=O – 1730 cm^{-1}) and ether group (C – O – C – 1300 – 1000 cm^{-1}), Figure 3.

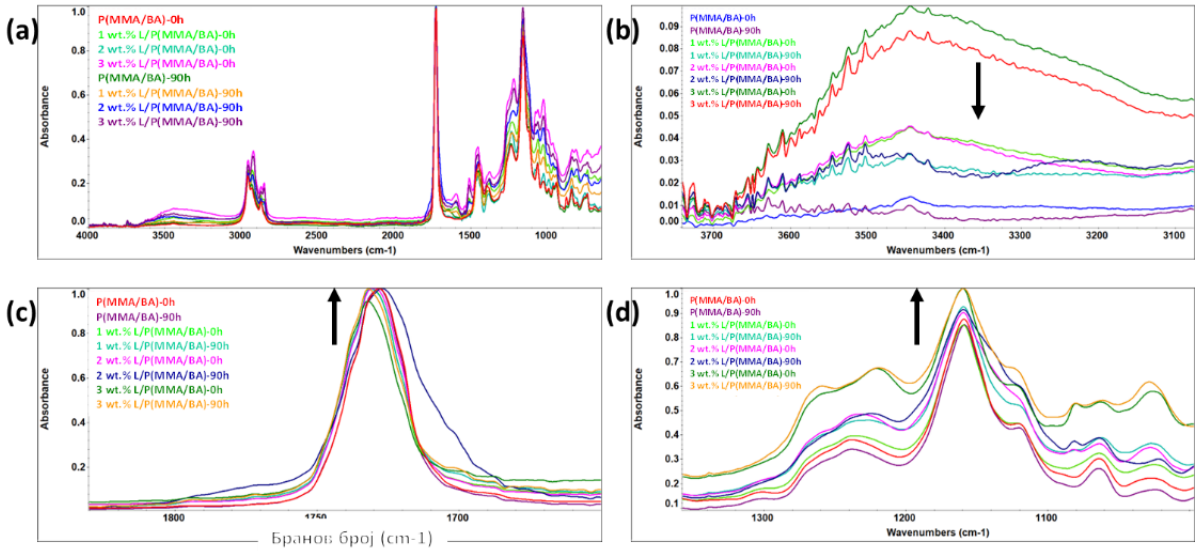

Figure 3. (a) FTIR spectra of the samples after 90 h of UV exposure, zoomed characteristic bands for (b) hydroxyl group (OH – 3700 – 3100 cm^{-1}), (c) carbonyl group (C=O – 1730 cm^{-1}) and (d) ether group (C – O – C – 1300 – 1000 cm^{-1})

To compare the aging progress, the ratios between the carbonyl and hydroxyl group, as well as the ether group and the hydroxyl group before and after irradiation were determined for the composites and the copolymer. These results are given in Figure 4.

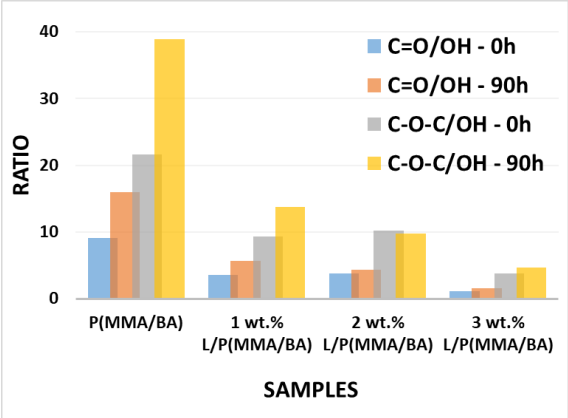

Figure 5. Ratios between the carbonyl and hydroxyl group, as well as the ether group and the hydroxyl group before and after irradiation

From Figure 4 can be observed that the copolymer suffers greatest chemical changes during the UV exposure. While the composites with 2 wt.% and 3 wt.% lignin the differences in the ratios before and after 90 hours of UV irradiation are significantly smaller. Such results indicate that lignin successfully captured and neutralized the free radicals that are formed during degradation, thus slowing down the aging process of the composites.

4. CONCLUSION

Lignin-based polymer composites were synthesized via in-situ miniemulsion polymerization. Lignin was added at a concentration of 1, 2 and 3 wt.% relative to the monomers. Through infrared spectroscopy was determined that the incorporation of lignin into the polymer matrix was

successful. The spectra obtained by UV-Visible spectroscopy indicated that the addition of lignin leads to a shift of the absorption maximum of the composites to a higher wavelengthand increment of the absorption of visible light.
The copolymer and composites were exposed to 366 nm UV radiation at ambient conditions for 90 hours. The aging progress was monitored by infrared spectroscopy. From the obtained results, was concluded that the composites containing 2 and 3 wt.% lignin undergo significantly minor chemical changes after exposure to UV light.

A COMPREHENSIVE ANALYSIS: OFFSHORE RENEWABLE ENERGY METHODOLOGIES, BENEFITS, AND LIMITATIONS

Ana Momčilović[1], The Academy of Technical Applied Sciences Belgrade
Marta Trninić[2], The Academy of Technical Applied Sciences Belgrade

Abstract: *In the realm of sustainable energy solutions, significant attention has been drawn to the boundless offshore resources. This paper focuses on the innovative approaches and advancements in offshore renewable energy technologies. The capabilities and advantages of floating photovoltaic solar energy systems have been meticulously analyzed. Additionally, the consistent and reliable energy derived from wave and tidal movements has been examined. Emphasis has been placed on the potential synergies realized from integrating various renewable energy sources, specifically the combination of offshore wind with solar and wave energies. Through this comprehensive exploration, the challenges, present scenarios, and prospects of these promising offshore renewable technologies have been systematically unraveled.*
Keywords: Offshore Technologies, Sustainable Energy, Energy Methodologies, Advantages.

1. INTRODUCTION

In the pursuit of sustainable and environmentally friendly energy solutions, attention has been increasingly directed towards the vast resources available offshore. Energy from the sun, wind, and waves has been recognized for its unparalleled potential in addressing the escalating power needs without exacerbating the planet's ecological challenges. In 2020, the European Commission published an EU Strategy to harness the potential of offshore renewable energy for a climate neutral future. The Offshore Renewable Strategy aims to dramatically increase the EU's production of electricity from offshore renewable energy sources from 12 gigawatts (GW) at the present rate to over 60GW by 2030 and 300GW by 2050 [1]. In this paper, advancements and innovations in offshore renewable energy are explored. The immense potential of floating photovoltaic solar energy systems is discussed, and the consistent power derived from tidal movements is examined. The potential benefits of integrating multiple renewable energy sources, such as the combination of offshore wind and solar farms, are also highlighted. Through this exploration, the current state, challenges, and prospects of these offshore renewable technologies will be revealed.

2. INTEGRATING OFFSHORE ENERGIES: A STUDY OF WIND, SOLAR, AND TIDAL TECHNOLOGIES, THEIR SYNERGIES, BENEFITS, AND CHALLENGES

As the global quest for sustainable energy solutions intensifies, the potential of offshore wind, solar, and tidal sources is increasingly recognized. This chapter delves deep into the individual technologies employed to harness the relentless power of winds, the consistent radiance of the sun, and the rhythmic energies of the tides. Beyond the exploration of individual sources, a significant portion of this chapter is dedicated to understanding the synergies when these technologies are combined. The advantages and challenges of such integrations, as well as the singular benefits and limitations of each energy source, are meticulously scrutinized. By the chapter's conclusion, readers will have been

[1]amomcilovic@atssb.edu.rs
[2]mtrninic@atssb.edu.rs

granted a comprehensive insight into the current state, potential benefits, challenges, and synergistic possibilities of combining offshore wind, solar, and tidal energy technologies.

2.1 Floating Photovoltaic Systems

Floating Photovoltaic Systems (FPVS) are defined as photovoltaic power plants consisting of modules mounted on floating elements situated on bodies of water, such as lakes, reservoirs, or seas. These systems employ traditional solar panels, which convert sunlight into electrical energy through the photovoltaic effect. Once energy is generated by the panels, it is transformed from direct current to alternating current by inverters, preparing it for grid distribution. These systems are anchored to the seabed, shorelines, or adjacent structures. The floating base, constructed from UV and corrosion-resistant materials, not only allows for the solar panels to safely float but also reduces water evaporation and utilizes otherwise unused water surfaces. Owing to the cooling effect of the water, increased yields have been observed in FPVS compared to conventional ground-mounted systems [2]. While installations with double-digit megawatt capacities can be found in Asia, German installations are limited to a maximum of 750 kW due to financial barriers. As of February 2022, the largest FPVS in Europe is in the Netherlands, boasting a nominal capacity of 27.4 MW [2]. A dynamic growth in FPVS was witnessed in recent years, with over 2.6 GW installed globally by early 2021 [3]. In Germany, potential locations for FPVS include open-pit lakes, former gravel pits, and, in some cases, reservoirs [2]. The first German FPVS, situated in a repurposed quarry near Renningen in Baden, was connected to the grid in late May 2019 and has a capacity of just 750 kW [3]. Beyond lakes, FPVS technology can also be utilized at sea, whether offshore or nearshore. Additional applications include the integration of FPVS on agricultural water reservoir liners or fishponds. For instance, a floating solar film was installed on a water reservoir in Cyprus, reducing both water evaporation and contamination while producing energy for pumping equipment [3]. FPVS implementation over canals is also feasible.

Advantages of Utilizing Floating Photovoltaic Systems (FPVS):

1. FPVS does not occupy terrestrial space, addressing the increasing demand for agricultural and construction lands, and avoiding deforestation and ecosystem disruption [2].
2. Photovoltaic panels, when cooled by water, maintain a higher efficiency under rising temperatures. Experiments in Hyogo, Japan showed an approximate 11% increase in energy production in FPVS compared to land systems.[5]
3. The shadow produced by FPVS can help reduce algal blooms, aiding in preventing water eutrophication, and decreasing water evaporation, thus preserving water resources [5].
4. Maintenance is simpler for FPVS than land-based systems, with reduced dust accumulation and Mibet's FPVS design featuring a maintenance pathway for easier panel cleaning [4].
5. Aesthetically arranged FPVS attracts tourists, offering additional economic benefits [5].
6. The open water surface minimizes shading from trees or mountains, an issue often faced by land-based solar installations.[5]
7. Proximity to settlements, villages, and cities enables efficient local electricity distribution and consumption [4].

Disadvantages of Utilizing FPVS:

1. FPVS have a lifespan exceeding 25 years, highly demanding corrosion-resistant materials with longevity demand and high load-bearing capacities, a challenge with current materials [3].
2. Initial investment costs for FPVS can surpass those of traditional solar panel installations due to setup requirements of specialized equipment and expertise [4].

2.2 Wave and tidal energy

Energy generated from tides is a sustainable energy source that leverages the kinetic and potential energy from ocean tides and currents to produce electricity. As the height difference between high and low tides (tidal range) increases, more energy can be harnessed. Tidal energy harnessing

technologies include tidal barrages, tidal stream generators, and tidal fences, all of which utilize tidal turbines. Despite its potential, tidal power is yet to be widely adopted, with only a handful of significant tidal power stations in operation globally. Some of the most substantial tidal power stations in terms of capacity are:

1. La Rance Tidal Power Plant, France: Located near Saint-Malo in Brittany, this power plant was the world's first large-scale tidal power station and started its operations in 1966. It boasts an installed capacity of 240 MW.
2. Sihwa Lake Tidal Power Station, South Korea: Operational since 2011, this station is currently the world's largest in terms of installed capacity at 254 MW. It was constructed by transforming an existing sea barrage into a tidal power station.
3. Annapolis Royal Generating Station, Canada: Located on the Annapolis River in Nova Scotia, this power station began its operations in 1984. It has a capacity of approximately 20 MW.

Despite the impressive capabilities of these stations, tidal energy faces challenges, such as environmental concerns, high capital costs, and technological hurdles. However, with a global potential estimated at around 2 TW (excluding the area of 30 nautical miles from the polar caps), the opportunities in this sector are vast. As technology evolves and the demand for renewable energy sources increases, it's expected that more countries will explore tidal energy as a viable and sustainable energy source.

Tidal barrages, positioned across tidal inlets, function similarly to traditional hydroelectric dams. Anchored to the seabed, they employ turbines that are activated by both incoming and outgoing tides. These turbines, connected to generators, convert tidal movements into electrical energy. Though efficient, they are costly due to the required concrete infrastructure and pose significant environmental challenges, acting as barriers to marine life.

Tidal fences, blending characteristics of tidal barrages and turbines, utilize vertical rotating structures akin to turnstiles. These structures, moved by tidal currents, are connected to generators, producing electricity. Unlike barrages, tidal fences don't necessitate large concrete constructions and are typically less impactful on ecosystems, being fully submerged and allowing more marine mobility.
Advantages of Tidal and Wave Energy [7]:

1. It's a renewable energy source.
2. No greenhouse gas emissions during electricity generation.
3. Highly predictable energy production.
4. Can produce large amounts of electricity due to water's density.

Disadvantages of Tidal and Wave Energy [7]:

1. Specific location requirements, predominantly coastal areas with significant tidal differences.
2. High initial investment costs.
3. Potential environmental impacts on marine life and local ecosystems.
4. Inconsistent energy output despite its predictability.

2.3 Offshore wind energy

Offshore wind energy harnesses the power of ocean winds, converting it into electricity and delivering it to the onshore electrical grid. Wind turbines transform the kinetic energy of the wind into electrical energy. As wind blows, it moves the turbine blades, which are attached to a rotor. This rotor rotation produces mechanical energy. The rotor is connected to the main shaft, driving a generator. Inside the generator, the shaft's rotation causes relative motion between a magnetic field and a conductive wire, creating electrical energy through electromagnetic induction. Wind turbines can be standalone, supplying power to a single or very few users, or they can be clustered to form a wind farm. Each turbine comprises of a set of blades, a nacelle, and a shaft. Wind turbines tend to be either white or very pale gray – the idea being to make them visually unobtrusive. The world's first wind farm was

inaugurated in New Hampshire, USA, in 1980 [8]. With a capacity of 1.2 GW, Hornsea One is one of the largest offshore wind farms globally. It is situated 120 km off the Yorkshire coast in the North Sea [12].

Advantages of Offshore Wind Farms:

1. Provide renewable energy without consuming water, emitting pollutants, or greenhouse gases [8].
2. Reduced noise and environmental impact due to distance from population centers [8].
3. Potential creation of 60,000 jobs in the USA with increased capacity by 2022 [9].
4. Offshore winds are stronger and more stable, leading to higher energy production [9].
5. Can meet the high energy needs of densely populated coastal regions [9].

Disadvantages of Offshore Wind Farms:

1. Concerns about habitat loss, disturbances, and collisions due to climate changes [8].
2. Challenges in constructing in deep waters (beyond 60m) [9].
3. Risk of damage from intense storms or hurricanes [9].
4. High costs for underwater energy cable installation [9].
5. Unclear effects on marine life and birds.
6. Potential aesthetic concerns impacting tourism and property values near coasts [9].

2.4 Combined offshore wind and solar energy systems

Pérez-Collazo et al. [10] explored the potential of floating wind turbines and solar panels near the Asturias coast, emphasizing their combined benefits. Using meteorological data, the total available renewable energy in the region was estimated. The expected energy output from both solar panels and wind generators was calculated, both individually and when combined, based on current commercial technology. Both technologies were compared in terms of their nominal power, sea space usage, and production variability. Results suggest that marine-based combined wind-solar parks possess a production synergy worth considering in future marine renewable energy projects [10].

Advantages of Combined Systems [10]:

1. Higher Energy Output: Combined wind and solar farms can achieve a density of 57.5 MW/km² and a specific yield of 61.2 GWh/(km²·year).
2. Stable Energy Production: Combining both systems reduces output variability by 68% compared to standalone wind farms, ensuring a more predictable energy flow.
3. Optimal Sea Space Usage: Hybrid farms maximize output per unit of sea area.
4. Reduced Temporal Variability: Combining both systems improves power output consistency.
5. Superior Wind Farm Performance: Using a commercial 6.2 MW wind turbine, energy production and capacity factor are significantly higher than solar farms.
6. Better Sea Surface Usage: Solar farms don't require deep waters for optimal energy production, unlike wind farms.

Disadvantages of Combined Systems [10]:

1. Need for Floating Technology: The studied area's depth requires floating structures, except in the narrow coastal zone.
2. Variable Wind Resources: Wind resources decrease towards the coast, possibly affecting closer regions' yields.
3. Need for Further Research: Being the first of its kind, this study suggests that more in-depth research is needed to fully understand combining these two systems.

Combining wind and solar energy can efficiently harness marine resources for renewable energy production, but more research is needed to determine all aspects and potential challenges.

2.5 Combined offshore wind and wave energy systems

Combined wind and wave systems represent an innovative approach to harnessing renewable energy sources for electricity generation. These systems rely on the integration of wind turbines and wave

energy capturing devices, creating a unique platform that simultaneously exploits both wind and ocean wave energy. Such a configuration allows for a continuous and stable production of electricity. Even when the wind isn't blowing, ocean waves can generate energy and vice versa. This integrated approach not only increases the system's efficiency but also reduces the need for energy storage and ensures a more consistent supply to the electrical grid. Combined wind and wave systems can be categorized based on technology, water depth (shallow, transitional, or deep water), or location relative to the coast. Pérez-Collazo et al. [11] proposes a new classification based on the degree of connectivity between the wind turbines and wave energy converters, defined as co-location systems, hybrid systems, and island systems.

Co-location Systems: The simplest option in the current development phase is the co-location system. These systems combine a wind farm with a series of wave converters but share the same maritime area, grid connection, etc. They can be independent or combined [11].

Independent Arrays: These are systems where the wind farm and wave park are based in separate maritime areas but are close enough to share the same grid and other services [11].

Combined Arrays: In contrast to independent arrays, combined arrays share the same maritime area. They can be further classified into three categories: Peripherally Distributed, Uniformly Distributed, and Non-uniformly Distributed systems [11].

Hybrid Systems: Hybrid systems combine a wind turbine and a wave energy converter on the same structure. They are part of a broader category of multi-purpose platforms that integrate various marine applications [10].

Fixed Hybrids: Fixed wind and wave hybrids represent innovative systems emerging from the evolution of current substructures employed by the offshore wind industry, adapted to accommodate a wave energy converter. Alternatively, integration of the converter into an existing wind turbine can be considered, but both alternatives require further research [11]. Concepts within this category include Wave Star, proposed by a Danish company; Wave Treader, by Green Ocean Energy from Scotland; and WEGA, developed by the Portuguese company Sea For Life [11].

Floating Hybrids: Floating hybrids are a novel concept that has begun to be explored given the development of floating wind turbine prototypes. Interest in this concept stems from the greater wave energy reserves in deep waters and the absence of continental shelves in some countries with high wave energy potential, such as Spain or Portugal [11]. Some examples of floating hybrids include: W2 Power by Pelagic Power AS; OWWE by the Norwegian company Ocean Wave and Wind Energy Ltd.; Poseidon Floating Power by Floating Power Plant AS from the Netherlands; WindWaveFloat by the American company Principal Power; and Offshore Ocean Energy System by Float Inc.
Highlighted are the following advantages and disadvantages of combined hybrid systems [11]:
Advantages:

1. Technology Synergy: Combining wind generators with wave energy exploitation devices can lead to a more efficient energy production as some regions may experience strong winds when waves are not powerful, and vice versa.
2. Space Optimization: By combining both systems, the same maritime space is used for energy production from two sources, which can be advantageous in areas where maritime space is limited.
3. Resource Sharing: Combined systems can share resources such as grid connection infrastructure, maintenance and management equipment, and personnel.
4. Production Stabilization: Multiple energy sources can reduce the variability of total energy produced, meaning that energy can be produced more steadily over different time periods.
5. Design Flexibility: There are multiple ways these systems can be configured (e.g., PDA, UDA, NDA) to optimize energy production and minimize potential environmental impacts.

Disadvantages:

1. Design Complexity: Combining two different technologies can lead to technical challenges, especially when integrating with existing systems or adapting substructures.
2. System Interaction: Further research is needed to understand the interaction between the wind generator and wave energy exploitation device and how this interaction can affect overall performance.
3. Costs: Initial development, installation, and maintenance costs for combined systems might be higher compared to deploying individual systems.
4. Lack of Mature Technologies: Since some of these concepts are relatively new, there may be technological risks and unknowns that need to be addressed before commercial deployment.
5. Ecological Impact: Combining two systems might result in a larger ecological footprint, especially if potential negative impacts on the marine ecosystem are not considered.

3. CONCLUSION

In conclusion, the integration of wind and wave energy systems presents a promising avenue for enhancing renewable energy production from maritime resources. The combination of these technologies offers several advantages, including increased energy output, optimized use of space, resource sharing, production stability, and design flexibility. However, this innovative approach also comes with challenges, such as design complexity, the need for further research into system interactions, higher initial costs, the development of mature technologies, and potential ecological impacts. As these combined hybrid systems continue to evolve and mature, they hold significant potential for contributing to a more sustainable and diversified energy landscape in the future. Further research and development efforts will be crucial in addressing these challenges and unlocking the full potential of integrated wind and wave energy systems.

Abstract: *Considering wind as a load and its impact on buildings and their environment is gaining importance due to increasingly pronounced climate changes and the occurrence of strong winds. Increasingly intensive residential construction and transformation of existing settlements, justified or unjustified construction of new buildings, leads to changes in the wind comfort of entire residential blocks. The subject of research is residential towers characteristic of multi-family housing in the 70s and 80s of the 20th century in former socialist countries. The focus is on the analysis of changes in wind comfort caused by the construction/addition of a new building - individually and by multiplying it around a typical residential tower. The effect of the wind was analyzed in a modern way using numerical fluid dynamics, CFD.*
Keywords: Wind, Wind comfort, Computational fluid dynamics, Atmosferic boundary layer.

1. INTRODUCTION

Residential construction in the seventies and eighties of the 20th century on the territory of former socialist countries, among others, is characterized by large housing estates and the appearance of high-rise buildings - residential towers with organized free inter-block space for various purposes. A few decades later, there were frequent cases of that space being occupied by the construction of new residential buildings with slightly lower height compared to the existing towers. This intervention changes the air flow around buildings, which affects the change in wind comfort in the entire environment. Wind as a natural phenomenon [1] characterized by stochastic behavior has always been a challenge for people. The aspiration of ordinary people to understand the behavior of the wind and to provide shelter from its destructive effect in the past, leads to modern research approaches where the wind is viewed not only theoretically [2] and through standards [3] but also with an experimental approach through wind tunnels, and using modern numerical simulations.
The paper analyzed the behavior of the wind around the residential tower as an isolated object, and at the level of the entire residential block when there are lower buildings in the vicinity of the tower with a different position compared to the primary object (residential tower). The wind is considered in a complex way in accordance with its nature, using computational fluid dynamics (CFD).

2. METHODOLOGY

The conducted research included four models (M0, M1, M2, and M3) (Fig. 1). The initial model M0, represents an isolated residential tower (Gnd + 10 lvl.) with dimensions of base 16x22 m and height

[1]danijela.djuric.mijovic@gaf.ni.ac.rs
[2]danijela.milanovic@gaf.ni.ac.rs
[3]jelena.savic@gaf.ni.ac.rs
[4]milos.nedeljkovic@gaf.ni.ac.rs
[5]dusan.randjelovic@gaf.ni.ac.rs

40 m. The wind acts perpendicularly to the longer side of the facade. To the initial model (M0) were added lower residential buildings (Gnd + 4 lvl.) with a height of 15 m and with base dimensions of 16x16 m, as individual ones: in front (model M1) and on the side (model M2) of the tower, and also all grouped together (model M4) representing one characteristic residential block. The relative position of the buildings, their base dimensions and distances are shown in Figure 1. The wind speed for all models is assumed to be 50 m/s, with its direction as shown in Figure 1.

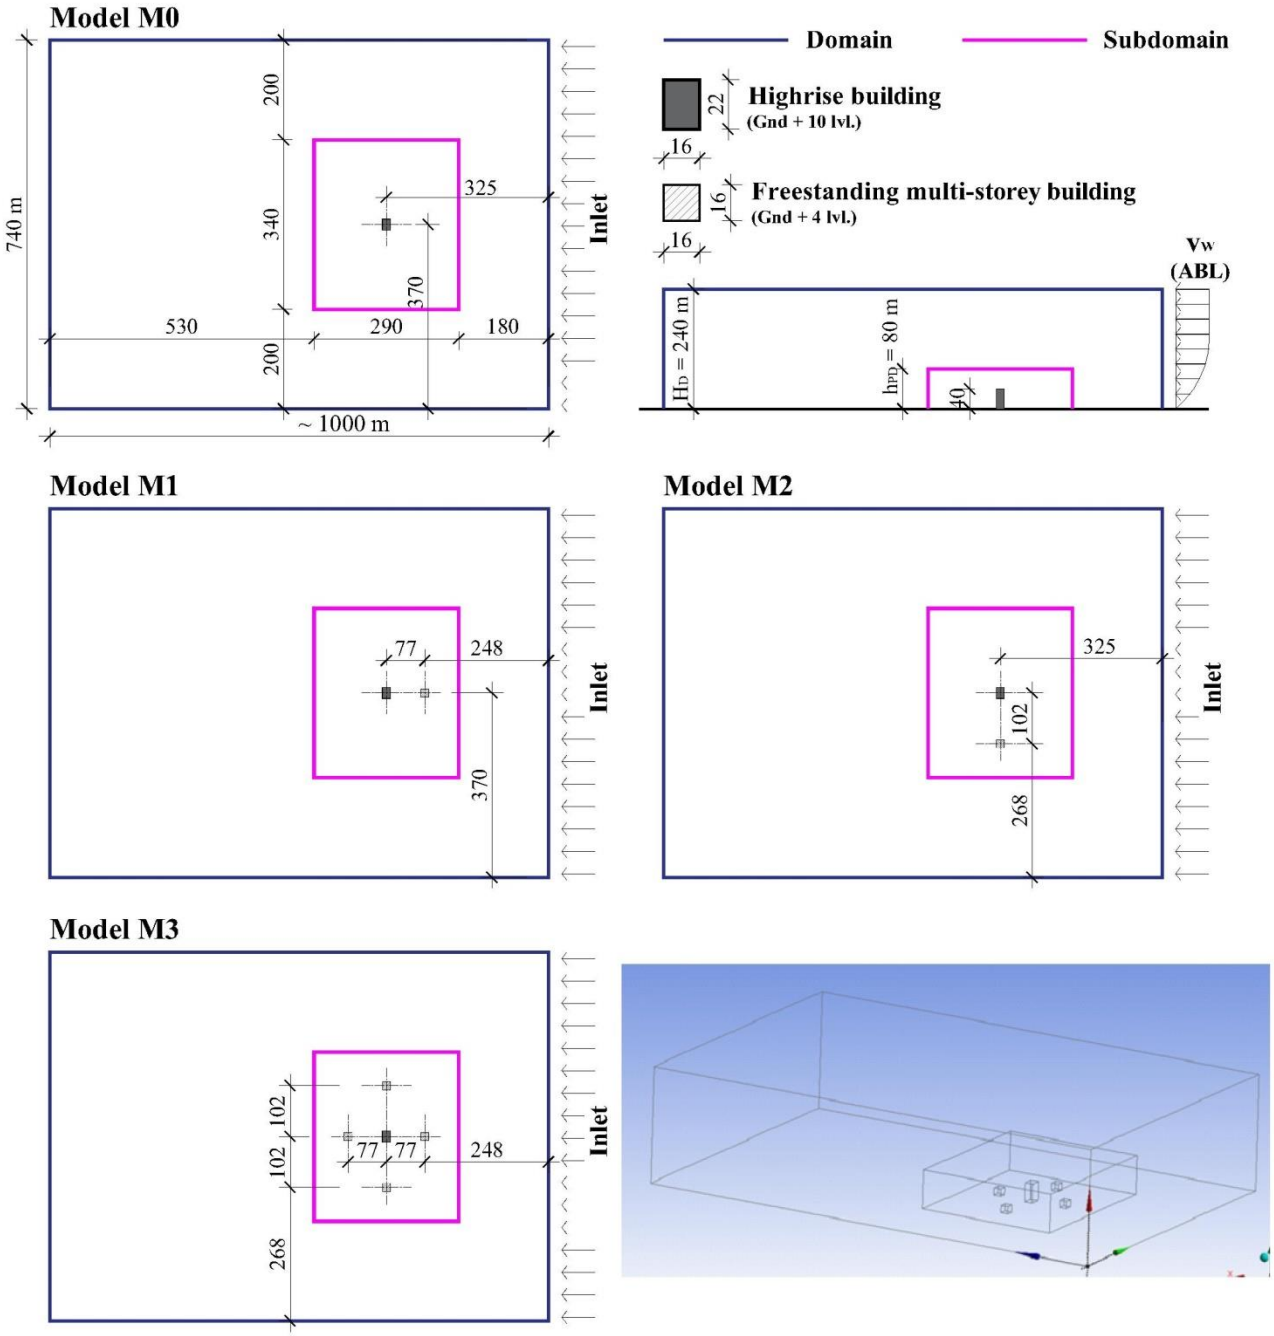

Figure 1. Model formulation
Source: Authors

For all models, a single computational domain was adopted (Fig. 1) according to the current recommendations of Franke 2004 [4] and Franke 2007 [5] for this type of analysis, and according to the recommendations of Ferziger & Perić [6], the mesh quality of finite volumes was adopted.

2.1 Theoretical framework

The influence of the wind was analyzed for each model in ANSYS Workbench 19.0 (CFX) software [7, 8] using numerical fluid dynamics CFD. The wind velocity varies with height by defining the Atmospheric Boundary Layer, ABL. The air flow in the ABL belongs to turbulent flows, and the numerical solution of any fluid mechanics problem requires the solution of the continuity equation (1) and the Navier-Stokes equations (2).

$$\frac{\partial \rho}{\partial t} + \frac{\partial (\rho u_j)}{\partial x_j} = 0 \tag{1}$$

$$\frac{\partial (\rho u_j)}{\partial t} + \frac{\partial (\rho u_i u_j)}{\partial x_j} = -\frac{\partial P}{\partial x_i} + \nu \frac{\partial}{\partial x_j}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right) \tag{2}$$

$$P = \frac{p}{\rho} \tag{3}$$

$$\nu = \frac{\nu_t}{\rho} \tag{4}$$

In equations (1) to (4), the following symbols were used: u_j represents the components of wind flow velocity [m/s], x_i is the spatial coordinates of the rectangular coordinate system, p is the static pressure [Pa], ρ is the air density [kg/m3], ν - kinematic viscosity [m^2/s] and ν_t - turbulent (dynamic) viscosity [kg/(s*m)].

When studying the effect of wind on structures, the Reynolds averaged Navier-Stokes equations (RANS) are most often used to calculate turbulent flows [9]. The continuity equation (equation of conservation) (1) and the moment equation (Navier-Stokes equations) (2) together with initial and boundary conditions, are considered sufficient to describe turbulent flows. Nowadays, there are many different turbulent models that describe the flow, and for the purposes of this research, the two-equation Re-normalization group, RNG k-ε model [10] are used, which involves solving two additional transport equations to determine the Reynolds stress tensor [11]. The Reynolds stresses have a linear dependence with the turbulence kinetic energy, k (5) and the mean velocity gradients (6).

$$k = \frac{1}{2}(\overline{u_i' u_i'}) \tag{5}$$

$$\overline{u_i' u_j'} = \frac{2}{3} k \delta_{ij} - \nu_t \left(\frac{\partial \overline{u}_i}{\partial x_j} + \frac{\partial \overline{u}_j}{\partial x_i}\right) \tag{6}$$

$$\delta_{ij} = \begin{cases} 1, & j = i \\ 0, & j \neq i \end{cases} \tag{7}$$

$$\nu_t = C_\mu \frac{k^2}{\varepsilon} \tag{8}$$

In equations (5) to (8), k is the kinetic energy of turbulence, δ_{ij} – Kronecker's delta operator, C_μ is the empirical constant of the turbulent model, and ε is the dissipation rate.

3. DISCUSSION

The numerical simulation results of wind effects are shown in Figure 2 (a-d) through a horizontal and vertical section of the computational domain for all models (M0, M1, M2 and M3). Wind flow streamlines are shown in the pictures. Considering M0 model, it is noticeable that the wind flow is predominantly uniform in front of the tower, while its speed increases at the sides because a separation of the flow appears. The vortex trail behind the residential tower (model M0) shows vortices but of lower velocities than in front of the building (Fig. 2a). By adding an object in front of the tower (model M1) a vortex is formed between the buildings, but the sides of the tower are now in a calmer

flow and lower velocities (Fig. 2b). In the M3 model, which includes the tower and four buildings added on each side, is noticed that the side buildings do not significantly affect the comfort due to the effect of the wind, while the buildings located directly in front of the windward and behind the leeward side of the tower, have an impact (Fig. 2d). The vortex zone covers a larger area, but the velocities are lower. The most pronounced flow with the most intense velocities occurs on the sides of the tower because so-called "wind canyons" are formed (Fig. 2d).

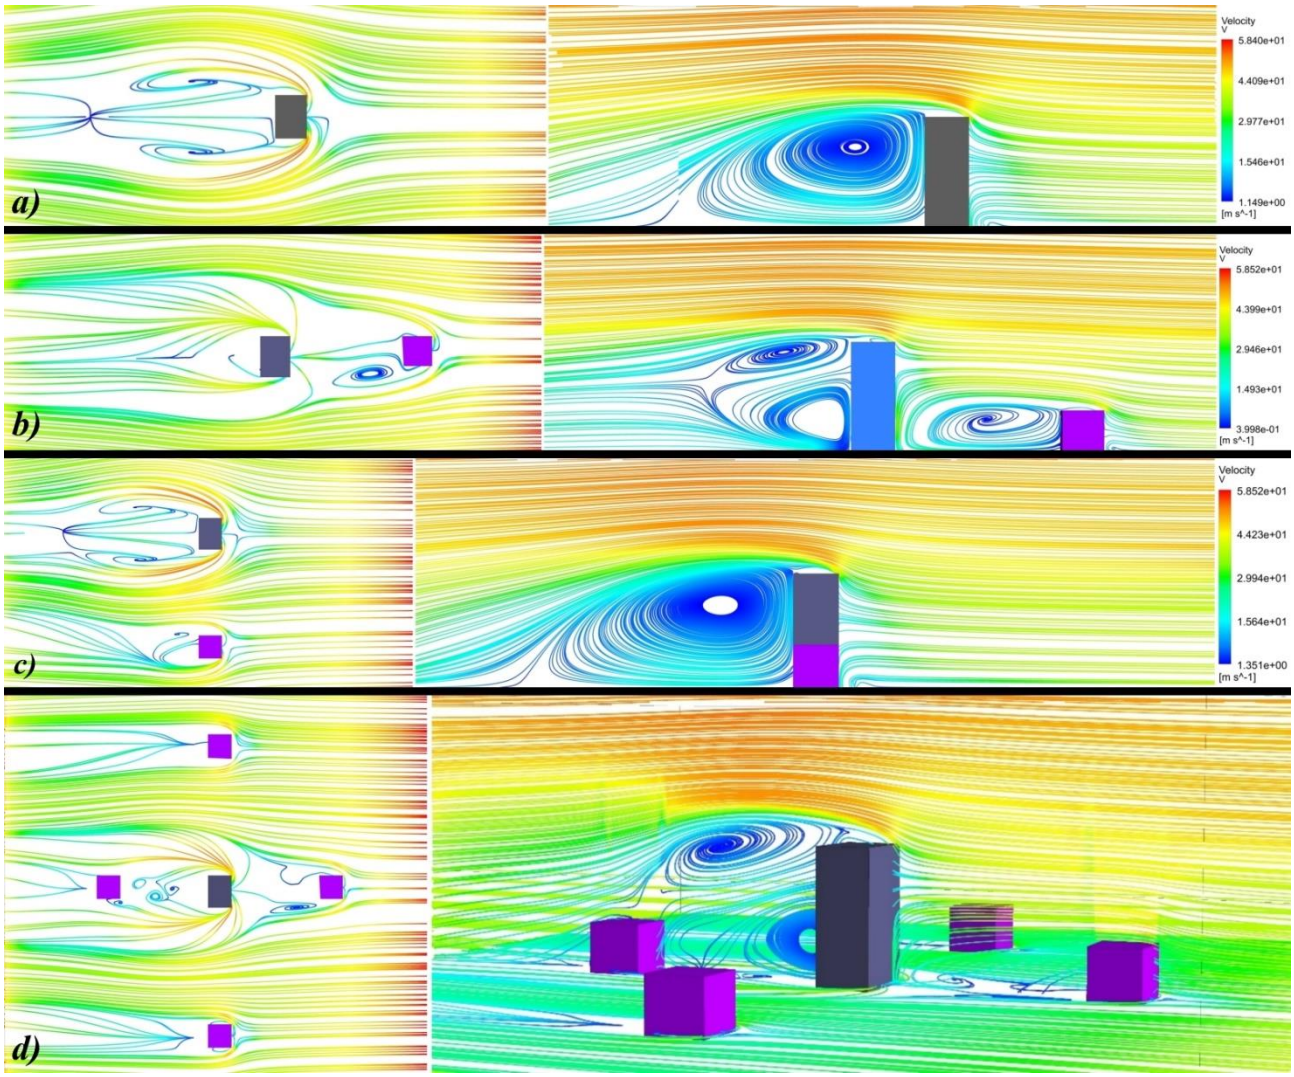

Figure 2. The results of numerical simulations

4. CONCLUSION

In the last decades, the development of awareness about the possible consequences of climate change actualizes wind as a complex load, and because of that, it has become the subject of numerous researches. At the same time, modern achievements in computer technology significantly improve and speed up numerical procedures and lead to the realization of advanced numerical simulations of the wind effect on buildings and their environment. Increasingly, free space around residential towers has been usurped by new buildings that change the microclimate and air flow around the existing towers. Although it seems that additional buildings would reduce wind speeds around the building, this is not always the case and depends on numerous factors. Vortex zones are created that are sometimes independent and sometimes overlap with the existing ones, while on the sides there is an increase in wind speeds, usually due to the formation of a "wind-canyon". All this implies that the

wind analysis must be carried out in detail using available advanced methods, so that the space around the buildings receives an adequate purpose in the best possible way.

Abstract: *Drinking water, whether previously purified or not, even if entirely clear, can often be contaminated with bacteria, viruses, or harmful microbes, necessitating disinfection. Disinfection serves as the final and sometimes the sole process in preparing drinking water. This paper presents a solution for the on-demand production of active chlorine (sodium hypochlorite) without the need for storage, aiming to prevent its degradation and ensure the safety of workers during handling.*
Keywords: Drinking water, sodium hypochlorite, chlorine

1. INTRODUCTION

Disinfection of water is most commonly performed using gaseous chlorine and chlorine compounds, during which oxidation reactions predominantly take place. Chlorine readily oxidizes alcohols, aldehydes, amino acids, various inorganic substances, and substances causing water discoloration, among others. Disinfection is carried out by precisely dosing chlorine compounds into the water using a dosing device (such as a dosing pump, dropper, or ejector). These quantities typically range from 0.3 to 0.5 g/m3 and depend on the quality of the filtered water, specifically on the content of substances susceptible to oxidation. These amounts are adjusted so that the disinfected water contains residual chlorine levels of 0.3 to 0.4 mg/l immediately before use. This free chlorine serves as a convenient indicator that an adequate amount of disinfectant has been used, while also preserving the bacteriological safety of the water for a certain period. Chlorination of water serves as both primary and secondary disinfection. This means that chlorine is used for both the primary inactivation of microorganisms in the water and to provide protection to the distribution system through residual action. The residual chlorine aims to maintain biological stability and protect against secondary contamination. Maintaining the biological stability of the system involves keeping the water in a state that does not promote the growth of microorganisms in the distribution system. For small-capacity facilities, disinfection is commonly carried out using sodium hypochlorite, NaOCl. The active chlorine content in the solution is about 15%. Gaseous chlorine is primarily used in high-capacity waterworks but is being phased out from water treatment processes due to the risks associated with handling and storing chlorine gas cylinders. Water solutions of sodium hypochlorite, produced in large petrochemical complexes or on-site generation units, are increasingly being used. In both cases, the water solution of the raw material (chloride salts) and the finished product (sodium hypochlorite) are stored in tanks exposed to atmospheric temperature and, potentially, sunlight radiation. Storage under such conditions triggers a thermochemical reaction in which sodium chlorate is formed from sodium hypochlorite, which is three times less effective in the water disinfection process. This

[1]ztrisovic@atsbb.edu.rs
[2]tomislav.trisovic@itn.sanu.ac.rs
[3]virginia.socalici@fih.upt.ro
[4]corneliu.birtok@fih.upt.ro

problem is particularly pronounced during the hot summer months when the air temperature exceeds 30 degrees Celsius. To prevent the degradation of sodium hypochlorite, climate-controlled storage spaces and containers that do not allow UV radiation must be provided. In addition to hypochlorite degradation caused by heat and UV radiation, there is also spontaneous degradation defined by a half-life of approximately one and a half months. Since the solutions are alkaline, contact with carbon dioxide from the air leads to a reaction with sodium hydroxide, forming sodium carbonate, further complicating the operation of dosing systems by clogging nozzles, pump suction baskets, droppers, and injection valves.

2. BACKGROUND

In recent years, several companies worldwide have developed on-site sodium hypochlorite production devices, but they have mainly presented two design solutions: devices with flow and batch-type reactors, both involving the storage of the resulting sodium hypochlorite solution. These solutions have demonstrated various advantages over gas chlorination technology in practice. However, they tend to be large in size, considerably expensive, and susceptible to the degradation of sodium hypochlorite, particularly when left in the receiving tank for extended periods. When situated in air-conditioned environments, operational costs escalate significantly, which poses a substantial financial burden, especially for devices with smaller capacities. On the other hand, for non-air-conditioned settings, the installation of heat exchangers becomes imperative, both in the reactor itself and in the tank containing active chlorine. To ensure the reliability of the disinfection process, sizable storage tanks are implemented, containing significant amounts of sodium hypochlorite.

This precaution safeguards the continuity of the disinfection process in the event of device malfunctions. The intricate nature of the construction [1-3] justifies the need for product storage, guaranteeing the uninterrupted flow of the dosing process during any necessary device repairs. Similar challenges persist across the operation of batch, flow, and recirculation reactors. The initial prototype of one such device emerged in the USA under 'Capital Controls,' featuring a flow reactor, table salt reservoirs, an active chlorine tank, a water chemical preparation system (for softening), and an active chlorine dosing system. Fully automated, the device operates with minimal human supervision. Similarly structured devices were later developed in our country during the early 1990s, with the first model crafted by 'Fabrika vagona' in Kraljevo and commercially produced by 'Sigma' in Kula. By the late 1990s, various European manufacturers introduced new iterations of these devices, including 'Wallace Tiernen,' 'Fisher Porter,' 'Dinotec,' 'ProMinent,' 'Siemens Plc' OSEC-NXT with a membrane electrolyzer, and 'Water Engineers Ltd.' The designs, though diverse, predominantly rely on flow reactors and the accumulation of active chlorine. Notably, some devices utilize seawater in the electrolysis process to generate active chlorine, such as those from 'EU-CHLOR Ltd' in England and 'Prima Atec' in Korea, employing 'NC' cell types for the conversion of seawater. More recent entrants into the global market, including 'Titanium Tantalum Products Ltd' from India, have introduced electrochemical cells with carbon steel cathodes and titanium anodes activated with RuO_2, polarized monopolarly. Asian manufacturers, such as 'IEC Fabchem Limited' in India, 'Water Engineers' in Singapore, 'WestWater Enterprises Pty Ltd.' in Australia, 'Prima Atec Inc.' in Korea, 'Kalf Engineering' in Singapore, and 'Nagpur Aquatech Ltd.' in India, have also developed devices for on-site active chlorine production. These systems are constructed with flow reactors and active chlorine storage, catering to both seawater and table salt solutions for electrolysis.

Cleaning of the electrolyzer is accomplished by ceasing the process, filling the electrochemical cell with an acid solution to eliminate potential limescale buildup, expelling the acid, and resuming electrolysis using kitchen or sea salt. Most of these automated solutions are tailored for large-scale systems generating over 50 grams of active chlorine per hour. This paper introduces a novel device designed to address the limitations observed in previously described systems, primarily focusing on rectifying the issue of sodium hypochlorite degradation. The storage of sodium hypochlorite in tanks exposed to atmospheric temperature and potential solar radiation triggers a thermochemical reaction, converting it into chlorate, significantly diminishing its effectiveness in water disinfection, up to three

times less effective. This problem is particularly acute during the sweltering summer months when temperatures exceed 30 degrees Celsius. To counteract the degradation of sodium hypochlorite, the provision of air-conditioned storage facilities and the use of UV-resistant materials for containers become imperative. Apart from causing water contamination with chlorate, which possesses lesser disinfectant properties than sodium hypochlorite, prolonged storage elevates the cost of utilizing this disinfectant solution.

3. PROBLEM STATEMENT AND SOLUTION

To address the noted deficiencies in existing solutions, we have developed a device for active chlorine production featuring a coaxial reactor design. This innovative system generates sodium hypochlorite in quantities precisely matching the demand for water disinfection, eliminating the need for its storage. In our novel coaxial and cabinet reactor solution, the water undergoing chlorination circulates around the reactor housing, ensuring that the electrolyte temperature remains in close proximity to the cooling tap water temperature.

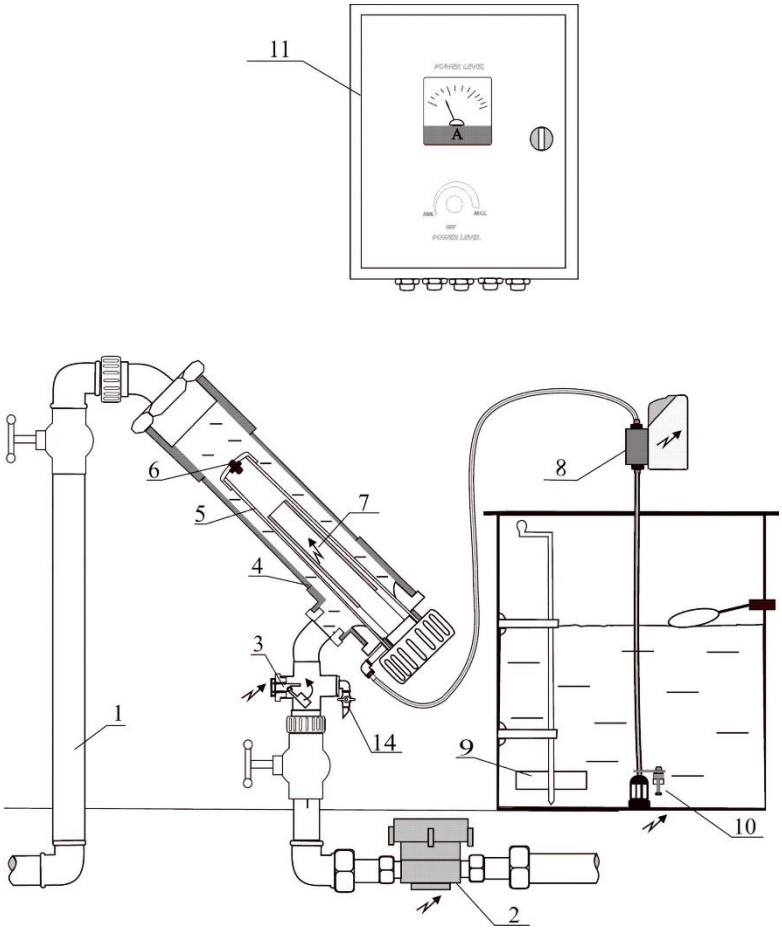

Figure 1. Device for the electrochemical production of active chlorine from dilute chloride solutions with a coaxial reactor mounted on a pipeline

Consequently, the sodium hypochlorite solution produced at the reactor outlet remains below 30°C, considering that tap water typically ranges between 10°C and 20°C. Essentially, the water undergoing chlorination doubles as a cooling agent. This design maintains the outlet temperature below 28°C, minimizing the risk of thermochemical degradation of hypochlorite to chlorate.

Our design circumvents the necessity for a thermoregulator and heat exchanger, only requiring a water flow sensor in the pipeline, leading to substantial simplification and material, electrical component, and automation savings. The device's proper operation is ensured through the installation of two sensors, one for monitoring the water flow to indicate the operational status of the pumping

pump and another for the minimum chloride solution to prevent the dosing pump from running dry. The electrolyzer activates only when there is a flow through the pipeline and the chloride solution exceeds the minimum threshold.

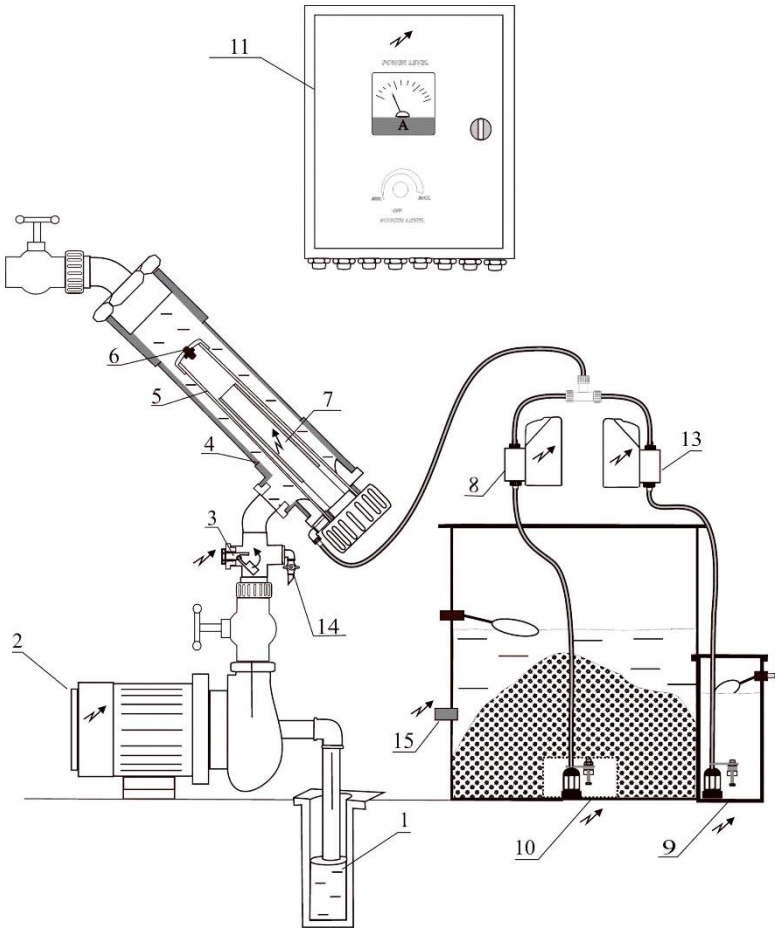

Figure 2. Device for the electrochemical production and dosing of active chlorine from a concentrated chloride solution with a coaxial reactor mounted on the pressure of the pumping pump

Our innovative solution, with its water-cooled coaxial and cabinet reactor, obviates the need for temperature sensors, thermoregulators, and their corresponding automation. Furthermore, the design eliminates the requirement for hydrogen separation and venting, as all reaction byproducts are introduced into the raw water along with the active chlorine. The dosage of active chlorine and hydrogen into the treated water remains below 1 mg, ensuring environmental friendliness. During operation, the dosing pump draws in a diluted chloride solution (3%) (refer to Figure 1). Alternatively, two dosing pumps may be employed, one drawing clean water and the other a concentrated table salt solution, mixed just before entering the reactor to produce a diluted chloride solution (3%) (refer to Figure 2). The frequency of diluting the sodium chloride solution depends on the monitoring intensity, with the option to refill the diluted solution container more frequently (every ten days) in more closely monitored settings. For locations with less frequent monitoring (distant sites), two dosing pumps are used, necessitating a higher input of concentrated salt solution into the container, achieving a 3% solution ratio upon mixing at the reactor inlet.

Within the tubular reactor, chlorides undergo electrochemical conversion to hypochlorite, with the resulting solution passing through a non-return valve before entering the water treatment process. The dosing pump flow, reactor current strength, water flow, and pipeline pressure are regulated based on the water flow and pressure. The minimum pressure requirement in the pipeline is 0.1 bar, with a flow rate of 0.1 liters per second. This device can be conveniently installed on the pump's discharge or suction line (as depicted in Figure 1) or anywhere along the pipeline, necessitating the installation of a flow meter instead of a flow sensor to signal the reactor's activation and operational intensity.

With its straightforward design, modular reactor system, and user-friendly servicing, our system ensures dependable operation and maintenance efficiency.
The device comprises an electric block, a sodium chloride tank, and a hydraulic assembly. The hydraulic assembly is composed of dosing pumps, an inlet valve, a flow sensor, a coaxial reactor or reactor cabinet, and an outlet valve. The sodium chloride solution, sourced from the tank (either 3% or 30% NaCl), is conveyed through the pipeline via dosing pumps. It is then mixed with clean water and subsequently introduced into the coaxial or cabinet reactor through a non-return valve.
Upon entering the reactor, chlorides undergo an electrochemical transformation, with active chlorine being generated at the anode and hydrogen released at the cathode. The resultant reaction products are directed through the upper non-return valve into the water circulating around the reactor housing, simultaneously undergoing chlorination.
Inside the reactor housing, a dosing pump maintains a pressure higher than that in the pipeline, ensuring the continued hydraulic transportation of the reacted solution. Subsequently, the solution is injected back into the pipeline through another non-return valve. This process guarantees that the chloride solution, or the active chlorine solution within the reactor housing, remains at the temperature of the well water (typically ranging between 7°C and 19°C). These optimal conditions facilitate the electrochemical synthesis of active chlorine.

4. CONCLUSION

This paper introduces a cutting-edge device for on-demand sodium hypochlorite production, eliminating the need for storage to prevent degradation and safeguarding workers during handling. The device ensures enhanced reliability in dosing system operations by generating a slightly alkaline solution with a pH of around 8 through the electrolysis of diluted solutions, thereby reducing the impact of CO2 reactions. Notably, this solution prioritizes user and environmental safety and represents a significant innovation compared to preceding methodologies.

ANALYSIS OF ENERGY-SAVING MEASURES IN RESIDENTIAL BUILDINGS CONNECTED TO DISTRICT HEATING SYSTEMS USING INFORMATION TECHNOLOGY

Đorđe Karić[1], The Academy of Applied Technical Studies Belgrade
Aleksandra Sretenović-Dobrić[2], Faculty of Mechanical Engineering, University of Belgrade

Abstract: *The thermophysical properties of the building materials and elements from which the buildings are constructed determine the heat losses of the building structures. When looking at the percentage share, the energy consumption in buildings in the USA and the EU is higher than that in industry and transportation. To achieve minimal energy standards, rules have been put into place, such as the European Union Directive on energy efficiency in buildings. The implementation of energy efficiency measures heavily relies on the improvement of building quality and suitable component selection. Energy efficiency measures are still important to implement in buildings built before the present standards and directives were adopted, as well as in newly constructed buildings. The research is based on buildings aged 30, 40, and more years, insulated, covered by the Energy Retrofitting of Buildings project in Šabac, implemented by the Distict Heating Company (DHC) "Toplana-Šabac" in collaboration with the European Bank for Reconstruction and Development (EBRD). The aim of the study is to track real-time heat energy consumption using Supervisory Control and Data Acquisition (SCADA) information systems over the past six years, or six heating seasons, before and after the energy retrofitting. The ultimate goals of the energy-saving measures are to reduce greenhouse gas emissions and decrease the operational costs of the facilities.*

Keywords: information technology, district heating systems, energy efficiency, residential buildings, reduction of CO_2

1. INTRODUCTION

The modern world is confronted with large challenges in the field of energy. The primary issue is the shortage of energy and its unreliable supply, while the secondary encompasses environmental pollution and the consequences of climate change, resulting from irresponsible energy consumption. The production, distribution, and utilization of energy play a pivotal role in all aspects of human activities, deeply influencing the societal and economic development of every country.

Questions of sustainable energy consumption have long been neglected, but today, they are in focus and recognized as an urgent problem requiring immediate solutions. But, despite the heightened attention to the social, environmental, economic, and security aspects of energy use, the existing uncontrolled model of energy consumption has proven to be unsustainable. Thus, the priority should be achieving sustainable energy consumption through a strategic approach to energy consumption itself and the implementation of energy-efficient measures in all segments of the energy systems of each country.

Buildings constitute the largest individual consumers of energy, exhibiting a growing trend in tandem with rising standards of living. In Europe, around 40% of the total energy is used in the construction sector, followed by transportation at 32%, and industry ranking third with 28% energy consumption [1–2]. Moreover, buildings serve as significant sources of environmental pollution,

[1]djkaric@atssb.edu.rs
[2]asretenovic@mas.bg.ac.rs

contributing to increased energy consumption and carbon dioxide emissions. This underscores the crucial potential for energy reduction within the realm of energy efficiency in the construction sector. Achieving the fundamental aim of energy efficiency in construction involves adopting measures and mechanisms for a sustained reduction in energy consumption in new buildings, utilising novel design methods and materials, and through the judicious reconstruction of existing buildings [3]. The implementation of regulations, adoption of directives, and formulation of guidelines on energy efficiency in buildings are planned to result in a substantial reduction in energy consumption for both new and existing structures [4].

In Serbia, a significant part of energy is dedicated to space heating, a factor contingent on the heating system type, heat distribution, and thermal characteristics of the building envelope, as well as the size, geometry, and orientation of the structure itself. When the energy efficiency of the building envelope is insufficient, considerable amounts of energy are required to achieve the desired temperature [5]. The building envelope assumes a critical role as the interface between the interior space of the building and the external environment, with components such as external walls, windows, roofs, ceilings, floors, and doors exerting a large impact on the energy consumption needed for heating and cooling.

The efficiency of a building envelope depends on various factors, including the type of building, climatic conditions, construction methods, geographical location, and the age of the structure. The significance of a quality building envelope is evident in the fact that heating and cooling buildings constitute a large part of the energy consumption globally, ranging from 30% to over 50%, depending on climatic conditions. In the residential sector, this consumption can exceed 60% of the total energy consumption [6]. According to the 2022 population census in Serbia, there are a total of 2.6 million residences, indicating significant potential for energy savings in buildings. The majority of constructed structures exhibit energy consumption for heating in the range of 150 to 200 kWh/m^2, highlighting inefficient energy use in these constructions [7, 8].

From the perspective of energy consumption, the construction period is crucial. Between 1950 and 1980, many residential and non-residential-constructed structures were erected, which now represent significant energy consumers, with average energy consumption for heating exceeding 200 kWh/m^2. In 1980, new requirements of thermal protection of buildings were introduced, reducing the allowable heat transfer coefficients by approximately 30%. The standards issued in 1987 were in effect in Serbia until September 30, 2012, when the implementation of the Regulation on the Energy Efficiency of Buildings and the Regulation on the Conditions, Content, and Procedure for Issuing Energy Performance Certificates in Construction began [9]. In this regard, the focus should be on the reconstruction of buildings constructed before 1987.

2. MATERIAL AND METHODS

2.1 Research description

The aim of this work is to enable benchmarking of energy efficiency indicators by comparing buildings that have implemented project activities with those that have not undergone such a program. The energy consumption for heating buildings should fall within the limits specified by the Regulation on the Energy Efficiency of Buildings, corresponding to the energy class "C." The anticipated reduction in energy consumption after implementing energy efficiency measures (building insulation) while preserving comfort and heating quality leads to a decrease in fossil fuel consumption, so resulting in lower emissions of suspended particles.

The analysis covers six residential buildings, two of which are connected to the "Trkalište" Heating Plant, and four to the "Benske Bare" Heating Plant. The capacity of the first plant is 66 MW, while the second is 24 MW. All buildings are connected to the SCADA system, through which all significant parameters are monitored. The buildings are selected so that each one is on a separate substation and does not share heat capacity with any other building. Heat sources are also managed through the SCADA system.

One of the parameters taken into consideration is that for each analysed building, there are preserved measurement results on heat energy consumption for at least two years before and two years after insulation, ensuring the reliability of the conclusions drawn. All the analysed buildings are located in the city centre, and they all share the commonality of being older than 30 years. The oldest building was constructed in the 1960s, while the youngest among them was built in the early 1990s. The study includes the following heating seasons (the period when the building uses heat energy from the district heating system, from October 15th to April 15th of the following year): the seasons 2017/2018, 2018/2019, 2019/2020, 2020/2021, 2021/2022, and 2022/2023. A list of objects with ID numbers of measuring points, heat capacity, year of construction, and the period in which energy retrofitting of the object was performed is given in Table No. 1.

2.2 Results

Due to varying average temperatures from season to season, all buildings are normalized to the same average temperature using the coefficient of the outside temperature. Temperatures are also obtained from the SCADA system and averaged for the entire season (Ta,avg). The specific heat consumption (SHC) is calculated according to formula (1). The coefficient of the outside temperature (*k*) is calculated according to formula (2).

$$\mathrm{SHC} = \frac{\text{Energy consumption for the heating season}}{\text{Heated area}} \left[\frac{\mathrm{kWh}}{\mathrm{m}^2}\right] \tag{1}$$

$$\text{The coefficient of the outside temperature} = \frac{20 - \mathrm{Ta,avg}}{20 - (-15)} \tag{2}$$

Where it is -15°C, the external projected temperature is for the city of Sremska Mitrovica [4]. The same temperature is used for the city of Šabac. A temperature of 20 °C is the design temperature of the room.
The specific heat consumption whit k (SHC*k*), taking into account the coefficient of the annual outside temperature *k*, is calculated according to formula (3) [11].

$$\mathrm{SHC}k = \frac{\text{Specific heat consumption} \times |k_{season\ i+1}|}{k_{season\ i}} \left[\frac{\mathrm{kWh}}{\mathrm{m}^2}\right] \tag{3}$$

For each building, a season is selected as a reference for analysis. Based on the values for the non-insulated season, the percentage savings for insulated seasons are obtained. The percentage savings (PS) are calculated using the formula (4).

$$\mathrm{PS} = \frac{\mathrm{SHC}k_{season\ N} \times \ \mathrm{SHC}k_{season\ N+1}}{\mathrm{SHC}k_{season\ N} \times 100}\ [\%] \tag{4}$$

The research results are presented in Figure 1. Percentage savings compared to the year without energy saving measures (Benchmark year) are shown in Figure 2.

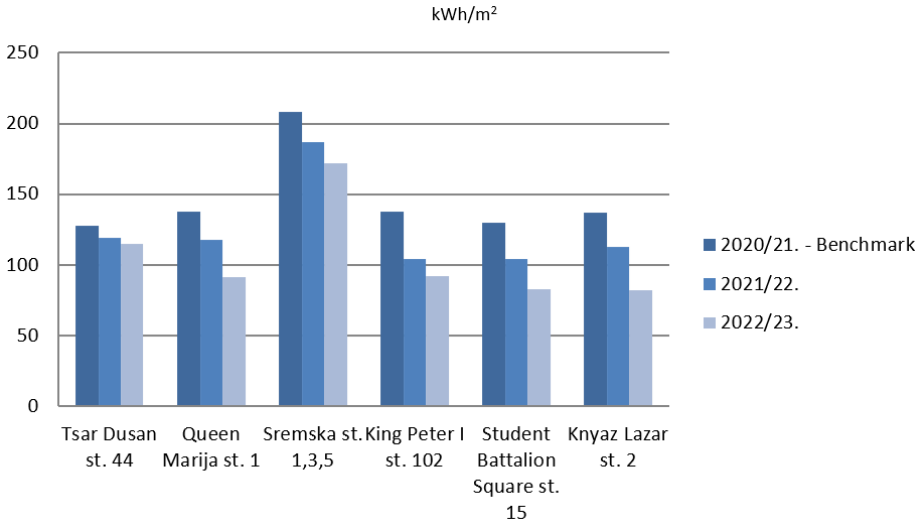

Figure 1. Specific Heat Consumption whit coefficient *k*
Source: DHC „Toplana Šabac“

Based on the obtained results, it is evident that the energy efficiency package has yielded results in reducing thermal energy consumption. The percentage of savings varies from 8% to even 40%. Various factors influence the percentage of savings, such as windows and doors in buildings not covered by this project, the building's position, construction period, quality, and age of installations, as well as the maintenance level of installations. The behaviour of end-users and their use of thermostat valves also play a crucial role. The energy efficiency package has delivered significant results and serves as a good practice example. The average savings based on the analysis of the energy efficiency package in these six buildings range from 15% to 28%.

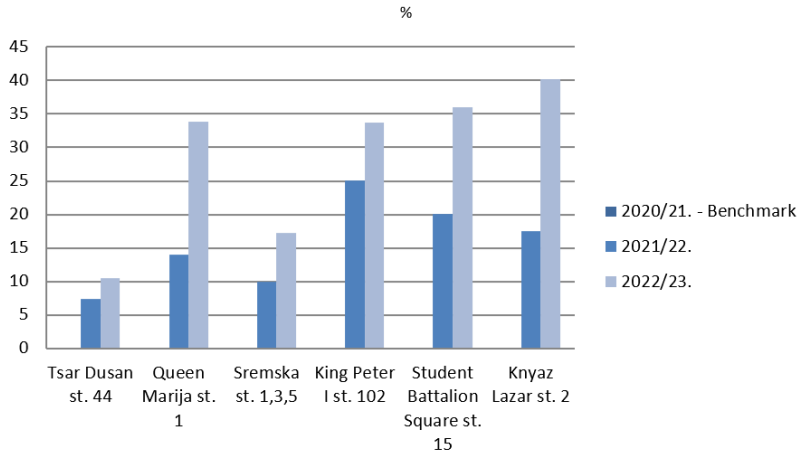

Figure 2. The percentage savings compared to the year without energy savings measures

3. CONCLUSION

The energy policy of a local community (LC) that relies on energy management in the public sector, as well as strengthening the capacities of residential building managers to prepare and implement energy efficiency measures, would contribute to reducing the consumption of thermal energy for heating and cooling in public, commercial, and private residential buildings (single-family and multi-family). Informed decision-making on the implementation of energy efficiency measures, as well as the financial and technical sustainability of these measures, leads to the successful implementation of individual projects and the achievement of planned goals defined in strategic documents, programs, and action plans.

Examples of good practices motivate citizens and decision-makers to plan and implement activities over an extended period, ensuring that the local community remains resilient to rising fuel and energy prices, maintains energy supply security, works on environmental preservation, and improves the quality of life. It also aims to protect vulnerable and marginalised groups from the emergence and consequences of energy poverty and actively support the decarbonisation process and the development of a "green" economy.

In this context, it is crucial to analyse the thermal energy consumption in buildings, as well as the effects of applied energy efficiency measures, and publish the results and gained experiences through various communication channels to stakeholders. It is necessary to explore financing models and, based on conducted surveys, propose improvements to existing financing models and all other support mechanisms, as well as suggest innovative solutions that could be sustainable and accepted by all actors and direct and indirect participants in projects, especially decision-makers.

Maximising the contribution to a successful energy transition involves increasing the share of renewable energy with the aim of completely abandoning local energy based on fossil fuels in a pre-defined period. The specificities of local communities and the application of different solutions that are based on efficient "green" technologies should also be taken into account. For this reason, it is necessary to explore the level of technical knowledge and awareness, primarily of building managers, about the possibilities of applying renewable energy technologies and the attitudes of citizens and their needs to raise awareness about the way of implementing and financing renewable energy projects.

The research process begins with compiling a list of stakeholders, such as decision-makers, energy managers, citizens, including the media, representatives of the civil sector, as well as educational institutions and experts in local energy, energy efficiency, and renewable energy sources. Without good information, the participation of experts, and effective support mechanisms, the goals defined in energy policies, strategic documents, and energy efficiency programmes will not be achieved. Users of research results are often members of local communities who have no experience with similar projects, emphasising the importance of collaboration between local communities in transferring information, knowledge, and best practices.The results of the analysis conducted based on the research will be of great importance to other local communities that have not yet started implementing projects to improve the thermal properties of buildings, both the optimal implementation of energy efficiency measures (insulation of existing buildings) and choosing a finncing model.

ENVIRONMENTAL ACCOUNTING EDUCATION FOR SUSTAINABLE DEVELOPMENT: A COMPREHENSIVE OVERVIEW

Bosiljka Srebro[1], The Academy of Applied Technical Studies Belgrade
Stefan Milojević[2], Faculty of Business Economics, Educons University
Miljan Adamović[3], Pharmacy Institution "Zdravlje lek"

Abstract: *Reporting on an organization's financial performance is no longer the only emphasis in corporate reports, as investors and other relevant addressees increasingly require companies to also provide information on their impact on the environment and society as a whole. Therefore, environmental accounting and reporting are becoming increasingly important for stakeholders and profit-oriented organizations, since the environmental and social performance of the organization has a significant impact on the status of the organization's financial health. The purpose of this research is to review the current situation in this area and make certain recommendations.*
Keywords: environmental accounting, sustainable, reporting, education

1. INTRODUCTION

Accounting is a discipline that, in its practical application, can, among other things, include environmental aspects, especially when it is used to monitor and disclose information about the impact of companies' operating activities on the environment. Green accounting is a branch of accounting science that companies accept in order to contribute to environmental protection. The primary focus is on promoting sustainability and the company's role in the environmental context. It is crucial to emphasize these principles throughout the organization and to ensure that they are recognized by all stakeholders. Green accounting is also called "environmental accounting", "environmental protection accounting", "ecological accounting" and is related to ecological services and goods. Moreover, it is recommended that academic circles use the term "environmental accounting" uniformly. The implementation of green accounting in companies has caused debate, and the results of previous research suggest that there is no universally accepted standard model for its implementation to improve performance (Astawa et al., 2018).
Environmental accounting was generally viewed as a subset of social accounting until the late 1980s, whereas today it is viewed as a "predominantly new" area of accounting consideration. Environmental accounting in the modern environment plays a key role in understanding the role that businesses play in economic security and general well-being, especially in the context of environmental security. Green accounting is an approach that emphasizes the long-term efficient use of resources in the company's production processes, in order to achieve synergy between corporate growth and environmental responsibility, which ultimately contributes to social benefit (Indriastuti & Mutamimah, 2023).This accounting provides information that highlights the contribution of business enterprises to economic development, on the one hand, but also information on costs initiated through pollution or resource degradation, on the other hand. Due to the increasing needs of financial statements users related to the disclosure of green information, on

[1]bsrebro@atssb.edu.rs
[2]stefan.milojevic@educons.edu.rs
[3] zdravljelek@gmail.com

the one hand, and the increasingly pronounced tendency to deal with the shortcomings of traditional disclosure, it has given rise to the need to develop an accounting standard that would include consideration of green or environmental disclosure (Maama & Appiah, 2109).
Green accounting has a dual purpose. The first purpose is to improve the financial environmental performance of the business, while the second purpose is to analyse the impact of the organization's business on the environmental system. The implementation of green accounting within the organization's management system has a key role in achieving progress, both in environmental and economic performance of the organization.
This paper is structured as follows. First, the background to environmental accounting is outlined. The second part deals with the methodology, the third part presents the results of the research and the accompanying discussion. Finally, some concluding remarks are made.

2. LITERATURE REVIEW

Environmental protection is an extremely important issue, among other things, also in a normative sense (Owen et al., 1997; Knežević, 2011; Knežević, et al., 2013; Thornton, 2013; Stanković &Mitrović, 2021; Mitrović et al., 2022).).In its full capacity, "green accounting" should refer to the actual accounting of an organization's environmental impact (Cho & Patten, 2013). However, the question arises as to how likely it is that the effects of companies' environmental actions will be included in their financial statements. Additionally, it raises the question of whether companies will continue to provide information about these initiatives. Understanding corporate disclosure and its impact remains as relevant today as it was two decades ago, which is of particular importance to the accounting academic community.
When applying "green accounting", it is crucial to identify and numerically express the impact of the investment project on the environmental aspect, as well as the costs resulting from reducing this impact, such as land restoration, water purification and other measures to restore the environment. In addition, we must not forget to take into account the irreparable damage to the environment and human health. Without such analyses, investment managers can make decisions that can be extremely "expensive" for future generations (Stanojević et al., 2010).
"The literature on green accounting in distorted economies remains comparatively small" (Vincent, 2000, p. 18). Awareness of environmental constraints has led to a proliferation of accounting methodologies designed to measure the impact of human activity on Earth's ecological systems and resources. Current practice usually focuses attention on parallel reporting, while financial accounting still remains dominant. Green accounting remains largely voluntary and unaudited.
Companies can become leaders in promoting green initiatives by integrating them into their operations, thereby also motivating other organizations to do the same. When green accounting is incorporated at all levels of the organization, a greater level of environmental responsibility can be achieved (Agarwal & Kalpaja, 2018, p. 207). Introducing the concept of green accounting into the organization's management system plays a key role in improving the organization's environmental and economic performance. However, we are facing challenges when it comes to the implementation of this type of accounting in Serbia due to the lack of information that would be available to interested parties regarding the additional costs and effects brought by the implementation. Most companies are not sufficiently familiar with the potential results and therefore may be hesitant to implement this tool.

3. METHODOLOGY

This research study was conducted in Belgrade in 2023.The sample consists of 159 respondents, who are students and people from the economy, who are classified into three groups - employees, lawyers and businessmen. For the purposes of the research, a questionnaire was structured in accordance with the objective of the research, which was distributed to respondents via e-mail, thus collecting primary data. A Likert scale of 1 (strongly disagree) to 5 (strongly agree) was used.The

collected data were classified and tabulated for analysis in accordance with the objectives of the study.

4. RESULTS AND DISCUSSIONS

Using Google Forms, we collected primary data through questionnaires and analysed them to obtain the final results. In the first phase of the analysis, we applied a percentage analysis to explore the general profile of the respondents (Table 1).

Table 1. Analysis of the respondents' general profile
Source: *Primary Data*

	Classification	No.of respondents	Percentage
Gender	Male	91	57.2
	Female	68	42.8
	Total	**159**	**100**
AgeGroup	18-30yrs.	38	23.5
	31-40yrs.	43	27
	41 - 50 yrs.	59	37.1
	51 - 60 yrs.	12	7.5
	61 and above	6	11.11
	Total	**159**	**100**
Occupation	Employees	55	34.6
	Student	26	16.4
	Lawyer	12	7.5
	Businessmen	66	41.5
	Total	**159**	**100**

The primary data was collected with the help of 159 respondents. Table 1 shows that out of 159 respondents, 91 (57.2%) respondents were men, and 68 (42.8%) were women. There were 38 (23.5%) respondents in the 18-30 age group, 43 (27%) in the 31-40 age group, 59 (37.1%) respondents were under 41-50 years of age, 12 (7.5%) were in the age group of 51-60 years, and 6 (11.11%) belonged to another age group except the above-mentioned age groups. Of these, 55 (34.6%) respondents were employees, 26 (16.4%) were students, 12 (7.5%) were lawyers, and 66 (41.5%) were businessmen.

Considering the defined goal (according to: Agarwal& Kalpaja, 2018), the paper provides answers to three research questions – Figures 1-3.

When 159 respondents were asked whether environmental accounting must be included in all companies (Figure 1), only 28.3% of the respondents strongly agreed, 24.5% were neutral, 23.9% agreed that environmental accounting should be incorporated in all companies, and 7.5% said they disagreed with it. The results of the survey on this matter indicate that slightly more than 50% of the respondents are aware of the importance of including environmental accounting in all companies, considering the benefits related to the fact that companies can monitor two things: what is taken from the environment and what is received in return.

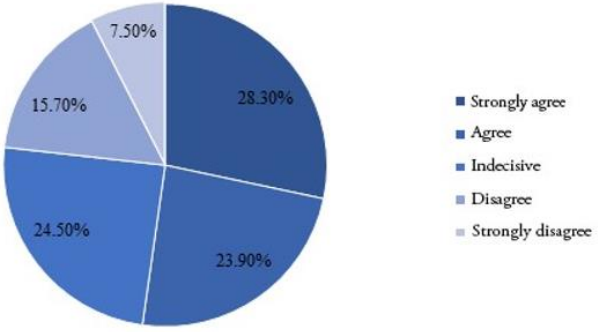

Figure1. Integration of environmental accounting in all companies
Source: Authors

Then, the respondents were asked whether it is useful to increase awareness of environmental accounting. The following answers were obtained: as shown in Figure 2, it can be seen that 34.6% of the respondents strongly agree with the statement, 31.4% of the respondents agree, while the rest of the respondents are either not very sure about the contribution of environmental accounting to profit-oriented organizations or are they strongly disagree.

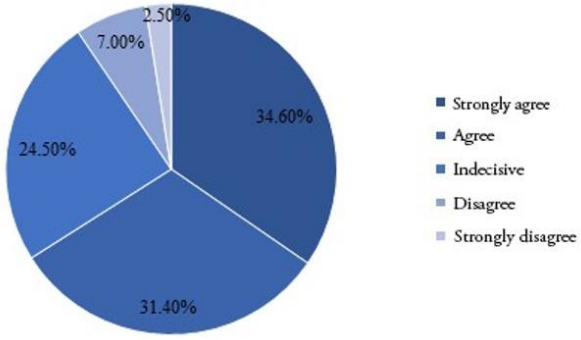

Figure 2. Increasing awareness of environmental accounting
Source: Authors

Furthermore, when the respondents were asked whether the government must take strict action if environmental reporting is not followed (Figure 3), 9% of them strongly disagree and 6% disagree. More than half of the respondents are of the opinion that the government must take strict measures if environmental reporting is not respected (agree or strongly agree).Furthermore, 23.9% of them were neutral on this issue. Governments should encourage activities and performance measures in the sphere of environmental impact to a greater extent.

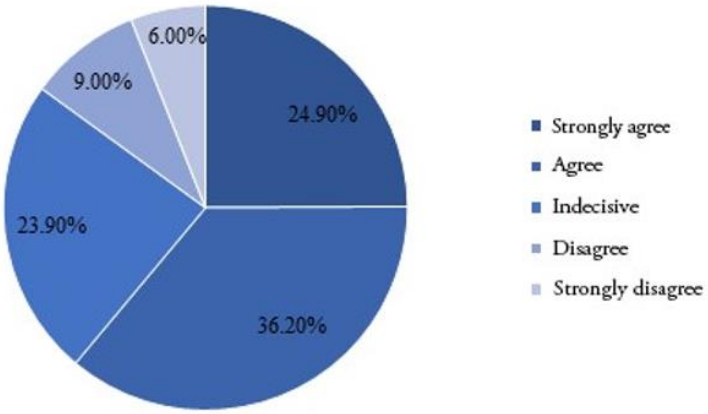

Figure 3. Government influence on environmental reporting
Source: Authors

Based on the above brief review and analysis of Serbia's achievements in environmental accounting research in the last two decades, we believe that in order to improve theoretical research and practical application of environmental accounting in Serbia, it is necessary to make significant efforts in various fields.First, it is necessary to integrate environmental accounting research and systematically build a theory, which would design an engineering system for the establishment of environmental accounting.Second, it is necessary to encourage larger number of empirical research and as an example the research can be cited related to identifying the differences between the share prices of companies that disclose environmental information and companies that do not disclose information.Third, it is necessary to attract the attention of companies to focus more on environmental factors in making management decisions, where the introduction of the concept concerning the development of environmental management as an internal driving force would help.In order to achieve all three goals, it is necessary to increase education, both formal, at business and other faculties, as well as informal education through various types of training from this practice.

5. CONCLUSION

Viewed from the content of current research on environmental accounting, most scientists pay more attention to theoretical research on environmental accounting theories, such as the goal of environmental accounting, subject matter, basic assumptions, etc., but conducting specific research is necessary on how technical methods are borrowed and used from of other disciplines and as such are called upon to be applied to operational problems in the practice of environmental accounting. Research on the application of environmental protection in the segment of accounting recognition and measurement methods in practice should also be strengthened.

Achievements of theoretical research should be applied in the practice of environmental accounting of companies. The theory should be checked and corrected through practices in order to improve its practicality. The academic community can play a major role in this. Starting from the fact that environmental accounting is a comprehensive tool for introducing environmental considerations into business decisions, it is necessary to investigate more deeply the issue of depletion of natural resources. The study also highlights the significant importance of environmental accounting education as a core course within universities. It is necessary to incorporate environmental considerations into the practices of financial and management accounting, which would best support the making of eco-responsible business decisions.

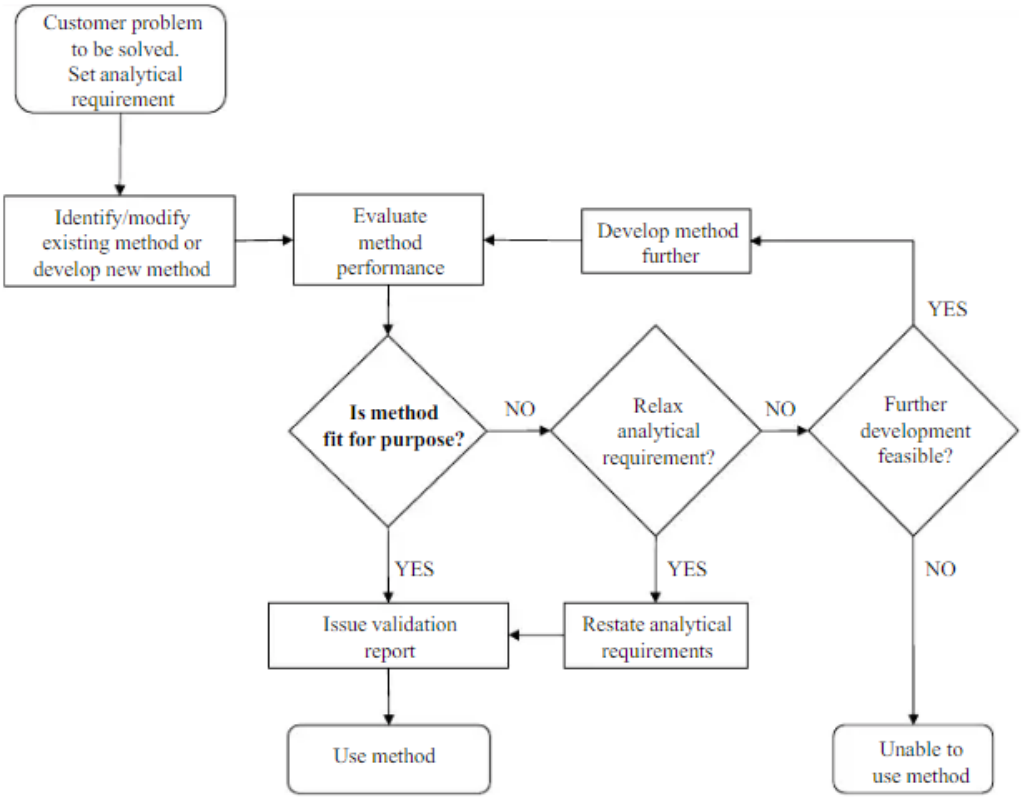
Abstract: *Every research or analytical method requires validation to ensure the accuracy, reliability, and precision of the results. Validation is a critical component of research, especially in areas such as water analysis or any field where the presence of elements or chemical compounds is measured and analyzed. In this study, we investigated the validation of the Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES) method for determining the elemental composition of water, along with the application of analysis of variance (ANOVA). The validation of the analytical method and the use of ANOVA analysis play a crucial role in ensuring the reliability and precision of results, as well as in exploring the variability among different samples. This paper emphasizes the significance of analytical method validation and the application of variance analysis in securing accurate and reliable results in water analysis, contributing to better water quality control and environmental protection.*
Kaywords: validation, LOD, precision, accuracy, linearity.

1. INTRODUCTION

Validation of an analytical method is a documented process that confirms the suitability of the applied procedure for obtaining useful data and thereby fulfills its intended purpose [1]. Validation begins immediately after the development of a specific method and is a prerequisite for its application. If feasible, a standard method published by international, regional, or national organizations should be selected. Such a method has already been validated - it has been determined that the testing method is suitable for its intended use. However, to use such a standard method for testing, it is necessary to confirm its feasibility in the working conditions of a specific laboratory, using its own resources such as equipment and personnel, and this process is called verification. In cases where a laboratory wishes to use a method developed in-house, a non-standard method, or a modified standard method (in-house), there is an obligation for it to be properly verified and validated before implementation [2,3].
From the initiation of an analytical problem to the laboratory's decision on whether the request can be executed using the identified method, a series of steps are followed (Figure 1). The validation process concludes with a determination and statement of whether the analytical requirement has

[1] vdjurdjevic@atssb.edu.rs
[2] ajanicijevic@atssb.edu.rs
[3] dbrkic@atssb.edu.rs
[4] apopovic@atssb.edu.rs
[5] mstamenovic@atssb.edu.rs
[6] abozic@atssb.edu.rs

been met or not. The results of the validation work are reported in a documented form that confirms the successful completion of all steps.
This paper presents the procedure and content of validation for the application of Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES) to determine the elemental composition, specifically the content of Ba, Fe, and Pb in wastewater. The method is in accordance with the EPA 200.7:1994 standard, and measurements were conducted using the ICP-OES 9820 SHIMATZU spectrometer.



Picture 1*:* Diagram of the method validation process
Source*:* [4]

2. EXPERIMENTAL SECTION

Before aliquoting for the direct determination of elements, the pH of the water samples was measured to confirm proper preservation (pH < 2). To determine dissolved elements, the sample must be filtered through a membrane with a pore size of 0.45 μm before analysis. A blank sample is prepared and analyzed alongside the actual samples. The experimental plan is shown in Table 1 in accordance with the specified data quality requirements. The sample types and concentrations to be analyzed are presented in Table 2.

Table 1: Experimental plan with specified data quality requirements

Validation Parameter	Sample Type	Description	Number of Repetition Tests
LOD, LOQ	Blank	Blank sample	10
Linearity	Calibration Solutions	Calibration solutions at 7 concentration levels	Duplicate measurements
Precision	Real Samples	Real wastewater samples	6 series in duplicate
Тачност	CRM	Synthetic samples with nominal concentrations	6 series in duplicate
	Spike Sample	Spiked samples at 3 concentration levels	6 series in duplicate

Table 2: Method Validation Samples

	Description
Sample A	Blank - DI water
Sample B	Wastewater from Henkel
Sample C	A + 0,2 mg/L mix metals
Sample D	A + 0,45 mg/L mix metals
Sample E	A + 0,75 mg/L mix metals

2.1 Calibration and standardization

For calibration and standardization, the following solutions are used:

a) Calibration Mix

The calibration curve is formed by diluting the calibration mix solution in a concentration range from 0.005 to 1.00 mg/l at 7 points (As, Se, Cd, Fe, Co, Pb, Cr, Ni, Cu, Mn, Ag, Sr, Ti, V, Al, Ba, Be, Mo, Sb, Na, K, Mg, Ca, Zn, Sn).

b) Blank (Blank Sample)

For the analysis, two types of blanks need to be prepared: calibration blank and reagent blank. The calibration blank is prepared by adding an acid to water in the same concentration as that used in making standard solutions. The reagent blank is prepared for each type of material according to the sample dissolution instructions but without adding the sample, only the chemicals used in its dissolution.

c) Initial Calibration Verification Standard (ICV)

These solutions are prepared from the same basic standard solutions used for calibration standards. They serve for periodic verification of instrument performance during the analysis.

d) Control Calibration Verification Standard (CCV)

These solutions are used for the initial and periodic verification of calibration standards to check instrument performance. They must be prepared independently of the solutions used for calibration.

2.2 Measurement

The instrument is configured with the appropriate operational parameters. After selecting the appropriate program from the ICPsolution package, the instrument is re-profiled by scanning argon lines while distilled water is dispersed into the plasma. The instrument is ready for measurement, and wavelengths are selected from the provided list of lines on which measurements will be performed. Prepared solutions are then introduced into the plasma.

The linearity of the calibration curve is verified by measuring calibration points in duplicate at concentrations that cover the entire range (0.005; 0.01; 0.05; 0.1; 0.25, 0.5; 1 mg/L). First, the calibration blank is measured, followed by standards from the lowest to the highest concentration. Distilled water is dispersed after each solution to rinse the system and prevent contamination. The choice of wavelengths (λ) for measurement depends on the type of material being tested, specifically the composition of the sample matrix and the potential interference of the measured line with the matrix lines. Lower concentrations are recorded in axial mode, while higher concentrations are recorded in radial mode. Determining the limits of detection (LOD) and limits of quantification (LOQ) involves tenfold repeated measurements of the blank at the λ used for element detection. The limit of detection for each element is determined by multiplying the standard deviation of the measurement results by 3. The limit of quantification for each element is determined by multiplying the standard deviation of the measurement results by 10 [4,5].

2.3 Pre-work verification

The measurement procedure on the instrument involves comparing the emission intensities of the test samples with synthetic standards, which means that recalibration is performed with each measurement. Quality control of measurements is carried out in each measurement series as follows: during each series of measurements of real samples, the calibration curves are checked by verifying the values for the calibration blank and one calibration solution, the initial calibration verification standard (ICV), which is recorded as an unknown sample. This verification is mandatory at the beginning and end of the measurement series. The calibration blank solution, prepared from the reagents used for dissolution, serves as a check for possible contamination. Along with the samples being analyzed, a control standard, the control calibration verification standard (CCV), is also measured, which is prepared independently of the solutions used for calibration. This type of control is conducted in each measurement series in parallel with the real measured samples. This measurement method checks the calibration curves and the instrument's stability over an extended time period, especially in cases of series with a large number of samples.

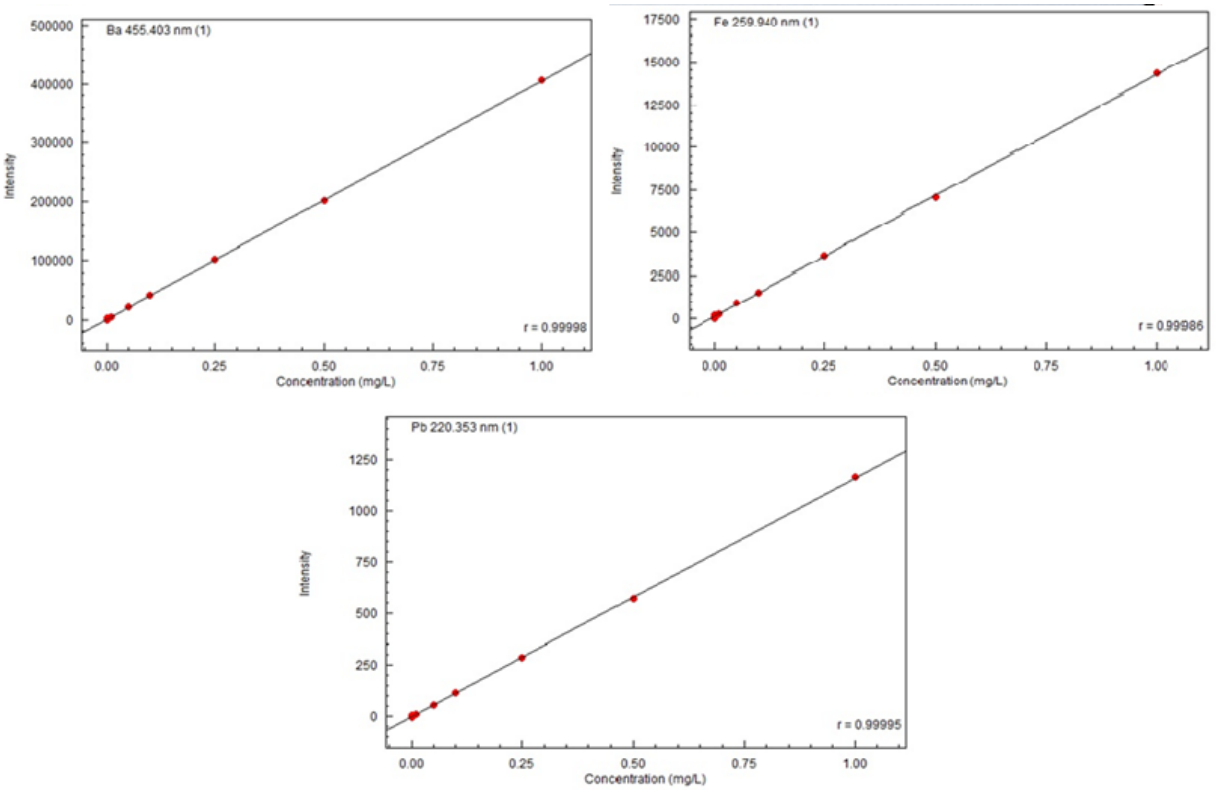
3. RESULTS AND DISCUSSION

The ICP spectrometer is connected to a computer, and data acquisition and processing are carried out using the ICPsolution software. This software automatically calculates the calibration curve from the signal intensities of the calibration standards and the blank sample while correcting the measured signals for the background. It then calculates the concentration of the test element from the resulting curve. Negative results are those where the presence of the test element is not detected, while positive results are those above the Limit of Detection (LOD) and quantitatively above the Limit of Quantification (LOQ).
The method for determining elements in aqueous solutions using ICP-OES is expected to meet the conditions presented in Table 3 [6]. These values represent the expected performance and quality control standards for the method. The relative standard deviation indicates the precision of the method, accuracy ensures that the results are within an acceptable range, and the minimum correlation coefficient value demonstrates the linearity of the calibration curve. These criteria help assess the reliability and robustness of the analytical method.

Table 3*:* Characteristic values of the method
Source: *[6]*

Relative standard deviation	≤ 10 %
Accuracy	85-115%
Minimum value for the correlation coefficient	0,990

From the calibration plots, it can be observed that the calculated correlation coefficient (R) is above 0.999 (0.99998 for Ba, 0.99986 for Fe, and 0.99995 for Pb) for all metals (Figures 2-4). This high correlation coefficient indicates a strong linear relationship between the concentration of the analyte and the signal intensity, demonstrating the linearity and reliability of the calibration curves for these elements.
Accuracy and precision have been determined by spiking the sample matrix at three levels of interest (20%, 45%, and 75%). The data collected for the assessment of precision and accuracy have been processed using the Anova: Single Factor method from the MS-Excel package, which is one-way analysis of variance (ANOVA). The obtained results are presented in Table 4.



Picture 2: Calibration curve for Barium (Ba, Fe, Pb)

Table 4: The determination of precision and accuracy using a single-factor ANOVA approach

Analite	Concentration		Ricavery %	No.	Precision		
	Expected (mg/l)	Determined (mg/l)			Reproducibility	Repeatability	Overall Precision:
					S_b (mg/L) CV_b (%)	S_w (mg/L) CV_w (%)	S_{tot} (mg/L) CV_{tot} (%)
B – Wastewater							
Ba	/	0.216	/	2	0.00417 (1.93)	0.005115 (2.37)	0.00660 (3.05)
Fe	/	1.183	/	2	0.00500 (0.42)	0.019579 (1.65)	0.02021 (1.71)
Pb	/	0.033	/	2	0.00033 (1.01)	0.000698 (2.11)	0.00077 (2.34)
C (A+0,20 mg/l)							
Ba	0.20	0.206	96.15 – 98.04	2	0.00072 (0.36)	0.00112 (0.56)	0.00133 (0.66)
Fe	0.20	0.197	97.56 – 111.73	2	0.00538 (2.69)	0.00612 (3.08)	0.00819 (4.09)
Pb	0.20	0.202	96.62 – 101.01	2	0.00398 (1.99)	0.00100 (0.50)	0.00410 (2.05)
D (A+0,45 mg/l)							
Ba	0.45	0.463	95.74 – 98.47	2	0.002149 (0.48)	0.00450 (1.00))	0.00499 (1.11)
Fe	0.45	0.455	94.74 – 102.51	2	0,006568 (1.46)	0.01052 (2.34)	0.012409 (2.76)
Pb	0.45	0.464	94.14 – 100.22	2	0.005968 (1.33)	0.00505 (1.12)	0.007812 (1.74)
E (A+0,75 mg/l)							
Ba	0.75	0.759	95.54 – 103.45	2	0.01782 (2.38)	0.00488 (0.65)	0.01848 (2.46)
Fe	0.75	0,761	97.28 – 99.73	2	0.00356 (0.48)	0.00632 (0.84)	0.00726 (0.97)
Pb	0.75	0.771	94.57 – 99.47	2	0.01233 (1.64)	0.00735 (0.98)	0.01435 (1.91)

The determination of the limit of detection (LOD) and the practical limit of quantification (LOQ) involves a computational analysis. The results obtained from this analysis are presented in Table 5. Afterward, the obtained limit of detection is verified by measuring a diluted Standard Reference Material (SRM) at a level of interest.

Table 5: The determination of the LOD and LOQ

	Ba (mg/L)	Fe (mg/L)	Pb (mg/L)
LOD	9.49E-05	0.000645	0.001273
LOQ	0.000316	0.002150	0.004244

It appears that the method has demonstrated excellent performance in various aspects of analytical validation. Here are some key points from the provided information: The method exhibits excellent linearity with correlation coefficients above 0.999 for all metals, indicating a highly linear response over a wide range of concentrations.The method shows satisfactory repeatability with coefficients of variation (CV_w) ranging from 0.50% to 3.08%. This indicates that the method can produce consistent results when the same sample is analyzed multiple times under the same conditions. The method demonstrates satisfactory reproducibility with coefficients of variation (CV_b) in the range of 0.36% to 2.69%. This suggests that the method can produce consistent results when applied by different operators or in different laboratories. The total precision of the method, expressed as CV_{tot}, falls within the range of 0.66% to 4.09%, which aligns with the specifications for data quality outlined in EPA method 200.7. The recoveries of the analyzed samples range from 94.14% to 111.73%, meeting the accuracy requirements of the method (85-115%). The method's LODs for validated metals are significantly lower than the LODs specified in EPA method 200.7, which indicates high sensitivity. The LODs are reported as 9.49E-05 mg/L for Barium (Ba), 0.000645 mg/L for Iron (Fe), and 0.001273 mg/L for Lead (Pb).

4. CONCLUSION

Based on the conducted validation of the ICP-OES method for measuring concentrations of Ba, Fe, and Pb, it can be concluded that the method has been successfully adapted, validated, and documented according to the standard EPA method 200.7, using the ICP-OES 9820 SHIMATZU spectrometer. Taking all the mentioned factors into account, it is evident that the ICP-OES method meets the requirements for precision, accuracy, sensitivity, and linearity. This is crucial for reliable measurements of Ba, Fe, and Pb concentrations in wastewater and can be used in routine work within the defined scope of application in the Polichem laboratory. The application of ANOVA analysis has proven to be an important step in our research, allowing us to analyze differences between samples and method parameters more efficiently, resulting in more reliable results in the analysis of the elemental composition of water.

Abstract: *Proficiency testing (PT) is a valuable tool for quality control and assurance in various industries, including manufacturing, healthcare, environmental monitoring, and more. It plays a crucial role in ensuring the accuracy and reliability of test results, measurements, and processes. Within the SRPS ISO/IEC 17025:2017 standard, there is a requirement related to ensuring confidence in the quality of test and calibration results. According to this requirement, a laboratory must have quality management procedures in place to monitor the validity of performed testing and calibration. This monitoring must be planned and reviewed, and one of the steps involves participation in inter-laboratory comparison programs or proficiency testing programs. In order to maintain its competence, the Polihem laboratory, which is part of the Academy of Applied Technical Studies Belgrade, conducts internal and external quality control. In this paper, inter-laboratory comparisons will be presented as a form of external quality control in which the Polihem laboratory has participated.*
Kaywords: Proficiency testing, laboratory, quality control

1. INTRODUCTION

According to the definition from ISO/IEC Guide 43-1, inter-laboratory comparison (ILC) is the organization, execution, and evaluation of test results for the same or similar test items or samples by two or more laboratories under predetermined conditions. Proficiency testing, often referred to as PT or interlaboratory comparison, is a formalized process in which a sample of known properties is distributed to multiple laboratories or testing facilities for analysis. The participating laboratories are unaware of the sample's true properties, and their test results are compared to a reference or consensus value [1,2].
Quality assurance in a testing laboratory is a complex and demanding task. It involves establishing policies and objectives, assigning responsibilities for meeting these requirements, continuously improving laboratory operations through the development and implementation of new testing methods, identifying errors/non-conformities, taking corrective actions, and planning and conducting internal and external quality control through participation in proficiency testing programs [3].

[4] apopovic@atssb.edu.rs
[5] mstamenovic@atssb.edu.rs
[6] abozic@atssb.edu.rs

In every analytical procedure, whether related to scientific, technical, environmental, or health issues, three interconnected parameters are inevitable: the problem, the sample, and the method.
The concept of quality in the field of analytical practice can be succinctly defined as a set of characteristics of a procedure or method that produces analytical results meeting the expected and prescribed requirements, satisfying the needs of the users of those results [4].
Quality control is a mechanism used to verify the acceptability of obtained test results, and it is applied to assess the effectiveness of quality management. Quality control can be internal and external control an program ensures the management and monitoring of the validity of conducted tests. Control results can indicate various aspects of data quality obtained in routine work. If the results fall outside acceptable limits, they should be reviewed until the method is verified or validated.
The foundation for creating a quality control program includes participation in proficiency testing (PT) and internal laboratory control. Criteria for the quality control of testing are established during method validation or verification and encompass parameters, frequency, and criteria for the acceptability of results [5].
In this paper, inter-laboratory comparisons will be presented as a form of external quality control in which the Polihem laboratory has participated.

2. PROFICIENCY TESTING

Proficiency testing, often abbreviated as PT, is a critical component of quality assurance and quality control in various industries, particularly those involving testing and measurement. It is a systematic and objective evaluation process used to assess the accuracy and precision of a laboratory or testing facility's analytical or testing methods.
Key aspects of proficiency testing are:

a) Objective Assessment: proficiency testing is designed to objectively evaluate a laboratory's performance in conducting specific tests or measurements. It provides an external benchmark against which a lab's results can be compared.
b) Independence: Proficiency testing is typically conducted by external organizations or regulatory bodies that are independent of the laboratory being tested. This ensures impartiality and eliminates potential bias.
c) Regular Testing: Laboratories typically participate in proficiency testing programs on a regular basis, often annually or semi-annually, depending on the industry and the specific tests being performed.
d) Sample Exchange: A proficiency testing program involves the exchange of test samples between the testing laboratory and the external provider. The laboratory analyzes these samples using their standard methods, and the results are submitted to the external provider for evaluation.
e) Assessment and Feedback: The external provider assesses the laboratory's results by comparing them to known or reference values. They provide feedback to the laboratory on their accuracy and precision. If discrepancies or errors are identified, the laboratory is typically required to take corrective actions.
f) Improvement and Compliance: Proficiency testing helps laboratories identify areas for improvement in their testing methods and procedures. It also ensures that the laboratory complies with relevant quality standards and regulations.
g) Quality Assurance: By participating in proficiency testing programs, laboratories can demonstrate their commitment to quality assurance and build confidence in their testing capabilities among clients, regulatory bodies, and the public.
h) Certification and Accreditation: In some industries, proficiency testing is a requirement for obtaining and maintaining certification or accreditation. It is often a key component of ISO 17025 accreditation for testing and calibration laboratories.

i) Cost-Effective Evaluation: Proficiency testing is a cost-effective way for laboratories to assess their performance without the need for in-house validation studies, which can be expensive and time-consuming.

PT is widely used in fields such as healthcare (clinical laboratories), environmental testing, food safety, pharmaceuticals, and materials testing. It plays a crucial role in ensuring the reliability and accuracy of test results, which, in turn, contributes to the safety and quality of products and services in various industries.
Common types of inter-laboratory comparisons include:

a) Successive Testing Technique: In this approach, participating laboratories sequentially test the same sample according to a predefined order. A drawback of this method is the extended testing period. It requires sample stability, consistency, and homogeneity.
b) Simultaneous Testing Technique: In this method, participating laboratories simultaneously test the same sample at a predetermined time set by the organizer. The key factor in this type of comparison is the homogeneity of the sample.
c) Split Sample Technique: This method is often used by laboratory users. A single sample is tested simultaneously in two participating laboratories. It is advisable for the user to retain an additional sample for a "third" laboratory in case of significant differences in test results. This approach is known as „superanalysis“. Each of these techniques has its advantages and limitations, and the choice of method depends on the specific goals and requirements of the inter-laboratory comparison [6].

Laboratories should participate in programs relevant to their scope of testing, including reference proficiency testing (PT) schemes, national programs, and internal proficiency testing programs. Additionally, they must have a documented policy for participation in PT activities in their internal laboratory documents, procedures for analyzing PT results, and procedures for taking corrective actions.

2.1. Plan and Program for Participating in PT Activities

When selecting appropriate PT schemes, a laboratory should consider:

a) The compatibility of available PT activities.
b) The alignment of the PT sample with the test subject.
c) Whether the quantity of PT sample provided is sufficient to conduct the testing method within the measurement range corresponding to the parameter being tested.
d) Whether the PT provider has defined a statistical plan (planning, data collection, analysis, reporting of proficiency results).
e) Compliance with ISO/IEC 17043 [7].
f) The deadline for submitting results.

When determining the level and frequency of participation, other means of ensuring confidence in testing results should also be considered. This includes the possibility of using certified reference materials, comparing analysis results obtained using different techniques, and other internal/external comparisons (blind testing) in the laboratory.
Furthermore, attention should be paid to factors that can impact the level of risk (the number of tests conducted, staff experience and education, availability of reference materials, validation reports, and the significance and ultimate use of the results). Legal regulations that prescribe the frequency of participation in PT activities should also be taken into account.
Accredited testing laboratories should pay particular attention to the selection and participation in PT schemes, as this builds and demonstrates confidence in the testing results and allows them to monitor the trend in their results (improvement or deterioration of performance) [8, 9].

2.2. Evaluation of Testing Results in PT Program

The evaluation of testing results for individual analytes is performed by the organizer of the proficiency testing (PT) program. Based on this evaluation, an official document is issued, providing an assessment of the performance or proficiency of all participants in the program for determining specific analytes in a particular material. Typically, this assessment is done by comparing reported results with calculated z-scores.
For the evaluation of reported results from participating laboratories to be valid, the PT program organizer must ensure that the sample is homogeneous, that the assigned value for the analyte is determined using an appropriate method, and that the target standard deviation is established. The procedure for determining the assigned value is provided in ISO 13258:2015. When the material used in the PT scheme is a certified reference material (CRM), the certified reference value is used as the assigned value.
The target standard deviation (σ) is calculated as the product of the assigned value (X) and the inter-laboratory coefficient of variation (CV). The z-score indicates how much the reported result differs from the assigned value. The assigned value (X) and the standard deviation (σ) are critical elements in calculating the z-score and must be calculated using appropriate methods to ensure a realistic assessment of laboratory performance or proficiency.
The formula for calculating the z-score (z) is as follows:

$$z = \frac{x - X}{\sigma} \quad (1)$$

Based on the determined z-score, reported results are assessed as follows:
a) Satisfactory when $z \leq 2$,
b) Questionable when $2 < z < 3$, and
c) Unsatisfactory when $z \geq 3$.
This evaluation helps determine the accuracy and reliability of the results reported by participating laboratories in the proficiency testing program [10,11].

3. PARTICIPATION IN PT POLIHEM LABORATORIES

Laboratory Polihem participated in Proficiency Testing (PT) with the following objectives:

1. To identify potential deficiencies in laboratory practices.
2. To guide staff in implementing corrective measures necessary for improving these practices.
3. To assess the reliability of methods, materials, and equipment and propose appropriate corrective actions.

In addition, this external verification was essential for the laboratory's accreditation by the Accreditation Body of Serbia (ATS). Laboratories applying for accreditation are required to participate satisfactorily in relevant and available PT activities at least once before accreditation is granted. The recommended minimum participation for accredited laboratories is once for each major sub-discipline within the scope of accreditation for the accreditation validity period. If significant changes occur in the laboratory (equipment changes, key technical personnel changes, etc.), ATS may require reconfirmation of the laboratory's technical competence through participation in PT activities when deemed necessary.
The provided figure displays the z-score related to the testing of copper content in water. The organizer of this PT scheme is LGC, a provider accredited to ISO 17034 [7]. The PT scheme took place in January 2023, and participating laboratories are identified by identification numbers. Laboratory Polihem's Lab ID is CN1095. Based on the results shown in the figure, it can be concluded that Polihem achieved a satisfactory z-score, confirming their expertise in copper determination in water using the ICP-OES method.

Analyte: Copper

Lab ID	Method	Result (mg/L)	z score
CN0022	ICP-OES	7.80	-0.62
CN0117	ICP-OES	8.70	1.61
CN0726	ICP-MS	9.27	3.03
CN0822	ICP-MS	7.43	-1.54
CN0923	ICP-OES	7.11	-2.34
CN1039	ICP-OES	77.23	171.88
CN1042	ICP-MS	8.47	1.04
CN1095	ICP-OES	8.04	-0.02

Histogram

4. CONCLUSION

Proficiency testing serves as a powerful and indispensable tool for maintaining and enhancing the quality of laboratory test results in the realm of environmental pollution analysis. This practice not only ensures the accuracy and reliability of data but also instills confidence in the outcomes of environmental assessments and regulatory compliance. Laboratories that actively engage in proficiency testing demonstrate their commitment to excellence, continuous improvement, and the highest standards of analytical competence. As environmental concerns continue to grow, the role of proficiency testing remains vital in providing the trustworthy data needed for informed decision-making, safeguarding public health, and protecting the environment. Based on the results from PT , i PT scheme it can be concluded that Polihem achieved a satisfactory z-score, confirming their expertise in copper determination in water using the ICP-OES method.

Jelena Petrović[7], Mining and Metallurgy Institute Bor

Abstract: *The influence of copper mining and metallurgy operations on the quality of surface water in Bor area watercourse has been taken into consideration in this paper. Monitoring of the water quality was performed on five rivers and one industrial wasterwater. The concentration of Cu, As, Ni, Cd, and Pb ions during four selected quarters in period November 2019 – June 2021 were determined on all samples. Water samples were analysed using atomic emission spectrometry with inductively coupled plasma or mass spectrometry with inductively coupled plasma depending on the ions concentration. The highest values of the concentration were recorded for the As ions in the metallurgical wastewater. Also, the concentration of Ni, Cd, Pb, and Cu ions had the highest values in samples from metallurgical wastewater.*
Keywords: mining, metallurgy, monitoring, surface water quality, heavy metal ions.

1. INTRODUCTION

The mining industry brings substantial economic growth and benefits to countries, generating revenues and creating jobs. Mining operations can have a huge local impact on the environment and population. They produce many types of air, water and soil pollutants that may ultimately affect human health. Furthermore, the disposal of an enormous volume of waste materials (from mining and metallurgy operations) poses a serious risk to the surrounding environment through air pollution with fine particles blown by the wind, land degradation by erosion and leaching of soluble inorganic potentially toxic chemical species (Cu, Ni, Pb, Zn, Cd, Cr, etc.) occurring in a variety of minerals present in those materials. Last but not the least, in the area of disposal of the mining waste, the acid mine drainage (AMD) is generated from sulphide-rich minerals.
Taking into account the complexity of the pollution produced by mining and metallurgy operations, adverse health effects of those leaving near, downstream or downwind of mines can be substantial. According to the EPA classification some of these pollutants are very harmful and belong to the group of substances that have been proven to be carcinogenic to humans [1].
The main goal of monitoring is to provide timely response and warning to possible negative processes and accident situations, gain a more complete insight into the state of the environment and determine

[1]radmila.markovic@irmbor.co.rs
[2]zoran.stevanovic@irmbor.co.rs
[3]zstirbanovic@tfbor.bg.ac.rs
[4]vojka.gardic@irmbor.co.rs
[5]renata.kovacevic@irmbor.co.rs
[6]vesna.marjanovic@irmbor.co.rs
[7]jelena.petrovic@irmbor.co.rs

the need to take protection measures depending on the degree of threat and type of pollution. Knowledge of water and soil quality from the point of view of the content of organic and inorganic pollutants is reflected in the possibility of risk assessment, location and remediation of polluted areas as well as urban planning in terms of identification and relocation of pollution sources.

Water monitoring involves testing the content of a number of inorganic elements and organic compounds by modern methods of instrumental chemical analysis. Some of the most hazardous elements that can be found in acid mine waters are arsenic, cadmium, lead, nickel, copper, etc.

Arsenic (As) and Cadmium (Cd) are widely distributed in the environment, come from natural and anthropogenic sources and have no biological role for human. Important anthropogenic sources of As and Cd include mining (usually wastewater), industry and waste management activities [2]. Arsenic induces the formation of reactive oxygen species and exposure deregulates several cellular processes at the molecular level [3]. Cadmium exposure is commonly associated with renal tubular dysfunction, osteomalacia, and osteoporosis as a result of calcium competition, endocrine disruption, glucose metabolism disorders, cerebral infarction, and heart failure [4,5]. Both elements can cause multiple cancers in humans [6]. Once inside the human body, cadmium and arsenic accumulate at high levels in several organs [7].

Lead (Pb) is the most toxic element present in the environment as a result of natural and anthropogenic sources. It is not necessary for human health, because it is not involved in biological processes. When absorbed, lead binds to erythrocytes and travels through the blood to various tissues (liver, kidneys, lungs, brain, spleen, muscles, heart) and further moves to bones and teeth, and affects every organ in the body by disrupting basic biochemical processes and has numerous effects on human health [8].

Nickel (Ni) is a metal broadly distributed in the environment. It is released from both natural sources and anthropogenic activity and is present in the air, water, soil and biological materials. Literature data illustrate that nickel at high doses and in certain forms is toxic to both humans and animals [9,10]. In case of consumption of water contaminated with nickel salts, the registered health effects were: gastrointestinal disturbances and altered hematological parameters.

Copper (Cu) has important roles in the metabolic processes of the human body being an essential element required for hemoglobin synthesis, absorption of iron, and cardiovascular integrity [11,12]. The toxicity of copper is relatively low compared with other heavy metals, but excess copper accumulation in subjects following high-dose chronic exposure and in sensitive populations results in hepatic cirrhosis with jaundice, hemolytic anemia, and degeneration of the basal ganglia, cardiotoxicity (hypotension, tachycardia, tachypnea) gastrointestinal disorders (ulcerations, mucosal acute hemolysis, and hemoglobinuria), nephropathy (azotemia, oliguria) and central-nervous-system manifestations (dizziness, convulsions, lethargy, headache, stupor, coma) [13]. In order to find measures and solutions for the reduction, rehabilitation and elimination of polluting substances, it is necessary to be aware of all consequences that more than a century of continuous mining and metallurgical activities have left in Bor area.

The main rivers in Bor mine area are Bor, Krivelj, Ravna, Bela River and Timok. There are also small river creeks and many AMD resulting from mining operations, along with industrial wastewater from metallurgical processes that flow in some of the mentioned rivers. As the consequence of mining and metallurgy activities, Bor and Krivelj rivers became very polluted mostly by heavy metals (Pb, Zn, Cd, Ni, Se, As, Fe). According to the Serbian legislation for surface water, contents for almost all of the analyzed elements in rivers from Bor city to the confluence of Bela River and Timok, are above the maximum allowed concentration (MAC).

This paper presents results of monitoring the water quality from rivers for five selected elements (Cu, As, Ni, Cd, and Pb) during four selected quarters in period from November 2019 to June 2021.

2. MATERIALS AND METHODS

Surface water samples (rivers water and industrial wastewater) were sampled by hand tools according to the standard sampling methods. Containers (cans of 1 l) for water sampling were rinsed three times in the river or water that was being sampled, prior to taking a sample, in order to prevent

contamination of the sample with previous water that was sampled. Water sample was then poured in the plastic bottle of 50 ml without prior washing because there was present 2.5 ml HNO_3 conc (63%). Exactly 50 ml of the sample was poured in syringe and after that the bottle was sealed and labelled. Before using the syringe, it was rinsed three times with water sample and contents were discharged. The samples were properly stored and transported in the laboratory in Mining and Metallurgy Institute Bor for chemical analysis.
Methods prescribed by relevant international and European standards were used to measure pollutant concentrations. The procedure described the analysis of the following heavy metals ions: As, Cd, Cu, Ni, and Pb.Water samples were analyzed using atomic emission spectrometry with inductively coupled plasma (ICP-AES) and mass spectrometry with inductively coupled plasma (ICP-MS).
Quality control of chemical analysis was performed in the laboratory by running certified reference material (CRM). Analysis of replicate test portions will provide an indication of the repeatability and precisions of measurement.

3. EXPERIMENTAL PART

The impact of copper mining and metallurgy activities on water quality is analyzed by monitoring of surface water close to active and abandoned mines and metallurgical plants. Monitoring includes area from the copper mine in Bor, all the way to the confluence of the Bela River and Timok River. This area was chosen because the mine location has a negative impact on the surface water system, Bor, Krivelj, and Bela Rivers that belong to the watershed of the Timok, which is tributary of the Danube. All mentioned rivers flow near to the largest mining and metallurgy complex in the Republic of Serbia where mining activities continuously exist for more than 115 years.
The influence of copper mining and metallurgy operations on the quality of regional surface water has been taken into consideration in this paper. Accordingly, sampling was done from local defined profile of the Bor River (W5), as well as from locations upstream and downstream of the Bor River (marked W4, W6, W7, W8, W11 and W12). Coordinates of the locations of surface water sampling are measured by GPS device (Global Positioning System) and presented in Table 1. Sampling was performed during four campaigns, in the period from November 2019 to June2021.

Table 1. Coordinates and marks of sampling locations

Water sample mark	Sampling location	GPS
W4	Industrial wastewater	N 04880342, E 07591076
W5	Bor River (local defined profile)	N 04877524, E 07594505
W6	Krivelj River	N 04876932, E 07597572
W7	Bela River (after confluence of Bor River and Krivelj River)	N 04876866, E 07597572
W8	Ravna River	N 04876953, E 07597650
W11	Timok before confluence with Bela River	N 04867539, E 07605955
W12	Timok River after confluence with Bela River	N 04884420, E 07625930

4. RESULTS AND DISCUSSION

The present paper is one of the broadest investigations of the multi-element content in wastewater generated from copper mining and metallurgy activities. It may thus represent a reference point for observed concentrations in future studies conducted in Eastern Serbia or other areas of mining waste discharge. The water samples originated from different rivers and industrial wastewater stream are extremely enriched with toxic elements such as arsenic and cadmium. The results show that the concentration of almost all heavy metal ions from collected water samples during the period November 2019 - June 2021 are above the MAC value according to Serbian legislation for surface water.

Table 2. Category of water and MAC values according to the Serbian legislation
Source: *[14,15,16]*

Heavy metal	Category of water and MAC values		
	II category (Danube River from the Hungarian border - to the Bulgarian border)	**III category (from the confluence Bela River and Timok River till to confluence of Timok and Danube River**	**IV category (from Bor city to the confluence Bela River and Timok River)**
Cu, mg/l	0,005 (T=10) to 0,112 (T=300)	0.5	1
As, µg/l	10	50	100
Ni, µg/l	34	34	34
Cd, µg/l	0.45	0.6	0.9
Pb, µg/l	14	14	14

T - water hardness (mg/l $CaCO_3$)

In the Figure 1 are presented the concentration of As, Ni, Cd, and Pb ions in water samples from: a) I quarter (November 2019), a) II quarter (June 2020), c) III quarter (November 2020) and d) IV quarter (June 2021), respectively.

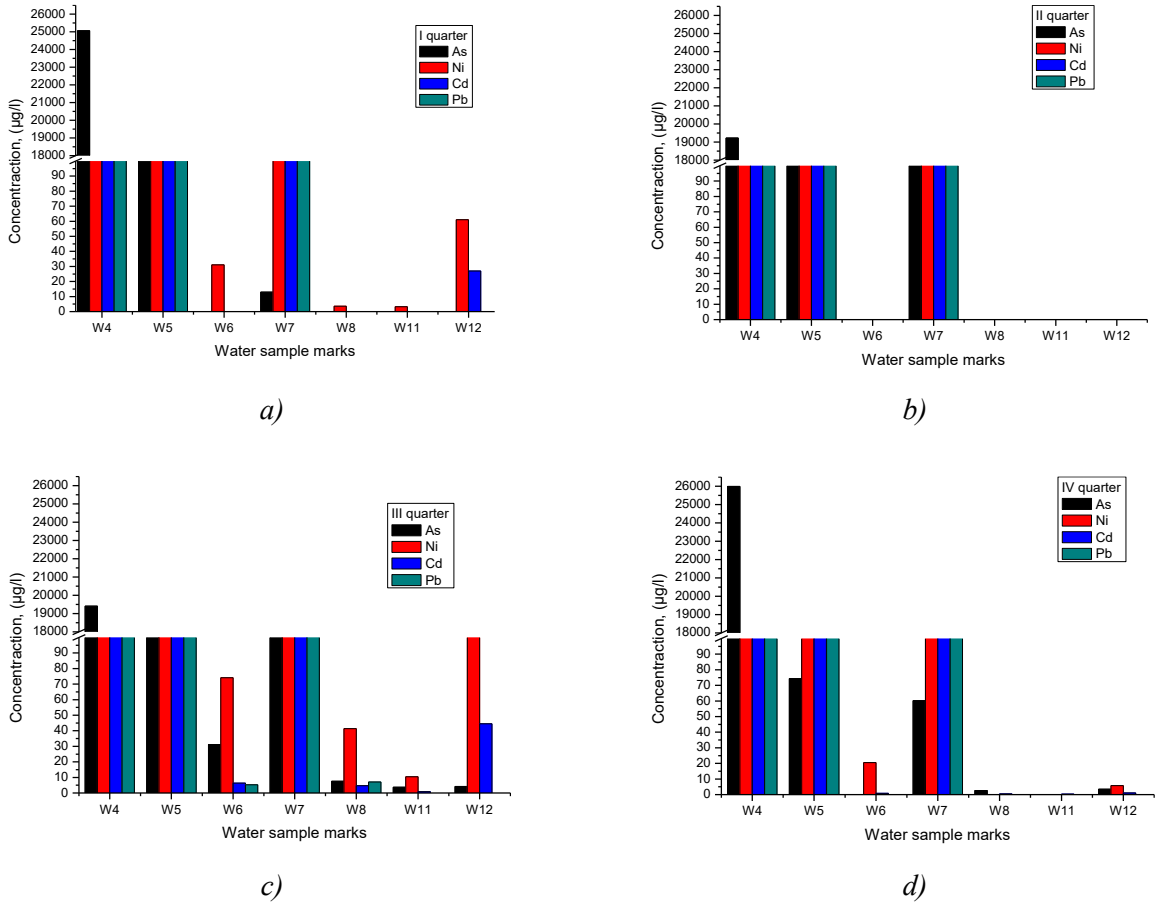

Figure 1. Concentration of As, Ni, Cd and Pb ions in the water samples

Ni, Pb and Cd ions concentration values are higher than MAC values, for samples from locations: W4, W5 and W7. Middle values for concentration of the target ions in Bor River (W5) before the influence of mining and metallurgy activities are as follows, µg/l: As: 5.4; Ni: < 7; Cd: 0.32; Pb:< 2.1; and Cu: 480. Comparing values for Bor River from the Figure 1 with ones before the influence of the mining and metallurgy operations, it is obvious that the concentration of all monitored metal ions became much higher after inflows of metallurgical wastewater. Arsenic ions concentration in the

industrial wastewater is extremely high (more than 19000 μg/l), in all tested samples. As the industrial wastewater inflows in the Bor River it is clear that increasing of As ions concentration is the consequence of its presence in W4 sample. Also, high concentration of Ni, Cd, and Pb ions are the consequence of their presence in W4 which inflows in the W5.
Bela River (W7) which arises by confluence of W5 and W6 is also with high concentration of target ions. Ravna River is out of the influence of mining and metallurgy activities, so the concentration of monitored metal ions are below MAC values.
Negative impact of mining and metallurgy activities on the water in Timok (W12) can be seen in I and III sampling periods. The same situation is registered for the concentration of the Cu ions (Table 3). Higher values than MAC are registered in the samples from the locations: W4, W5 and W7. The concentration of Cu ions in W4 has the direct impact on its concentrations in W5 and W7 samples.

Table 3. Cu ions concentration in the water samples

Water sample mark	Cu (mg/l)			
	I Quarter	II Quarter	III Quarter	IV Quarter
W4	291.40	209.16	171.63	155.27
W5	68.31	38.26	37.09	25.50
W6	<0.005	<0.005	0.58	0.14
W7	46.27	16.70	60.45	19.70
W8	0.04	<0.005	0.37	0.01
W11	<0.005	<0.005	0.10	0.02
W12	0.24	0.05	0.24	0.04

5. CONCLUSION

The recorded values for Ni, Pb and Cd ions concentration are higher than MAC values for the samples from locations: W4, W5 and W7 according to the surface watercourses category, excluding W4 which is wastewater originated from the copper metallurgical plants. Based on the results for target ions concentration in Bor River before the influence of mining and metallurgy activities (μg/l): As: 5.4; Ni: < 7; Cd: 0.32; Pb:< 2.1; and Cu: 480, it is clear that industrial wastewater has essential impact on the quality of the surface water.
Bor River (W5) and Krivelj River (W6) form Bela River (W7) which inflows in Timok River before the confluence with Bela River (W11) and after those confluence Timok River (W12) flows to Danube River. The contents of recorded metals exhibited a high degree of contamination, indicating that these surface water may pose a significant to extreme risk to nearby residents.

SUSTAINABLE SYNERGY: ALKALI-ACTIVATED COAL FLY ASH AND CDW IN SUSTAINABLE CONSTRUCTION

Biljana Angjusheva[1], Faculty of Technology and Metallurgy, Ss. Cyril and Methodius University in Skopje
Ildiko Merta[2], Institute of Material Technology, Building Physics, and Building Ecology, Faculty of Civil and Environmental Engineering, TU Wien, Austria
Emilja Fidancevski[3], Faculty of Technology and Metallurgy, Ss. Cyril and Methodius University in Skopje

Abstract: *Alkali activation, a process that transforms industrial by-products such as coal fly ash (CFA) and construction and demolition waste (CDW) into viable construction materials, is a promising solution towards sustainable practicies in the construstion industry. This study suggesst the synthesis of alkali activated materials (AAMs) from CFA and CDW as alumosilicate precusors while water glass and sodium hydroxide was used for preparation of the activation solution. The characterization of raw material was performed from chemical and physical aspects while alkali activated materials was studied by Fourier transform infrared (FTIR) spectroscopy, and Scanning electron microscopy (SEM). The compressive strength of the alkali activated materials vares from 12.14 to 34.5 MPa, depending on the CFA/CDW ratio and the solid/liquid content.*
Keywords*:* sustainable, coal fly ash

1. INTRODUCTION

The rapid urbanization and industrialization of contemporary society have intensified the demand for construction materials, resulting in a significant depletion of natural resources and a surge in construction and demolition waste (CDW). To mitigate these challenges and promote sustainable construction practices, researchers and practitioners have turned their attention toward the utilization of industrial by-products, such as coal fly ash, in alkali-activated composites. Alkali activation is an innovative technology that can transform coal fly ash, a by-product of coal combustion, and CDW into eco-friendly construction materials. There are already numerous reviews of AAMs in general [1-5] dealing with characterisation, durability processing and environmental impact of AAMs. Generally, AAMs have broad field of applications like as eco-friendly mortars and concrete [6, 7], in ceramics [8, 9], as well as in refractories [10].
The paper presents the investigation relating to the synthesis, properties, and potential applications of alkali-activated materials based on the utilization of coal fly ash and CDW composites in the way to support construction industry for sustainable circular solutions.

2. MATERIALS AND METHODS

The samples of CFA used in this study were collected from thermal power plant REK Bitola, located in the southwest of the country and CDW (only waste demolition brick – WDB) were collected at local construction/demolition sites in Skopje, N. Macedonia. The raw materials were crushed and then ground up in a planetary mill (Fritsch pulverisette 5) for 30 minutes and passed through a 125 μm sieve. Lasser granulometry (Laser Cilas 1090) was employed for determining the particle size

[1]biljana@tmf.ukim.edu.mk
[2]ildiko.merta@tuwien.ac.at
[3]emilijaf@tmf.ukim.edu.mk

distribution of the CFA and WDB (-0.125mm) and chemical composition was carried out by x-ray fluorescence spectroscopy (ARL 9900XP instrument). The picnometric method was used to define the specific gravity of both materials. The specific surface area of the powders was estimated by the Blaine method.
Alkali activated materials (AAMs) were synthetized using CFA and WDB as precursors, mixed in different ratio (10, 20 and 50 wt.% WDB) with an alkaline solution (Na_2SiO_3+NaOH). Curing time of the samples was 24 h at 60^{o}C than 2, 7 and 28 days at room temperature. The prepared AAMs were characterized using Fourier transform infrared (FTIR) spectrometer (Perkin Elmer Sigma 100) in the wavenumber range between 4000 and 700 cm^{-1} at a resolution of 4 cm^{-1} using the attenuated total reflection method (ATR). Scanning electron microscopy (SEM, instrument JEOL, JSM-IT200) was used to determine the microstructure of the samples. Compressive strength was detected on samples with dimension 50 x 50 x 50 mm after 7/28 days using the ToniNORM Toni-Technic testing machine (Zwick) at a loading rate of 0.04 kN/s. Three samples were used and the results was averaged.

3. RESULTS AND DISCUSION

The chemical composition of CFA and WDB is presented in Table 1.

Table 1. Chemical composition of CFA and WDB

Oxide [wt%]	**SiO_2**	**Al_2O_3**	**Fe_2O_3**	**CaO**	**K_2O**	**Na_2O**	**SO_3**	**MgO**	**LOI**	∑
CFA	58.79	13.60	9.28	3.59	2.51	3.83	0.18	1.72	5.79	99.11
WDB	61.12	17.58	8.45	7.82	0.29	0.33	/	3.01	0.86	99.64

The chemical composition shows the presence of typical oxides: SiO_2 and Al_2O_3 (lower presence of CaO, MgO, Na_2O, K_2O) accompanied by 9.28 wt.% Fe_2O_3. The higher CaO content (7.82 wt. %) in WDB is associated with the presence of cement in waste material, while higher content of LOI in CFA (5.79 wt.%) is associated with the presence of unburned coal particles in the investigated fly ash. Both selected materials are promising aluminosilicate precursors since it contains amounts of SiO_2 and Al_2O_3 that are necessary for the alkali activation reaction.
The specific gravity of CFA and WDB was 2.65 g/cm^3 and 2.70 g/cm^3, while the specific surface area of CFA and WDB was 3.09 m^2/g and 0.5597 m^2/g, respectively. The mean diameter (D_{50}) for CFA and WDB was 17.99 and 12.33 μm, respectively. The morphology of CFA and WDB is presented in Fig. 1.

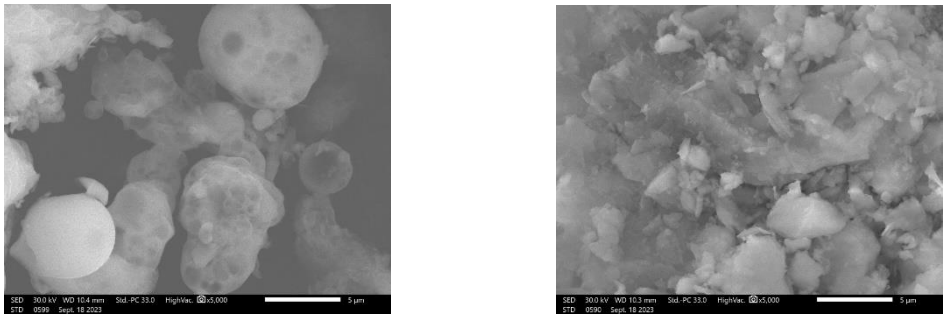

Figure 1. SEM micrographs of CFA and WDB, x5000 bar 5μm

As seen from Fig. 1 the CFA particles are mostly spherical corresponding to the typical morphology of CFA reported in the literature [11], while the WDB particles are sharp edges with irregular geometry. Fig. 2 presents the scheme for the synthesis of AAMs, while Fig. 3 present the moulded and final samples of AAMs.

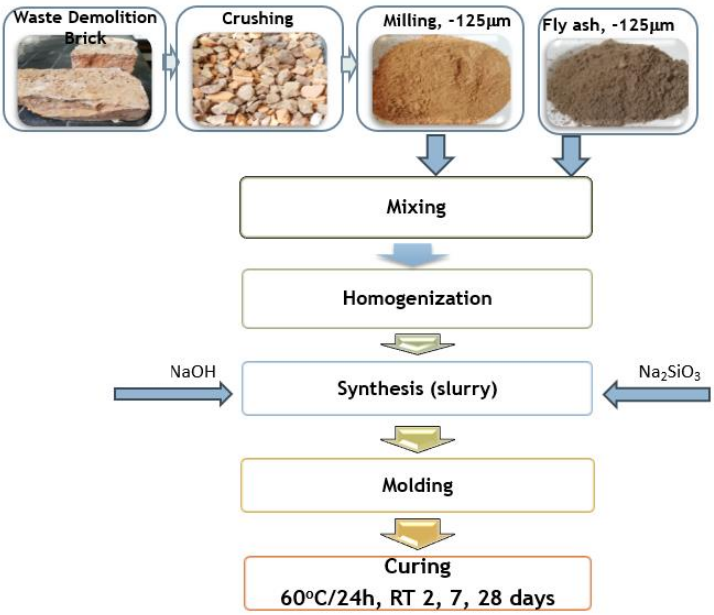

Figure 2. Scheme for AAMs synthesis

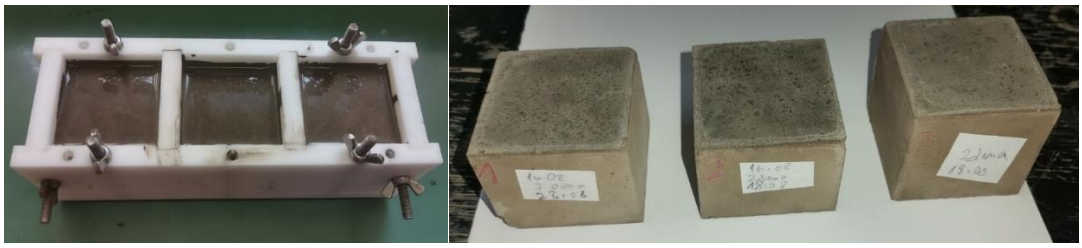

Figure 3. Moulds and final samples of AAMS

The FTIR spectrum (Fig.4) is mainly characterised by the presence of a broad band in the region 3700-3100 cm^{-1} (O-H stretching vibration) and the band at about 1650 cm^{-1} (H-O-H bending vibration) in the spectra of all AAMs are related to the water present in the samples. The silicate structure is characterized by the main peak located at 1000 cm^{-1} related to the stretching Si-O-T (T=Si, Al) vibration, while vibrations at 1400 cm^{-1} are characteristic of the $[CO_3]^{2-}$ ions, indicating carbonization [12].

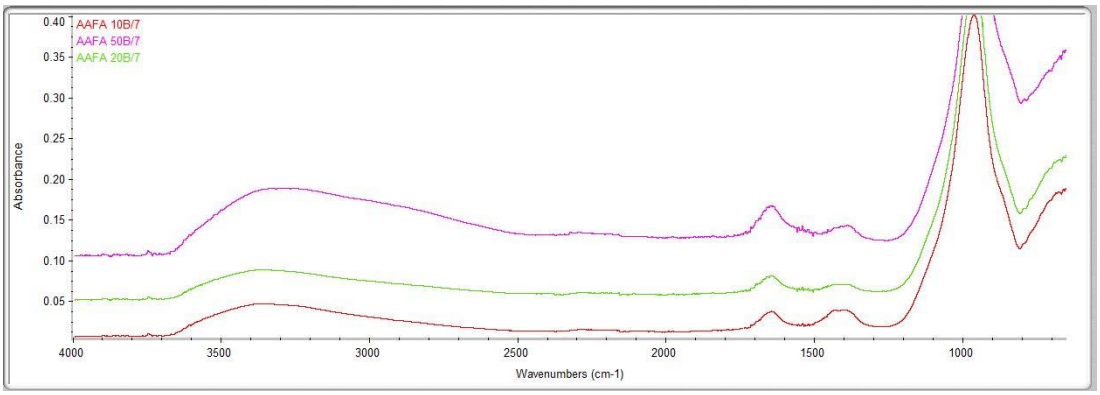

Figure 4. FTIR spectra of some AAMs

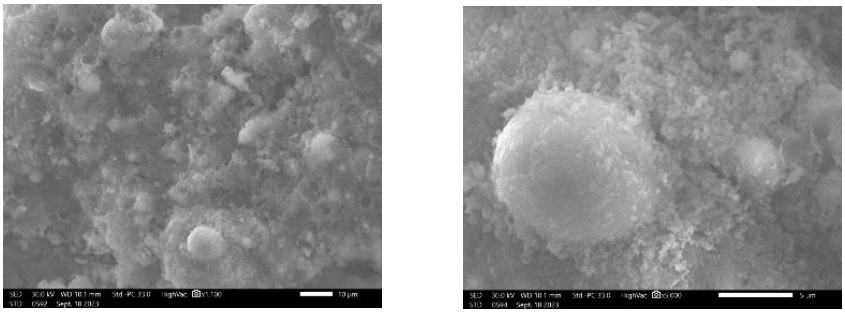
The compressive strength after 7 and 28 days of curing are shown in Table 2. Generally, the compressive strength for all samples was growing gradually throughout the curing period, as it was expected. AAMs containing 50 wt.% WDB (AAFA50B) shows the lower compressive strength i.e. 12.14 MPa and 16.5 MPa, respectively, after 7 and 28 days of curing. Generally, the higher CFA

content (lower content of WDB), the higher the compressive strength, most probably due to the amorphous nature of the CFA. The highest compressive strength was achieved by 10 wt.% WDB addition to CFA.

Table 2. Compressive strength of the AAMs

Sample	AAM (CFA)	AAM with 10wt.% WDB	AAM with 20wt.% WDB	AAM with 50wt.% WDB	AAM (CFA)	AAM with 10wt.% WDB	AAM with 20wt.% WDB	AAM with 50wt.% WDB
Cured time, days	7	7	7	7	28	28	28	28
σ [MPa]	18.2	22.3	18.34	12.14	23.7	34.5	21.4	16.5

Figure 5 shows the SEM micrographs of AAM with 10 wt.% WDB, cured for 28 days. The spherical particles of unreacted CFA covered with a gel and closed pores are clearly seen within the AAMs microstructure. The small number of spherical pores were likely formed as a result of the entrapment of air during mixing of the slurry.



(a) (b)

Figure 5. SEM images of the AAFA10B cured for 28 days a) x1000 bar 10μm, b) x5000 bar 5μm

4. CONCLUSION

The paper presents the preliminary results for designing alkali activated materials based on coal fly ash and construction and demolition waste (waste demolition brick). The best results, in the frame of the current investigation, in respect to compressive strength has the alkali activated material with 10 wt.% addition to fly ash. Further investigations in relation of mineralogical composition have been in progress to clarified the corelation compressive strength – mineralogical composition. This approach addresses waste disposal challenges in line to the principles of circular economy (lower environmental footprint) positioning alkali activated materials as a potential solution for a greener and more resilient construction industry.

This research work was funded by the Ministry of Education and Science of R N. Macedonia, Bilateral Project with R. Austria "Eco-based alkali-activated composites containing recycled aggregates". The authors thank Dr Jadranka Blazevska-Gilev for providing FTIR graphics.

GLOBAL ESG PERSPECTIVES AND THE CHANGING WORLD OF 2023: A SUSTAINABILITY ODYSSEY

Vaishnavi Inamdar[1], Blend Financial Services Ltd, Mumbai, India
Ana Popović[2], Academy of Applied Technical Studies Belgrade

Abstract: *The paper summarizes global environmental, social and governance (ESG) perspectives in 2023. ESG, presented with those three succinct letters, represent a profound global shift that has captivated our world. ESG related topics are reshaping business operations, performance measurement, and risk management, introducing both new challenges and opportunities. Key insights and perspectives of ESG are provided, exploring a growing recognition, various initiatives, factors and value creation using ESG in recent years. In spite of presented developments, a need to raise the flags and create an open marketplace of innovation and global sharing on solutions is present. The conclusion leads to the call on a joint journey towards sustainability, requiring stronger coordinated efforts at the global, national, and local levels from governments, businesses, and individuals.*
Keywords: ESG, global, environment, sustainability, governance.

1. INTRODUCTION: ESG - A 2023 Odyssey

In recent years, there has been a growing recognition of the significant economic and financial impacts of climate change and environmental, social and governance (ESG) risks. Forward-thinking companies' approach in ESG analyses, investments and reporting is not merely a box-checking exercise, but a meaningful way to create value for their organization. Beyond benefiting the planet and society, ESG and sustainability measures create value and correlate with financial performance [1]. This paper briefly summarises this global trend, offering a step into a realm beyond time, a journey through the territories of ESG. Therefore, this is not the typical ESG narrative, but an enriching odyssey filled with intelligent insights and facts. The conclusion leads to the call to embark on the journey towards sustainability together, because only together, with joint efforts of all parties, it can be achieved.

2. ESG - A BEACON OF CONTEMPORARY DISCOURSE

Gone are the days when ESG was a cryptic abbreviation. In 2023, it embodies the zenith of modern wisdom. ESG has risen as a prominent protagonist in the global sustainability narrative. Sustainability, once a peripheral concern, has assumed a centre stage. Multinational corporations have taken solemn vows to achieve net-zero emissions. Governments have woven environmental consciousness into the fabric of their policies, and even modest businesses champion ethical practices. ESG has become an integral part of our collective consciousness.
ESG has emerged as a beacon of contemporary discourse mostly due to its ability to address and provide a framework for some of the most significant challenges and expectations facing the modern world. It is influencing corporate behaviour, investment decisions, and public policy discussions, making it a central topic in today's economic, environmental, and social dialogues.

[1]vaishnavikhedulkar2@gmail.com
[2]apopovic@atssb.edu.rs

Still, the most recent KPMG study published in October 2023 found that 75% of companies are still in the early stages of ESG assurance preparedness, across a range of key factors including governance, skills, data management, digital technology and value chain, with even the top 25% of identified “leaders” having significant work ahead to become ESG assurance ready [2]. The study indicated that 56% of companies are publicly reporting ESG data, and while 93% of these are providing some level of external assurance, only 14% are obtaining reasonable assurance, and 16% limited assurance. Among other, capacity building and collaboration with external stakeholders may provide the necessary support and guidance for companies lagging in readiness. Fostering initiatives aimed at SMEs and firms in regions and sectors where readiness is low can offer significant help in bridging the compliance gap across the business landscape [2].

3. CARBON NEUTRALITY - A RESOUNDING CALL

Carbon neutrality, also known as climate neutrality or net-zero emissions, refers to the state in which an entity, such as a country, company, or individual, balances the amount of greenhouse gases (GHGs) it emits into the atmosphere with an equivalent amount removed or offset. Achieving carbon neutrality is a critical goal in the fight against climate change, as it helps limit global warming to well below 2^0 Celsius above pre-industrial levels, as outlined in the Paris Agreement. It is a complex and challenging goal, but it is increasingly recognized as essential for addressing climate change and ensuring a sustainable future for the planet. It requires coordinated efforts at the global, national, and local levels from governments, businesses, and individuals.

In 2023, carbon neutrality is a growing concept and an epoch-defining call. Many countries and regions have set ambitious targets to achieve carbon neutrality. Some notable examples include: European Union, aiming to become carbon-neutral by 2050, with many member states adopting similar targets; United States, UK and Japan has also set a goal to reach carbon neutrality by 2050, while China, the world's largest emitter of greenhouse gases, has pledged to achieve carbon neutrality by 2060.

Corporations and businesses are committing to carbon neutrality as part of their environmental and sustainability efforts. They are setting targets to reduce their emissions and are investing in renewable energy, energy efficiency, and carbon offset projects to achieve their goals. Numerous corporations engage in a spirited race, vying to reduce their carbon footprints with a zeal matching the rapid proliferation of renewable energy. The spotlight shines on Tesla, a pioneering electric vehicle manufacturer, while global food giants like McDonald's embark on ambitious initiatives to curb greenhouse gas emissions. Carbon neutrality, once an elusive goal, is now an attainable and commendable pursuit [3].

4. THE RENAISSANCE OF ECO-WARRIORS

In a world electrified by environmental consciousness, a legion of eco-warriors takes centre stage. It is important to note that addressing climate change and other burning issues in environment today requires a collective effort, and eco-warriors play a crucial role in driving action, influencing policies, and inspiring others to make positive changes in their own lives and communities. Their dedication is instrumental in the fight against the global climate crisis. For example, Greta Thunberg symbolizes the face of a global uprising, with young activists leading the charge, receiving Nobel prize nominations consequently from 2019 to 2023 [4].

These eco-champions hold governments and conglomerates accountable for their ecological transgressions. These sustainability torchbearers are not just representatives of the future; they are present-day eco-chivalric heroes. They may be involved in a variety of activities and initiatives, including: 1) advocacy and lobbying for climate-friendly policies, participating in protests, 2) education, research and outreach, 3) promotion of sustainable living, use of renewable energy sources, sustainable agriculture etc., 4) conservation efforts, such as reforestation projects, wildlife protection, and habitat restoration, 5) involvement in environmental organizations, such as

Greenpeace, the Sierra Club, the World Wildlife Fund or local civil society organizations, 6) social media and online activism, as social media platforms are powerful tools to raise awareness, connect with like-minded individuals, and advocate for change.

5. THE INCLUSION REVOLUTION - AN ODE TO EQUITY

There is a growing recognition that ESG, diversity, equity and inclusion are interconnected. Companies that prioritize ESG often incorporate diversity and inclusion initiatives within their strategies. This is because promoting diversity, inclusion, and equity is a social responsibility aspect of ESG, and it can contribute to a more sustainable and socially responsible business model. It also aligns with broader societal goals of reducing inequality and promoting social justice. Therefore, businesses often strive to create inclusive workplaces, and government policies and initiatives also aim to address systemic inequalities in society.

Amid the limelight on environmental sustainability, the resonance of the Inclusion Revolution resonates with the cadence of justice. In 2023, women rise to prominence in corporate leadership, leaving an indelible mark as entrepreneurs and visionaries. Diversity and inclusion, once ethereal ideals, are now critical pillars of progress. Gender pay gaps are narrowing, workplaces are becoming bastions of inclusivity, and ESG has evolved into a revolutionary force for justice and equality.

6. ETHICAL GOVERNANCE - A DEFINITIVE PARADIGM

ESG and ethical governance go hand in hand, with ESG principles encompassing environmental, social, and governance responsibilities, and ethical governance serving as the framework for ensuring that these responsibilities are met in an ethical, transparent, and accountable manner. Both concepts are essential for fostering sustainability, trust, and ethical behaviour in the business world. The custodians of ethical governance have taken the stage, ensuring the adherence to corporate rectitude. Unscrupulous practices no longer evade scrutiny. Whistleblowers are celebrated emissaries of transparency, wielding the power of revelation. ESG metrics have established a framework of corporate accountability, anchoring corporate behaviour to principles of responsibility. Corporate boards are evolving to embrace diverse voices, and ethical governance is not just an option but an essential mandate [5].

7. SUSTAINABILITY FOR ALL

Sustainability is no longer the province of stereotypical 'hippies.' In 2023, it is an inclusive doctrine. Sustainable practices have transcended niche realms and are embraced by a diverse range of participants. Even unexpected candidates have become fervent proponents. Fast-food giants are championing eco-centric initiatives, while tech behemoths are taking monumental strides in recycling and waste reduction. Sustainability has morphed from a niche concern into a universal movement. Notably, the electric vehicle market anticipates a 35% growth in 2023 [6], with projections showing its expansion to $1,716.83 billion by 2032 [7].

8. THE GUARDIANS OF ETHICAL INVESTMENT

In the last quarter of 2023, CFA Institute responsible investing organization Principles for Responsible Investment (PRI) and the Global Sustainable Investment Alliance (GSIA) announced the release of Definitions for Responsible Investment Approaches, a new guideline aimed at harmonizing sustainable investment terminology for more effective investment industry communication and to reduce greenwashing risk. The guidance was developed in response to a set of sustainability-related investment and finance recommendations published in 2021 by the International Organization of Securities Commissions (IOSCO), the leading international policy

forum and standards setter for securities regulators, which included developing common terminology for sustainable finance terms and ESG approaches [8].
The guardians of ethical investment are no longer mere 'watchdogs,' but formidable sentinels of moral virtue in the financial realm. Rating agencies and data analysts have become potent forces, guiding investors along the path of ethical investment. ESG scores embody the ethical compass of investing, steering capital toward virtuous ventures. The finance sector has been transformed by the ascent of ESG, no longer a domain of rampant greed, but rather an ethical crucible where data replaces the sword. We are seeing more whistle blowers and warriors fighting to bring equality into investing, governance and aligned areas.

9. CONCLUSION

Internationally, industry participants, investors, regulators, and policy makers have stepped up their efforts to address sustainability-related risks, opportunities, and impacts and to help improve ESG-related disclosures. As we bid farewell to this expedition through the ever-evolving ESG landscape in 2023, one truth remains undeniable: the world is changing, and sustainability is no longer optional. ESG has transcended its status as an acronym, evolving into a global movement. It's no longer the domain of activists and environmentalists; it has become a mainstream narrative.
The world has awakened to the imperatives of responsible business, ethical governance, and environmental stewardship. Institutions, like the Global Reporting Initiative (GRI), which have been the torchbearers on Sustainability Practices are coming up with more relatable, globally acceptable, and refined Sustainability Standards and Practices to follow [9]. It’s a code of conduct all nations must adhere to in order to achieve the mammoth goal in front of us as we approach 2030. To gain broader stakeholder confidence and mitigate the risk of greenwashing, ESG reporting should be subject to a level of scrutiny comparable to the financial information that users depend on [2]. In this cerebral yet entertaining odyssey through the world of sustainability in 2023, we have witnessed governments, corporations, and individuals uniting to address the challenges of our time. We have celebrated the rise of eco-warriors, the champions of justice, the embrace of ethical governance, and the elevation of sustainability as an integral aspect of daily life. Achieving the UN's 2030 Sustainable Development Goals (SDGs) is like setting sail on a global adventure where every nation has a treasure map to a brighter tomorrow. To begin this quest, we need a crew of nations, corporations, and individuals who are as united as a well-oiled pirate crew chasing after the same target on the map. Instead of plundering gold, our treasure is a world free of poverty, inequality, and the impending doom of climate change. At the moment, we are in an era where ideas can cross borders faster than one can imagine. Therefore, a need to raise the flags and create an open marketplace of innovation and global sharing on solutions is present, which will benefit the world. For example, if we would imagine trading ideas like Pokémon cards, however these cards hold the solutions to real-world problems, such as clean energy innovations, healthcare breakthroughs or similar. With a sprinkle of creativity, a hearty dose of determination, and a touch of humour, there is an opportunity to turn our world into a sustainable paradise where everyone gets a VIP pass to the greatest show on Earth. A powerful message emerges, as we must leave it a better place than we came at. It is not just about saving the planet. Finally, it needs to be taken into account that the future is promising, with the potential to be more inclusive, green, and equitable. In order to reach it, embracing sustainability is not merely a perspective; it's a way of life. Together, we have the power to mould a world marked by sustainability, inclusivity, and transformation.

Abstract: *Polychlorinated Biphenyls (PCBs) are synthetic chemicals with a biphenyl structure and varying degrees of chlorination. In this final paper, the determination of selected polychlorinated biphenyls (PCB 138 and 153) in waste oil was conducted using gas chromatography with an electron capture detector. The determination of PCBs in waste oil was carried out using the internal calibration method. The methodology of this research utilizes extraction with dimethyl sulfoxide (DMSO) and hexane isolation to identify the presence of PCBs in oil samples. The results of this work emphasize the importance of detecting PCBs in waste oils and indicate the need for strict regulations and advanced analytical methods to protect the environment and ensure human safety.*
Keywords: PCB, waste oil, chromatogram

1. INTRODUCTION

Waste oils encompass mineral or synthetic oils that are no longer usable for their original intended purposes, such as hydraulic, motor, turbine oils, marine oils, insulation oils, heat transfer oils, and others. Waste oils contain various harmful components that can pollute the air, soil, and waterways, directly impacting the health of humans and animals. When considering the management of this type of waste, it is important to emphasize that it may contain PCBs as unwanted pollutants. The presence of polychlorinated biphenyls in waste oils may result from the previous use of electrical transformers and other equipment where PCBs were used as insulating fluids. The management of waste oils is regulated by the rules and procedures outlined in waste oil management regulations. [1].
Polychlorinated Biphenyls (PCBs) are synthetic organochlorine compounds that are exclusively produced as a result of human activity. PCBs feature a modified biphenyl structure where hydrogen atoms are replaced by chlorine atoms. These modifications involve different degrees of chlorination, resulting in the creation of various PCB compounds (congeners). While theoretically there could be 209 different congeners, around 130 have been identified in practice.
PCB compounds are lipophilic and very poorly soluble in water. As such, they readily bind to organic particles in aquatic and biological systems, soil, and sediments. With an increase in the number of chlorine atoms in biphenyl, solubility in fats increases, as does stability. They are stable at high temperatures and resistant to degradation by light and chemical agents such as bases, acids, and oxidants. PCB compounds are difficult to break down due to strong covalent bonds between carbon-carbon and chlorine atoms. These bonds require high energy to be broken, contributing to the

[6] vdjurdjevic@atssb.edu.rs

molecules' stability. Because of their persistence, PCBs are classified as Persistent Organic Pollutants (POPs). They can persist in the environment for extended periods because they degrade very slowly in nature. The half-life is not the same for all compounds and can range from several decades to over a hundred years. They have the potential to accumulate in ecosystems and pose risks to both animals and humans. PCBs can accumulate through the food chain in organisms, further extending their impact on ecosystem [2,3].
Since 1979, their use has been banned due to their toxicity, carcinogenicity, mutagenicity, and other hazardous properties. To determine the presence and accurate concentrations of PCBs in waste oil, direct testing is required, which is the fastest and most efficient way to prevent contamination and maintain the integrity of equipment, as well as process safety. If the presence of a significant amount of PCBs is identified, it may require special measures and procedures for the safe disposal and removal of these oils to prevent their further spread in the environment. One solution applied is the installation of secure and impermeable barriers to prevent their penetration into the surroundings.
Through extensive and complex analyses resulting from intensive scientific and technological progress, it has been determined that PCB compounds can be degraded and eliminated from the environment. The effectiveness of these procedures depends on the chemical composition and the location where their presence is detected. Microorganisms, bacteria, fungi, and algae have the capability for biodegradation when the presence of PCB samples is identified in soil or sediments [4].
In this study, the determination of selected polychlorinated biphenyls (PCBs 138 and 153) in waste oil was carried out using gas chromatography with an electron capture detector (GC-ECD) on the instrument - GC 2010Pro SHIMATZU, with a SHIMATZU RHi-5ms column, 30 m x 0.32 mm i.d., film 0.25 μm. The analysis was performed in waste oil and soldered waste oil using the internal calibration method.

2. EXPERIMENTAL PART

The waste oil sample is extracted using an appropriate solvent. The extract is concentrated by evaporation, and the analysis is performed using gas chromatography. Different compounds are separated using a capillary column with a low-polarity stationary phase. Detection is carried out using an electron capture detector. PCBs are identified and quantified by comparing the relative retention times and relative peak heights (or peak areas) to added internal standards.

2.1. Characteristics of waste oil for the study

For the experiment, waste oil labeled as SAE 5w-30 was used as the sample. According to sampling regulations, the oil has its inventory number, name, designation, sampling time, and the signature of the responsible person. This type of oil is commonly used in light gasoline and diesel engines. The "w" in the name signifies winter, and the numbers 5 and 30 refer to the oil's viscosity, indicating its thickness at low and high temperatures. It can be used within an external temperature range of -35°C to +30°C, making it ideal for engines and applications with relatively low temperature variations.

2.2. Identification PCB in oil

A copper wire with a thickness between 2 and 3 mm is heated using a flame. After a brief cooling period and immersion in the oil sample for a few seconds, the fat remains on the surface of the wire. Then, the wire is heated once again. The appearance of a faint green color in the flame after a certain time indicates the presence of copper ions, which is evidence that chlorine is present in the oil, and the sample can be treated as PCB oil [5].

2.3. Extraction of PCB from Oil

The three different oil sample (1 mL) were dissolved in 10 mL of DMSO in an Erlenmeyer flask and extracted by shaking or sonication for 10 minutes. This process was repeated three times. All the DMSO extracts were combined. The resulting solution was transferred to a separation funnel, and 60 mL of n-hexane and 30 mL of deionized water were added to deactivate the DMSO. With vigorous shaking for 10 minutes, the PCBs transition into the nonpolar phase, i.e., the n-hexane layer. The layers were separated, and the lower DMSO-water mixture was returned to the separation funnel, while the hexane fraction was retained.

The DMSO-water mixture were further extracted in the separation funnel with an additional 30 mL of n-hexane, and then the layers were separated. The hexane fractions were combined, and the extract was further concentrated. Purification of the extract can be carried out using silica gel columns with a volume of 3 mL, commercially available Florisil columns, or by partitioning between DMSO and n-hexane.

2.4. Chromatographic conditions for GC-ECD

The chromatographic conditions for GC-ECD optimized for gas chromatography [6]:

a) Separation column: capillary column;
b) Oven temperature program: 60°C for 2 minutes, ramp at 30°C/min to 120°C, ramp at 5°C/min to 300°C, hold at 300°C for 15 minutes;
c) Injector temperature: 260°C;
d) Undivided injection of 1 μL;
e) Carrier gas: nitrogen at a flow rate of 0.8 ml/min to 1 mL/min.

2.5. Preparation of standard solutions PCB

Calibration solutions of PCB with concentrations of 0.005, 0.01, 0.05, 0.075 and 0.1 μg/mL for waste oil are prepared by serial dilution of the basic standard with the addition of internal standards at a concentration of 0.1 μg/mL. The relative response factors for the original PCB and internal standards are calculated from the obtained calibration curve by plotting the graph of the mass concentrations versus the peak area ratio (or peak height ratio).

2.6. Quantitative and qualitative analysis

Gas chromatography with electron capture detection (GC-ECD) chromatograms of the extracts are recorded. Based on relative retention times, peaks corresponding to PCB congeners and their corresponding internal standards are identified. The presence of each determined compound is verified by repeating the gas chromatographic analysis using a column with a moderate polar phase in combination with ECD.

The quantification of PCBs in the waste oil is determined using the formula:

$$\omega_n = \frac{\left(\frac{A_d}{A_n} - b\right) \times q_d \times 100}{s}$$

ωn – The content of the PCB congener found in the sample, in mg/kg dry mass.
A_d - The measured response of the corresponding internal standard in the sample extract.
A_n - The measured response of the PCB congener in the sample extract.
s - The slope of the calibration function or relative response factor.

b - The intercept of the calibration curve with the ordinate.
q_d - The mass of the internal standard added to the sample, in µg.

This formula allows you to quantify the concentration of PCB congeners in the waste oil sample based on the measured responses and the known properties of the internal standards used.

3. RESULTS AND DISCUSSION

By heating a copper wire immersed in waste oil using a burner, the emission of a greenish flame was not detected, indicating that either the concentrations are low or PCBs are not present (Figure 1).

Figure 1. Heating waste oil on copper

After recording calibration solutions and performing regression analysis, it was concluded that the mentioned calibration curves have a satisfactory degree of regression. Calibration curves have correlation coefficients (R) of 0.995 and 0.996, satisfying the linearity condition. Based on the linear equation, concentrations of each tested PCB (PCB 153 and PCB 138) were calculated, and the values are presented in Table 1. Chromatographic spectra of the recorded waste oil are shown in Figure 2.

Table 1. Concentrations of PCB in the samples

PCB	Concentrations of PCB in sample 1 (µg/kg)	Concentrations of PCB in sample 2 (µg/kg)	Concentrations of PCB in sample 3 (µg/kg)
153	0,008	0,049	0,060
138	0,003	0,042	0,055

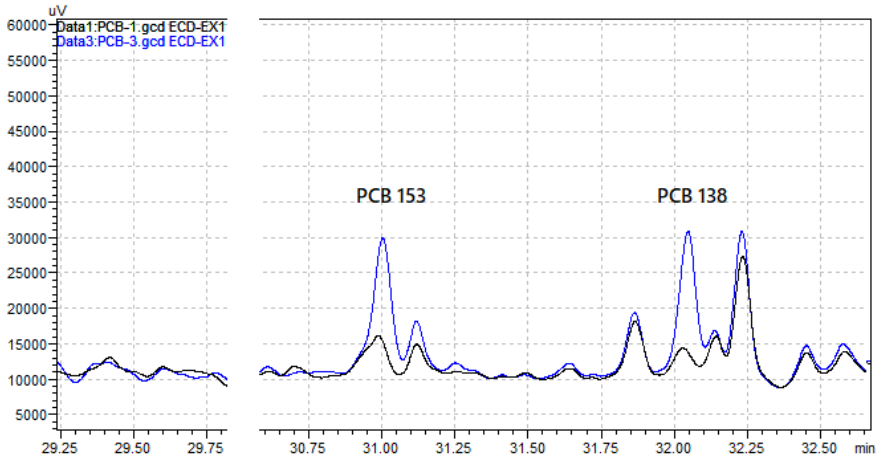

Figure 2. Graphical representation of results, samples 1 and 3

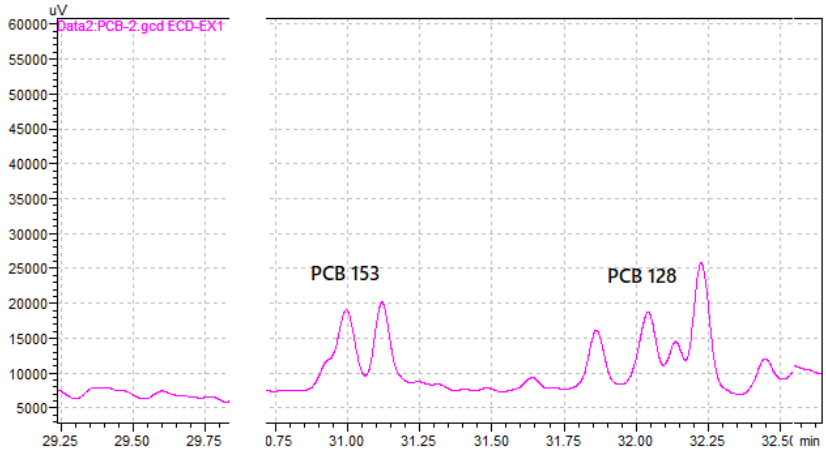

Figure 3. Graphical representation of results, sample 2

Considering that the concentrations in the waste oil sample are very low, we can conclude that the minimal amount of PCB 138 and 153 has been detected. The values are below the limit of quantification, and their precise quantification cannot be performed (Table 1). International laws, as well as the laws of the Republic of Serbia, prescribe different treatments for waste oils depending on the concentration of PCB. Based on the principles of waste oil management depending on the concentration of PCB presence [7], it can be concluded that this oil can be recycled and disposed of in landfills because its concentration is less than 2 ppm.

4. CONCLUSION

This research successfully identified and detected concentrations of PCB 138 and PCB 153 in the waste oil sample. The results show that the concentrations are below the limits prescribed by the European Union, indicating minimal amounts of these compounds in the examined sample.
These findings have significant implications for environmental protection and the use of waste oil. Considering the very low concentrations, it can be concluded that this oil is safe for recycling and disposal in landfills. This research opens doors for further studies in the processing and management of waste oil to enhance environmental protection.

Abstract: *Environmental pollution with phenolic compounds, petroleum derivatives, petroleum hydrocarbons, including polycyclic aromatic hydrocarbons (PAHs), as well as crude oil itself, represents a hazardous risk, both for the ecosystem as a whole and for human health. The increasing prevalence of these toxic compounds, their relatively low biodegradability, and their everyday use in large quantities lead to the pollution of water, soil, and air. PAHs have the ability to intensely absorb into the organic fraction of soil and the ability to evaporate, enabling them to easily spread through the ecosystem. In this paper, the concentration of PAHs, which the European Union defines as important indicators of environmental pollution: acenaphthylene, anthracene, acenaphthene, benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene, benzo[ghi]perylene, benzo[k]fluoranthene, chrysene, dibenzo[a,h]anthracene, fluoranthene, fluorene, indeno[1,2,3-cd]pyrene, naphthalene, phenanthrene, and pyrene were examined in contaminated hospital waste gloves using the GC/MS method.*
Keywords: medical waste, PAHs, GC/MS method

1. INTRODUCTION

Polycyclic aromatic hydrocarbons (PAHs) represent one of the most widespread groups of organic pollutants in the environment. Chemically, these are organic compounds that contain two or more condensed aromatic rings in their structure. They consist mainly of carbon and hydrogen, but this group of compounds also includes derivatives of PAHs in which carbon atoms are replaced by nitrogen, sulphur, or oxygen atoms, making them heterocyclic aromatic compounds. There are over 100 different PAHs, with varying numbers of condensed rings. The most common in the environment are PAHs containing two to seven benzene rings [1].
In addition to the different number of condensed rings, PAHs also differ in the arrangement of rings and the presence and arrangement of side chains. For example, PAHs with the same number of condensed rings can vary significantly in their properties depending on whether these rings are arranged linearly, angularly, or in a clustered form [1,2, 3].
The toxicity of PAHs is closely related to their structure. Different structures exhibit varying levels of carcinogenic activity, which increases with the introduction of functional groups into the PAH molecules. As the molar mass of PAHs increases, their carcinogenicity also increases, while acute toxicity decreases. When present in the human body, they enter the blood and lymph and undergo

[1] dvasic2022.13053@atssb.edu.rs
[2] vdjurdjevic@atssb.edu.rs

[4] abozic@atssb.edu.rs
[5] ajanicijevic@atssb.edu.rs
[6] dbrkic@atssb.edu.rs

metabolism in the liver and kidneys, with the absorption of PAHs in the body being dependent on their lipophilicity. The most significant confirmed toxic effects of PAHs are related to carcinogenicity and immunotoxicity [4,5]. Medical waste is defined as all waste, hazardous or non-hazardous, generated during the provision of healthcare services. It is a heterogeneous mixture of waste, with 10-25% of it being hazardous waste that poses a risk to human health and the environment. Waste originating from healthcare facilities is only a part of medical waste, which can be further categorized into several different categories. Gloves represent pharmaceutical waste that arises in the production and distribution of medicines and medical supplies [6,7].

In this paper, the characteristic of hazardous waste with the code H15 was examined. According to the Regulations on Waste Categories, Testing, and Classification, the characteristic of waste H15 is defined as follows: "Waste that has the property to, in any way, after disposal, produce another substance, e.g., leachate, which has one of the specified characteristics (H1-H14)." The characteristic H15 specifies that the concentration of polycyclic aromatic hydrocarbons (PAHs) should not exceed a value of 100 mg/kg dry mass (dm) in hazardous waste. These specific limits for the concentration of PAHs are in place to ensure the safe handling, storage, and disposal of this hazardous waste, considering the potential toxicity of PAHs. Such limitations are important for environmental preservation and the protection of human health in the management of hazardous waste [8].

For the examination, contaminated gloves were used, taken from the medical institution 'Sveti Luka' in Smederevo, and for the extraction of PAHs from the sample, a hexane-acetone solvent system was applied. The determination of the concentration of PAHs from the sample was carried out using the GC/MS method at the Polihem Laboratory.

2. EXPERIMENTAL PART

PAHs were extracted from the samples using an acetone-hexane solvent system. The obtained extract was further purified through column adsorption chromatography. The extract was analysed using gas chromatography with mass spectrometric detection (GC-MS) utilizing a low-polarity capillary column. The concentrations of PAHs were quantified using the external standard method.

2.1 Materials

The following chemicals were used for the extraction: acetone, *n*-hexane, anhydrous sodium chloride, and anhydrous sodium sulphate. For purification, silica gel 60 (particle size ranging from 63 μm to 200 μm) and quartz wool or silanized glass wool were employed. Commercially available purification columns can also be used for the purpose of purification.

2.2 Methods

The procedure for the analysis of PAHs consists of:

a) sampling and homogenizing the sample to enhance extraction
b) extraction is performed to effectively separate PAHs from the sample matrix and convert them into a suitable medium for analysis
c) instrumental analysis by GC 2010Pro by SHIMATZU

2.4. Calibration Curve

The calibration curve for individual PAHs is constructed by plotting the peak area of the ion chromatogram's most intense ion for the analysed compound against the relative response ratio for the original PAH, considering the concentration of the individual PAH. The linear range of the detector is established based on the calibration curve.

2.5. Data Processing

For the processing of the obtained analysis results, the GCMS Postrun program was used. The analysis and processing of the obtained results involve the following steps:

a) Setting up a new batch of samples and standards.

b) Establishing a new quantification method based on the selection of standards with the highest concentration.
c) Selecting the desired components.
d) Automated quantification and result storage.

These steps outline the process for handling the data generated by the GC-MS analysis. The software appears to facilitate the organization of sample and standard data, selection of quantification methods, and automated quantification of the components of interest, with results being saved for further analysis or reporting.

3. RESULTS AND DISCUSSION

Based on the chromatograms obtained by recording the medical waste samples (Figure 1), prepared in an appropriate manner, qualitative analysis can be performed.

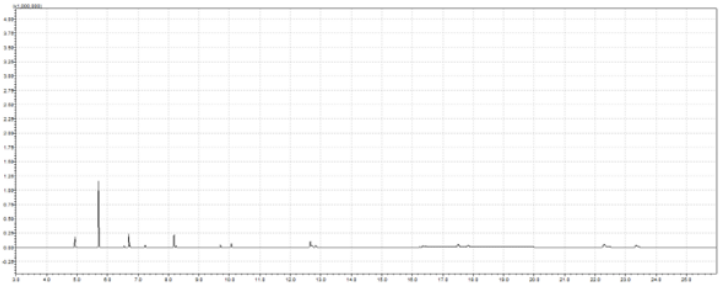

Figure 1. Chromatogram obtained by recording sample 1 in SIM mode

Quantitative analysis of PAHs in the samples was performed based on calibration curves obtained through the analysis of a series of standard solutions. Calibration curves for naphthalene, as well as the R values are shown in Figure 2.

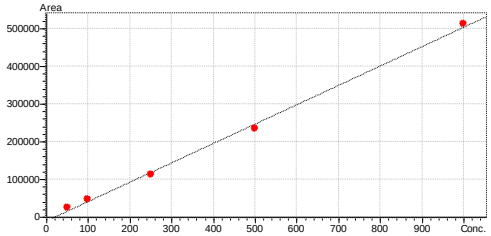

Figure 2. Naphthalene calibration curve, R = 0.9988638

Based on the equations of the line, the concentrations of each of the tested PAHs, as well as the total amount of all PAHs, were calculated in individual samples. The obtained values are shown in Table1.

Table 1. Obtained concentrations of PAHs in the sample

PAH	The obtained value mg/kg	The permissible maximum value for H15 mg/kg
Naphthalene	0,5	
Acenaphthylene	0,2	
Acenaphthene	0,5	
Fluorene	0,05	
Phenanthrene	0,03	
Anthracene	<0,01	
Fluoranthene	0,5	
Pyrene	0,5	
Total	2,3	100*

*- The reference value for the hazardous H15 characteristic

As can be observed from Table 1 and from Figure 2, the values of PAHs in the sample range from <0.01 mg/kg, such as anthracene, to 0.5 mg/kg for naphthalene, acenaphthene, and pyrene. The total amount of all PAHs in this sample is <2.3 mg/kg, which is within the permissible concentrations for PAHs specified under the hazardous characteristic H15, with the highest allowable limit of 100 mg/kg of dry matter.

4. CONCLUSION

This paper presents the determination of the concentrations of individual PAHs in medical waste samples, and quantitative analysis of prepared samples was performed using the GC/MS method. The PAHs were extracted using a hexane-acetone solvent system, and this method has proven to be one of the best for sample preparation.

For the purposes of this study, the concentration of PAHs that the EU prescribes as important indicators of environmental pollution was examined: acenaphthylene, anthracene, acenaphthene, fluoranthene, fluorene, naphthalene, phenanthrene, and pyrene. In a representative sample, the concentration of PAHs was below the permissible values associated with the hazardous H15 characteristic.

The primary sources of contamination of the tested sample were naphthalene, acenaphthene, and pyrene, which were present in higher concentrations compared to all other PAHs. Anthracene had the lowest concentration in the sample, and its obtained value was at the limit of quantification.

EU TAXONOMY AS A FRAMEWORK FOR A FUNCTIONING CIRCULAR ECONOMY

Vesna Alivojvodic [1], The Academy of Applied Technical Studies Belgrade
Aleksandra Vučinić [2], Ministry of Environmental Protection of the Republic of Serbia

Abstract: *Clearly defining the concept of circularity has been one of the critical barriers to adopting circular economy principles across various industries. Although progress has been made in developing new circular economy business models, adopting a common understanding of the benefits of implementing more sustainable models is extremely important. To build this new framework, there is the need to create a system of classifying values to ensure a complete understanding of system values' types and categories. The main objective of this science-based classification system is to define sustainable activities clearly. This paper presents an overview of the development of the EU Taxonomy, the technical screening criteria of environmental objectives of this regulation, activities making substantial contributions to the circular economy transition, and difficulties that could arise through implementation processes.*
Keywords: Taxonomy, Circular Economy, Monitoring Framework, Action Plan.

1. INTRODUCTION

The circular economy is a model where resources are used to their fullest potential before being recovered and regenerated. Implementing circular economy (hereafter: CE) principles is increasingly recommended to achieve sustainable development goals. Academics, industrialists, and politicians worldwide agree to use CE-related measuring instruments to facilitate the transition at various systemic levels [1]. Similarly, the analysis of 221 CE-related definitions by Kirchherr et al. (2023) [2] provides quantitative evidence that CE also means different things to different people [1] .
New tools are necessary to assist practitioners, decision-makers, and policy-makers in adopting more CE practices and monitor their effects.[1] When considering the lifecycle of a product, it's important to broaden the scope and take into account the interactions among a range of policies. The complexity of this system is shown by Figure 1, where various policy mechanisms are being explored in different policy arenas of the production-consumption approach [3].
However, there needs to be coordination among these mechanisms. Nevertheless, many policy tools can be used to apply both positive and negative pressures to promote a shift towards a CE. Producers, users, and waste recyclers can be pressured to modify their activities and move towards a circular model using a mix of policies.
The interactions between different actors in a circular economy are numerous and complex. This creates a complicated policy landscape that extends across different parts of production and consumption systems and directly or indirectly affects several other parts in the value chain. Considering these interactions' impacts is crucial to fully understanding the circular economy.

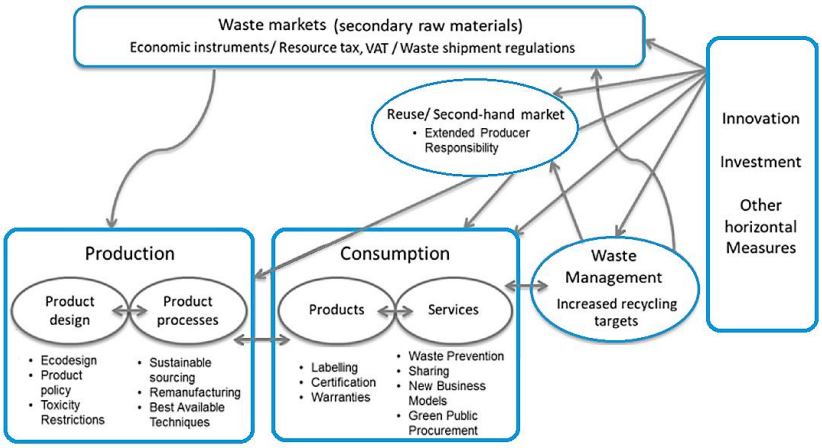

Figure 1. Overview of different policies oriented towards CE

Source: adapted from Milios, L. Advancing to a Circular Economy: Three Essential Ingredients for a Comprehensive Policy Mix, *Sustainability Science,* 13(3), (2018) pp. 861–78. ISSN 1862-4065.

To fully implement the principles of CE, it is crucial to have discussions that establish a shared understanding and language towards accomplishing this goal. Taxonomy, the science of classification in a broad sense, can become a valuable tool for achieving common definitions, criteria, and common metrics within activities in the field of circular economy.

2. CIRCULAR ECONOMY ACTION PLAN

The European Commission introduced the *New Circular Economy Action Plan* in 2020 as one of the main building blocks of the European Green Deal - a new strategy for sustainable growth in Europe [4]. A historical timeline listing policy milestones for the EU Action plan for CE, is shown in Table 1.

Table 1. Timeline of EU actions and initiatives

Source: https://environment.ec.europa.eu/strategy/circular-economy-action-plan_en

2023	Revision of the circular economy monitoring framework
2023	Proposals on green claims and right to repair proposal for a Directive on green claims
2022	Measures proposed in the circular economy action plan (revision of EU rules on Packaging and Packaging Waste)
2022	Proposals for revised EU measures to address pollution from large industrial installations
2022	Package of measures proposed in the circular economy action plan
2021	Proposal for new rules on waste shipments
2021	Proposal to update rules on persistent organic pollutants in waste
2021	Global Alliance on Circular Economy and Resource Efficiency (GACERE) launched
2020	Proposal for a new regulation on sustainable batteries
2020	New circular economy action plan
2019	European Green Deal
	•••
2015	1st circular economy action plan

The new action plan aims to improve the entire life cycle of products, proposing a series of connected initiatives to create a robust and consistent policy framework that promotes sustainable products, services, and business models and encourages a shift in consumption patterns towards sustainable consumption, so that waste is prevented from being generated in the first place while keeping resources in the EU economy for as long as possible. The plan includes legislative and non-legislative measures targeting areas where action at the EU level can bring real added value.

Even the first Action plan (2015) included a clear timeline for the actions proposed and a plan for a simple and effective monitoring framework for the circular economy. *Revised EU monitoring*

framework for the CE (accepted 2023 by the European Commision), that takes account of the CE priorities in the context of the European Green Deal, aims to provide a comprehensive overview by measuring direct and indirect benefits of increasing circularity. It comprises 11 indicators grouped into five dimensions: (1) production and consumption, (2) waste management, (3) secondary raw materials, (4) competitiveness and innovation, and (5) global sustainability and resilience [5].
Even though circularity indicators, known as C-indicators, can provide a comprehensive evaluation of circularity in various contexts, it is essential to understand what the available indicators measure to use them properly. Monitoring frameworks must standardise terminology and definitions, establish quantifiable baselines for metrics comparisons, and find practical solutions to improve data quality and availability to capture the multi-dimensional nature of circularity fully.
Within the monitoring framework, the taxonomy shall serve as a tool to distinguish sustainable from non-sustainable economic activities. The taxonomy aims *to guide capital into innovations that are (or have the potential to be) more circular than the status quo and to accelerate changes towards the circular economy* [6].

3. THE EU TAXONOMY REGULATION

An economic activity should meet specific technical screening criteria to be deemed environmentally sustainable. The Taxonomy aims to provide "a robust, science-based classification system, allowing non-financial and financial companies to share a common definition of sustainability and thereby providing protection against greenwashing" [7].
EU taxonomy for sustainable activities (henceforth "EU Taxonomy") is a framework designed by the European Parliament and Council, adopted in 2020, to classify environmentally sustainable economic activities to promote sustainable finance and investments. The EU Taxonomy is a crucial part of the European Green Deal. It can be interpreted as a dictionary defining a list of economic activities qualifying as sustainable concerning defined environmental criteria [8].
The goals of the taxonomy can be summarised in three key points:

- Reorientation of capital flows towards sustainable investments;
- Establishing sustainability as a component of risk management;
- Foster transparency and long-term investments and economic activity [9].

The EU Taxonomy defines six primary environmental objectives (Figure 2). Each objective specifies a list of economic activities and criteria to ensure that the activity contributes significantly to the objective's goal while not causing significant harm to the other objectives [10].
The current version of the EU Taxonomy covers a limited number of economic sectors. However, more sectors are expected to be added over time [10].

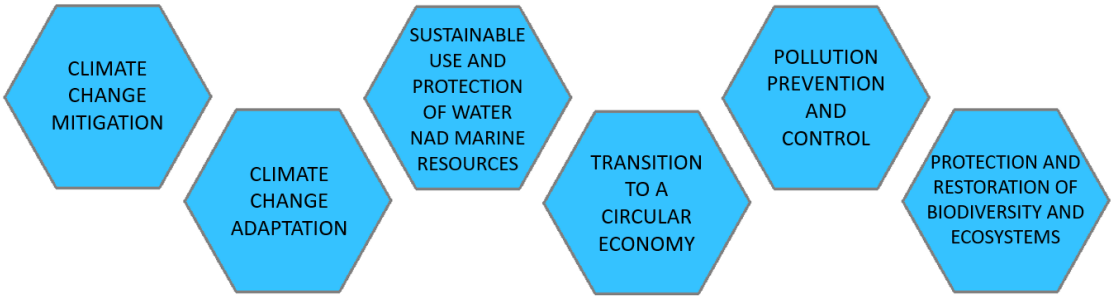

Figure 2. Six primary environmental objectives defined under the EU Taxonomy

One of its six equally weighted environmental objectives is to support the transition to a circular economy [11] and promote the use of secondary raw materials, prolonging the lifespan of products and materials and implementing a closed material loop to prevent waste generation [12].
This framework aims to help companies, investors, and other stakeholders understand and communicate the environmental performance of their assets, products, services, and investments. In addition, it will enable companies to identify opportunities to improve their environmental performance and access new markets and investors interested in sustainable and responsible

investments. By implementing the CE objective of the EU Taxonomy, it is possible to achieve significant economic and environmental benefits [12].

3.1 Activities making substantial contributions to the circular economy transition

The European Commission (EC) published recently (June 2023) the final Environmental Delegated Act, specifies criteria for determining whether economic activities cause significant harm to any of the other environmental objectives and has separate annexes for each environmental objective [13].
The delegated act defines the technical screening criteria of the four other environmental objectives of the Taxonomy Regulation:

i) Sustainable use and protection of water and marine resources;
ii) Transition to a circular economy;
iii) Pollution prevention and control;
iv) Protection and restoration of biodiversity and ecosystems.

Each annex defines the economic activities under the respective objective and the corresponding technical screening criteria.
Annex II of this document gives technical screening criteria for determining the conditions under which an economic activity qualifies as contributing substantially to the transition to a CE and for determining whether that economic activity causes no significant harm to any of the other environmental objectives.
Activities are listed under 21 categories, grouped into five sectors (Table 3):

- Manufacturing;
- Water supply, sewerage, waste management and remediation activities;
- Construction and real estate activities;
- Information and communication, and
- Services.

Table 3. Activities on the transition to a CE / 21 activities within five sectors
Source: Environmental Delegated Act (C(2023) 3851), Brussels (2023); Annex II

Manufacturing

1.1. Manufacture of plastic packaging goods
1.2. Manufacture of electrical and electronic equipment

Water supply, sewerage, waste management and remediation activities

2.1. Phosphorus recovery from wastewater
2.2. Production of alternative water resources for purposes other than human consumption
2.3. Collection and transport of hazardous waste
2.4. Treatment of hazardous waste
2.5. Recovery of bio-waste by anaerobic digestion or composting
2.6. Depollution and dismantling of end-of-life products
2.7. Sorting and material recovery of non-hazardous wastes

Construction and real estate activities

3.1. Construction of new buildings
3.2. Renovation of existing buildings
3.3. Demolition and wrecking of buildings and other structures
3.4. Maintenance of roads and motorways
3.5. Use of concrete in civil engineering

Information and communication

4.1. Provision of IT/OT data-driven solutions and software

Services

5.1. Repair, refurbishment and remanufacturing
5.2. Sale of spare parts
5.3. Preparation for re-use of end-of-life products and product components
5.4. Sale of second-hand goods
5.5. Product-as-a-service and other circular use- and result-oriented service models
5.6. Marketplace for the trade of second-hand goods for reuse

3.2 Potential challenges in implementation

There may be certain difficulties that could arise during the process of putting an EU Taxonomy and its CE objectives into action.
One of the primary challenges is the lack of knowledge and expertise in the CE among companies and investors. This makes it difficult for companies to comprehend and adhere to the technical screening criteria and for investors to evaluate the environmental performance of economic activities. Moreover, the absence of infrastructure (more recycling and refurbishment facilities) and systems (the lack of regulations and policies to facilitate the shift towards a CE) to support the CE also poses a challenge. Companies can also face difficulties or obstacles when transitioning to a CE due to the lack of incentives and support. Additionally, regulations and policies are scarce to support the transition to a circular economy.

4. CONCLUSION

The European Commission's circular economy taxonomy system can be used to create comprehensive criteria for the transition to a circular economy. The framework is extensive and adaptable enough to tackle several challenges in transforming our linear economies into circular ones across sectors. This sustainable finance taxonomy can clarify circular economy activities and direct finance towards them. With regulatory and economic policy instruments, the taxonomy can accelerate sustainable economic activities, but it is still in the early stages of implementation, with numerous challenges on its way. Nevertheless, despite that, new regulation offers hope for closing the financial gap and improving the adoption of circular practices.

ENVIRONMENTAL CONCERNS OF LITHIUM BATTERY DISPOSAL

Milica Marković[1], Faculty of Sciences and Mathematics, University of Niš
Ana Momčilović[2], The Academy of Technical Applied Sciences Belgrade
Maja Stanković[3], Faculty of Sciences and Mathematics, University of Niš

Abstract: *Technological advancements and lifestyle changes have increased reliance on electronic devices, leading to a surge in battery demand, particularly lithium-ion batteries. These batteries are prevalent in consumer electronics and vehicles due to their efficiency and lightweight composition. This study focuses on the vital role of batteries in everyday life, specifically examining lithium-ion batteries, their composition, and types. The paper differentiates between primary (single-use) and secondary (rechargeable) batteries, underscoring the growth in lithium-ion battery production, influenced by global initiatives aimed at reducing carbon emissions. The lifecycle of lithium-ion batteries, encompassing production, disposal, and recycling, is scrutinized. Challenges in battery chemistry variance, collection, and recycling processes are discussed, with manual dismantling of battery modules presented as a more effective recycling method than material shredding. The environmental implications of improper disposal, especially the risks of landfill fires intensified by these batteries, are a significant focus. The release of toxic gases and heavy metals from such fires, adversely affecting air, soil, and water quality, is detailed. Furthermore, the impact of these heavy metals on human health is briefly explored. Conclusively, this paper highlights the extensive environmental footprint of lithium-ion batteries, emphasizing the critical need for enhanced recycling and disposal strategies to minimize their detrimental environmental and health impacts.*
Keywords: Lithium-Ion Batteries, Environmental Impact, Recycling Challenges, Landfill Risks, Toxic Emissions

1. INTRODUCTION

In the wake of technological advancements and evolving lifestyle patterns, the world has witnessed a significant surge in the use of various electronic devices. This increase has, in turn, escalated the demand for efficient and reliable power sources, prominently lithium-ion batteries. Lithium-ion batteries, characterized by their lightweight and high-energy density, have become integral in powering a wide array of devices, from mobile phones and laptops to electric and hybrid vehicles. This widespread adoption, however, brings forth critical environmental challenges. This paper delves into the comprehensive lifecycle of lithium-ion batteries, from their production to eventual disposal and recycling. It highlights the critical distinction between primary and secondary batteries and emphasizes the growing global demand for lithium-ion batteries. This demand is partly driven by international initiatives like the European Green Deal and the UK's ban on internal combustion engines, signalling a shift towards a low-carbon economy [1, 2]. The focal point of this study is the environmental impact of these batteries, particularly concerning their disposal. The improper disposal of lithium-ion batteries poses significant environmental hazards, notably in landfills where they can exacerbate fires, releasing toxic gases and heavy metals [3]. These emissions have far-reaching consequences on air quality, soil, and water, extending beyond immediate ecological damage to pose

[1]markovicmilica993@gmail.com
[2]amomcilovic@atssb.edu.rs
[3] maja.stankovic@pmf.edu.rs

serious health risks [4]. In addressing these challenges, the paper examines various recycling methods, with a special emphasis on manual dismantling as a more efficient alternative to material shredding. The complexities associated with the recycling process, owing to the varying chemistries of lithium-ion batteries, are also explored. Ultimately, this paper aims to shed light on the urgent need for improved recycling infrastructure and innovative disposal methods. By doing so, it seeks to mitigate the harmful environmental and health impacts associated with the growing use of lithium-ion batteries, thus contributing to a more sustainable and environmentally responsible future.

2. CONSEQUENCES OF IMPROPER DISPOSAL OF LITHIUM BATTERIES ON ECOSYSTEMS AND HEALTH

The rapid advancement in technology and lifestyle changes have led to a surge in the use of electronic devices, subsequently increasing the demand for batteries. Lithium-ion batteries, characterized by their high energy density and efficiency, are now ubiquitous in powering a range of devices, from mobile phones and laptops to electric and hybrid vehicles. These batteries are pivotal in modern life, yet their disposal poses significant environmental challenges. A large increase in lithium-ion batteries demand for electric vehicles is predicted in 2030. The entire market will need 1293 GWh, and the largest part will be needed by China with about 500GWh, 320GWh by the US, 280GWh by the rest of Europe and about 200GWh by the rest of the world [5]. Lithium-ion batteries, which utilize lithium as an anode, are preferred for their lightweight and high energy capacity [6]. They come in two forms: primary (single-use) and secondary (rechargeable), with the latter gaining more prominence due to longer lifespan and higher capacity. However, the increase in lithium-ion battery production and use raises critical concerns about their disposal and recycling. The paper particularly distinguishes between the batteries used in consumer electronics, which are smaller and less likely to be recycled, and those in vehicles, which are more frequently processed in recycling facilities. The recycling challenges are amplified by the diverse chemistry of lithium-ion batteries, impacting their composition, performance, and application.

2.1. Recycling of lithium-ion batteries

Recycling lithium-ion batteries is a critical aspect of mitigating their environmental impact. Among the various recycling methods, manual dismantling has emerged as a particularly effective approach. This process involves the physical disassembly of batteries to separate and recover valuable components and materials. Manual dismantling is preferred over other methods like material shredding for several reasons. Firstly, manual dismantling allows for the precise separation of different components of lithium-ion batteries. These batteries consist of several key materials, including lithium, cobalt, nickel, and various plastics and metals. By carefully disassembling the batteries, recyclers can more effectively segregate these materials, reducing the risk of contamination that often occurs during shredding. Shredding, while quicker, tends to mix all materials together, making it challenging to extract pure substances. The purity of recovered materials is crucial for their reuse in new batteries or other applications. Manual dismantling yields a higher return of pure active materials. This purity is vital as it ensures that the recycled materials retain their original properties and functionality. For instance, cobalt and lithium recovered through this process can be reused in the production of new batteries without significant degradation in performance. Moreover, manual dismantling minimizes the loss of valuable materials. During shredding, small particles of precious metals and other materials can be lost or become too difficult to separate efficiently. This is not the case with manual dismantling, where the careful separation process ensures maximum recovery.
Another advantage of manual dismantling is the reduced environmental impact. Shredding processes can generate dust and other pollutants, which can be harmful if not properly managed. In contrast, manual dismantling, when done in controlled conditions, results in fewer airborne pollutants, making it a more environmentally friendly option. However, it's important to note that manual dismantling is labor-intensive and can be more time-consuming than automated processes like shredding. This can

impact the scalability of this method, especially as the volume of batteries needing recycling continues to grow. The labor-intensive nature of the process also raises concerns regarding worker safety and health, as employees are exposed to potentially hazardous materials. To optimize the recycling of lithium-ion batteries, a combination of manual dismantling and automated processes might be the most effective approach. The initial manual dismantling can ensure the purity and maximum recovery of valuable materials, while subsequent automated processes can handle the higher volumes and manage the less critical aspects of recycling. It was estimated that in 2018 97,000 tons of lithium-ion batteries were recycled, of which the most was recycled in China and South Korea with 67,000 and 18,000 tons. A certain amount of batteries have a longer life than expected, while some are reused and other are stored in warehouses immediately after production, reducing the overall number of recycled batteries. Certainly, the greater part of batteries that reach the end of life comes from electronic devices, not from electric vehicles (as much as 80%) [7].

2.2. Disposing lithium-ion batteries on landfills

The disposal of lithium-ion batteries poses a significant environmental and public health challenge, particularly when these batteries end up in landfills. Landfills are the primary method for solid waste disposal. Electronic waste makes up as much as 4% of municipal waste that is disposed of in landfills, and most of this electronic waste consists of batteries [8]. Despite advances in battery technology, the recycling infrastructure for lithium-ion batteries remains underdeveloped, leading to a majority of these batteries being discarded in landfills. These sites, often the go-to solution for municipal waste due to their cost-effectiveness and operational ease, inadvertently become hotspots for environmental pollution. Landfills are not designed to handle the specific challenges posed by lithium-ion batteries. When these batteries are disposed of alongside general waste, they introduce several risks. One of the most hazardous consequences is the potential for landfill fires. These fires can be sparked by the spontaneous combustion of methane—a common occurrence in landfills. Lithium-ion batteries exacerbate this problem. Their composition and residual charge can lead to thermal runaway reactions, especially when damaged or exposed to high temperatures. These reactions can intensify landfill fires, making them more frequent and harder to control.

The fires in landfills release a cocktail of toxic gases and smoke. Among these are polycyclic aromatic hydrocarbons, dioxins, furans, volatile organic compounds, and heavy metals like lead, mercury, and cadmium. These substances are known for their detrimental effects on air quality and public health. For instance, dioxins and furans are highly toxic and can cause problems ranging from skin disorders to more severe health issues like cancer and reproductive disorders. Heavy metals, when inhaled or ingested, can lead to neurological and developmental problems, particularly in children.

2.3. Widespread environmental damage of inadequate lithium-ion batteries disposal

In addition to air pollution, the impact of landfill fires and leachates can extend to soil and water systems. Lithium-ion batteries contain heavy metals and other toxic substances that, when released, can seep into the ground and contaminate soil and groundwater. This contamination not only affects the immediate landfill area but can also spread to neighboring ecosystems. The heavy metals and chemicals in these leachates can be particularly harmful, leading to soil acidification and affecting the soil's ability to support plant life. This disruption can have cascading effects on local ecosystems, impacting not just plant life but also the animals that depend on them for food and habitat.

The ecological impact of such contamination is far-reaching. Heavy metals accumulated in the soil can be taken up by plants, entering the food chain and affecting a wide range of species, from insects to larger mammals and birds. In aquatic environments, these contaminants can lead to the eutrophication of water bodies, disrupting aquatic life and leading to the loss of biodiversity. These ecological imbalances can have long-term effects on the stability and health of ecosystems.

The environmental implications of heavy metal contamination from lithium-ion batteries are profound and multifaceted. Batteries, being a significant source of cobalt, nickel, and manganese,

contribute to the accumulation of these heavy metals in the environment when disposed of improperly. This section delves into the various aspects of such contamination and its cascading effects on ecosystems.

When lithium-ion batteries are discarded in landfills, the heavy metals they contain can leach into the soil and water systems. Over time, these metals accumulate in the environment, leading to several ecological problems. In soil, heavy metal accumulation can result in reduced fertility, altering its composition and affecting its ability to support plant growth. This change can disrupt the balance of local ecosystems, as plants form the foundation of most terrestrial food webs.

In water bodies, these metals can lead to the contamination of aquatic ecosystems. The presence of heavy metals in water can be toxic to aquatic life, causing a reduction in biodiversity and altering the balance of these ecosystems. Fish and other aquatic organisms can accumulate these metals in their bodies, which can then be transferred up the food chain, affecting predators and, eventually, humans who consume these fish.

The presence of heavy metals in the soil can also alter microbial activity. Microbes play a crucial role in soil health, aiding in nutrient cycling and organic matter decomposition. Heavy metal contamination can inhibit these microbial processes, leading to a decrease in soil quality and health. This can have a direct impact on plant life, as plants rely on healthy soil for nutrients and growth.

The long-term environmental consequences of heavy metal contamination from lithium-ion batteries are significant. One of the potential outcomes is changes in land use due to soil degradation. As soil becomes less fertile and more contaminated, it may no longer be suitable for agricultural or recreational purposes, leading to shifts in land use patterns. This can have socio-economic implications, particularly in regions where agriculture is a primary livelihood.

In aquatic ecosystems, prolonged exposure to heavy metals can lead to changes in species composition and a decrease in water quality. These changes can disrupt the ecological balance, affecting not only the aquatic species but also the terrestrial species that rely on these water bodies.

The broader implications of heavy metal contamination include impacts on climate and biodiversity. Contaminated and degraded ecosystems are less capable of performing essential functions such as carbon sequestration, which is vital in mitigating climate change. Additionally, the loss of biodiversity due to heavy metal contamination can lead to the loss of ecosystem services, which are critical for maintaining the balance of the environment and supporting human life.

3. CONCLUSION

The comprehensive analysis of the impact of lithium-ion batteries on the environment and health elucidates a pressing concern in the context of our rapidly advancing technological world. As the reliance on electronic devices continues to escalate, so does the use and disposal of lithium-ion batteries, a cornerstone in powering these devices. These batteries, known for their efficiency and high energy density, have become integral in modern life, but their end-of-life management poses significant environmental and health challenges. The environmental repercussions of improperly disposed lithium-ion batteries are manifold. Landfills, the most common destination for these batteries, become hotbeds for pollution. Here, the risk of fires is heightened by the presence of these batteries, leading to the emission of toxic gases and heavy metals. These emissions adversely affect air quality, contributing to broader atmospheric pollution. The leachates from these batteries further contaminate soil and water bodies, introducing heavy metals and other toxic substances into ecosystems. This contamination disrupts ecological balance, affects biodiversity, and poses a risk to plant and animal life. The health implications of such environmental degradation are profound. Exposure to toxic substances released from discarded batteries can lead to a range of health issues in humans, from respiratory problems to more severe conditions caused by heavy metal poisoning. The long-term effects on human health necessitate a deeper understanding and more robust management strategies. This situation underscores the urgent need for effective recycling and disposal methods for lithium-ion batteries. While current recycling methods, such as manual dismantling, offer a more efficient alternative to material shredding, there is a need for more innovative and sustainable

approaches. Such approaches should not only focus on effective recycling but also on minimizing environmental impact during the entire lifecycle of these batteries. In conclusion, the growing use of lithium-ion batteries, while beneficial for technological advancement, brings with it a responsibility to manage their disposal in an environmentally friendly and health-conscious manner. It is imperative that we develop and implement comprehensive strategies for recycling and waste management to mitigate the adverse effects on the environment and human health. This will require collaborative efforts from governments, industries, and communities to ensure a sustainable and healthy future.

AIR POLLUTION CAUSED BY MODERN-DAY ARMED CONFLICTS

Miloš Kovačević[1], The Academy of Applied Technical Studies Belgrade
Nataša Radić[2], The Academy of Applied Technical Studies Belgrade

Abstract: *Since the beginning of time, armed conflicts have killed people, destroyed infrastructure, led to forced migrations, and had many other short and long-term economic, social, and political consequences. An often overlooked fact is how these war activities affect air pollution and the environment before, during, and after the conflict. This paper will examine only the consequences of conventional warfare on air pollution, such as fuel consumption and carbon footprint of military equipment, burning of fuel, biomass, and waste, destruction of infrastructure, use of different kinds of ammunition and other explosive equipment, and increased industrial activity in all stages of the conflict. All these activities cause the emission of different types of pollutants into the air, which has a devastating effect on all living things and the environment, even far away from the conflict zone and, in most cases, long after the conflict.*
Keywords: Air pollution, armed conflict, environment

1. INTRODUCTION

Armed conflict can be defined as an act of war generated by two or more governmental groups, non-governmental groups, or international states that generally involve active military actions [1]. When considering armed conflict, the primary concern is the loss of human life, followed by short and long-term adverse health effects on both military personnel and civilian population, as well as severe economic, social, and political consequences. Still, another often disregarded consequence is damage to the environment where those conflicts occur [2]. Armed conflicts affect all components of the environment - air, water, and soil. This paper will discuss air pollution that occurs in all stages of the conflict. It can be indirect, for example, the carbon footprint that the military has during its activities that include fuel consumption and burning waste, the relocated carbon footprint that refugees have in the country they fled to, or the carbon footprint of post-war reconstruction and rearmament. Nevertheless, often, it is direct as participants tend to use tactics like burning fuel supplies and land biomass or destroying infrastructure and industrial facilities to prevent the opposition from moving over terrain or gaining valuable resources, as well as reducing visibility due to smoke from burning [3]. Those actions and many others can significantly contribute to air pollution in the territory where conflict occurs but also can affect environments far away from the conflict zone, as pollutants travel through the atmosphere. Therefore, the negative environmental effects can extend far beyond the space and time of the armed conflicts that caused them, possibly having long-term global effects on air quality [4]. The overall structure of this paper takes the form of three chapters, each covering one of three parts of the conflict that causes air pollution. Preparation for the armed conflict, the armed conflict, and the post-conflict period. This paper will not discuss political issues and the cause of the conflicts but only their impact on air pollution and the environment [1].

[2]nradic@atssb.edu.rs

2. AIR POLLUTION CAUSED BY THE PREPARATION FOR ARMED CONFLICT

Preparation for armed conflict involves many fossil fuel-intensive activities, emitting carbon dioxide equivalent (CO_2e) and other pollutants [5]. Those activities primarily include increased industrial activity due to the production of military equipment, ammunition, and fossil fuel consumption. Fossil fuel consumption is essential to military preparations since almost every land, air, and sea vehicle and a wide range of fuel-powered installations need fuel. Fuel consumption of military equipment is very high due to the prioritization of superior combat performance. Heavy military vehicles and aircraft consume large amounts of fuel and produce thousands of tons of CO, NOx, hydrocarbons, and SO_2 [6,7]. Data on military fuel consumption and greenhouse gas (GHG) emissions is generally limited due to many factors, one being that reporting military emissions is voluntary, as the Paris Agreement states. While sometimes data is reported directly by the military agency, another solution can be emission calculation done by independent researchers based on fuel consumption published by military agencies. Research suggests that if all militaries of the world were a single country, that figure would have the fourth largest national carbon footprint in the world, greater than that of Russia [8].

For example, we shall take the United States Department of Defense (US DOD), the largest energy consumer in the United States and the world's largest institutional consumer of petroleum. Equipment on the field deployed by the US DOD uses an incredible amount of fuel; the same goes for off-field equipment and operations. An example of fuel consumption is a High Mobility Multipurpose Wheeled Vehicle or "Hummve" with roughly 30 to 60 liters of diesel fuel per 100 kilometers, equivalent to three to six medium-sized passenger cars. Besides land, air, and sea vehicles, installations also consume significant amounts of energy and emit CO_2e. For example, the Pentagon building in Arlington, Virginia, emitted 24**,**620 metric tons of CO_2e in 2013 [5]. US DOD primarily uses diesel and jet fuel for its operations; around 70% of that fuel consumption goes to the US Air Force, resulting in jet fuel being the most used fuel by the US military [5]. Military jets fly at much higher altitudes than commercial aircraft, and special additives are used for that and other reasons. The concentration of military aircraft in a specific area can increase air pollution because of additives that include ammonium perchlorate, polyvinyl chloride, lead stearate, polybutadiene, and polyethylene. Furthermore, jet exhaust gases include NOx. Warships are excluded from all major international environmental regulations, resulting in the lack of studies on fuel consumption and environmental impacts [5,7].

3. AIR POLLUTION DURING THE ARMED CONFLICT

Fossil fuel consumption and carbon footprint are further increased when conflict begins, as fossil fuel-powered equipment and installations experience a higher degree of use. There are often airspace bans issued by countries and their allies involved in the conflict. A recent example is the conflict in Ukraine, where Russia and Western countries issued various airspace bans, cutting important airways between Europe and Asia by making nearly 18 million km^2 inaccessible for overflights, which caused airline companies to make detours which resulted in longer flight times, as well higher GHG emissions [6].

Besides air pollution caused by fuel consumption, there is uncontrolled burning of materials in the ambient environment. Open fires occur regularly during peacetime due to natural factors and as a result of accidents [6]. During the conflicts, the number of fires and areas affected by fires is significantly increased compared to peacetime due to shelling, bombing, explosions, and other conflict-related actions. Different materials are burned in uncontrolled settings, and acquiring representative information about emission factors is challenging. Still, overall emission from a source depends on activity level and the amount of combustible material. In the case of open burning, due to its less-than-ideal combustion conditions that include insufficient mixing of fuel and air and not high enough temperatures, there is the emission of soot and particulate matter (PM), carbon monoxide, methane, and other light hydrocarbons, volatile organic compounds (VOCs) and polycyclic aromatic

hydrocarbons (PAHs). Metals can also be emitted into the air during these combustions, such as lead and mercury, as well as polychlorinated dibenzo-p-dioxins and polychlorinated dibenzofurans (PCDDs/Fs) or polychlorinated biphenyls (PCBs) [6,9]. While the primary concern is the open burning of fossil fuels caused by the destruction of fuel storages, oil wells, and energy facilities, there is also the open burning of biomass, structure, and waste [4,6].

Fuel sources are often targeted during armed conflict; they include fuel depots, oil refineries, power stations, oil wells, and other similar facilities. During the uncontrolled combustion of fossil fuels, massive amounts of soot and particulate matter are emitted into the air, along with partially burned hydrocarbons and heavy metals, including nickel, vanadium, iron, aluminum, zinc, arsenic, lead, and other elements. Besides heavy metal release into the air, fossil fuel burning produces a wide range of combustion products, namely CO_2, CO, SO_2, NOx, O_3, VOCs, and acid aerosols [3]. An example of an environmental air pollution catastrophe due to armed conflict occurred during the 1991 Gulf War. While retreating, military forces ignited around 600 Kuwaiti oil wells, causing the emission of 5,000 tons of soot and particulate matter into the air every day while oil wells burned. Also, those oil fires emitted approximately 7,200 tons of vanadium, 2,000 tons of nickel, 900 tons of aluminum, 750 tons of iron, 430 tons of zinc, and 150 tons of mercury and cadmium [3]. Smoke and soot rose to about 3,000 meters, while severe air pollution was registered even at 6,000 meters. Smoke covered large areas, including Kuwait, Bahrain, parts of Saudi Arabia, Iran, and Iraq, severely affecting air quality. Thermal inversion over southern Kuwait and northern Saudi Arabia trapped polluted cold air near the ground preventing it from dispersing natrually, where humans and animals can inhale it. Some research suggests that these stagnation conditions in the atmosphere combined with polluted air led to a sharp rise in common cardiovascular and lung diseases in affected areas. High concentrations of smoke decreased sun radiation and the temperature of air and water, where the average temperature in 1991 on the Saudi coast was 2.5 °C lower than usual [3]. Some research estimated that about 75 to 80% of the sun radiation was absorbed, resulting in a reduction in mid-day temperature of 5-8 °C at 250 km from the source of the fires. Since many organisms in the northern Gulf live under temperature conditions close to their lowest tolerance point, it is indicated that these changes caused by air pollution very likely had a negative effect on them [4,3]. The burning of fossil fuel sources and depots is a trend that started well before the Gulf War and was repeated in almost every armed conflict after it [3]. Another example is the damage to the Pancevo oil refinery during 1999. NATO bombings in Yugoslavia [7]. More recently, missile strikes in Ukraine demolished the Kremenchuk refinery, the only operational refinery in Ukraine with a capacity of three million tons of oil annually. There are also reports of destroying at least 20 other reservoirs with petrol, diesel, liquefied petroleum gas, and fuel oil in the ongoing conflict in Ukraine [7].

Besides fossil fuel, there is intentional and accidental biomass burning during the conflict. Biomass fires are a dynamic process where a moving flame front passes over a fuel source, such as a forest, savannah, or agricultural fields, consuming it. During this type of burning, there is both smoldering and flaming combustion, resulting in different levels of air pollution [9]. The Copernicus programme estimates that during a natural wildfire, the level of $PM_{2.5}$ can reach 500 $\mu g/m^3$; similar levels are observed during wildfires caused by military actions. Those figures are incredibly high compared to the World Health Organisation's 24-hour mean standard of 15 $\mu g/m^3$ [10]. Burning of biomass due to conflict-related activities, especially burning that results in deforestation, also leads to loss of actual and future carbon sequestration [5].

Uncontrolled waste burning is one of the major air pollution factors during armed conflicts. Every human activity generates waste; the same goes for armed conflicts. Due to the destruction of infrastructure and local services responsible for waste management being unable to function, there are improvised solutions for waste disposal, one of which is waste burning, done by both civilian and military personnel during the conflict [11,9]. Armies often use the so-called burn pit to dispose of waste. Research shows that the US military has repeatedly used this method since 2001 at bases outside the United States, in Iraq and Afghanistan. Burn pits are large areas where tons of waste are burned in the open air, often using jet fuel containing benzene as an accelerant. Military waste can include chemicals, paint, medical and human waste, metal cans, batteries, weapons, uniforms,

munitions and other unexploded ordnance, petroleum and lubricant products, plastics and styrofoam, rubber, wood, discarded food, dead animals, and even human body parts. As a reference to how much waste is being made during the conflict, according to the United States Department of Defense, the US military in Iraq and Afghanistan generated close to 5 kg of solid waste per servicemember per day [11]. Burn pits can create large volumes of toxic gases, polluting the air significantly more than controlled burning of waste due to uncontrolled burning and temperatures much lower than those required for complete combustion of materials [12]. Research suggests that toxic matter from these burnings can release known carcinogens and respiratory sensitizers that affect the skin, eyes, respiratory and cardiovascular systems, gastrointestinal tract, and internal organs of military personnel and the local population [13,11].

Destruction and burning of infrastructure, industrial, and residential buildings generate large amounts of debris and emit different air pollutants depending on the destroyed structure. More precisely, they depend on the type of material the building is made of and the chemicals used in the destroyed industrial facility. Among those air pollutants, one of the most dangerous to human health is particulate matter. Debris from industrial facilities can be hazardous, as it can contain a wide range of chemicals depending on the type of facility. The report by UNEP (2009) from conflict in Gaza stated that fire emissions and residue polluted the air with PAHs or dioxins and furans, depending on the material of the destroyed building [7,8]. Another example is the destruction of the Company for Carton Mince and Industry in Lebanon, which generated a significant amount of ash that contained dioxins and other chemical compounds [3]. In the ongoing conflict in Ukraine, damage to the Nord Stream 1 & 2 pipelines caused leakage of large amounts of natural gas, which consist of methane, a potent GHG, which led to severe GHG emission. Some research suggests that this GHG emission is more significant than the current assessment of all emissions combined from that conflict [14]. The destruction of the World Trade Center released many pollutants, including toxic metals, asbestos, dioxins, PAHs, PCBs, and hydrochloric acid [15]. There is also air pollution by radioactive elements. Research suggests that the bombing of two Al-Tuwatha nuclear reactors in the 1991 Gulf War probably released some amount of Cesium-137 and Iodine-131 into the air. Once these radioactive elements are in human organs, they emit radiation, which can induce cancer [3].

Using bullets, shells, missiles, or any other type of explosive military equipment causes air pollution. From the moment of being produced, transported, fired, or launched to the moment of impact or explosion, particulate matter and gases are released in all stages. These pollutants then mix with the air and become its permanent component. In modern-day armed conflicts, bullets, shells, and missiles are produced and used in millions, seriously affecting air quality. For example, generic 152 mm and 155 mm artillery shells used by Ukraine and Russia in the ongoing conflict emit at the point of firing 2.74 kg of CO_2e and 0.19 kg of CO_2e during the detonation [14]. By some calculations, in the first year of the conflict, the total number of this type of shells used by both sides was around 11,250,000. Resulting in a significant CO_2e emission [6]. Besides air pollution at the point of firing and during the detonation, there is also a massive carbon footprint during the production of ammunition and the transportation of it to the conflict zone, which are considerably more significant than the CO_2e emission of the actual use of ammunition. In Ukraine conflict, total emissions of CO_2e from all types of ammunition, including small caliber rounds, all types of explosives, ammunition used by drones, shells used by tanks, land mines, hand grenades, artillery rockets, and air missiles, considering the use, production, and transport during the first year of the conflict is estimated to be around 2,000,000 tons, which is in comparison roughly the emission of 445,000 passenger cars driven for an exact period of one year [16].

3. POST-CONFLICT AIR POLLUTION

Destruction of buildings and infrastructure during the conflict is proportional to the accelerated reconstruction that will take place after it. Some will start during the conflict, but most will occur after it ends. Production of materials, transportation, and accelerated construction generates massive amounts of particulate matter and GHG; this embodied carbon is essential to total air pollution caused

by armed conflict. After the conflict has ended, it leaves a state of deteriorated security. For example, the conflict in Ukraine shows us how peace on the European continent cannot be taken for granted. Resulting in a rearmament of surrounding countries and rearmament of those countries that participated in the conflict. Rearmament, as well as other post-war military and industrial activities, consume a large amount of resources, resulting in considerable GHG emissions [14, 6].

6. CONCLUSION

This paper aimed to examine armed conflicts' effects on air pollution. Research has shown that all stages of the conflict can have severe consequences for the quality of air. Air pollution during the preparation for the conflict mainly consists of GHG emissions caused by increased military industry activity and fuel consumption. Migration of the conflict-affected population before and during the conflict presents a specific situation: their carbon footprint follows them from their country of origin to the countries they migrate to. During the conflict, besides GHG emissions, findings were that pollution could be more severe due to the uncontrolled burning of fuel and other materials and the release of chemicals and radiation due to damaged or destroyed industrial facilities. We can conclude that mid-conflict air pollution in its scope can be very similar to the industrial accidents and wildfires that occur during peacetime, except that local services responding to those catastrophes are unlikely to function correctly during the conflict, resulting in long-lasting emission of the pollutants into the atmosphere. Lastly, post-conflict air pollution, similar to pre-conflict activities, generates increased amounts of GHG due to the reconstruction and rearmament. All three stages of the conflict seriously affect the air quality not only of the conflict-involved countries but through transboundary pollution, it can affect the whole region, even the whole world. Consequences can last for many years after the conflict, especially regarding global warming and the world's problems along the path to decarbonization. The military's decarbonization is very much needed from the air pollution standpoint. Some ideas include using biofuels for ships and aircraft, increasing the energy efficiency of all installations, electrifying vehicles, using more fuel-efficient engines and lightweight materials, and other eco-friendly improvements. For any drastic change to occur, future international climate change treaties must legally bind not only the countries that ratify those documents but also their military actions. Previously, the Kyoto Protocol did not include military activities, such as self-defense, peacekeeping, and humanitarian relief, from emission targets. At the same time, the Paris Agreement made military emissions reporting voluntary.

At the end of the first quarter of the 21st century, armed conflict is an even more complicated phenomenon than before, with many serious negative effects, some environmental. Air pollution related to the conflict is industrial in its scope but lacks the technology and control mechanisms used in other industries to reduce pollution. This problem must get more attention in the future to prevent the long-reaching and long-lasting consequences of armed conflict on the air and the environment.

INFLUENCE OF "STUBO-ROVNI" DAM ON CLIMATE CHANGE IN THE CITY OF VALJEVO

Danijela Jeremić[1], The Academy of Applied Technical Studies Belgrade
Daniela Ristić[2], The Academy of Applied Technical Studies Belgrade

Abstract: *On the River Jablanica, 15km from Valjevo, between the village of Stubo on the right bank and the village of Rovni on the left bank, the dam "Stubo-Rovni" was built, which formed the reservoir "Stubo-Rovni" with a volume of about 50·106m³. The reservoir was intended to supply water to the city of Valjevo and the surrounding areas. That idea did not come true, however it will not be a subject of this paper. This paper will deal with climate changes in the city of Valjevo that occurred after the construction of the "Stubo-Rovni" dam. The results were derived on the basis of a survey of 49 respondents divided into two groups. In one group there are respondents with a place of residence in the center of Valjevo and Novo naselje, and in the second group respondents who live in the area at a higher altitude.*
Keywords: reservoir for water supply, climate change

1. INTRODUCTION

The town of Valjevo is located in western Serbia, less than 100 kilometers southwest of Belgrade. The city center is located in the valley through which the river Kolubara flows and it's surrounded by the mountains Maljen, Povlen, Jablanik and Medvednik, which rise over 1200 meters above sea level. According to the census from 2011, 90.312 inhabitants live on the territory of the city. Valjevo is located at an average altitude of 185 meters.

On the River Jablanica, 15 km from Valjevo, between the village of Stubo on the right bank and the village of Rovni on the left bank, the "Stubo-Rovni" dam was built, which formed the reservoir "Stubo-Rovni" with a volume of about 50·106 m^3. The reservoir was formed in the valleys of the Jablanica and Sušica rivers. Back in 1979, a study was commissioned for the long-term water supply of the town of Valjevo. This study envisages the construction of the regional system "Rovni" with an accumulation, as well as a plant for the preparation of drinking water with a capacity of 3600 l/s [1].

Data on the dam and reservoir are [2]:

- Basin area: 104 km^2
- Dam height: 74.5 m
- Elevation of the crown of the dam: 363.50 m
- Length of the dam in the crown: 8.0 m
- Elevation of the overflow crown: 360.00 m
- Elevation of normal descent: 360.00 m
- Elevation min. working level: 310.00 m
- Useful volume of the reservoir: 49.5 million m^3
- Maximum depth of the reservoir: 67 m.

[1]lela.jer@gmail.com
[2]dristic@atssb.edu.rs

Figure 1. Reservoir "Stubo-Rovni"
Source: https://sn.rs/o6pj9

The regional water management system "Stubo-Rovni" (Fig.1) is intended for water supply population, industry, mitigating the effects of floods, retaining sediment, ensuring the biological minimum and producing electricity [2]. During the summer months of 2015, conditions were met for the beginning of filling the reservoir.

2. THE IMPORTANCE OF ACCUMULATION IN CASE OF FLOODS

The causes of floods can be immediate and indirect, with the existence of a wide range of factors that lead to the occurrence of so-called high waters. The immediate causes for the occurrence of floods are precipitation (rain and snow), the appearance of ice on rivers, the state of the water level at the time of its rise, the meandering of the stream, the occurrence of landslides and the occurrence of the coincidence of large waters. Indirect causes include the size and shape of the watershed, the density of the river network, features of the relief, water saturation of the soil, the state of the groundwater level, the degree of forestation, the way agricultural areas are cultivated, fires that destroy forest segments, anthropogenic factors (non-observance of regulations, irregular maintenance of riverbeds, unregulated watercourses), climate change and the like.
Frontal precipitation that lasts for several days is a critical problem. Flooding often occurs at the transition between winter and spring, when melting snow coincides with heavy spring rains. The coincidence of high water occurs when there is an increase in the height of the water level on both tributaries and the main watercourse at the same time, and then flooding can be inevitable.
In the flood protection and rescue system, preventive measures and immediate protection have an extremely important place. It is important to organize, prepare and implement, primarily, preventive protection measures, in order to reduce the risk of floods. And then there are operational measures and procedures, no less important, which make immediate preparations for the participation of forces and means in protection, with the aim of mitigating and eliminating the immediate consequences caused by floods. Flood defence facilities were built to protect populated areas, industrial plants and agricultural land. In the area of Valjevo these are: the reservoir "Gradac" on the River Gradac in Valjevo; "Kamenica" reservoir in Valjevska Kamenica; the "Pocibrava" reservoir in Petnica and the "Stubo-Rovni" reservoir, the construction and anti-erosion management of which reduced the risk of flash floods and localized them to the tributaries of the River Kolubara downstream of Valjevo [3].

3. CLIMATE CHANGES

Climate changes are changes that are mainly caused by human activity. Long-standing production and burning of coal, oil derivatives and natural gas has led to an increase in the concentration of gases in the atmosphere and consequences for the climate: extreme heat, extremely heavy rains, droughts, reduced yields in agriculture. All these things are connected with the increase in temperature on our planet [3].
Meteorological, and thus climatological research in the Valjevo region began in 1856, only 8 years after the establishment of the first meteorological station in Serbia. The geographically excellent area, together with the forest cover and the morphology of the soil contributed to these areas being conducive to people's life. The general geographical and climatic conditions of the Valjevo region

are affected by the proximity of the vast Pannonian Basin and the transition from plain to hilly-mountainous areas, with a certain degree of continentality. The climate of the Valjevo region can be characterized as moderate-continental. The average air pressure in Valjevo is about 998 mb. Changes in air pressure are significantly greater in winter than in summer. The coldest month is January, and the warmest is July and August. In the area of Valjevo, the average annual amount of sunshine is 198.9 hours, with the sunniest month being July (281.8 hours) and the cloudiest month being December (68.6 hours). Precipitation in the Valjevo region has the characteristics of the Central European, Danube regime of annual distribution. The average annual rainfall in Valjevo is 785.7 mm; the rainiest month is June with 100.1 mm, and the driest is February with 45.9 mm [4].

3.1. Reporting on the state of the environment

On the territory of the city of Valjevo, monitoring of air quality, communal noise level, and soil quality is carried out, and the results are submitted to the Environmental Protection Agency, as defined in Article 73 of the Law of Environmental Protection. Actual city administration of Valjevo, within its internet presentation, has a page on which there are only some of the reports on quality and measurements in the environment. Certainly, this page should be more up-to-date and dedicated to all reports and relevant information related to the state of the environment in the territory of Valjevo. This primarily refers to the local register of pollutants, reports on air quality and the results of noise level measurements in the environment. In this way, the public would be provided with access to information relevant to the state of the environment, together with the results obtained from monitoring [4].

3.2. Survey: The impact of accumulation on the climate in the city of Valjevo

A mini-survey analyzed the opinion of the residents of the city of Valjevo and their subjective feeling about the climate in Valjevo after filling the reservoir, and the idea came from very loud stories about the current topic, although no official document recognized the citizens' appeals.
The survey is composed of 13 questions for which possible answers are offered (I completely agree, I agree, I neither agree nor disagree - I am undecided, I do not agree, I do not agree at all), all in order to facilitate data processing, displaying the processed data and making a conclusion (Table 1 and Table 2).
As it was mandatory to indicate the place of residence as a very important factor of analysis in the survey, the respondents were divided into two groups:

- 1st group: city center, new settlement (lowest points of the city),
- 2nd group: settlements at a higher altitude (from 190m and above).

Only respondents over the age of 25 were included. 49 respondents were surveyed, of which 34 lived in the lowest part of the city and 15 lived in the settlements located in the higher parts.

Table 1. Answers from respondents who live in the lowest parts of Valjevo (City Center, Novo naselje)

Number of Statements/ Questions	Statements/Questions	Answers				
		I totally agree	I agree	I neither agree nor disagree - I'm undecided	I do not agree	I don't agree at all
1.	The climate has changed in the city of Valjevo in the last 10 years	24 (71%)	7 (20%)	3 (9%)	(0%)	(0%)
2.	The air is too polluted	27 (79%)	4 (12%)	3 (9%)	(0%)	(0%)
3.	The biggest source of pollution is traffic	4 (12%)	10 (29%)	5 (15%)	15 (44%)	(0%)
4.	The biggest source of pollution is industry	(0%)	2 (6%)	5 (15%)	15 (44%)	12 (35%)

5.	The biggest source of pollution is the heating plant and individual fireplaces	2 (6%)	2 (6%)	3 (9%)	7 (20%)	20 (59%)
6.	Climate change was largely influenced by the reservoir "Rovni"	20 (59%)	13 (38%)	1 (3%)	(0%)	(0%)
7.	The "Rovni" dam closed the wind rose	30 (88%)	3 (9%)	1 (3%)	(0%)	(0%)
8.	Due to the accumulation, excessive air humidity appeared in the city	30 (88%)	3 (9%)	1 (3%)	(0%)	(0%)
9.	Due to the accumulation, the appearance of fog in the city has become an everyday occurrence	20 (59%)	13 (38%)	1 (3%)	(0%)	(0%)
10.	The air smells of soot	10 (29%)	9 (26%)	5 (15%)	8 (24%)	2 (6%)
11.	Too many people complain of health problems due to air pollution	22 (64%)	4 (12%)	5 (15%)	2 (6%)	1 (3%)
12.	The appearance of wind in the city has become a very rare occurrence	30 (88%)	3 (9%)	1 (3%)	(0%)	(0%)
13.	If I had the opportunity, I would move to another city	3 (9%)	4 (13%)	10 (29%)	4 (13%)	13 (37%)

Table 2. Answers from respondents who live in the lowest parts of Valjevo (settlements Sedlari, Peti puk, Popare, etc.)

Number of Statements/ Questions	Statements/Questions	Answers				
		I totally agree	I agree	I neither agree nor disagree - I'm undecided	I do not agree	I don't agree at all
1.	The climate has changed in the city of Valjevo in the last 10 years	11 (73%)	3 (20%)	1 (7%)	(0%)	(0%)
2.	The air is too polluted	9 (60%)	5 (33%)	1 (7%)	(0%)	(0%)
3.	The biggest source of pollution is traffic	3 (20%)	5 (33%)	1 (7%)	6 (40%)	(0%)
4.	The biggest source of pollution is industry	(0%)	(0%)	3 (20%)	12 (80%)	(0%)
5.	The biggest source of pollution is the heating plant and individual fireplaces	(0%)	2 (13%)	3 (20%)	10 (67%)	(0%)
6.	Climate change was largely influenced by the reservoir "Rovni"	11 (73%)	3 (20%)	1 (7%)	(0%)	(0%)
7.	The "Rovni" dam closed the wind rose	12 (80%)	2 (13%)	1 (7%)	(0%)	(0%)
8.	Due to the accumulation, excessive air humidity appeared in the city	7 (46%)	3 (20%)	1 (7%)	4 (27%)	(0%)
9.	Due to the accumulation, the appearance of fog in the city has become an everyday occurrence	11 (73%)	3 (20%)	1 (7%)	(0%)	(0%)
10.	The air smells of soot	9 (60%)	2 (13%)	1 (7%)	3 (20%)	(0%)
11.	Too many people complain of health problems due to air pollution	13 (87%)	2 (13%)	(0%)	(0%)	(0%)
12.	The appearance of wind in the city has become a very rare occurrence	5 (33%)	1 (7%)	9 (60%)	(0%)	(0%)
13.	If I had the opportunity, I would move to another city	(0%)	(0%)	(0%)	1 (7%)	14 (93%)

4. CONCLUSION

This analysis is based on a very small sample considering the number of inhabitants, but as it showed that the citizens of the city of Valjevo in a huge percentage confirmed that the climate change occurred after the filling of the “Stubo-Rovni” reservoir, it could be the basis for some future research. It is interesting, even if they are not in the same degree of danger, that the citizens from higher altitudes are also of the same opinion as their fellow citizens in the valley.

Over 80% of citizens of both the first and second groups confirmed that the “Stubo-Rovni” dam closed the rose of winds. As the city of Valjevo is located in a valley, surrounded by mountains, it was the only place where favorite “northerner” wind came from in already endangered city, considering its geographical position. In the city itself, low ozone was created, in which, as the air humidity increased, all the pollution remained, which caused an increased number of asthmatics and other respiratory diseases, but that's what it will be about in one of the future papers.

So, as “Stubo-Rovni” dam, which its creators are proud of, went up, so did the excesses of air pollution grow until they exceeded all limits and at some point even placed our city in the first place as the most polluted in Europe, especially during the heating season when the industrial facilities and the huge increase in traffic are joined by the heating plant and individual fire pits. The dam, 75 meters high, got in the way of air currents and thus prevented the natural ventilation of the city. After listening to many experts, and due to the need to produce this paper, the conclusion is that the function of the dam can be, in a positive sense, almost the only regulation of flood and drought waves, which raises the question, did it really have to be of such dimensions and is the prevention of one type eventual catastrophes worth causing a series of others, very possibly with far greater consequences.

APPLICATION OF 3D RANDOM E-GLASS FIBER COMPOSITES IN CONSTRUCTION HARDHAT DESIGN

Marta Trninić[1], The Academy of Applied Technical Studies Belgrade

Abstract: *The present paper investigates the potential use of 3D random fibers in the construction of industrial hardhats. The composite system investigated was based on e-glass chopped fibers in the epoxy matrix randomly distributed. This composite system has been of primer interest since the composites intrinsically have better mechanical characteristics than regular polymers (such as HDPE – high-density Poly ethylene) regularly used in hardhat production. Based on applicable standards (EN 397 1995 – Industrial safety helmets), the shock absorption test (section 6.6, EN 397 standard) was simulated using the FEA approach for hardhats made of regular HDPE and E-glass chopped fibers (3D randomly dispersed) in an epoxy matrix. It was found that hardhats made of 3D random fiber e-glass composites in an epoxy matrix, for the fiber volume fraction that renders the equivalent strain field for the same impact energy can withstand higher stresses and improve the strength of the hardhat analyzed.*
Keywords: hardhats, safety, design, composite

1. INTRODUCTION

Construction hardhats, often simply referred to as "hardhats", are essential personal protective equipment (PPE) designed to safeguard the heads of workers in construction and related industries. Their primary function is to provide protection against potential hazards such as falling objects, impact from structural elements, electrical shock, and other workplace dangers. These rugged and purpose-built helmets have become an iconic symbol of safety on construction sites worldwide.
Incorporating advanced materials and ergonomic designs, modern hard hats offer a balance of durability, comfort, and functionality. They are engineered to meet stringent safety standards, ensuring that workers can perform their tasks with confidence and reduce the risk of head-related injuries. This introduction delves into the key components, material considerations, safety standards, and crucial design features that make construction hard hats an indispensable piece of protective equipment in the construction industry.
Construction hardhats, often colloquially referred to as "hardhats," stand as a stalwart shield against potential hazards on construction sites. These critical pieces of personal protective equipment (PPE) are purpose-built to safeguard the heads of workers, providing a vital layer of defense against falling debris, impact from structural elements, electrical hazards, and a range of other potential dangers prevalent in construction and related industries. As an iconic symbol of safety in workplaces worldwide, hardhats represent a commitment to the well-being of workers in environments where risks are inherent.
The history of hard hats is a testament to the evolving understanding of workplace safety. Early iterations were rudimentary, often consisting of leather headgear. It wasn't until the 20th century that more advanced materials and designs were introduced. The transition to materials like steel, followed by the development of fiberglass, and subsequently, high-density polyethylene (HDPE), marked significant milestones in the evolution of hardhat technology.

[1]mtrninic@atssb.edu.rs

The Key Components of a Construction Hardhat:

1. Shell

The outer shell of a construction hard is its first line of defense. Typically constructed from materials like high-density polyethylene (HDPE), fiberglass, or other advanced composites, the shell is engineered to distribute and absorb the force of impacts. Its robust design ensures that even in the event of a falling object or collision with a structural element, the force is dispersed across the surface, reducing the risk of injury to the wearer.

2. Suspension System

The suspension system is the internal harness that cradles the head and helps absorb and spread the force of an impact. It is designed to maintain a gap between the shell and the wearer's head, allowing for shock absorption and ventilation. Made of materials like nylon or high-impact thermoplastics, the suspension system is adjustable to ensure a secure and comfortable fit for individuals with varying head sizes and shapes.

3. Chin Strap (if applicable)

In environments where additional security is crucial, such as working at heights or in windy conditions, some hard hats include a chin strap. This accessory helps ensure that the hardhat remains securely in place, even during dynamic movements or adverse weather conditions.

A typical hardhat and its components are presented in the following picture:

Figure 1. Construction Hardhat
Source: Mooremcphee

Materials used in the construction of the hardhats nowadays are:

1. High-Density Polyethylene (HDPE)

HDPE is a popular material choice for hardhat shells due to its exceptional strength-to-weight ratio. Its high impact resistance makes it well-suited for protecting against falling objects and structural hazards. Additionally, HDPE's resistance to chemicals and UV radiation ensures the hardhat's durability, even in harsh environmental conditions.

2. Fiberglass Composites

Fiberglass composites offer a unique combination of strength, rigidity, and durability. They are often used in hardhat shells, providing robust protection against impacts. The composite nature of fiberglass allows for intricate designs while maintaining structural integrity.

3. Thermoplastic Resins

Certain hardhats incorporate high-impact thermoplastic resins in their construction. These materials provide flexibility and resistance to deformation, ensuring that the hardhat can absorb and distribute forces effectively.

To ensure the efficacy of construction hardhats, regulatory bodies like the American National Standards Institute (ANSI) and the European Committee for Standardization (CEN) have established rigorous safety standards. Compliance with these standards is paramount, as it guarantees that the hard meets specific criteria for impact resistance, electrical insulation, penetration resistance, and other critical safety parameters.

The standard for impact testing of hardhats varies depending on the region or country. Here are some of the most commonly recognized standards for impact testing of hardhats:

1. ANSI/ISEA Z89.1 (USA)

This standard is set by the American National Standards Institute (ANSI) and the International Safety Equipment Association (ISEA). ANSI/ISEA Z89.1 establishes requirements for the performance, testing, and marking of protective helmets, including hard hats, in the United States [1].

2. EN 397 (Europe)

This standard is applicable in European countries (also in Serbia as SRPS EN 397:2014). EN 397 outlines the requirements and testing methods for industrial safety helmets, including impact resistance, penetration resistance, and lateral rigidity [2,3].

3. AS/NZS 1801 (Australia and New Zealand)

This standard is applicable in Australia and New Zealand. AS/NZS 1801 specifies the requirements for industrial protective helmets, including impact testing, penetration resistance, and electrical resistance.

4. CSA Z94.1 (Canada)

The Canadian Standards Association (CSA) sets standards for various personal protective equipment, including head protection. The CSA Z94.1 standard covers requirements for protective headwear, including impact resistance.

5. JIS T 8131 (Japan)

The Japanese Industrial Standards (JIS) specify the performance and testing requirements for industrial safety helmets in Japan.

These standards typically include specific procedures and criteria for conducting impact tests on hard hats. They specify factors such as the size and weight of the impacting object, the height from which it is dropped, and the pass/fail criteria based on the amount of force transmitted to a head from inside the helmet.

It's important for manufacturers, employers, and workers to ensure that the hard hats used on the job site comply with the relevant local standards and regulations. Regular inspection and maintenance of hard hats are also essential to ensure they remain effective in providing protection. Additionally, hard hats should be replaced if they show signs of damage or have been involved in a significant impact.

In this paper potential use of 3D random fiber composites, in hardhat design is investigated, complying with the above-mentioned standards in order to improve workers' safety.

2. 3D RANDOM FIBER COMPOSITE MATERIAL ANALYSIS

3D E-glass random fiber composites (Figure 2) refer to materials that are formed by embedding randomly oriented E-glass fibers within a matrix material. E-glass is a type of glass fiber known for its high electrical resistance, good chemical resistance, and high tensile strength. It is commonly used as a reinforcing material in composite structures due to its excellent mechanical properties. In 3D E-glass random fiber composites, the E-glass fibers are arranged in a random orientation within the composite material. This means that the fibers are distributed in multiple directions, providing reinforcement throughout the material (3D).

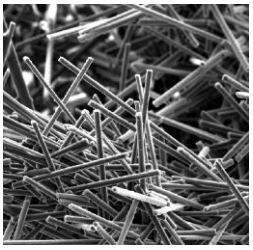

Figure 2. 3D random fibers SEM micrograph

Source: Markforged

A composite material is a combination of two or more distinct materials that, when combined, result in a material with improved properties compared to the individual components. In this case, E-glass fibers act as the reinforcing material, while another material (usually a polymer resin) serves as the

matrix that holds the fibers together. The term "3D" indicates that the E-glass fibers are distributed in three dimensions within the composite material. This means that the fibers are oriented not only along the length and width of the material but also in the thickness direction.
Overall, 3D E-glass random fiber composites are engineered materials designed to take advantage of the high strength and stiffness of E-glass fibers. The random fiber orientation provides reinforcement in multiple directions, leading to a material with enhanced mechanical properties.
Using the Finite Element Approach, the impact response as per EN 397 is performed. Material elastic coefficients required for the analysis are determined, as a function of the fiber type, matrix phase type, and the fiber volume fraction. When designing with composites it is always challenging to select the appropriate material theory for the problem in hand (composites are considered to be anisotropic) and correctly calculate material elastic coefficients (such as Young's moduli, Shear moduli, Poison ratios etc.) [5,6,7].
Several theories predict behaviour of 2D and 3D random fiber polymer composites. Assuming isotropic properties of repair material Pan's theory can be used to determine elastic parameters of 3D random fiber polymer material.
Defining a relationship between the fiber volume fraction V_f and the fiber area function A_f when fibers are not unidirectionally aligned and introducing probability density function defined by a pair of angles (Θ,Φ) in the spatial curvilinear coordinate system, the composite modulus can be expressed as (1):

$$E_c(\Theta,\Phi) = E_f \cdot \Omega(\Theta,\Phi) \cdot V_f + E_m \cdot (1 - \Omega(\Theta,\Phi) \cdot V_f) \tag{1}$$

In the preceding equation E_c is the modulus of the composite, E_f and E_m are moduli of constituents (fibers and matrix) respectively, V_f is fiber volume fraction and $\Omega(\Theta,\Phi)$ is the value of the probability density function in direction (Θ,Φ). In the case of three-dimensional random fiber orientation, the tensile modulus is given by:

$$E_c^{3D} = E_f \frac{V_f}{2\pi} + E_m(1 - \frac{V_f}{2\pi}) \tag{2}$$

and, the Poisson's ratio by the equation:

$$E_c^{3D} = E_f \frac{V_f}{2\pi} + E_m(1 - \frac{V_f}{2\pi}) \tag{3}$$

In equations (2 and 3) E_f and E_m are moduli of elasticity of fibers and matrix, and V_f, V_m are their Poisson's ratios. Using This approach, the elastic coefficients Can be determined, provided that the mechanical characteristics of the composite phases are known and the fiber and matrix volume fractions respectively.
In the present analysis for the materials coefficient's calculation the numerical approach for elastic coefficients calculation is deployed and is based on the lattice model [4]. The representative volume element (RVE) of 3D random fiber (E-glass/epoxy matrix) is presented in the following picture.

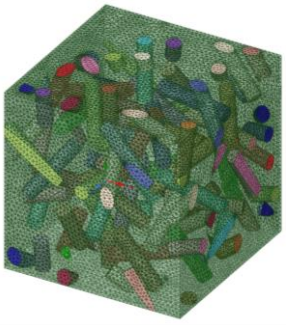

Figure 3. RVE model of 3D random fiber composite
Source: Fraunhofer

The obtained results for the material elastic coefficients are presented in the following table.

Table 1. Random fiber composite (e-glass / epoxy) with Vf=0.12 [-]

E1	5279.5	MPa
E2	5263.4	MPa
E3	5090.7	MPa
G12	1905	MPa
G23	1924.7	MPa
G31	1878.7	MPa
nu12	0.32249	
nu13	0.33662	
nu23	0.34352	

It can be seen that the material analyzed can be considered as quasi-isotopic, and these values are used in the further impact analysis.

3. IMPACT ANALYSIS

Based on the finite element approach, with respect to EN 397 standard, sec 6.6 the drop test on the hard hat top is simulated, and the results of the obtained stress-strain field are analyzed. Stress fields for the two identical hardhats (in the geometry domain) but made of different materials (HDPE and 3D random fiber composite e-glass /epoxy) are calculated and compared in order to justify to potential use of the composites (3D random) in the hard hat design. The finite element model, with the obtained stress field is presented in the following picture.

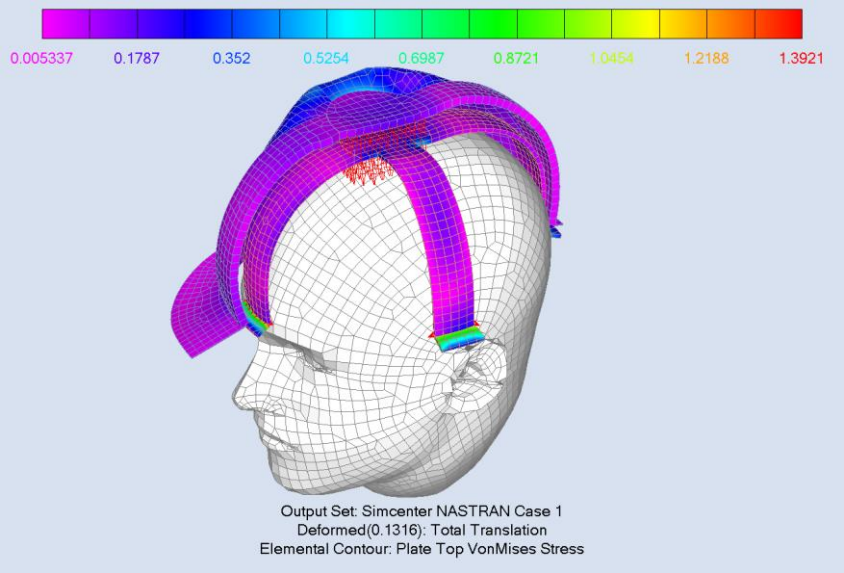

Figure 4. Hardhat Impact test FEA model stress-strain field

4. CONCLUSION

In the present paper potential use of composites in a 3D chopped fiber form is analyzed. Based on the standards applicable the impact test is simulated and the stress-strain fields for hardhats made of HDPE and 3D random fiber composites are compared.
It is found that for the volume fraction of e-glass fibers in an epoxy matrix that renders the same strain field as in HDPE material hardhat can absorb more energy before hardhat break (withstand higher impact loads), which makes the composite hardhats safer. Composites have the potential to withstand

higher impact loads than HDPE (high-density polyethylene) due to their unique material composition and hence represent good material candidates for construction hardhat design.
The recommendation for future work is to analyze other commercially available fibers, such as S-glass, and different carbon fibers, and to assess their potential use in hardhat application. Also, the impact analysis should be performed for the side and back impact.

This research was supported by the Aeroelasticity Laboratory of the University of Belgrade Faculty of Mechanical Engineering.

COST-BENEFIT ANALYSIS IN EMPLOYEE HEALTH AND SAFETY PROTECTION

Drago Pupavac[1], Polytechnic of Rijeka
Ljudevit Krpan[2], University of North
Josip Knežević[3], Croatian Railways Infrastructure, d.o.o.

Abstract: *Cost-benefit analysis is becoming increasingly relevant in decision-making processes about the justification of investments in programs to lower the risk of disease and injury at work. Thus, the cost approach to risk reduction program investments is replaced by the investment method, and the financial approach to human resource management is replaced by the development approach. Employee health and safety are prioritized in the development strategy, making employees more satisfied, productive, and dedicated to their work and the organization in which they work. The research findings are based on an examination of a practical example using the net present value and simulation methods. All computations and simulations were carried out in an MS Excel spreadsheet.*
Keywords: Cost-benefit analysis, Net present value, Employees, Health and safety

1. INTRODUCTION

People work in complex organizational systems that are not fundamentally secure. People are the ones who create security, unlike organizational systems that put other, very often contradictory demands and expectations before them. Accidents at work can also happen in companies that are dedicated to occupational safety as much as possible. Accidents can cause injuries or injuries with minor or serious consequences. They also cause material losses due to downtime in production, and damage to work equipment or materials. Work-related injuries, illnesses, and deaths result in high economic costs for individuals, employers, government, and society. The negative effects of poor occupational health and safety management include costly early retirement, loss of skilled staff, absenteeism, and "presenteeism" (when employees come to work despite illness, thereby increasing the likelihood of errors), and high medical costs and insurance premiums. It is estimated that the social cost of work-related injuries and illnesses is 3.9% of global GDP and 3.3% of EU GDP, or at least 476 billion € every year [1].
Despite this, practice shows that the top management of numerous companies usually sees investments in the safety and health of employees as an additional cost, not as a benefit. Accordingly, the hypothesis of this paper was also set: The application of cost-benefit analysis in the evaluation of employee health and safety protection programs highlights the development of a more financial approach to human resource management. In order to prove the hypothesis, the results of the research are based on the implementation of a cost-benefit analysis on a practical example using the method of determining the net present value. Solving the problem will be presented not only mathematically, but also using an MS Excel spreadsheet.

[3]Josip.Knezevic3@hzinfra.hr

2. THEORETICAL BACKGROUND AND RESEARCH PROBLEM

Cost-benefit analysis is widely used in assessing the expediency of investments. The focus of this method is on the assessment of costs and benefits in the near and distant future. When it comes to financial investments in the protection of health and safety at work, the prevailing opinion is that such investments do not result in adequate financial returns. This leads to minimal, legally prescribed investments in the protection of the health and safety of employees and neglect of the health and safety function within the company. With a forensic approach to monitoring costs that arise as a result of accidents at work and related injuries, downtime in business, court costs, compensation, fines, etc., management can see the financial interest in investing in preventing their occurrence [2]. The necessity of a forensic approach is also confirmed by the fact that the indirect (hidden) costs of accidents at work can be up to 36 times higher than the direct (visible) costs. Direct costs are those costs that can be directly attributed to accidents at work and related injuries and deaths (costs of paid insurance, costs of damage to buildings, equipment, and vehicles, production losses, investigation costs, medical care costs, legal costs, death compensation costs, costs of permanent disability). Indirect costs refer to costs that are not covered by insurance and are less tangible costs [3]. They can be classified as costs arising from the diversion of time to deal with the consequences of an accident, which can also affect productivity, and they include: cleanup of the accident site, costs of hiring temporary equipment, waste disposal, temporary work, costs of consulting and hiring external experts, lost working time, sick pay, overtime and temporary work, and loss of business reputation [4,5,6,7,8].

Here, it seems appropriate to point out the division into corrective and preventive costs. Corrective costs are the result of accidents that have already occurred and their impact on the health and safety of employees and include the costs of wages during sick leave, overtime costs due to the compensation of injured workers, fines and compensation resulting from reduced productivity, costs of turnover, absenteeism, etc. Preventive costs are aimed at preventing accidents at work and worker illnesses and include investments in the safety of working conditions, protective equipment, education, preventive health examinations, etc. Management is most often focused on preventive costs, i.e. their minimization. Such an approach is especially pronounced in times of crisis. Therefore, the task of occupational health and safety experts is to convince management that higher preventive costs mean lower corrective costs, that is, that investments in programs to reduce the risk of accidents at work will result in greater benefits.

The benefits of managing employee health and safety can also be direct and indirect. Direct benefits of health and safety management include cost savings. Additional savings beyond accident costs include time savings, medical care costs, and possible reductions in accident costs as a result of improvements. Direct benefits include: reduction in insurance premiums; reducing litigation costs; reduction of sick leave costs; improving the rate of production and productivity and reducing the rate of accidents reducing material damage [5]. Indirect benefits include reduced absenteeism, improved corporate image, improved job satisfaction, reduced sick pay, less lost time, less overtime, and cleaning. Accordingly, occupational health and safety professionals must learn to speak a language understandable to management, which is the language of money. When it comes to protecting the health and safety of employees at work, it seems appropriate to point out that in recent times risk assessment is usually accompanied by a cost-benefit analysis. The task of such an approach is to evaluate all costs and benefits of control and risk reduction (cf. figure 1).

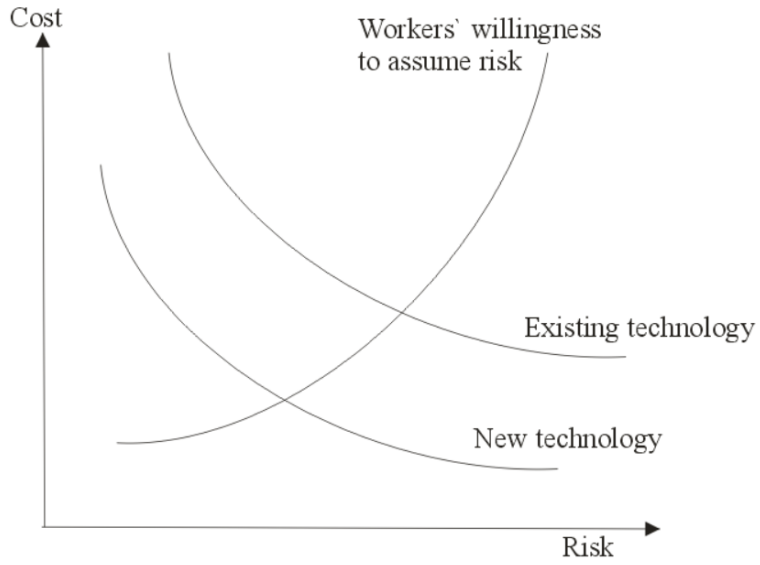

Figure 1. The impact of new technology on risk and health and safety costs
Source: authors` prepared according [9]

On the basis of Figure 1, it is clear that technological progress continuously contributes to the reduction of risks and the reduction of the total costs of protecting the health and safety of employees. Costs can refer to investment costs, maintenance costs, and training costs, while benefits can refer to reduced insurance premiums, higher work productivity, and better product quality. The rate of return on funds invested in risk reduction (except for the smallest ones) is usually estimated over a period of two to five years. Although the benefits are often very difficult to quantify, a cost-benefit analysis is helpful to estimate a certain level of costs with the aim of reducing potential risk.

3. MATHEMAICAL MODEL

When evaluating investment projects, and applying cost-benefit analysis, it is possible to use a number of methods, namely: the net present value method, the internal rate of return method, the benefit-cost ratio method, and the investment payback method. In this paper, the emphasis is on the method of determining the net present value. In this paper, the emphasis is on the method of determining the net present value. The mathematical model for conducting a cost-benefit analysis using the method of determining the net present value derives from the following relationship [10]:

$$\text{NPV} = \frac{B_0 - C_0}{(1+i)^0} + \frac{B_1 - C_1}{(1+i)^1} + \frac{B_2 - C_2}{(1+i)^2} + \frac{B_3 - C_3}{(1+i)^3} + \ldots + \frac{Bn - Cn}{(1+i)^n} \quad (1)$$

That is

$$\text{NPV} = \sum_{n=0}^{t} \frac{B_0 - C_0}{(1+i)^0} \text{ whit condition that NPV} \geq 0 \quad (2)$$

Where are:
NPV – net present value
B - benefits
C – costs
i – discount rate
n – number of years of project duration, from 0 to t
The alternative project or program that provides the maximum possible ratio of NPV ≥ 0, i.e. that provides the highest net present value, is acceptable.

4. DATA AND RESEARCH METHODOLOGY

For the purposes of this scientific discussion, the following practical example is presented. An employee health and safety specialist developed a three-year workplace risk reduction program at his company. It is a new technological procedure that will result in a reduction of the risk level from medium to low. The implementation of the risk reduction program requires initial costs in the amount of €30,000. After the first year, the costs of occupational safety management will be €6,000 higher. However, due to the reduction of the level, there will be a significant reduction in the number of accidents and accidents at work, the new management system will enable annual savings in the amount of €18,500. All amounts are given in current values. Table 1 provides an overview of the cash flow needed to perform a cost-benefit analysis.

Table 1. Overview of the expected cash flow of the proposed occupational health and safety program

Year	0	1	2	3
Estimated cash flow	0	18500	18500	18500
Estimated cash outflow	30000	6000	6000	6000
Estimated net cash flow	-30000	12500	12500	12500

Since the emphasis in this paper is on the method of determining the net present value, it seems appropriate to point out that future flows are discounted using the discount rate, i.e. reduced to the present value (e.g. at a discount rate of 8%, 100,000 € in 20 years is worth the current 21,454 .82 €). The discount rate can be seen as the rate of return required by the investor.

5. RESEARCH RESULT AND DISCUSION

Using the data from Table 1, based on equations (1) and (2), the net present value of the proposed risk reduction program for the workplace was calculated, assuming that the cost of capital (discount rate) is 10%. Such a high discount rate is a consequence of inflationary threats.

Table 2. Calculation of NPV of the proposed risk reduction program for the workplace (€)

Year	0	1	2	3
Estimated cash flow	0	18500	18500	18500
Estimated cash outflow	30000	6000	6000	6000
Estimated net cash flow	-30000	12500	12500	12500
Present value 1 €	1	0,9091	0,8264	0,7513
Present value = future value × p	-30000	11363,75	10330	9391,25
Net present value of the proposed program	-30000	-18636,3	-8306,25	1085

The net present value is greater than zero (€1085), which implies the justification of investment in reducing the estimated risk. The same result can be obtained much faster and more simply by using the MS Excel spreadsheet, that is, by applying the NPV formula in the spreadsheet (cf. Figure 2).

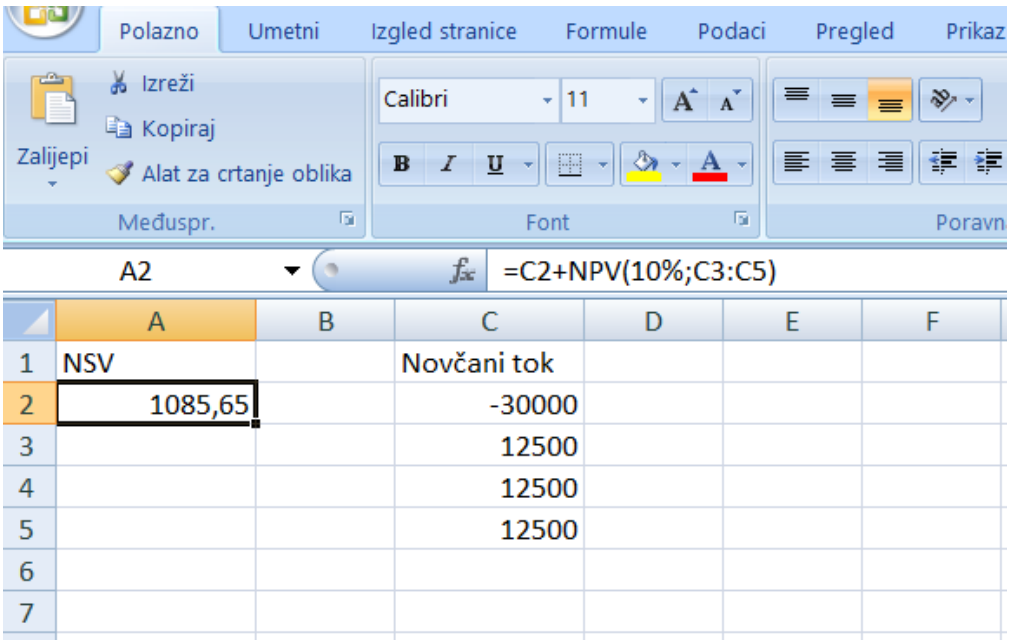

Figure 2. Calculation of NPV using a spreadsheet (in €)

Based on the data from Figure 2, it is clear that first in the address string C2:C5 the data on the predicted cash flow is entered, and then in the address field A2 the appropriate formula for calculating the net present value of the proposed investment (=C2+NPV(10%;C3:C5)). After the formula is entered and the enter key is pressed in the address field A2, the net present value of the proposed risk reduction program (€1085.65) will appear. This simple simulation model also enables numerous "what-if" answers. For example, if it starts from the assumption that investments in the risk reduction program should amount to €32,000 with an unchanged inflow and outflow of money in the three-year period, then the proposed investment would not be economically justified (cf. Figure 3).

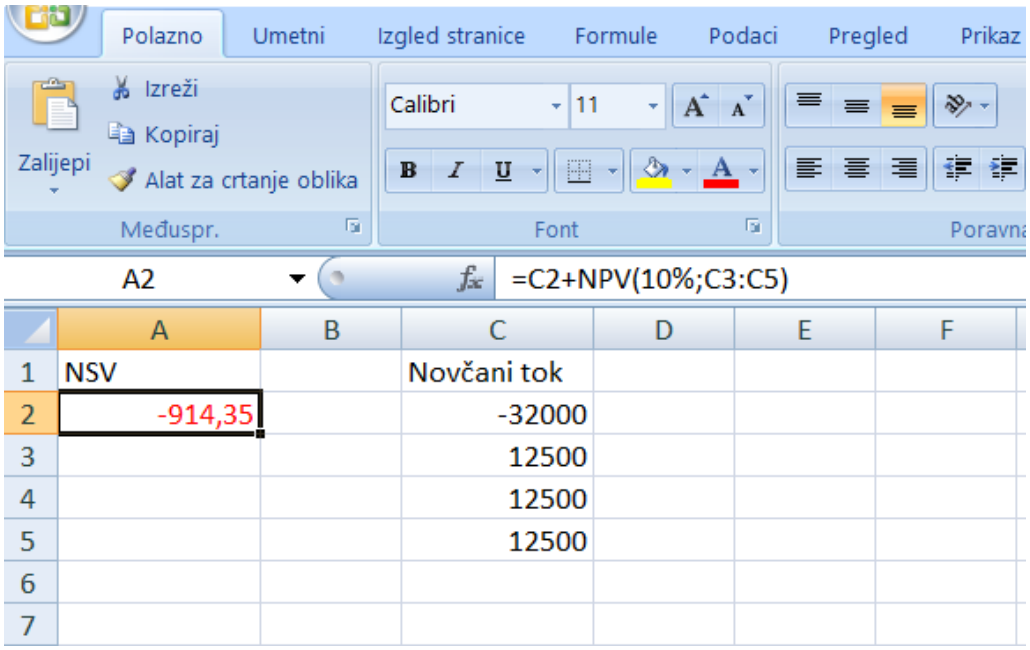

Figure 3. Calculation of NPV under modified investment conditions (in €)

Likewise, if due to high inflation it would be necessary to raise the discount rate to 13%, the investment would result in a negative NPV (-€485.59) and would not be economically justified. All lower discount rates of 13% result in a positive NPV and economic justification of the investment.

6. CONCLUSION

Cost-benefit analysis is increasingly used when assessing the justification of investment projects that aim to reduce risks in the function of protecting the health and safety of employees. Very often, these are investments that bring effects not only for employees and shareholders but also for customers, the environment, and society as a whole. Evaluation of the profitability of projects aimed at reducing risk is an indispensable tool for employees' health and safety protection experts in order to clearly present the economic profitability of such programs to company management. The net present value method represents one of the best approaches to the valuation of individual projects. The paper also demonstrated the effectiveness of the application of the spreadsheet in calculating the net present value and selecting economically justified projects with the aim of reducing risks in the function of protecting the health and safety of employees.

CENTRALIZED INFORMATION SYSTEM FOR MONITORING WORKPLACE INJURIES

Svetozar Sofijanić[1], The Academy of Applied Technical Studies Belgrade
Vladan Pantović[2], Faculty of Information Technology and Engineering
Veljko Ognjanović[3], Syneos Health

Abstract: *This paper aims to point to the necessity of introducing a centralized information system in the Republic of Serbia for the software monitoring and analysis of workplace injuries as key indicators of the state of safety and health at work, and to explain the significance of the efficient management of a unique register of workplace injuries, in order to systemattoically act and indicate the necessary amendments to the current Law on safety and health at work. The adequate application of information technologies will enable more efficient risk management in the field of health and safety of employees, a quality analysis of the situation in the subject area with an emphasis on reducing the number of workplace injuries and an up-to-date status at all times, which would more effectively influence legal regulations, that is one of the priorities of the Republic of Serbia in its effort to raise safety and health at work to a higher level.*
Keywords: Safety & health at work, information technologies, software analysis, workplace injuries

1. INTRODUCTION

On 28 April 2023, the International day of safety and health at work, The National Assembly of the Republic of Serbia adopted a new Law on safety and health at work [1] (hereinafter: Law on SHW), which provides numerous changes to the previously defined terms of which we highlight the following below:

- The definition of workplace was changed and it now includes tasks the employee conducts in a working environment in which he/she is residing or has access to during work and which is under the direct or indirect control of the employer.
- The definitions of working from home, as well as work that an employee conducts using information and communication technologies from the place of residence and remote work conducted from another space that is not the residence of the employee, nor a space under the direct control of the employer, were included.
- Terms such as consultant for safety and health at work and associate for safety and health at work, instead of the term person in charge of safety and health at work, were introduced.
- A new term, the Register of workplace injuries as a centralized, electronically-managed database on workplace injuries, which is maintained based on the reports of workplace injuries, was introduced.

The need to introduce a new law after 18 years arose as a result of the changed working conditions. Although the old law partly encompassed working in a different environment, the COVID-19 situation resulted in the need to include working from home and remote work in the new law. The

[1] ssofijanic@atssb.edu.rs
[2] vladan@pantovic.rs
[3] veljko.ognjanovic@gmail.com

law provides the obligation of employers to conduct risk assessments and prescribe the measures for safe and healthy work from home and remote work.
Considering that the new Law on SHW has been in force since 7 May 2023, and taking into account that employers have a two-year deadline to align with the same, there is an obligation to align certain provisions immediately and before all the by-laws are adopted.
The by-laws adopted based on the old law continue to be applied until the passing of the by-laws provided for by this law, which will be passed within 18 months from the day the law came into force. This means that legal continuity has been established between the old and new laws.
Issues in the application of the law previously in force which business entities usually pointed to were reflected in, among others, the implementation of the risk assessment procedure and bringing an act on risk assessment, concluding the agreement on common implementation of safety and health measures at the workplace when several employers share a workspace, the inadequate transmission of the provisions of Directive 89/391/EEC related to organizing safety and health tasks at the workplace, monitoring of employees' health status, informing in a timely manner and cooperation with employees with a view to realizing rights and conditions prescribed by the law [2].
In the last few years, numerous workplace injuries have been recorded, so this new law encompasses this segment as well. The conditions for conducting high-risk jobs are tightened, but responsibility and monetary fines for employees who do not respect safety rules are introduced as well. For the employer, employee training in the field of safety as well as determining the procedure and way a work license is issued are mandatory. Also, the employer is obliged to refer an employee, upon his/her request, for a doctor's checkup at regular intervals. The new law introduces a centralized register of workplace injuries, on which this paper will particularly focus.
The Register of workplace injuries is a centralized, electronically managed database on workplace injuries, which is managed based on reports on workplace injuries. The Register of workplace injuries (hereinafter: the Register) in electronic form is established and led by the Administration for workplace safety and health, with the technical support of the Government service, which is in charge of the designing, harmonizing, developing and functioning of the electronic management system, for the purposes of maintaining statistics on workplace injuries.
The Register contains correct and up-to-date information on workplace injuries and enables users of the data to perform tasks of entering and downloading the data in order to determine the facts necessary for realizing health insurance rights. The Register uses valid codes and classifications.
The data users, in line with their responsibilities, access and use the Register by authorizing access to the Register or by using the data from the Register through a software solution of data users at a service bus of the organ or through a data exchange system. However, what this specifically means what responsibilities users have while entering workplace injuries into the electronic Register which obligations the employer has and what problems employees may face, we will consider later in the paper.

2. EXPERIENCES FROM THE INTERNATIONAL ENVIRONMENT FROM THE POINT OF VIEW OF KEEPING SOFTWARE RECORDS OF WORKPLACE INJURIES

Workplace injury as a term is often mentioned and analyzed both in theory and in practice, but further is a reason for a large number of disputes between employers and employees, not only in Serbia, but abroad as well. Due to this, in this next part of the paper, we will try to further analyze all the relevant aspects of this topic with the intention of especially putting an emphasis on the necessity of the software monitoring of workplace injuries and thus facilitate understanding the implications which follow an incident such as a workplace injury, which would create a more favorable situation in society and thus manage workplace injury records more efficiently, which would later contribute to more precise analyses and suggesting more innovative protection measures.
The rulebook [3] which regulates the current creation and delivery process of workplace injury and occupational disease report form (hereinafter: Report) to the Administration for workplace safety and health was last amended in 2019. It defines that the employer fills out the Report in five copies, at the

latest within 24 hours from finding out that a workplace injury or an occupational disease occurred. After that, all five copies were delivered to the healthcare institution where the checkup was conducted, within 24 hours from the moment of recording the data at the latest. The healthcare institution has a deadline of two days upon reception to fill out the Report and return it to the employer the next day at the latest. Here we can observe the first discrepancy between practice and regulations, since often this part of the process takes significantly longer. The reasons are usually justifiable, since due to the doctors' shift work, it is not possible to fill out the report within two days. When the employer receives all the copies of the Report from the healthcare institution, he/she has two days to deliver them to the competent branch of the Republic fund for health insurance. In the branch, all five copies of the Report are verified, one copy is kept and the other four are returned to the employer. Here, a deadline during which the Report has to be verified and delivered to the employer is not defined. At the end, the employer keeps one copy of the Report, one is delivered to the employee, one to the competent branch of the Republic fund for pension and disability insurance and one to the Administration for workplace safety and health.

2.1 A review of the applied solutions of reports of workplace injuries and occupational diseases in the European Union

The national program for adopting the acquis communautaire of the European Union (hereinafter: EU), adopted on 21 July 2022 [4] has in Chapter 19 – Social policy and employment, defined Serbia's obligation to align with the EU in terms of safety and health at work.
By analyzing the available data on the ways solutions are applied for recording workplace injuries and occupational diseases in EU countries and countries that have a special alignment of their social protection system relationship with the EU [5], we conclude that most countries practice the use of some sort of information system for recording. Most of them have kept the possibility of sending documents electronically, via email. Some of the analyzed countries still leave the option of delivering the documents in paper form.
A few countries have left the possibility of recording workplace injuries and occupational diseases on the part of the employee himself/herself or the doctor who conducted the first checkup directly through the information system for recording.

2.2 Tort liability of the employer abroad

Based on article 100 of the Law on SHW, a fine of RSD 1.5 million to 2 million (between USD 13,500 and 18,100) for an employer as a legal entity and from RSD 50,000 to 150,000 (around between USD 450 and 1,400) for directors, i.e., other responsible individuals, is prescribed if the employer does not report a workplace injury or occupational disease to the competent inspection.
By analyzing the available data in EU countries and countries that have a special alignment of social protection systems relationship with the EU, these amounts are up to a maximum of EUR 50,000 (USD 53,000) (for not reporting more serious workplace injuries or occupational diseases). However, in most countries, the prescribed fines for this kind of violation are within the same range as in the Republic of Serbia.

3. DATA ANALYSIS AND DISCUSSION

The solutions applied in the EU, the disadvantages of the current Rulebook, the provisions of the Law on SHW but also the existing e-Administration system implemented in various spheres of administration can point us to the direction in which we should go concerning the information system which would enable us to monitor workplace injuries and occupational diseases.
Connecting all the subjects in the process would result in significant time savings, better transparency in the process itself with the possibility of controlling the efficiency of each participant, and above all, transferring the biggest part of the communication from the business entity to the state institutions.

Since, if we recall the current process, the employer creates the Report, takes it to the healthcare institution, and then to the competent branch of the Republic fund for health insurance and at the end delivers it to the competent branch of the Republic fund for pension and disability insurance and the Administration for workplace safety and health. The goal of the information system would be to transfer all these steps (after the report is delivered by the employer) to the digital sphere and optimize the processing time, but also contribute to a better analysis of the data itself.

4. SUGGESTION FOR SOFTWARE IMPLEMENTATION

A software solution for managing business processes in the area of workplace safety can have significant connections to healthcare information systems in Serbia, especially in the context of advancing integrated healthcare and better healthcare data management.
It is necessary to provide maximum mutual interoperability of the central safety and health at work and the central healthcare information system at the level of the Republic of Serbia:

- Centralized monitoring and reporting on workplace injuries and occupational diseases will enable a comprehensive review of the health status of employees and identify samples of injuries or diseases connected to certain work tasks or environments.
- Efficient management of employees' medical records, including information on checkups, diagnoses and therapies. This is important for monitoring employees' health status and providing the appropriate healthcare.
- Data analysis can help in identifyingthe the need for preventive measures with the aim of reducing workplace injuries and occupational diseases. Based on this data, plans and strategies for improving safety and health at work can be developed.
- Using this system can improve employee awareness and responsibility..
- Integration with systems for managing the workplace can facilitate monitoring and reporting on workplace safety and health risks.
- A comprehensive assessment of the efficiency of the applied safety and health at work measures through monitoring changes in the health status of employees and the reduction of injuries.

A software solution for managing business processes in the area of safety and health at work can significantly improve the work of the healthcare service in several ways:

- Automatization and digitalization of different aspects of safety and health at work, including monitoring and managing incidents, report preparation, planning trainings and inspections. This decreases the need for manual processes and paperwork
- Better monitoring and reporting of safety incidents, workplace injuries and occupational diseases, as well as generating detailed reports. This helps the healthcare service to better understand workplace safety and health risks and to take preventive measures.
- Managing training and development is of crucial importance for ensuring that employees, who are generally with an appropriate level of digital literacy [6], are familiar with safety and health procedures and that they adhere to the standards.
- Monitoring equipment and assets and personal protective equipment, as well as their regular maintenance. This helps ensure that the equipment is in good condition and reduces injury risk.
- A documentation management system can serve as a central system for managing all documents and regulations related to safety and health at work. This makes documentation more easily accessible, enables the faster updating of policies and procedures and provides all employees access to current information.
- Increased compatibility can help the healthcare service be in alignment with all legal and regulatory demands regarding safety and health at work and reduce the risk of fines.
- Analytics and performance improvement help identify areas that require improvement. Based on these analyses, the healthcare service can bring better informed decisions and implement safety and health at work improvement strategies.

- Better communication and cooperation between employees, management and safety and health at work experts enables a faster response to incidents and exchanging best practices.

Here are a few crucial principles for developing this type of IS:

- **User-Centric Approach**: The main principle of the development of any information system is that it has to satisfy the users' needs. This means including feedback from employees who will be using the system. By using the user experience (UX) design, the system needs to be intuitive, easy to use, and to support users in performing their everyday tasks.
- **Cooperation with safety and health at work experts**: This system needs to be developed in close cooperation with safety and health at work experts in order to ensure that it is suitable for specific needs and standards in the area of health and safety. This also includes cooperation with doctors and medical staff in order to provide the correct use of healthcare data management.
- **Enable complete transparency:** All users need to have a clear picture of how the system works, how data is collected, stored and processed, and how decisions are made. Transparency is key in the field of healthcare information systems due to the confidentiality of healthcare data.
- **Flexibility and adaptability:** IS needs to be flexible and adaptable to changes in legislation, procedures and users' specific needs. This includes the possibility of faster implementation and updating of the system in order to follow the changes in the field of safety and health at work.
- **Alignment with legislation and standards:** The system needs to be aligned with all existing laws and regulations related to data privacy protection, the security of the information and other relevant areas.
- **Maintaining data safety and privacy:** Data safety is crucial in healthcare information systems, especially in the field of safety and health at work where sensitive information is handled. The system has to have strong measures of cybersecurity in order to ensure all data is safe and protected from unauthorized access and abuse.
- **Continuous user training and support:** User training and technical support need to be provided in order to help users use all the advantages of the system and solve problems.
- **Evaluation and improvement:** Regular system evaluations need to be conducted in order to establish its efficiency and identify potential problems.

5. CONCLUSION

Based on article 69 of the Law on SHW, the data is entered into the Register by the employer. The Register takes the data from the integrated healthcare information system of the Republic of Serbia and the information system of the institution competent for health insurance. The employer, i.e., the competent authorized official of the employer who records the data in the Register, enters the data of the employer, i.e. the user employer or the natural person employer, of the injured individual, of the workplace injury, of the direct supervisor and of the witness. The employer is obliged to electronically deliver the data of the authorized official who conducts the data entry to the Administration for workplace safety and health. When the employer enters the data in the Register, the chosen doctor, through the integrated healthcare information system of the Republic of Serbia, enters the findings and the opinions of the doctor who conducted the first checkup of the injured. After the chosen doctor enters the data, the organization competent for health insurance, through the information system, enters the workplace injury assessment. The Administration for workplace safety and health keeps a record of the authorized official. According to the aforementioned, the question of implementing mandatory integrated training of all the aforementioned persons with the aim of efficiently conducting the defined process is raised.

Based on Article 70 of the Law on SHW, data exchange is conducted in line with the regulations governing electronic administration. The employer, chosen doctor and organization competent for health insurance are responsible for the accuracy of the entered and downloaded data in the Register.

Enabling access and data access protection measures in the Register are conducted in line with the regulations governing the field of electronic administration, electronic identification and information security. The Register is located in the State center for data storage and management which secures the physical protection of the data in line with the law governing electronic administration and information security.

It is in the interest of society, all the subjects and each individual to realize the highest level of safety and health at work, so that unwanted consequences such as workplace injuries, occupational diseases and diseases related to work are reduced to the smallest extent possible, i.e. to realize working conditions in which the employee would be satisfied when conducting his/her professional tasks, but also securing the credibility of the electronically gathered data with the aim of quality analysis of workplace injuries. To achieve this goal, a systemic approach to preventive action and connecting all subjects who are the bearers of certain obligations and activities at the national level compatible with international institutions in this area is necessary. It is their duty to take care of the implementation of the established rules, measures and standards on working conditions and their constant concern with their amending and harmonizing with the technical-technological and socio-economic development in order to enhance employees' safety and preserve their health. Perhaps passing special by-laws that would prescribe mandatory software training for employer's representatives who will be in charge of entering the data in the electronic database should be considered, which would further organize this area.

The view of using modern technology with new content of work requires new skills and constant innovation (the use of drones, IoT-Internet of things, 5G, AI-Artificial intelligence) for the successful conducting of work tasks, as well as the efficient delivery of information, should be considered. These changes certainly require a new way of organizing safety and health at work tasks with a view to realizing safe working conditions, the realization of which should catch up with technical-technological progress as soon as possible.

The development of an information system for managing business processes in the field of workplace safety requires careful planning and the application of certain principles in order to achieve successful implementation. For the successful realization and integration of a central safety and health at work information system and a healthcare information system, cooperation between the sectors of safety and health at work, medical staff and IT experts is necessary.

Improving safety and health at work through software solutions can not only reduce workplace injuries and occupational diseases, but also lead to more efficient work of the healthcare service and a better employee experience.

SAFETY CONCERNING CABLEWAYS

Dragan Živanić[1], Faculty of Technical Sciences, University of Novi Sad
Nikola Ilanković[2], Faculty of Technical Sciences, University of Novi Sad

Abstract: *Modern cableways represent a highly efficient type of transport over short and medium distances for the transport of people and materials with particularly pronounced advantages when operating in mountainous and inaccessible areas. As such, they are defined by safety regulations that determine the conditions for construction, reconstruction, maintenance, etc. At the beginning of the paper, the basic elements of the cableway will be presented. Next, an overview of the most important standards regarding the safety of cableways will be given. Finally, an analysis of incident situations on passenger cableways that have occurred throughout history will be done.*
Keywords: Safety, Cableway

1. INTRODUCTION

Modern cableways represent a highly effective type of transport over short and medium distances (2÷50 km), for transporting people and materials with particularly pronounced advantages when operating in hilly and inaccessible areas. In a broader sense, they represent a continuous transport device where the carrying and pulling element is a rope. They can work on the most difficult terrains with large height differences in the level of the end stations, they enable bridging inaccessible terrains of over 500 m, while overcoming climbs of over 45°, which depends on the relief of the terrain through which the cableway passes. In mountain conditions, cableways have many advantages over other modes of transport, and sometimes they are the only possible solution. In cableway transportation, energy consumption per ton of transported material is very low and the utilization rate of the entire system is very high, reaching up to 95% [1].
Cableways provide very economical transportation, even on completely flat terrain, where they are a more favourable solution than truck transportation with the construction of a new road or than using belt conveyors. Transportation by cableway is 3÷5 cheaper than transportation by trucks [2].
The basic parameters of the cableway are capacity, speed, length, height difference of the end stations and useful load of the trolley. The development of cableways means, first of all, an increase in capacity, which can be achieved by adopting higher cableway speeds, increasing the useful load and reducing the distance between trolleys. The length of the lines of passenger cableways is several kilometres, where the speed and number of people, i.e. the carrying capacity of the trolley, are determined by the specific type of cableway. For fixed cableways with a circular flow, speeds range up to 2.5 m/s. The speeds of single and double rope cableways with a circular motion are limited to 4 m/s, with a capacity of up to 2,000 people/hour. In contrast to them, the speeds of double rope cableways with alternating movement are up to 10 m/s. With freight cableways, it is possible to use higher movement speeds because it is not necessary to meet the conditions of driving comfort and strict regulations for the safety of individual parts of the cableway. The number of people in passenger cableways depends on the shape of the trolley [3]. The number of people is limited to 15 in unescorted cableways and there is no limit to the number of people in escorted ones.

[1] zivanic@uns.ac.rs
[2] ilankovic@uns.ac.rs

In the past, in most countries of the world, cableways were used to access remote mountainous areas and inaccessible terrains. In modern times, except in ski centres, in tourist centres there are requests for this type of passenger transport, Figure 1.

Figure 1. Cableway Kotor-Lovćen, Montenegro
Source: www.vijesti.me

2. CABLEWAY BASIC ELEMENTS

Cableways are complex mechanical and construction systems made up of a large number of different elements and objects. Here, only the basic mechanical equipment will be processed, which includes steel ropes, trolleys and towers attached to the cableway line and the characteristics of the drive and tension mechanism as station equipment with their mechanization-automation.

2.1 Steel ropes

Depending on the type of cableway, the steel rope appears as a carrying and pulling rope in double rope cableways and as a transport rope in single rope cableways. The cableway trolleys move on their wheels on a carrying rope that is anchored at one end and tightened at the other by a tension weight. The pulling rope is an endless flexible element to which trolleys are tied at a certain distance. By moving the pulling rope, the trolleys on the carrying rope also move. In single rope cableways, the role of the carrying and pulling rope is taken over by one, the so-called transport rope.

2.2 Trolleys

Trolleys consist of three characteristic parts - the lower part for accommodating cargo or passengers, the middle part representing the frame and the upper part - the driving part. In single rope cableways, the trolleys are firmly connected to the transport rope during movement between stations, while in double rope cableways, the trolleys are firmly connected to the pulling rope and move along the carrying rope via a set of wheels. Trolleys can be open or closed.

2.3 Clutches

Clutches are an integral part of the trolley through which it is attached to a rope. Clutches represent the most delicate part that must work with high reliability. Depending on the type of cableway, there are fixed clutches of single rope cableways, separable clutches with springs that are used in single rope and less often in double rope cableways, and gravity clutches of double rope cableways. Clutches must meet the following conditions:

- the resistance to slippage of the clutch on the rope must be within certain limits - the minimum value must be sufficient to transfer the resulting tangential force, and the maximum value must allow slippage in exceptional circumstances to prevent cableway damage;
- in the case when the rope is stretched during work, i.e. reduced in diameter, the clamping force of the clutch must remain within the permitted limits;
- the clutch must not damage the rope;
- fixed clutches must allow simple movement and easy control of the rope inside the clutch;
- clutches must not cause large shocks when passing over the wheels of the wheel battery;
- clutches must not be opened under the influence of a negative load.

2.4 Towers

The steel ropes on the cableway line rest on towers. Steel towers of grid construction and reinforced concrete towers are used.

2.5 Station equipment

At the end of the cableway line, there are stations that, depending on the purpose, can be loading or unloading, i.e. driving, tensioning or bending. Although the aim is for the route of the cable car to be a straight line connecting the end stations, in some cases, due to unfavourable relief or environmental requirements, the route can be a curved or broken line.

3. SAFETY REGULATIONS

Directive 2000/9/EC defines conditions for the construction, reconstruction, maintenance and other requirements for cableways, conditions for passenger cableways for the protection of health, personal safety and property safety, safety components of passenger cableways, management of passenger cableways, etc. This directive covers many standards, and only the most important ones will be given here.

3.1 EN 1709 – Inspection, maintenance, operation control and pre-commissioning checks

During the implementation of these activities, dangerous situations may occur. It is possible to prevent them by applying this standard. Some of these situations are non-compliance of the construction with the documentation; malfunction of individual components; defects caused by long-term operation; insufficiently qualified and trained persons in charge of inspection and maintenance; incorrect installation of components; the absence or non-compliance with the procedures of prescribed security measures and dangers originating from the environment.
It is necessary to apply the following safety measures in order to eliminate dangerous situations - inspection before commissioning, to confirm the correctness of all components; regular maintenance; regular inspections and checks to determine the working characteristics of the device and all activities should be performed in accordance with prescribed safety measures.

3.2 EN 1908 – Rope tensioning devices

Due to inadequate tensioning of ropes, dangerous situations can occur. Some of the possible dangerous situations are exceeding the permissible limits for tension and variations in the length of the rope; exceeding the permissible limit values of the pressures in the hydraulic tensioning device; rope jamming or pinching; improper operation of the tensioning device; improper behavior of persons near the tensioning device, etc.
Safety measures that can be implemented to eliminate the above dangerous situations are ensuring that the tension of the rope is maintained within the permissible limits; prevention of mechanical failures of hydraulic components, as well as systems for measuring force and pressure; prevention and detection of failure of tensioning devices, etc.
Modern cableways have a device for measuring and wirelessly sending data about rope tension, Figure 2. After being installed on the cableway, it reads and sends data in real time, based on which the rope tension can be adequately corrected. The device has the ability to read the value of the tension force for different dimensions of the rope. The rope is placed between three pulleys and due to the pressure exerted by the rope on them, the tension of the rope can be determined. If the force falls below the permissible limit, a signal is sent wirelessly that activates the rope tensioning device.

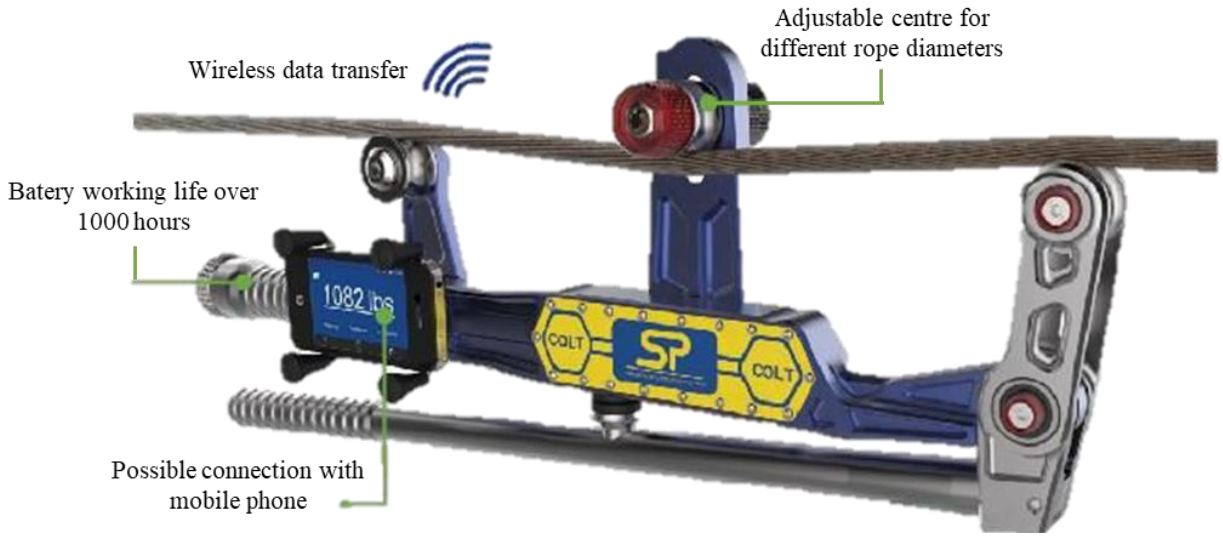

Figure 2. Rope tension measuring device
Source: own archive

3.3 EN 1909 – Rescue and evacuation

Events that can lead to dangerous situations, which can be avoided or limited by applying the safety requirements of this standard, are prolonged exposure to bad weather conditions such as wind, cold, snow, freezing rain; prolonged stay on the cableway; incompetence, incapacity or negligence in the rescue operation of passengers; absence or inadequacy of work organization and rescue organization; inappropriate behaviour of passengers.
All cableways should be designed, constructed and built in such a way that in the event of prolonged downtime it is possible to quickly inform passengers and ensure their safe return, i.e. descent within a reasonable time without jeopardizing their safety or the safety of the personnel responsible for the evacuation. In such circumstances, it is most desirable to return the passengers to the exit stations, and if this is not possible, then it is necessary to evacuate the passengers in accordance with the previously determined evacuation plan. Evacuation is carried out by trained rescuers using appropriate equipment. They approach the passenger trolley via a rope, descend to the passenger and put a safety belt on them, which allows them to safely lower the passenger to the ground. Figure 3 shows the evacuation procedure and the safety belt.

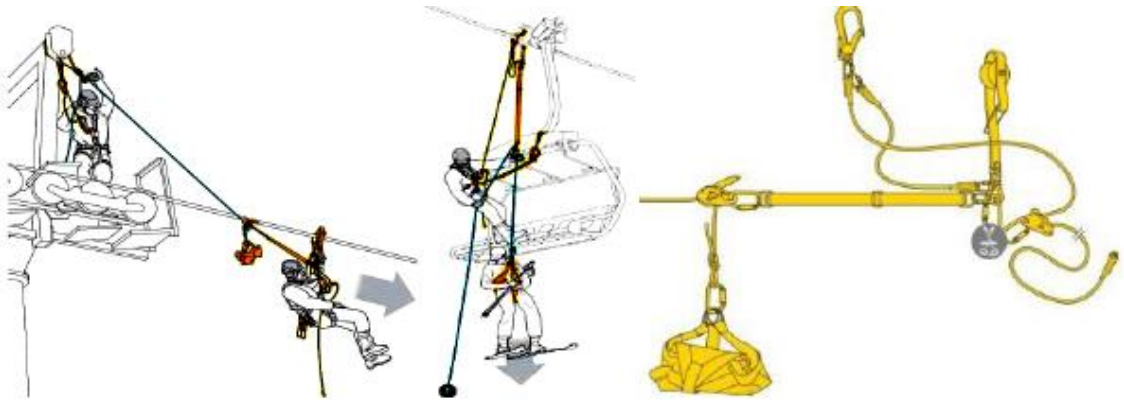

Figure 3. Evacuation procedure and the safety belt
Source: own archive

3.4 EN 12927 – Ropes

Within this standard, there are several sections dealing with safety measures related to steel ropes used in cableways.
In section EN 12927-1, the standard deals with the adequate selection of ropes and connecting elements in order to avoid breaking the rope or failure of the function of the connecting elements, as well as deterioration, i.e. rope damage.
In section EN 12927-2, the standard deals with the safety factors that must be taken into account to ensure the required level of safety for steel ropes – tension factor, bending coefficient and transverse force factor.
In section EN 12927-3, the standard deals with the safety requirements that apply when joining the steel waists of ropes.
In section EN 12927-4, the standard deals with joining and fixing the ends of steel ropes by solid casting, click steel clamps, steel clamps with screws, tension pulley, pressed ends with aluminum eye, steel slings.
In section EN 12927-5, the standard deals with methods of storage, transport and installation of steel ropes. Ineffective protection of the rope during storage can lead to corrosion which can cause premature deterioration of the rope. During transportation, care must be taken that the rope rolls are fixed, and during installation, it is necessary to properly unwind the rolls so that the ropes are not damaged.
In section EN 12927-6, the standard deals with the criteria for replacing ropes. It is necessary to monitor the condition of the rope, especially its diameter. Excessive reduction of the cross-sectional area of the rope may lead to breakage, breakage may occur if corrosion is present, etc.
In section EN 12927-7, the standard deals with safety requirements for inspection, repair and maintenance of steel ropes of passenger cableways. The appearance of deposits on the surface of the rope can lead to the failure of the components of the cableway, such as the clutch.
In section EN 12927-8, the standard deals with the magnetic testing of ropes.

3.5 EN 12929 – General regulations

Within this standard, it is defined that all cableways must be constructed in such a way that the risk will be avoided or limited by appropriate design or construction measures. Furthermore, it indicates the necessity of taking protective measures in relation to the remaining risks that cannot be avoided by design or construction. It defines the precautionary measures that must be taken and the responsible persons informed about them, in order to reduce the risk that could not be completely avoided by previous preventive and protective measures. It is necessary to take into account dangers such as passenger falls, passengers' limbs being caught by elements of the cableway, damage to passenger health due to exposure to adverse weather conditions, etc.

4. CABLEWAY ACCIDENTS

Analysis of accidents is carried out in order to determine the cause and to prevent potential future occurrences of a similar kind. These analyses are performed by experts including forensic specialists, engineers or health and safety consultants. Table 1. gives a list of accidents on passenger cableways with a description of the causes.

Table 1. Accidents on cableways

5. CONCLUSION

Judging by the current trend, it is to be expected that cableways will be used in the future in the form of cableways with cabins. Open and closed cabins, for comfortable and convenient transport, enable the popularization of this type of urban transporter. The basic requirements that are put before manufacturers are an increase in capacity, an increase in line speed, an increase in the number of passengers in the cabin, additional safety, an increase in the automation of mechanical components, all with the aim of achieving additional safety and minimizing operating costs.

BASIC SAFETY MEASURES FOR CHAIN CONVEYORS

Dragan Živanić[1], Faculty of Technical Sciences, University of Novi Sad
Nikola Ilanković[2], Faculty of Technical Sciences, University of Novi Sad

Abstract: *Conveyors with a pulling element in the form of a chain, so-called chain conveyors, belong to continuous transport devices. After the adoption of the new Rulebook on the procedure for inspecting and checking equipment for work and testing the conditions of the working environment, they are also subject to periodic inspections and checks, which was not the case in Serbia until now. These conveyors are often of closed construction, so the only places where injury can occur are the loading and unloading area, as well as on the elements of the drive mechanism. This paper will provide basic guidelines on how to implement basic safety measures for chain conveyors.*
Keywords: Safety, Chain conveyors

1. INTRODUCTION

A special group of transport machines with continuous operation consists of conveyors in which a chain appears as the pulling element, and the carrying element is adapted to the purpose of the conveyor, according to which plate, bucket, scraper and overhead conveyors are distinguished.
Plate conveyors are used for transporting bulk and piece material under very difficult working conditions - abrasive materials, material at high temperatures, castings, heavy machinery, etc. These conveyors have found application in various branches of the industry, primarily in mining, metallurgy, chemical, cement and metal industries, for the transport and handling of heavy objects. They are also used in technological processes where, in addition to transportation, certain technological operations are performed (heating in furnaces, cooling, drying, tempering, dyeing, etc.) and during the assembly of heavy machinery. Recently, they have been widely used as feeders and dispensers in loading bunkers [1].
Scraper conveyors are used exclusively for transporting bulk material. The basic characteristic of these conveyors is that the material is pushed in stationary gutters (grooves) by means of pushers - scrapers connected to one or two pulling chains. Scraper conveyors with one chain are used for small widths (<400 mm), and two chains are used for larger widths. These conveyors are not suitable for transporting wet and sticky materials, which stick to scrapers and gutter walls and create difficulties during loading and unloading, which significantly reduces the capacity of the conveyor. They are also not suitable for the transport of highly abrasive materials, which wear out gutters, or for the transport of brittle materials that lose their quality when crushed. Materials heated up to 300°C can be transported.
Bucket conveyors are used to transport bulk materials. The pulling elements of these conveyors are two lamellar chains. Unlike elevators, they can also transport material horizontally, that is, to have a complex route with a closed contour in the vertical plane.
Overhead conveyors are primarily used for the transport of piece material along a complex spatial route. The characteristic of these conveyors is the installation of a supporting structure above the working space (under the ceiling) on which the trolley moves, with a supporting element, which are connected to each other by a pulling chain. These conveyors have a very important role as a means

[1] zivanic@uns.ac.rs
[2] ilankovic@uns.ac.rs

of internal transport in assembly plants and warehouses. They are suitable for performing certain technological operations during transportation: assembly, mechanical cleaning, painting, heat treatment, quality control, etc. Thanks to the characteristics of these conveyors, complete automation of the production process is possible.
The paper will describe the safety measures that must be taken when installing chain conveyors and that must be followed during use in order to avoid injury to people and damage to equipment. Since the safe maintenance of conveyors is of vital importance, safety procedures will be explained when approaching mechanical and electrical work on conveyors.

Figure 1. Plate, overhead and scraper conveyors
Source: own archive

2. SAFETY WITH CHAIN CONVEYORS

Conveyors are safe when used properly but can be very dangerous if operators do not follow safety procedures when working on or around them. The transported material should be safely loaded onto the conveyor in order to be transported. In the case of manual unloading of piece material from the conveyor, personel must be especially careful as the material can create pinch points. The way someone is dressed, loose clothing, long hair and jewelry, when working on or around the conveyor can pose a risk of entanglement in the moving elements of the conveyor. When repairing or cleaning the conveyor, all moving elements of the conveyor must be locked or blocked, and the operation controls marked. If it is necessary to clean chains or sprockets while the conveyor is in operation, it is necessary to ensure that the protective elements are in the appropriate place and that no part of the equipment can be accessed. There are other general precautions that everyone should follow, even if they don't work directly with conveyors. No one should ever climb over or crawl under moving parts of the conveyor and never ride on it. It is necessary to pay particular attention to the maintenance and inspection of electrical equipment and devices. All personnel working on or around the system should be aware of and adhere to the prescribed rules [2].
There are many hazards associated with working on or near conveyors, including:

- rotating parts or nip points;
- confined or prefabricated areas (the area between a fixed and a moving object) that can be sheared or crushed;
- parts that slide or reciprocate (press) can be crushed;
- objects that can break or be thrown out of the transport system;
- objects that can fall from the conveyor;
- danger of electricity, fire or explosion.

When an employee works near any conveyor, it is necessary to:

- wears protective equipment;
- ties (and tucks in) long hair;
- knows the location of the emergency "shutdown" device and how to use it;
- ensure that all protective devices, including cages, barriers, guardrails, warning signals and other required safety devices are in place and working;
- knows how to work safely around machinery.

On the other hand, it is forbidden to:

- loose clothing or jewelry is worn;
- climbs, steps, sits or rides on moving elements of the conveyor;
- guards or safety devices are changed or removed;
- jammed objects or debris are removed until the conveyor is switched off and locking is ensured;
- the conveyor is serviced without following lockout procedures.

In order to ensure adequate security, the following steps should be followed:

- implement a training program - only technicians and operators trained to work on the conveyor should be allowed access to its controls or perform service and repair procedures. In addition to safety programs based on Occupational Health and Safety Administration standards, each manufacturer must provide operating, maintenance and installation instructions with the conveyor, which should be used to educate personnel about the equipment and its proper use;
- use safety markings - safety markings are placed on and around the conveyor. These visual signals alert personnel to various potential hazards presented by the equipment, including moving parts, high voltage, pinch points, protection requirements, safe maintenance procedures, contact avoidance, etc.;
- place physical barriers - to prevent personnel from walking or working near the conveyor, place safety barriers or warning colors on the floor to warn operators of the potential danger of getting too close to the equipment;
- do not touch or ride on equipment while in operation - notify personnel of hazards, such as injury or death, associated with climbing, sitting, standing, walking, riding, or touching conveyors during operation;
- allow only qualified, trained personnel to perform maintenance - only technicians and operators trained in the use of the conveyor should be allowed to access its controls or perform service and repair procedures;
- disconnect all power sources before maintenance - all power systems should be locked, blocked or released before servicing the conveyor. The same goes for clearing jams.
- use safety guards - make sure guards and covers integrated into the conveyor are always in place and secure before operation;
- adhere to defined capacity - conveyors are designed to match specific application requirements on load size, weight, shape, distribution, speed, etc. Do not introduce new conveyor materials, without first ensuring that they are in accordance with the designed specifications, otherwise stalling, motor overload, chain breakage, product damage or load falling from the conveyor may occur, increasing the risk of personnel injury;
- use the controls correctly - do not modify or alter the conveyor controls.

3. SAFETY CONTROL DEVICES ON CHAIN CONVEYORS

3.1 Emergency stop controls

Chain conveyors must be provided with controls to stop the conveyor or conveyor system in an emergency. These stop commands are activated manually. The electrical circuit in which the emergency stop controls are implemented should be designed to be safe and effectively protected against failures. Emergency stop controls shall be capable of being operated with minimal effort without danger to the operator and shall be provided where the operating control is clearly visible and readily accessible even to inaccessible conveyors.
Emergency stop controls are provided as follows:

- for conveyors not longer than 2.5 m located less than 2.5 m above the floor, passage or platform - one control in the middle of the conveyor;

- for conveyors longer than 2.5 m located less than 2.5 m above the floor - one control at the ends and at intervals not exceeding 30 m along the conveyor;
- for conveyors placed more than 2.5 m from the floor - in accessible locations at intervals that do not exceed 100 m along the conveyor;
- in positions near the conveyor where the conveyor can be started.
- at each permanent workstation.

Lock-out or Tag-out is a basic procedure that protects people who could be exposed to dangers and risks due to service or maintenance work on the device. The lock-out procedure represents the application of physical locking and preventing access to energy sources on the device. Energy sources can be mechanical, electrical, pneumatic or hydraulic. In this way, the power source is turned off, and there is a clear label on it that warns all personnel in the area. When several people perform tasks as part of a more complex system, it is necessary to apply group locking of the energy source using folding scissors. In this way, each person separately locks the scissors with their own padlock, that is, interrupts the energy selection [3].

Figure 2. An example of a stop button, an isolation switch and a protective grid
Source: own archive

3.2 Remote isolation device

Where it is necessary to remotely isolate a conveyor, the following shall be provided for this purpose:

- the device must be locked in the isolated position and be of the manual reset type;
- the device should isolate the energy source from the drive system:
  - direct isolation of energy sources;
  - indirect isolation of energy sources through the management system;
- when indirect isolation of the energy source through the control system is used, the following shall be reported:
  - the remote isolation device shall cause the isolation of the drive energy from the conveyor through at least two independent means to ensure the integrity of the system;
  - a system must be provided that indicates on the remote isolation device that the drive energy is isolated;
  - a warning system is provided before starting.

3.3 Pre-launch warning system

Where an otherwise uncontrolled hazard may arise when a conveyor or conveyor system is started, an automatic pre-start warning system will alert people to the fact that the conveyor is starting to operate and a potential hazard exists. The system should be in the form of a visual or audible warning within an appropriate time limit given before the conveyor is started. Where audible or visual warnings are provided, they must not be a substitute for physical protective measures.

3.4 Marking of control devices

Any manual stop, start, or other function control shall be marked with markings, signs, or labels in writing that clearly indicate the purpose of the control. Notwithstanding the generality of this requirement, the following also applies:

- emergency stop devices must be marked with a sign;
- emergency stop device actuators must be colored red;
- signs must be placed at each end and every 30 m along the conveyor where an emergency stop rope is used;
- provided isolation devices must be marked with signs that clearly indicate the function and purpose of the device.

3.5 Physical protection

A physical barrier is the most effective means of protection against dangerous points on conveyors. It is a means of physically preventing access to hazardous areas and is a legal requirement. Guards will be designed and installed in accordance with the requirements of occupational safety and machine safety. Guards should be designed to prevent:

- for persons to enter the danger zone;
- that clothes and hair or other parts of the body are caught by moving parts of the conveyor;
- risk of component failure;
- unintentional contact with a dangerous point on the conveyor;
- inadvertent contact with hot or hazardous fluids from fluid couplings or torque converters.

All guards shall be secured so that they cannot be removed without the use of tools unless an interlocking device is provided to automatically stop the conveyor in the event of the guard being removed. Guards should be designed so that they do not need to be removed for minor servicing (e.g. lubrication) or for inspection purposes. Guards must be made of solid material, mesh or equivalent construction. The thickness of the sheet protector must not be less than 1.5 mm. Protective nets should not be less than 1.5 mm wire thickness, or 3 mm for 50 mm square nets and more.

3.6 Places for loading and unloading

Wherever a person has access to a loading, unloading, work station, transfer or unloading area, guards in the form of a fence are installed.

3.7 Safety in mechanical and electrical maintenance

Conveyor lubrication is done when they are not in motion. Only trained personnel who are aware of the dangers of a moving conveyor should be allowed to lubricate an operating conveyor. After the conveyor has been lubricated, it is checked that none of the lubricant or other process fluids have been spilled or dropped on the floor. These liquids create a dangerous condition. If dripping is observed, install a drip tray or other means of eliminating the hazard. When an equipment problem occurs, the first priority is to ensure that power is removed from the affected area, as well as from the control panel where troubleshooting and repairs are performed. Once power is confirmed to be out, be sure to notify other personnel in the area of the situation so that they do not unexpectedly restore power. After all employees have been notified, check the power again to make sure the power is off. When performing any type of maintenance or repair involving electrical components, the following guidelines should be followed:

- never reset a circuit breaker or replace an open fuse before determining and correcting the cause;
- never bypass or use a bypass to replace any limit switch, fuse, circuit breaker or other circuit, protective or safety device;

- never replace an open fuse with another one that is not designed for the appropriate current and voltage, always double-check the correct specifications of the fuse instead of replacing an open fuse with one of the same current and voltage;
- never place tools on motors, gearboxes, connection strips or other control panels or electrical components, all tools used should be stored in a tool box or bag;
- never restore power or restart equipment before checking that all personnel are aware of the condition and are safely away from the equipment;
- always replace and remove safety devices and guards during maintenance or repair before restoring power or restarting equipment;
- always use extreme caution and follow recommended safety procedures while performing any electrical inspections or maintenance operations.

4. CONCLUSION

There are several types of chain conveyors for the transport bulk and piece material from the loading to the unloading point. In order to achieve the greatest possible efficiency, it is necessary to monitor the basic parameters on the conveyors in order to reduce the possibility of breakdowns and personnel injuries.

It is important to carry out periodical services so that the equipment has as long and economically profitable working life as possible. Preventive maintenance is always a better option than emergency maintenance. The devices and equipment should be manipulated by qualified personnel and during these actions, they should wear personal protective equipment and observe safety regulations in order to avoid incident situations.

Safety on these machines is very important, with the equipment manufacturer providing safety guidelines that must be followed. Any deviation from the safety compliance by the operator of the conveyor prescribed by the manufacturer of the equipment, the manufacturer is no longer responsible for the actions that occurred and the responsibility falls on the user of the equipment.

Adequate maintenance, training, marking of devices with safety markings, use of protection and adequate barriers, use of controls and use of personal protective equipment raise the safety of work on chain conveyors to a high level and the possibility of breakdowns and injuries to employees is reduced to a minimum.

TESTING OF MICROCLIMATE AND PHYSICAL HARMS IN THE SAWMILLS

Nataša Ćirović[1], Western Serbia Academy of Applied Studies
Ana Petrović[2], Western Serbia Academy of Applied Studies
Marija Burilo[3], Western Serbia Academy of Applied Studies

Abstract: *The wood industry has a dynamic working environment, so various hazards are present in the workplace. Most often, these are mechanical hazards as a result of working with pieces of wood (logs, sawdust, boards) and with work equipment used in the wood industry (saws, planers, other machines for mechanical processing of wood, conveyors, machines for loading and unloading logs, etc.). In addition to mechanical hazards, there is a danger of high noise levels and unfavourable microclimatic conditions in most workplaces in the wood industry. Assessing the size of the risk arising from those dangers and taking measures to reduce them is key to ensuring safe working conditions. The employer is obliged to ensure the use of only functional and safe machines, which are subject to control. If the inspection determines that there have been changes that endanger the safety and health of the workers, the machine must not be used until it has been restored. The paper presents the results of measuring microclimatic parameters and physical hazard at certain workplaces, that is, on machines used in sawmills*.
Keywords: testing of working environment conditions, microclimate, noise, protection measures

1. INTRODUCTION

In some workplaces in the wood industry, especially in sawmills, workers perform certain work activities outdoors. They are exposed to the influence of microclimate parameters of the environment, which include temperature, relative air humidity, air flow velocity and thermal radiation. Working outdoors in the summer months at high temperatures and in direct sunlight, combined with heavy physical work, can lead to health damage with possible serious consequences, such as burns, sunstroke and heat stroke. By taking some simple preventive measures (avoiding work in the hottest part of the day, taking shorter breaks in the shade more often, drinking enough water, using light, breathable clothing that covers most of the body, using sunscreen, cream with a protective UV factor) the mentioned health risks can be avoided.
The measurement of microclimatic conditions in working and auxiliary rooms is carried out under normal operating conditions with the system for ventilation and heating of the room turned on.
The wood industry is a production activity in which workers are exposed to increased noise levels, which can lead to occupational disease. Most of the workers in sawmills, especially operators of mechanical woodworking machines, are exposed to daily noise that is on average higher than the upper limit value of 85dB(A), (Rulebook 96/2011,78/2015,93/2019), but due to insufficient use of protective equipment, the employees' hearing is damaged. For this reason, it is necessary, primarily by applying the basic rules of safety at work, such as avoiding danger (buying machines where the operators are not exposed to increased noise) or reducing the risk to an acceptable level (by placing the machines or operators in a separate area - remote control) to ensure safe the work of workers. If it is not possible, by applying special rules (organization of work, application of appropriate personal

[1]natasacirovicvv@gmail.com
[2]petrovic.hannah@gmail.com
[3]mburilo04@gmail.com

protective equipment), ensure that as few workers as possible are exposed to increased noise for as short a time as possible and provide workers who are exposed with appropriate personal protective equipment for hearing protection and ensure that workers regularly use protective equipment, Figure

Figure 1. The selection of personal protective equipment depends on the noise level at the workplace

2. RESULTS OF TESTING MICROCLIMATE PARAMETERS AND NOISE IN THE SAWMILL

The measurements of microclimatic conditions and noise level in working and auxiliary premises are carried out under normal operating conditions of machines and devices, during the operation of heating, ventilation and dust removal systems.
The device HT - 3007SD was used to measure temperature and relative air humidity. The TESTO 480 device was used to measure the air flow valocity in the working environment. A phonometer, manufactured by Brüel&Kjær, type 2260, indoor microphone type 4189, was used to measure the equivalent noise level, an instrument with a built-in 1 and 1/3 octave filter. The characteristic quantity to be measured is the equivalent noise level in dB(A).
Examination of working environment conditions is carried out in accordance with the Law (135/2004, 36/2009, 36/2009,72/2009, 43/ 2011), as well as the (Rulebook 15/2023). Microclimate tests in the summer period are carried out when the outside temperature is above 15˚C and in winter period when the outside temperature is below 5˚C. Measurements of noise level were carried out in accordance to (Rulebook 96/2011, 78/2015, 93/2019).
The following machines, among others, are subject to noise level inspection of equipment for work in sawmills, Figure 2: brent with trolley, transverse circular saw, automatic circular saw, multi-leaf circular saw, conveyor, transverse circular saw, bansek, crusher and longitudinal circular saw. Inspection and checking of work equipment used in lathes includes the following description: switches, short-circuit protection and protection against dangerous contact voltage are selected according to operating requirements and technological conditions in the room. Power cables are selected according to the power used to power electrical installations. The cables are properly laid and mechanically protected from contact. Based on the performed inspection and examination of the technical protection measures performed on the device, it is concluded that the prescribed safety measures at work have been applied.

According to the (Rulebook 96/2011, 78/2015, 93/2019), standard SRPS EN ISO 9612:2016 and Table 1, the measured microclimate parameters (temperature, relative air humidity and air flow velocity) and noise level in the sawmill, at different measurement places, do not exceed the permitted values. Increased harm was not determined by measurement and there is no risk to the health of workers.

3. PROTECTIVE MEASURES

3.1 Protective measures on machines and tools for wood processing and similar materials

The special occupational safety measures that are applied during the mechanical processing of wood and similar materials are established by (Rulebook 51/1988): all types wooden boards bound with synthetic and mineral binders (chipboards, fibreboards), veneer boards (plywood), carpentry boards (panel boards), chipboards, refined chipboards and fibreboards, decorative laminates, cork boards, wood briquettes, as well as other materials that processed with machines for mechanical processing and wood processing.

Premises in which there are machines for the processing of wood and similar materials must have a built-in system of general and local ventilation, which ensures the removal of sawdust, wood and other dust, gases and smoke. Work tools and other means of work cannot be put into operation, if the device for dusting on the work tools is not turned on and they can only be used if they are working.

Smoking, use of open flames and hot objects are not allowed in places where wood and similar materials are processed and stored. Workplaces must be regularly cleaned of debris and other material. The factory ground area must be fenced and free of canals, pits and other obstacles. If individual pits, canals, pools, etc., are required for the technological procedure and where the work is performed by at least two workers, they are covered or protected by safety fences in accordance with the technological work process. If certain places cannot be fenced off due to the technological process, they must be illuminated and marked with danger warnings in visible places.

Places that serves as a storage area, logs, sawn timber and other material are arranged in such a way as to prevent their falling down and ensure the necessary visibility of the storage area. During work at night and in conditions of reduced visibility, the organization circle must be illuminated. Dangerous places (pools, pits, canals, etc.) within the organization that cannot be fenced off or otherwise protected are illuminated and marked with red light. If there is a track in the working rooms for mechanical processing of wood and similar materials, the upper edge of the track rails must be at the height of the floor surface. Turnstiles for wagons are secured against turning when passing over them.

Before starting work, the machine operator checks whether the tool is functional and safe, correctly positioned and securely attached and the unnecessary tool is put away in the appropriate place. Attaching and removing tools from the machines is done only with the help of the provided tool according to the manufacturer's instructions for handling and maintaining the machines.

4. SPECIAL PROTECTION MEASURES ON MACHINES

4.1 Harvesting machines

Gather must have an audible signal to announce the start of work. For mechanical processing and woodworking, only saws with counterweights secured against shifting can be used. In the case of horizontal gatekeepers, the connecting rod and the flywheel must be enclosed, and the frame must be secured against falling out. When leaving the gather, the ends of the logs are secured against lifting and lowering. During the cutting of logs on the saw, the worker must not be on the log.

4.2 Circular saws

The protective device of the circular saw blade is fixed so that it cannot move along or perpendicular to the saw blade during cutting. It is placed in such a way that it does not reduce visibility during cutting, with the fact that the distance between the device and the upper edge of the object to be cut must not be greater of 5 mm. The circular saw blade with a pendulum is provided with a solid protective cap up to the cutting height. For wood processing only manual circular saws with a movable protective device that automatically covers the entire perimeter of the saw blade when idling can be used. In the case of circular saws with multiple blades and automatic material movement, a kickback protection device is installed. The pressure rollers for the automatic movement of the material to the circular saw are protected by a solid armor. In the case of cylindrical saws for tendons, devices are installed for catching or rejecting the cut tendons.

4.3 Band saws

The band saw blade is provided with a protective shield along its entire length, except for the place where it is directly cut. Manual adjustment of the band saw blade guide is done while the saw is not in operation. In the case of circular saws and log saws, the movement of the log carriage is ensured by an automatic switch. The supports and holders of logs or other objects to be cut with the saw are placed so that they cannot come into contact with the saw blade. The commissioning of the incoming log conveyor from the storage area to the cart of the scraper band saw and log saw is announced by a sound signal.

4.4 Milling machines

The milling cutter tool must be covered with a protective shield. It is not allowed to use the shaft attachment (mandrel) without using the upper bearing on the milling machine. Flattening of material can only be done with round heads (knife holders) or other special tools. The protective shield must not touch the chain on the side of the guide. The tools of the capping machine are protected in all places, except at the point of cutting.

4.5 Veneer cutting machine

Only machines with a mechanism for starting the knives can be used for veneer cutting, which is activated by pressing two switches simultaneously, using both hands at the same time. Machines for veneer cutting (slicing) with horizontal or vertical knives must have a suitable device for stopping the knife in case the worker's body or part of it comes into the dangerous area of the knife.

4.6 Veneer cutting scissors (scissors package)

Only scissors with the mechanism for placing the scissors with the drive adjusted the working part (knife and pressure rod) can be started by simultaneously acting on the two-hand controls or in another

appropriate way, can be used for cutting veneers. It ensures the protection of the workers and stopping the working part in its upper position at the latest. The mechanism for putting the scissors into operation must ensure that, by stopping the action on any of its parts, an immediate stop of the working part of the scissors is automatically performed.

4.7 Wood chipping machines (wood chippers)

A wood chipper must have switches to stop the metal belts for feeding the material being chipped and to run the belts in the opposite direction. The wood chipping machine must have a device to stop the metal strips, in the event that thicker material is encountered than the intended material for chipping. During the operation of the chipping, the workers are on the side of the conveyor that delivers the chipping material, at a safe distance from the machine, i.e. the conveyor.

5. CONCLUSION

The microclimatic parameters of the working environment (air temperature, relative air humidity and air flow air velocity) and noise were measured during working hours and during the execution of the normal work process. Based on the measurements, it can be concluded that the air temperature at the measuring points does not exceed the maximum allowed value prescribed by the reference legal acts for the summer period; that the air velocities at the analyzed measuring points does not exceed the maximum allowed value; that the relative air humidity at all the analyzed measuring points is within the permitted limits according to the valid legal acts for the summer period and that the registered noise levels at the analyzed measuring points are within the limits according to the reference valid legal acts.
Regulations in Serbia prescribe only some protection measures during processing of wood. It must be emphasized that it is not possible to process in detail and include all the protection measures of the technological procedure for all machines, but by installing various protections on existing or purchasing more modern machines, the safety of workers can be increased.

NOISE LEVEL INVESTIGATION IN PRODUCTION PROCESS

Ana Petrović[1], Western Serbia Academy of Applied Studies
Nataša Ćirović[2], Western Serbia Academy of Applied Studies

Abstract: *This paper deals with the noise problem in production halls at two factories. In both factories, noise values were measured at seven presses, which are the sources of noise. From the measured equivalent noise levels and from the noise exposure for the whole shift, the normalized levels of noise exposure $L_{A,EX,8h}$ for individual employees were calculated. Results were presented in table and diagram for better understanding.*
Keywords: noise, working environment, pressing devices

1. INTRODUCTION

The work environment is defined as a set of factors affecting human activity in a certain space, or a set of conditions under which the work process takes place. These conditions must be in accordance with the physiological, hygienic, psychological and aesthetic requirements of the workers. The working environment is then one of the most important working conditions that affect the performance, satisfaction and reliability of workers [1]. Safety and health protection at work must be ensured on the basis of valid legislative regulations, while it must constantly progress and improve in order to eliminate work accidents, occupational diseases and, last but not least, the death of an employee.

In every production organization, we encounter risk factors that can harm the health of the employee, therefore an active approach to safety, compliance with the prescribed measures and the use of appropriate personal work equipment are necessary. Engineering plants have a specific position in industry. The nature of the production, the focus and the technology of the production process is the first prerequisite for the machine equipment of the production halls. For this reason, we encounter very diverse devices in them. They are either single-purpose or multi-purpose machines that are the source of noise. Noise sources are mainly grinders, benders, hammers, cutters, presses, welding units, leveling tables, compressors, milling machines, automatic chisels, etc. The noise level of individual devices depends on the operating load. In a production or assembly hall, there is a mutual interaction of noise sources, each of which has its own characteristic directional radiation. Obstacles of the screen of the reflective surface of the halls condition the creation of a sound field in a closed space. With the help of acoustic measurements, the noise situation in this space (isobar) is objectified and the noisiest sources can be identified, which makes it possible to implement anti-noise measures at the source, but also in the path of propagation of sound energy [2].

Among the most serious risk factors in the production organization when working with pressing equipment is noise, which is the most common and very difficult to eliminate in such work. Noise has adverse effects and affects each employee differently, it can also affect their performance, not just their health. Employees who are exposed to noise for a long time may have health consequences in the form of gradual damage to the hearing organs, or hearing loss may occur, and increased noise may also cause accidents during the performance of work.

[1]petrovic.hannah@gmail.com
[2]natasacirovicvv@gmail.com

Specific causes of noise and vibration in mechanical engineering include impacts on objects (heavy machines, hammers, presses); aerodynamic forces (aerodynamic noise), noise from variable friction mechanisms of individual machine distributions. Other causes are electromagnetic forces (electric motors, transformers) and hydrodynamic processes (hydraulic devices). All these causes are related to the function, work and technological process in production. The effects of these causes intertwine during the work process, therefore acoustic measurements are important during the operation of machines directly in the production process (noise level, sound pressure and power level or currently intensity). On the basis of specific results, anti-noise measures can then be chosen [2].
The prevention of excessive noise and the negative impact of noise already occurs in the preparatory phase of the production organization, when all possibilities are addressed to keep the noise level as low as possible. If the limit values for noise exposure are exceeded, it is necessary to take corrective anti-noise measures, which can be defined by [3,4], on minimum health and safety requirements to protect employees from risk factors related to noise exposure. Anti-noise measures can include organizational changes, technical changes, technological changes, or personal protective work equipment.

2. MATERIALS AND METHODS

2.1 Description of the companies

Factory 1 deals with the sale and production of fasteners and screws aimed to the automotive industry, chemical-heat treatment of metals, assembly of screws and surface treatments of metals. The company also deals with production of various components and technical springs for automotive industry. In addition to the group's production, this company also offers its services as a custom color shop with heat treatment with a protective atmosphere for external customers. Supplies special fasteners mainly for the European market of the automotive, aviation and consumer industries with a focus on small and medium series production, which produces approximately 2000 types of products. Noise measurement was carried out on 7 pressing devices out of 15. Measurements were not performed on all presses due to planned equipment shutdown and maintenance.
Factory 2 deals with the production of anchoring and supporting elements for reinforced concrete constructions. In the hall there are 11 forging presses - for the production of steel material, which are operated by employees classified as forging press operators. Employees in the profession of hydraulic press operator use a hydraulic press to bend material. Noise measurement was carried out on 7 pressing devices.

2.2 Measuring device and method

Brüel & Kjær is an integrated sound level meter type 2240. This sound level meter is easy to use and meets all current standards for its use. It ranks among the sound measurement accuracy class 1 - it can be used to measure the average value or the direct value of the sound pressure. It is also possible to simultaneously measure the maximum value, the instantaneous value and the peak value.
Brüel & Kjær 2240 sound level meter can be used in the assessment of environmental noise, it can be used to measure noise in the working environment, and it can also be used to perform various general noise measurements, such as the noise level of household appliances and many others.
The measurement was carried out in a hall of press plant according to the [4]. Pressing equipment of various sizes and parameters are sources of noise. Other auxiliary machinery is not considered a potential source of noise. Noise was measured at points that were pre-selected in the preparatory work, before the actual measurement. The measurement points are distributed according to the equipment in the production halls where the measurement was performed. The height of the measuring sensor was at the height of the hearing organ of the press operator on the sensor. If the height of the workplace was changed sensor, the height of the measuring point was also changed. The measuring device was held in the position of the hearing organ at a distance of approximately 0.5 m

from the head. The length of the measurement was performed for 5 minutes, 3 repetitions at each noise source. The results of measurements are presented in Table 1.
The following values were measured with the measuring device:

- L_{AF} – instantaneous sound pressure level,
- L_{AFmax} – maximum sound pressure level,
- L_{Aeq} – effective sound pressure level value,
- L_{Cpeak} – the maximum value of the sound pressure level.

The level of daily exposure to noise, normalized to a nominal eight-hour working day, $L_{A,EX,8h}$, expressed in decibels, is given by the equation:

$$L_{A,EX,8h} = L_{A,eq,Te} + 10 \log (T_e/T_0) \quad (1)$$

where is:
T_e – effective duration of the working day
T_0 – reference duration of the working day (8 hours).

If the effective duration of the working day T_e is equal to 8 hours, $L_{AEX,8h}$ is equal to equivalent noise level, $L_{A,eq,Te}$. The equivalent noise level can be calculated according to the relation [4].:

$$L_{A,eq,Te} = 10 \log \left[\frac{1}{k}\Sigma_{i=1}^{n} 10^{0.1 L_{A,EX,8h}}\right] \quad (2)$$

3. RESULTS AND DISCUSSION

Tables 1 and 2, shows the results of noise level measurements at seven measuring points, both production halls as well as the calculated values of the level of daily exposure to noise, normalized to a nominal eight-hour working day, $L_{A,EX,8h}$ and effective sound pressure level value, L_{Aeq} according equations (1) and (2).

The obtained measurement results for the production processes are shown in form of diagrams on Figure 1 and Figure 2.

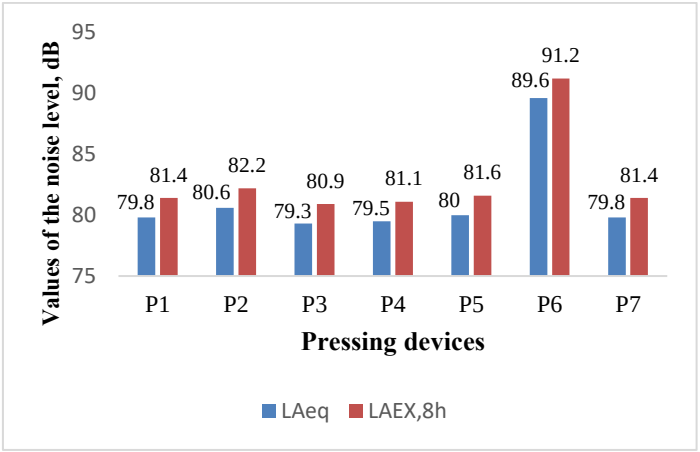

Diagram 1. Factory 1

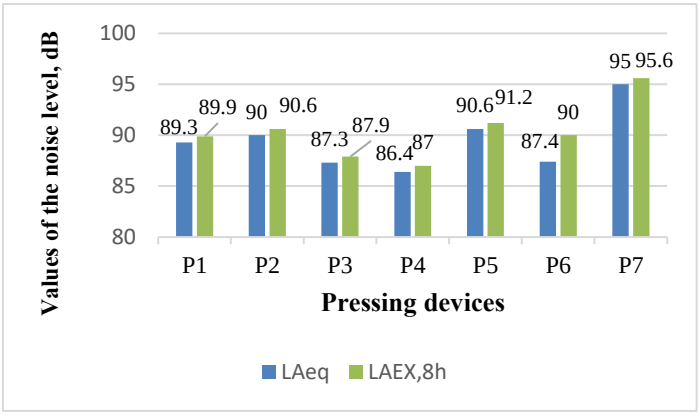

Diagram 2. Factory 2

The purpose of the work was to evaluate the noise level in two production halls, because according to [5,6], the impact of noise on people can cause an effect that is annoying and thus can harm health and create obstacles in the performance of the given activity. These noise impacts they depend on the given number of acoustic and non-acoustic subjects. Safety and health protection at work can be improved by various preventive measures, controls, which may be random or announced. Every employer has an obligation to improve the working conditions of employees, thereby reducing their psychological well-being but also physical load, to eliminate risks that can cause occupational accidents and illnesses from the profession and various other damage to the employee's health during work activities [7]**.**

According to the measurement results, it was determined that the measured values of noise exposure on certain devices exceed the prescribed values, in accordance with the Rulebook [4]. The calculated value of noise exposure on the pressing equipment, Factory 1, only in the case of pressing device, P5, exceeds the permitted values (4), while in the case of Factory 2, the calculated values of noise exposure on all pressing devices, are higher than the permitted values. All possible corrective measures in the form of organizational and technical changes, technological changes and personal protective equipment (PPE) were considered. All possible corrective measures in the form of organizational and technical changes, technological changes and personal protection equipment (PPE) were reviewed. Most manufacturing organizations solves such a situation by purchasing appropriate PPE because according to [8], PPE, which protect employees' hearing organs from adverse and harmful effects of long-term exposure to noise can reduce the noise to a reasonably safe level. According to the [9], the employer must provide PPE for employees. The solution is to exchange the original PPE for more effective PPE. Disposable plug protectors are often exchanged for more functional, shell protectors. Corrective action in the form of technical changes would be addressed in the company, while the anti-noise partitions would be assembled at the given noisiest devices. Anti-noise partitions can be located in the production hall, while their main function is soundproofing, which is possible up to 52 dB.

4. CONCLUSION

Based on the measurement results, certain risks have been identified that affect the safety and health protection during the work of workers, therefore it is necessary to take corrective measures in the form of appropriate PPE - working clothes, headphones or gloves.

Noise exposure has been assessed at production facilities that show increased noise production. Employees face this kind of threat to their health on a daily basis. During time and increasing wear and tear of the equipment it is necessary to separate noisy devices from others with a noise barrier, less noisy equipment and thus prevent the transmission of noise and at the same time increase protection employees. Anti-noise partitions are made of materials that they can absorb noise and are also used to reduce the level of reflected sound.

Last but not least, the employees who work on this equipment must be familiar with its operation, they should also be qualified and regularly trained. The equipment must undergo regular inspection and maintenance.

COMPARATIVE ANALYSIS OF RISK ASSESSMENT IN THE FIELD OF CONSTRUCTION

Vesna Marjanović[1], Western Serbia Academy of Applied Studies
Jelena Jelisić [2], Remontni centar d.o.o., Užice, Serbia

Abstract: *The main purpose of assessing safety risks at the workplace and in the working environment is the preventive assessment and prevention of injuries at work, occupational diseases as well as all other work-related diseases. The application of risk assessment directly affects the safety and health protection of employees. Many methods and types of risk assessment matrices are used to assess occupational risks. Work in construction is one of the riskiest activities in terms of injury and endangering the health of workers. After reviewing the existing state of safety and health at work in the workplaces in the field of construction, recognizing, determining, and analyzing hazards and harms, it is possible to perform a risk assessment, take certain measures and activities to protect the life and health of employees in the field of construction and other persons. The work aimed to use the PILZ and Risk Matrix 5×5 methods for assessing professional risks at the workplace in the field of construction, as well as to perform a comparative analysis to point out the possible advantages or disadvantages of the chosen methods. Based on the risk assessment using both methods, the same conclusion was drawn that the workplace in the field of construction with an increased risk was analyzed.*
Keywords: The risk assessment, PILZ method, 5×5 Risk Matrix

1. INTRODUCTION

Improving safety and health protection at work is a prerequisite for safe and humane working conditions for employees. In the field of construction activity, there are numerous and very different products that require different production technologies and create great opportunities but also obligations in terms of ensuring the safety of workers. Safety and health at work in construction are of particular importance, especially considering the relatively difficult working conditions during the construction of buildings. The safety of workers at work during the construction of buildings implies that the workers are safe [1]: (i) in all phases of work on certain parts of the building, permanent and temporary (stairs, passages, fences, entrances, trenches, excavations, scaffolding, etc.); (ii) when using (handling) various machinery and other mechanically or electrically powered devices, tools and equipment; (iii) when installing various materials or installations; (iv) in all processes and procedures, when applying the provided technologies for the execution of construction, construction-craftsmanship and installation works; (v) from the beginning of construction of the building to its end, i.e. on the entire building, as long as the work on it lasts and on the revitalization of the surroundings after the completion of the works on the building itself.
Safety must be ensured both for the workers performing the work and for other persons (surrounding population and passers-by, while the construction is in progress) and then also for the users of the given facility. Assessing risks at the workplace and in the working environment is the first step to eliminate all risk factors that endanger the lives and health of employees [2] and ensure safe and healthy working conditions.

[1]vesnamarjanovic031@gmail.com

This paper aims to assess the risk of hazards and harm for the rebar worker workplace in a construction company, that deals with high-rise and civil engineering. The risk assessment after the recognition and analysis of hazards and harms at the rebar worker workplace was performed using the 5x5 Risk Matrix method (OHSAS standard) [3] and the PILZ method [3].

2. TECHNOLOGICAL PROCESS AND ORGANIZATION OF THE WORK PROCESS

In this paper, an analysis of the workplace of a rebar worker in a construction company, which deals with the execution of construction and construction-rough works, was carried out. The activity of the company is the construction and reconstruction of buildings, the upgrading of already existing buildings, the preparation of construction sites for later construction activities, which includes the preliminary removal and demolition of existing buildings, the construction of all types of retaining walls, and protection against soil erosion.
Objects used as working and auxiliary space in a construction company are a construction site, a container for a wardrobe, a sanitary unit, and a container for tools and other necessary materials.
In the process of work, the rebar operator uses measuring devices (meter, plummet, spirit level, string), hand tools (reinforcing pliers, hammer, keys), an electric hand sander, a rebar table, mechanical scissors, and cantilever crane [4].
From the raw materials and materials at the workplace of the rebar worker, the employees use concrete iron, and rebar [4].

2.1 Equipment and means for personal protection at work

When performing technological and work processes, employees at the workplace rebar worker use means and equipment for personal protection at work, which include [5]:

- one-piece work suits or cloth work coats,
- leather gloves with reinforcement in the area of the fingers and palms,
- safety glasses that have a frame with side protection,
- Safety leather shoes with steel toe cap and anti-slip and anti-puncture soles,
- protective helmet,
- hearing protection devices (the use of protective cotton wool for the ears, earplugs, and earmuffs is determined by a noise level of 75 dB, over 85 dB to 105 dB),
- protective belt for positioning which has a wide back support with adjustable rope for positioning and carabiner,
- raincoat made of rubberized and waterproof material with hood and fastening on the front,
- leather shoulder protector, if a heavy object (weighing more than 15 kg) or an object with sharp edges is carried on the shoulder,
- Protective bras to protect against spine deformation due to constant carrying of a load on the shoulder or back,
- leather knee pads for working in a kneeling position.

2.2 Description of the rebar worker workplace

Jobs and tasks in the rebar worker workplace include loading and unloading the armature at the construction site, transferring the armature to the workplace, hand, and machine cutting, straightening, bending, tying, and installation of rebar, wire, and prestressing ropes [4].
The conditions for performing the work of a rebar worker are the completion of secondary vocational education and the passing of a professional exam. Rebar workers are over 21 years old, in good health, with good vision, hearing, and sense of balance, satisfactory physical strength, endurance, and psychomotor dexterity, and have a medical certificate for working at heights. Employees are subject to periodic medical examinations every 12 months [5].

From 5 to 10 male employees, among whom there were no persons with disabilities, were hired to perform rebar work in the observed construction company. Working hours are from 7:00 a.m. to 5:00 p.m., with two 30-minute breaks. The work is done six days a week. The work is done six days a week. During the performance of work at the workplace of the rebar worker, there may be a deviation from the established work organization on an emergency call.

3. ANALYSIS OF DANGERS AND HARMFULNESSES OF THE REBAR WORKER WORKPLACE

Identification and determination of hazards and harm in the analyzed workplace and the working environment was carried out based on data collected from the documentation owned by the employer, by observing and monitoring the work process at the workplace, obtaining the necessary information from employees and information from other sources, and classifying the collected data into the types (possible dangers or possible harms) to which these data indicate.
Based on the record of injuries at work in the period from 2016 to 2020, nine minor mechanical injuries occurred at the workplace of rebar workers. Six injuries are superficial wounds, in which only the skin is injured (peel off the skin and shallow cuts), while the other three injuries are deep wounds, where in addition to the skin, deeper tissues (muscles, blood vessels, and bones) are also injured. Professional diseases and diseases related to work were not recorded at the place of work of rebar workers in the period from 2016 to 2020.

3.1 Mechanical dangers arising from the use of work equipment at the place of work of the rebar worker

Mechanical dangers that occur when performing work using a grinder for cutting reinforcement as well as when using a cantilever crane due to rotating or moving parts of this work equipment can cause insufficient safety for employees. Rebar workers are exposed to the free movement of parts or materials that can injure them during the lifting and lowering of loads (rebar) with a cantilever crane, in the event of falling material stack, when unloading loads from a truck, as well as if the rebar is forcibly pulled from a pile of materials, et cetera. Also, they are exposed to dangers from the movement of work vehicles and machines on the construction site, which are used to transport construction materials and remove waste from the construction site.

3.2 Dangers that arise in connection with characteristics of the workplace

When installing reinforcement and moving over uneven ground surfaces and scaffolding on the construction site, rebar workers come into contact with dangerous surfaces that have sharp edges, spikes, and protrusions. The work of installing reinforcement and reinforcing mesh, accepting materials on a cantilever crane is performed by rebar workers working at height by the regulations on safety and health at work.
When performing reinforcement works, tripping may occur from construction material (rebars). If the tool is placed in places not intended for it, there is a tripping danger. When working with the sander, electrical cables are stretched across the floor and can cause tripping. Also, in the winter, the paths for the movement of employees can be slippery, which can cause slipping.

3.3 Dangers arising from the use of electricity

When working with a mechanized tool, that is powered by electricity, if the cable is damaged, the employees at the workplace of the rebar worker can be exposed to the danger of direct contact with parts of the electrical installation and equipment under voltage.

3.4 Harmfulnesses that arise or appear in the work process

The harmful impact of noise from construction machines and tools, although it is present on the construction site, is slightly less pronounced due to working in an open area. The workplace where the work of a rebar worker is carried out involves working outdoors (construction site), as well as staying in premises under construction that do not have windows and doors, which implies exposure to inappropriate flow speed and air humidity; in the summer under the influence of very high temperatures, while in the winter period under the influence of very low temperatures.

3.5 Harmfulness resulting from psychological and psychophysiological efforts

The work of the rebar operator, such as manual bending of the rebar mesh, manual transfer, and loading of the rebar onto the cantilever crane, is performed with great physical effort and body strain. While performing the work, the rebar worker is generally in a bent position, or crouching, or kneeling, that is, he has an unphysiological body position.

3.6 Harmfulness related to the organization of work

Since the organization of work in the construction industry depends on several factors, occasionally employees in the position of rebar workers have to perform tasks longer than full-time.

4. APPLICATION OF THE PILZ AND RISK MATRIX 5×5 METHODS FOR THE WORKPLACE OF THE REBAR WORKER

After identifying the dangers and harmfulnesses of the analyzed workplace, a risk assessment was performed [6, 7] using the PILZ method [3] and the 5×5 Risk Matrix (OHSAS standard) [3].
The probability of injury or disease, frequency of exposure to dangers and harmfulnesses, severity of possible injury and disease, and number of persons exposed to danger or harmfulness are risk factors used in risk assessment using the PILZ method.
Using the 5×5 Risk Matrix method (OHSAS standard), two parameters for risk assessment about hazards and harmfulnesses were analyzed, namely the probability of injury or disease and the possible severity of injury or health damage.
A comparative analysis of the estimated occupational risks using these two methods is shown in Table 1.

Table 1. Comparison of the level of professional risks at the workplace of rebar workers assessed using the PILZ method and the 5×5 Risk Matrix (OHSAS standard)

Identified dangers and harmfulnesses	Level of professional risks assessed by PILZ method	Level of professional risks assessed by 5×5 Risk Matrix
Insufficient safety due to rotating or moving parts of the work equipment	High risk (R4)	Moderate risk (R3)
Free movement of parts or materials that may cause injury to the employee	Moderate risk (R3)	Moderate risk (R3)
Internal transport and movement of work machines or vehicles, as well as movement of certain work equipment	Moderate risk (R3)	Moderate risk (R3)
Dangerous surfaces	Low risk (R2)	Low risk (R2)
Working at height in terms of occupational safety and health regulations	Unacceptable risk (R5)	Very high risk (R5)

Possibility of slipping or tripping	Moderate risk (R3)	Low risk (R2)
The danger of direct contact with live parts of the electrical installation and equipment	Moderate risk (R3)	Moderate risk (R3)
Physical harmfulness	Moderate risk (R3)	Moderate risk (R3)
Harmful climatic influences	Moderate risk (R3)	Moderate risk (R3)
Effort and body strain	High risk (R4)	High risk (R4)
Unphysiological position of the body	High risk (R4)	High risk (R4)
Work longer than full-time	Low risk (R2)	Moderate risk (R3)

Both methods use a risk ranking on a five-point scale. The analysis shows that by applying the PILZ method and the 5×5 Risk Matrix (OHSAS standard), risks of different ranks were assessed about two dangerous and one harmfulness.
This deviation can be related to the analysis of different parameters when applying these methods. It can be seen that by applying the PILZ method, there is a possibility of seeing the dangers and harmfulnesses through more parameters than is the case with the Matrix method.
Using both methods (PILZ method and Risk Matrix 5×5 (OHSAS standard)) the assessed risks in terms of dangers (work at heights, insufficient safety due to rotating or moving parts) and harmfulness (efforts or body strains and non-physiological body position) indicate that the workplace of a rebar worker is a workplace with increased risk.

5. CONCLUSION

This paper analyzes the dangers and harmfulnesses at one workplace in the field of construction and makes a comparison of the levels of occupational risks assessed using the PILZ method and the 5×5 Risk Matrix (OHSAS standard). Using both risk assessment methods, the rebar worker's workplace was assessed as a workplace with increased risk.
The results showed that the PILZ method takes into account the probability of injury or illness, the frequency of exposure to dangers and harmfulnesses, the severity of possible injuries and illnesses, and the number of people exposed to dangers or harmfulnesses, unlike the 5×5 Risk Matrix (OHSAS standard) which is based only on probability and the possible severity of the injury or illness.
Unlike the 5×5 Risk Matrix (OHSAS standard), the PILZ method is slightly more precise because it uses more factors for risk analysis, therefore the PILZ method is more reliable than the 5×5 Risk Matrix (OHSAS standard).

ANALYSIS OF ASSESSED PROFESSIONAL RISKS AT THE WORKPLACE OF FORKLIFT DRIVERS IN THE LOGO COMPANY WITH COMPARATIVE RISK ASSESSMENT METHODOLOGIES AND REFERENCE TO THE CURRENT LAW

Saša Kuzmanović[1], Trosador d.o.o.

Abstract: *In the modern era of business, we face an increasing number of professional risks as products of danger and damage to which employees are exposed during work. Professional risks due to inadequate risk management can lead to injuries at work, which can be minor, serious and fatal, as well as to the occurrence of occupational and work-related illnesses. Due to Article 4, point 21 of the new Law on Safety and Health at Work, according to which the position of the forklift operator is pre-classified as a workplace with increased risk without prior assessment by any of the methodologies, a research and comparative analysis of three methodologies for risk assessment was carried out in order to see if any of the methodologies define the workplace of a forklift operator as a workplace with increased risk in accordance with the applicable law.*
Keywords: Professional Risk, Risks, Risk Assessment Methodology

1. PROFESSIONAL RISK - Definition, division and purpose

The term risk means exposure to the action of various factors that can lead to unwanted consequences through their actions and activities, which is usually reflected in practice in the creation of certain types of costs or, what is much more significant, in the impairment of the health of employees or the creation of minor and serious injuries at work. The risk of the working environment (R) is most often defined as the product of the probability of occurrence of a risky event (Prd) and the severity of it's consequences (Cp) [1]:

$$\mathbf{R = Prd \times Cp} \quad (1)$$

1.1 Division of professional risks

Occupational risks can be:

- Internal - Risks occur at the workplace and in the working environment of the employer (business facilities of the company and the working environment where employees move).
- External - Risks occur outside the employer's workplace and facilities (public areas where the employee performs work for the employer's account or on the way from home to work and vice versa).
- Mixed - a combination of internal and external professional risks.
- Continuous - Risks that occur over a longer period of time, represent the risk of the business itself (mining, chemical industry, health care and security structure).
- Risks due to professional incompetence - They occur most often during the employee's work at workplaces on the employer's premises or in the field, and arise as a result of the incompetence of the Occupational Safety and Health Advisor to properly assess all dangers and hazards within the company, perform a proper risk assessment and determine measures to reduce the resulting professional risks, using one of the generally recognized methods of assessment and quality selection and allocation of personal protective equipment [2].

[1] sasa.kuzmanovic112@gmail.com

These are just some of the divisions by which occupational hazards can be classified, but it should be pointed out that many more subcategories of occupational risks can be made based on them.

1.2 Prevention and management of professional risks

Occupational risk prevention PRL consists of a set of prevention plans and measures implemented in companies to prevent and detect risky situations. PRL aims to eliminate or, if it is not possible to do so completely, then at least reduce the danger or risk that poses a danger to employees. PRL activity is regulated in most European countries and is carried out through specialized courses intended for company personnel. In Serbia, in accordance with the Law on Occupational Safety and Health, occupational risk prevention and risk management are carried out by the Occupational Safety and Health Committee. This Committe is made up of representatives of the employer and employees, or in the case if an Occupational Safety and Health Committee has not been formed, it is carried out by the Employer with the help of the Occupational Safety and Health Advisor and the Employee Representative [3].

2. GOAL OF ASSESSMENT OF PROFESSIONAL RISKS AND THE MOST COMMONLY USED METHODOLOGY IN ASSESSMENT

The main goal of the assessment of professional risks is to determine critical places in the work and technological processes where injuries and endangering of the employee's lives can occur. After the risk assessment, it is necessary to manage the risks, eliminate them or, in the case of impossibility of elimination, reduce the risk to an acceptable level, using for example, personal protective equipment, continuous education, medical examinations, examination of work equipment.
In the Republic of Serbia, there is no adopted Methodology for risk assessment, but several of them are used and it is up to the risk assessor which method to apply and use. The most common method in our country for assessing professional risks is the KINNY method. During risk assessment, many assessments are done in a uniform, copying manner, and the entire assessments for individual workplaces are copied from one company to another, without taking into account, for example, the probability of injury, the frequency of exposure to hazards and harm [4], and the consequences and possible injuries and diseases.
The assessment of occupational risks for many workplaces should be made by combining and comparing several methodologies, which is not always easy because such a thing requires the experience of the assessor and more time for the preparation and analysis of the assessed risks and methods.
In the continuation of the work, an analysis of the estimated risks will be performed using the LatiPro Methodology developed in Serbia by a multidisciplinary team of experts, the KINNY methodology and the Singapore (3×3) Methodology.
The main goal of the work and the analysis of methodological solutions is the assessment of professional risks for all recognized hazards and harms, in order to obtain a unique conclusion on the levels of risk for the workplace of a forklift operator and finally compare it with the provisions of the new Law on Occupational Safety and Health, as well as measures for additional risk reduction, through quality risk management.

3. USED METHODOLOGIES AND ASSESSMENT METHODS OF PROFESSIONAL RISKS AT THE FORKLIFT OPERATOR'S WORKPLACE

The basic legal basis for conducting risk assessment at the workplace and in the working environment is defined by Article 16 of the Law on Safety and Health at Work and the Rulebook on the method and procedure of risk assessment at the workplace and in the working environment [4,5].
Currently, in the Republic of Serbia, there is no single methodology for assessing professional risk, but several recognized methodologies are in use. A unique methodological procedure for the

assessment of occupational risk would enable a simple insight into the state of occupational safety and, therefore, a better management of occupational risk in economic entities by employers [6].
In accordance with the Rulebook on the manner and procedure of risk assessment in the workplace and in the working environment, articles 8 and 9, hazards and harms in the workplace and in the working environment are defined [4].
For the workplace of a forklift driver, the following hazards and harms have been determined, which we will adhere to in the assessment of professional risks using different methodological solutions.

Table 1. Hazards and harms at the workplace and in the working environment
Source: Rulebook on the manner and procedure of risk assessment at the workplace and in the working environment

Hazard group	Code	Hazard subgroup
1) Mechanical hazards arising from the use of work equipment such as:	(01)	Insufficient safety due to rotating or moving parts.
	(02)	Free movement of parts or materials that may cause injury to the employee.
	(03)	Internal transport and movement of work machines and vehicles, as well as movement of certain work equipment,
	(05)	Impossibility or organization of timely removal from the workplace, exposure to closure, mechanical impact, collision, etc…
2) Dangers that appear in connection with the characteristics of the workplace such as:	(07)	Dangerous surfaces (floors and all types of treads, surfaces with which the employee comes into contact with sharp edges, edges, spikes, rough surfaces, protruding parts, etc.).
	(10)	Possibility of slipping or tripping (wet or slippery surfaces)
	(16)	Danger of indirect contact with electricity. Installations and equipment under voltage.
	(18)	Danger due to tire impact and consequences of atmospheric discharge.
Harm group	**Code**	**Harm subgroup**
1) Harms that arise or appear in the work process, such as:	(21)	Chemical hazards, dust and fumes (inhalation, suffocation, introduction into the body, penetration into the body through the skin, burns, poisoning...
	(23)	Biological damage (infections, exposure to microorganisms and allergens).
	(24)	Harmful effects of microclimate (high or low temperature, humidity and speed of air flow).
	(25)	Inadequate-insufficient lighting.
	(27)	Harmful climatic influences (outdoor work).
2) Harms resulting from psychological and psychophysical efforts that are causally related to the workplace and tasks performed by the employee, such as:	(30)	Efforts or physical strain (manually carrying loads, pushing or pulling loads, various long-term increased physical activities, ...).
	(31)	Non-physiological position of the body (long-term sitting, sitting, crouching, kneeling,...).
	(32)	Efforts when performing certain jobs that cause psychological burdens (stress, monotony,...).
3) Harms related to work organization such as:	(34)	Work longer than full time (overtime), shift work, part-time work, night work, emergency preparedness

The first methodology used is the LatiPRO methodology developed in Serbia by a multidisciplinary team of experts.

The LatiPRO methodology uses four parameters in the assessment, which in the formula indicate: TP - severity of potential injury, UI - frequency of exposure to hazards, VP - probability of injury, BO - number of exposed persons, so it is:

$$\mathbf{RISK = TP \times UI \times VP \times BO} \quad (2)$$

Table 2. Risk categorization for the LatiPRO method
Source: *latipro.com*

Risk category	**Risk = TP x UI x VP x BO**
R1-Negligible risk	**0-5**
R2-Little risk	**6-50**
R3-Moderate risk	**51-250**
R4-High risk	**251-500**
R5-Unacceptable risk	**>500**

The second method used is the most commonly used, the Kinny method, where the occupational risk is the product of (V) the probability of occurrence of hazards, (P) the consequences of the occurrence of hazards and harms, and (U) the frequency of occurrences of hazards and harms:

$$\mathbf{R = V \times P \times U} \quad (3)$$

Table 3. Risk categorization for the KINNY method
Source: *Choice of method for risk assessment*

Risk category	**Risk = V x P x U**
R1-Very little risk	**R<20**
R2-Little risk	**20-70**
R3-Moderate risk	**71-200**
R4-Big risk	**201-400**
R5-Extremely high risk	**R>400**

The third method used is the Singapore method (3×3), where the risk is expressed as the product of the probability of occurrence of a work-related injury, health damage and illness (V) and the consequences of the severity of the injury, health damage and work-related illness (T):

$$\mathbf{R = V \times T} \quad (4)$$

Table 4. Risk categorization for the method (3x3)
Source: *Choice of method for risk assessment*

Risk category	**Risk = V x T**
R1-Negligibly low risk	**Acceptable risk**
R2-Very little risk	
R3-Little risk	
R4-Medium risk	**Increased risk**
R6-Big risk	**Unacceptable risk**
R9-Very high risk	

4. OBTAINED RESULTS OF ASSESSED PROFESSIONAL RISKS USING THREE METHODS

After the risk assessments, the most rigorous results were obtained using the Singapore 3×3 method, where we obtained as many as eight points of the third rank R3– (increased risk). Using the KINNY method, we obtained two points of the third rank R3– (medium risk). Using the LatiPRO methodology, we obtained two risk levels: R1– (negligible risk) and R2– (small risk), while the risks of the third level are not defined.
From the presented results, it can be concluded that the workplace of a forklift operator in the Logotem company is not a workplace with increased risk and that it is in violation of Article 4, Clause 26 of the Law on Occupational Safety and Health (Official Gazette No. 35/2023).
Although the ranks of the assessed risks differ, it should be taken into account that they represent the individual perception of the assessor and the employee, based on the answers received during the interview of the employee and the determination of the dangers and harms for the given workplace.

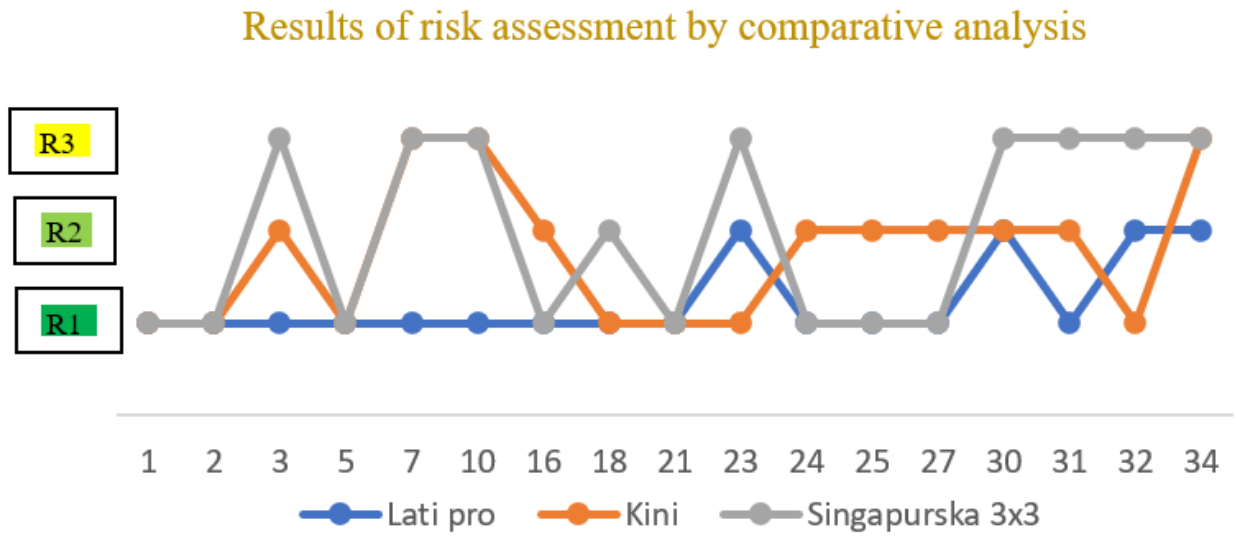

Figure 1. Results of risk assessment by comparative analysis for the workplace of a forklift operator

5. MEASURES TO REDUCE RISKS FOR THE WORKPLACE OF FORKLIFT OPERATORS THAT ARE APPLIED IN THE WORKING PROCESS

In order to properly treat the obtained levels of risk ranks and provide them with quality professional management, measures were determined to eliminate existing low risks and reduce moderate risks:

- An employee working as a forklift operator must be professionally trained in forklift operation at an accredited educational institution that has a license from the Ministry of Education;
- The employee must have a completed medical examination and a positive assessment on the fulfillment of the conditions for performing the duties of a forklift operator - periodically, once a year;
- The employee must be trained theoretically and practically for safe and healthy work at the workplace, with a knowledge check once a year;
- The forklift must be tested by an accredited laboratory every three years;
- All defects on the vehicle must be repaired immediately, and in the event of a defect, the employee is prohibited from working with the vehicle;
- It is forbidden to use a mobile phone while driving;
- The employee must be trained to move safely through the work area;

- The employee must wear personal protective equipment in accordance with the Act on risk assessment at the workplace and in the working environment;
- The employee must use the assigned personal protective equipment;
- The employee must handle the cart carefully;
- Aisles in the warehouse must be cleared of bulk and palletized goods;
- The employee must comply with all instructions and work procedures;
- The employee must move carefully on wet and slippery surfaces and use appropriate protective footwear prescribed by the Risk Assessment Act;
- Employees should correct their body posture while working, combined with breaks and occasional light stretching;

6. CONCLUSION

The term professional risk refers to the exposure of people and businesses to the action of various factors that can lead to unwanted consequences through their actions and activities, which in the practice is usually reflected by creation of certain types of costs or, what is much more significant, in the impairment of the health of employees or the creation of minor and serious injuries at the work of employees, occupational diseases and diseases related to work.
By dividing professional risks, we can get a more complete picture of the nature of the risks themselves and how they arise, as well as the prevention of professional risk, which consists of a set of prevention plans and measures implemented in companies to prevent and detect risky situations.
The main goal of the assessment of professional risks is to determine critical places in the work and technological processes where injuries and endangering the lives of employees can occur. After the risk assessment, it is necessary to manage the risks, eliminate them or, in the case of impossibility of elimination, reduce the risk to an acceptable level, using, for example, personal protective equipment, continuous education, medical examinations, examination of work equipment and the like.
The risk assessment for the forklift operator's workplace was performed using three methodologies LatiPRO, Kinny and Singapore (3×3).
From the presented results, it is concluded that the workplace of a forklift operator in the company Logotem is not a workplace with increased risk and that it is in contradiction with Article 4, Clause 26 of the Law on Occupational Safety and Health (Official Gazette No. 35/2023).
Although the ranks of the assessed risks differ, it should be considered that they represent the individual perception of the assessor and the employee, based on the answers received during the interview of the employee and the determination of the dangers and harmfulness for the given workplace, and that after assessing the risks, corrective measures for elimination should be taken risks or their reduction.

IMPLEMENTATION OF STRATEGIES FOR THE DEVELOPMENT OF CRITICAL THINKING IN ENGLISH LANGUAGE TEACHING AMONG THE STUDENTS OF THE OCCUPATIONAL SAFETY AND HEALTH STUDY PROGRAM AT THE ACADEMY OF APPLIED TECHNICAL STUDIES BELGRADE

Marija Mićanović[1], The Academy of Applied Technical Studies Belgrade
Tanja Radović[2], The Academy of Applied Technical Studies Belgrade

Abstract: *The process of foreign language teaching at the tertiary level of education should not be based on techniques that direct students to passive listening and mere memorization and reproduction of the teaching material. Accordingly, the methods applied in teaching should develop students' cognitive actions that are related to higher cognitive functions. Strategies for improving foreign language teaching at higher education institutions must also include the use of teaching methods that develop students' deep approach to learning, understanding problems, connecting knowledge from different fields, connecting new knowledge with the existing knowledge, connecting theoretical knowledge with everyday experience, etc. This paper deals with the implementation of strategies for the development of critical thinking in English language teaching among the students of Occupational Safety and Health study program at the Academy of Applied Technical Studies Belgrade. The paper presents strategies and specially designed activities that direct students to active participation in classes, nurture and develop the use of critical thinking in the process of learning English, with the purpose of improving the quality of English language teaching at the Academy.*
Keywords: Critical thinking, Occupational Safety and Health

1. INTRODUCTION

"Critical thinking is a reasonable reflective thinking focused on deciding what to believe and do" [1]. In order to understand the strategies that are employed to develop critical thinking skills, it is necessary to understand the process of learning. According to Marton, and Säljö, there are three approaches to learning: surface, deep, and achieving [2]. Surface and deep approaches describe the level of student's engagement in the actual assignment, while the achieving approach describes how students perform the organization the temporal and spatial contexts in which they do the assignment. These three approaches lead to diverse kinds of learning outcomes [3]. They basically study the connection between the student's approach to learning and the level of understanding that they eventually demonstrate. Students who demonstrate the surface approach towards learning possess the following characteristics: They learn with the specific goal of meeting the course demands, they are unable to connect previously gained knowledge with the new knowledge and they simply memorize and reproduce the material. On the other hand, students who have the tendency to learn by employing the deep learning approach will demonstrate the following characteristics: They acquire knowledge, understand the material and are able to connect the concepts. They exhibit the capability of relating ideas to previously gained experience and they can see the connection between the evidence and the conclusion. They demonstrate critical thinking skills and are able to provide independently drawn conclusions [2]. What matters is that when teachers set objectives of learning they incorporate the

[1] mmicanovic@atssb.edu.rs
[2] tradovic@atssb.edu.rs

strategies for the development of critical thinking among students, because critical thinking represents one of the main aspects of successful language learning.
According to Bloom, cognitive processes are classified into six different categories (Figure 1). In order to develop and improve the level of critical thinking it is necessary to apply strategies that would employ higher cognitive functions, such as invent, develop, assess, etc. [4].

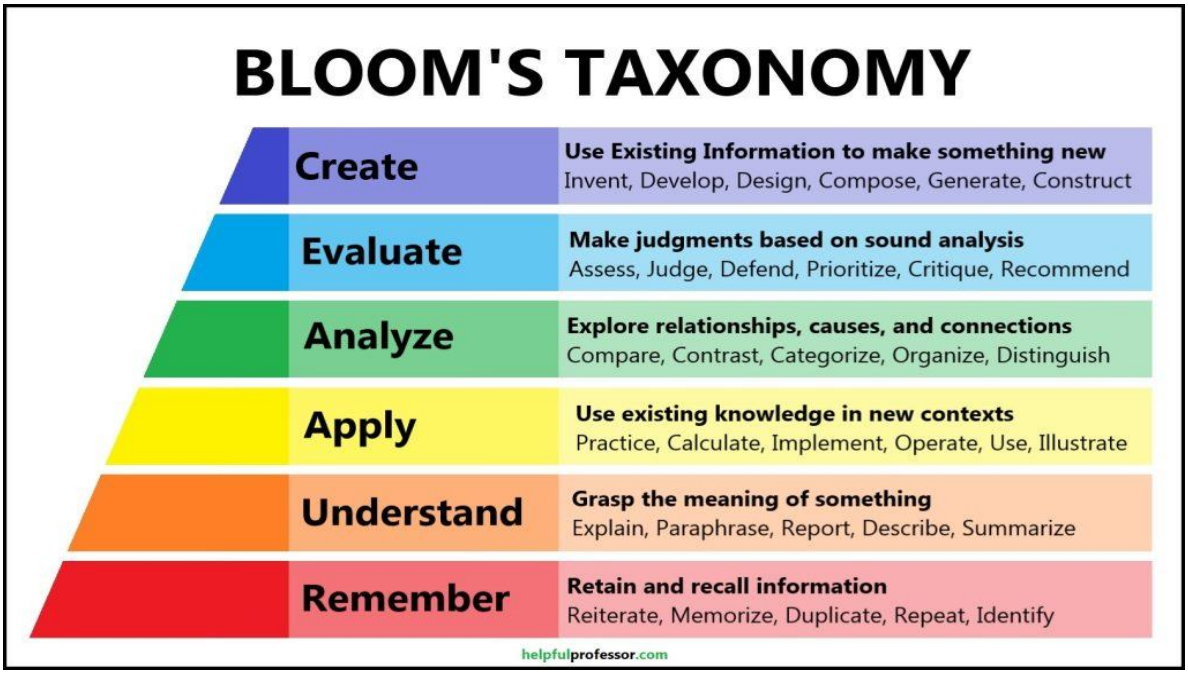

Figure 1. Bloom's Taxonomy

2. ACTIVITIES

The main reason why students of Occupational Safety and Health study program were elected among other study programs to be the part of this paper is the fact that they must think critically if they want to perform their duties professionally. Their primary assignment is to keep people safe and healthy, which is the most important aspect of every job. They need to be capable of recognizing hazards, and they need to know how to formulate plans to prevent these hazards from happening. They need to establish security guidelines, as well to take precaution measures to protect the workers and secure the buildings. All of this is achieved and improved by nurturing critical thinking among students and enabling them to draw their own conclusions, solve problems, develop and create. By incorporating these strategies into every aspect of their education they are provided with the opportunity to do so, and thus further sharpen their critical thinking skills. This is why it is essential to incorporate some of the following activities into their English language learning:

1) **A selection of photos and the question**: *What's going on in this picture?* [5]. A teacher should prepare a selection of photos that do not possess any kind of written title or explanation. This exercise can be done individually, in pairs or in groups. The answer can be a written description or an oral discussion. Students will have the opportunity to improve their critical thinking skills, analyze the photos, improve their vocabulary range, as well as to enhance their knowledge of grammar constructions.
2) **TED Talks and more video/listening resources:** Various video resources have proven to be very useful in English language acquisition. Apart from listening to native English language speakers, learning new information, new vocabulary and grammar constructions, the students can discuss the videos in groups, use dictionaries to find new vocabulary, use it in sentences. They can suggest their ideas for problem-solving situations, give their opinion and reinforce it with facts from the video.

3) **A long written text about Occupational Safety and Health and its analysis**: There are numerous activities that can be carried out using this material. They include writing a title for each paragraph, sentence transformations, making the glossary of the words from the text, transforming the words into different parts of speech, using new vocabulary in a sentence, giving suggestions for problem solutions, text translation, etc.
4) **Scenario Discussions:** The students get previously written scenarios about hypothetical situations concerning Occupational Safety and Health. Their tasks include coming up with possible solutions to the problem, giving suggestions, predicting possible problems, obstacles, proposing preventive measures, etc. This assignment can be done individually or in a group. This type of exercise has proven to be very useful for the development of critical thinking skills, since students are provided with the opportunity to think of solutions, present their point of view, discuss possible changes to the solutions, and hear other students' opinions concerning the given scenario. At the same time, they improve their English language skills, since they are supposed to prepare the solution's presentation in English, so they expand their vocabulary range by using dictionaries, online resources, etc. They also improve their grammar, writing skills as well as their speaking fluency.
5) **Ethical Dilemmas:** This kind of exercise has proven to be very beneficial in terms of development of critical thinking skills. The students are faced with an ethical dilemma. Bear in mind that the students of Occupational Safety and Health will have responsibilities that will include the safety of people. This is why there are endless options that can be used in this type of exercise. Students will have to assume a certain point of view and reinforce it with arguments supported by evidence.
6) **Presenting and active listening:** A student is appointed to prepare a presentation on a certain topic that is related Occupational Safety and Health. The rest of the class has to listen carefully, analyze, ask questions, and give impressions and suggestions. Students can be asked to paraphrase what the speaker has said, to write a short summary, reflect, ask questions etc., in order to check whether they understood the material, as well as to practice speaking.
7) **Classification:** classification will help students not only to memorize new vocabulary, but to put new words into context, thus giving them the opportunity to create certain associations to words, that they might use in future. For example, they can classify vocabulary into categories: PP equipment, types of safety officers, types of hazards, dangerous chemicals etc. Students can also classify vocabulary according to grammar features or parts of speech.
8) **Identifying arguments:** Stance (topic sentence), Evidence (supporting ideas, cited research, quotes), Explanation (explaining the evidence from your point of view), [6].
9) **Error correction:** Students are given a text with errors. Their task is to find the errors and fix them. By doing this exercise, students get multiple benefits. They develop critical thinking skills, identify text aspects, practice grammar and vocabulary etc.
10) **Argumentative essay writing:** Argumentative essay writing is one of the strategies that has proven to be very successful in developing skills such as careful thinking (reflective thinking), objective analysis and evaluation (rational thinking), and judgment formation (reasonable thinking) [7].Students are presented with the instructions on how to write argumentative essays. At first they write the outlines and present their ideas to the class. After class discussions, where they can point out the mistakes, give suggestions, but also to point out good aspects of the presented outlines, their assignment is to write the complete essays based on the outlines. Once again their work is the subject of class discussions.

3. CONCLUSION

Taking all the facts into consideration, it is clear that critical thinking is omnipresent in all aspects of foreign language acquisition. It is necessary for teachers to promote independent learning and explain how important it is. The reason for this lies in the fact that students with deep approach to learning tend to have developed critical thinking skills because they use cognitive skills of higher order.

However, students need to possess theoretical knowledge that they will use as a foundation that will be gradually upgraded. The combination of techniques for teaching theory and techniques that engage students into interactive activities that will develop their critical thinking skills has proven to yield excellent results in the acquisition of English language at the tertiary level of education.

BUSINESS COMMUNICATION OBSTACLES IN ENGLISH LANGUAGE IN OCCUPATIONAL HEALTH AND SAFETY EDUCATION

Tanja Radović[1], The Academy of Applied Technical Studies Belgrade
Marija Mićanović[2], The Academy of Applied Technical Studies Belgrade

Abstract: *In this paper the authors try to explain business communication obstacles in English language in Occupational Health and Safety education. Business communication is very important for students' future career. The main obstacles are sociocultural, psychological and organizational. All three of them have specific influence on students. The authors explain these obstacles more precisely in order to be more understandable. These obstacles can be solved by better understanding and determining business communication obstacles.*
Keywords: business communication, obstacles

1. INTRODUCTION

Communication in general sense implies message transmission from sender to recipient. The aim of communication is not only to receive the message but to understand it. It is important in all aspects of live. Its basic characteristics are: 1. It is comprehensive and represents the main element of culture, 2. It is continuous, endless, 3. It is based on message exchange, 4. It works in many , and between two or more groups, 5. It is held by equals and unequals no matter of gender, age, social status and education, 6. It contains predictable, expectable or conventional elements, 7. It has irreversible character and 8. It is contextual because it depends on context in which it is held.

2. COMMUNICATION OBSTACLES

Business communication is a type of communication which is used in business world. It represents the discipline of writing, presentation and communication in professional manner. Unfortunately, there are many obstacles in business communication. We can divide them into: sociocultural, psychological and organizational obstacles. They consist of everything that prevents the message to be received and understood. They are mainly of human origin, not technological.

3. SOCIOCULTURAL OBSTACLES

By participating in some culture, consciously or unconsciously, we obey social norms. Social norms are implicit or "informal" rules about what, how, when and where is something done. From the communicational perspective it is interesting that social norms and cultural characteristics are not important only because they enable better communication, but because these same norms can be communication obstacles. Key sociocultural elements that can become obstacles are: group thinking, conflict between values and beliefs, stereotypes and ethnocentrism, language and slang. Group thinking is the social phenomenon which appears when group behavior domineers or suffocates the process of decision making. It appears when social norms or group's tendencies to reach consensus overpower tendency to achieve decisions that are in the best interest of the group. It also happens

[1] tradovic@atssb.edu.rs
[2] mmicanovic@atssb.edu.rs

when common values and conformism get out of control. Characteristics of group thinking are: similarity and hidden differences, reliance on mutual rationalizations, collective models of defensive avoidance, the lack of awareness, hiding worrying deficiencies, unjustified optimism and thinking in slogans. Conflict between values and beliefs appears as a consequence of unsuccessful communication caused by ignoring mutual basic values and norms. Stereotype is an attempt to predict one's behavior based by their membership in certain group. It represents obstacle in communication because, due to them, we do not look at people as individuals and we do not listen to their messages. Ethnocentrism links to the stereotypes. Ethnocentric people look upon their culture as the only valid one. They measure out everyone according to their own culture standards which for they think as superior ones. It also, like ethnocentrism, leads to prejudice and discrimination. Language can represent communication obstacle even if interlocutors speak the same language. The status and class differences have influence on different language use which can identify or exclude entire groups of people. Slang can have the same purpose.

4. PSYCHOLOGICAL OBSTACLES

Psychological obstacles refer to the individual and their mental and emotional state. People tend to hear what they want to hear, and to see what they want to see. Our filters and prejudices are very often the result of personal values and cultural origin. These problems can be avoided by cautious listening and reading. We are constantly "bombed" by so much information that we practically cannot process, so certain amount of selectivity is more than necessary. The rare ones succeed to deal with so many information and data and that is called framework of thinking. It is caused by: limited time and other resources during information collection, different expectations of the manager and others concerning criteria that determine the importance of information and, limited ability of understanding, processing and using huge amount of information. Perceptions are the ways by which we observe the world. Our perceptions can become the communication obstacles. It happens that we don't want to understand what is received in communication because even before the communication happened we had made the idea in our head that it is not important to us. We actually never lose what we have experienced by acting, listening, reading, smelling and touching. However, maybe we cannot reach those memories. If we want to become a successful communicator, we should learn and practice memory exercises. The key elements which enable better memory are: understanding, the knowledge width, active remembering, pre-learning and associations. Bad listening includes daydreaming, reading, listening to the other conversation instead of the one we are participating in, sightseeing and generally situations where we are not concentrated on listening. Some problems connected to listening are obvious – problems caused by external disturbances or lack of interest. However, there are more subtle ones: verbal struggle (It happens that, instead of listening and absorbing what the other person is telling us, we start to discuss ideas in our head.) and fact hunt (when we, instead of listening to the basic topic or the argument point, concentrate on detailed facts and because of that we don't realize the whole message). There are few types of listeners: fake listener (the one who seems to carefully listen, even transmits appropriate non-verbal signals, but is really somewhere else in their head), limited listener (partially pays attention to what we are speaking, concentrates on specific details or comments so they can misunderstand other messages), egocentric listener (only cares about their own point of view and all they want of us is to agree. They choose only the communication elements which can be used as the support for their point of view.), and positive or active listener (the one who absorbs and processes information that they receive, but also encourages the other person to speak). In order to be an active listener, we should develop the following skills: the ability to participate (it relies on careful listening, awareness and absorbing of told things), the ability to follow (not only mental, but physical indication that we are following what the speaker is talking about), and the ability to consider (we should think about the material so it could transfer from sensory to our short- term or long-term memory). Emotions can also represent obstacles in sending and receiving messages. When a person is angry, sad or frightened, their communicational abilities can weaken.

Positive feelings can be an obstacle too, for example, too much humor is going to make our message not so important and serious.

5. ORGANIZATIONAL OBSTACLES

Organizational obstacles refer to the organizational structure, culture, work model and communicational flows. The most common organizational obstacles are: information overload (direct approach to information gives people the feeling of overcrowding), message competition (the quantity of information that we receive every day forces us to choose between things that are important and things that we can ignore), information distortion (information can be wrongly interpreted or even intentionally be blocked), message filtering (by filtering or inspecting we can choose the communication which is worth paying attention), contradictory messages (they can ruin its credibility), communicational climate and status differences. We can solve organizational obstacles by observation, accuracy, credibility and likeability. We can mitigate the obstacles by lessening level numbers in organizational structure. Less number of links in communication chain contributes to better communication.

6. CONCLUSION

Business communication in English language in Occupational Health and Safety Education is very important for students. If they are good English language speakers, they tend to convince themselves that their business communication skills are also good and they usually make mistakes. They are mostly affected by sociocultural and psychological obstacles. The teaching experience has shown us that they mostly tend to think as a group, use stereotypes, have wrong perceptions and overuse their emotions. That is the reason why we have to take this matter more seriously and help them to reach better business communication skills as well as in English as in their mother tongue.

A NOVEL TABULAR METHOD FOR ESTIMATION OF WATER FLOW RATE AT THE HYDRANT NOZZLE

Radenko Rajić[1], The Academy of Applied Technical Studies Belgrade
Ivan Arandjelović[2], Faculty of Mechanical Engineering, University of Belgrade
Nikola Tanasić[3], The Academy of Applied Technical Studies Belgrade

Abstract: *In order to estimate the flow rate of water at the hydrant nozzle, the standards such as SRPS Z.C1.050:1989 and DIN 14 440 cannot be applied to all types of nozzles that obey the requirements of reference standards SRPS EN 671-1: 2015 or SRPS EN 671-2:2015. In this paper the authors present tables that can be used for estimating flow in function of pressure and flow characteristic of hydrant nozzle with orifice diameter of 8 and 16 mm.*
Keywords: Hydrant nozzle, Flow characteristic of nozzle

1. INTRODUCTION

The most important numerical parameters for fire hydrant operation are: water static pressure, dynamic pressure and flow rate. During hydrant periodic testing, that is mandatory to be carried twice per year, static pressure is measured at each internal wall-mounted hydrant cabinet. Dynamic pressure is measured at the cabinet with the most unfavourable hydraulic position (where the lowest pressure values are expected, i.e. on the highest floor or the most distant form water source), while for other cabinets dynamic pressure is calculated. Flow rate at each cabinet can be determined by calculation or measurement. In paper [1], the procedure for determining the mentioned hydrant parameters is presented, as well as the procedure for determining the flow characteristics of hydrant nozzle. Standards [5] and [6], which are mandatory for application in Serbia according to the rulebook [3], define the minimum flow characteristic depending on the nozzle diameter and the minimum flow rate at pressures of 2.0 bar, 4.0 bar and 6.0 bar. In Serbia, the standard [4] is used to calculate the hydrant flow rate. This standard is practically a translation of the standard [8], in terms of text, equations and symbols that are identical, while the tables and nomograms are different. The difference is that in the standard [8] the flow rates resolution in tables and nomograms equals to 1 l/min while in the standard [5] it equals to 5 l/min. Please note that before the adoption of harmonized regulations [5], [6] and [7], the nozzle geometry and the procedure of nozzle manufacturing were standardized, but not the nozzle flow characteristics.
In a series of measurements that were carried out at the Centre for Fire Protection Engineering of the Faculty of Mechanical Engineering in Belgrade, it was shown that the flow characteristics of nozzles that are offered in Serbian market and that meet the requirements defined by standards [5] and [6] are significantly different from the flow characteristics that are obtained according to standards [4] and [8]. In paper [2], it was stated that for nozzles with a nozzle diameter of 12 mm, which are prescribed by regulation [3] for mandatory use when testing internal hydrant installations, the flow characteristic determined by measurement ranged from 76 to 83, while the flow characteristic determined by procedure given in standard [4] equals to 96 and by using standard [8] equals to 94. Hence, it can be

[1] rrajic@atssb.edu.rs
[2] iarandjelovic@mas.bg.ac.rs
[3] ntanasic@atssb.edu.rs

concluded that tables and nomograms given in standards [4] and [8] are not applicable for hydrant nozzles that are present on the market.
In paper [2], tables are given in which the flow rates of water at hydrant nozzle with a nozzle diameter of 12 mm are shown as a function of pressure, for different nozzle flow characteristics. In this paper, tables will be presented in which the flow rates of water at nozzles with nozzle diameters of 8 mm and 16 mm can be determined as a function of pressure, for different nozzle flow characteristics.

2. DETERMINATION OF NOZZLE FLOW CHARACTERISTICS

The procedure for determining the flow characteristic of the nozzle is given in detail in other paper [1]. Here it will be presented briefly. For the standard hydrant nozzle, which is shown in Fig. 1, the water flow rate through a constant nozzle orifice is directly proportional to the square root of the water pressure value. The proportionality coefficient is called the flow characteristic of the nozzle (K). Therefore, the relation can be expressed as:

$$Q = K\sqrt{P} \tag{1}$$

Where,
P – pressure [bar];
Q – flow rate [l/min];
K – flow characteristics $[\,l/(\min\sqrt{bar})\,]$.

When determining the flow characteristic, a pressure gauge (manometer) is mounted between the hydrant nozzle and hydrant hose. The nozzle to be tested is directed outdoor or to a drainage pit. By adjusting the valve position at the hydrant cabinet, the pressure in the installation is controlled. The flow is measured with an ultrasonic flowmeter, which is placed at the water supply pipe to the hydrant cabinet. Pressure (P) is set at fixed values of 2.0 bar, 2.5 bar, 3.0 bar; 3.5 bar, 4.0 bar, 4.5 bar, 5.0 bar, 5.5 bar and 6.0 bar. The estimation of the value of the nozzle flow characteristic is determined by the application of the least squares method [1]:

$$K = \frac{\sum_i Q_i\sqrt{P_i}}{\sum_i P_i} = \frac{\sum_i Q_i\sqrt{P_i}}{36}. \tag{2}$$

Figure 1. Standard hydrant nozzle (orifice diameter 16 mm, hose connection flange Ø75mm - type B, length 410 mm, height 126 mm, weight 1.75 kg)
Source: https://tehnoprom.rs

3. TABLES FOR CALCULATING FLOW RATE AS A FUNCTION OF PRESSURE

In Table 1, results are presented for a nozzle with an orifice diameter of 8 mm. Such nozzles are used at the internal hydrant cabinets in accordance with the standard [4]. According to the rulebook [3], this type of nozzles can be installed on internal hydrant networks in residential and commercial buildings that have a maximum of 5 above-ground floors and the technological process category is K3, K4 or K5. For such hydrant installations semi-rigid hoses wound on a reel can be applied. Their advantage is that the maximum permitted distance from the point in the protected area to the hose connection in hydrant cabinet is 30 m, which is greater than the connections defined by the standard [5].

The water flow rate [l/min] is expressed as a function of the pressure (*P*) [bar] and the flow characteristics of the nozzle (*K*) as shown in Table 1. It was adopted that the pressure value should be regulated with step of 0.5 bar, which ensures an accuracy of 0.25 bar, because greater accuracy is not achieved even by measuring with standard manometers.

Table 1. Flow rate at nozzle [l/min] as a function of pressure *P* [bar] and nozzle flow characteristics *K* – for nozzle orifice diameter of 8 mm

45	64	71	78	84	90	95	101	106	110	115	119	123

In Table 2, results are presented for a nozzle with an orifice diameter of 16 mm. This type of nozzles are defined by regulation [3] for mandatory use when testing external hydrant installations. The regulation also define minimum dynamic pressure at the connection of the external hydrant network of 3 bar and the flow rate of 5 l/s.

As in previous case the pressure values from 2.0 to 7.5 bar in Table 2 are with step of 0.5 bar, which ensures an accuracy of 0.25 bar, because greater accuracy is not achieved even by measuring with standard manometers.

4. CONCLUSION

In the former standards that were used before the adoption of harmonized regulations in Serbia in 2018, the geometry of the hydrant nozzle and the procedure of its production were standardized, but not the flow characteristics. In a series of measurements that were carried out at the Centre for Fire Protection Engineering of the Faculty of Mechanical Engineering in Belgrade, it was shown that the flow characteristics of the nozzles that are sold on Serbian market and that are in accordance with the harmonized regulations have lower flow characteristics than those for the nozzles defined by the standards [4] and [8]. Therefore, in this paper, tables are given in which the flow rate [l/min] through a nozzle with orifice of 8 mm and 16 mm in diameter is expressed as a function of the pressure [bar] and the flow characteristics of the nozzle. The use of these tables can significantly facilitate the work of engineers and technicians who carry out the initial and periodic testing of the performance of internal hydrant installations.

Abstract: *The choice of equipment and means for extinguishing forest fires is very often, along with the application of appropriate tactical extinguishing methods, important for the efficiency and success of extinguishing this type of fire. The use of mechanized forest firefighting equipment where possible can greatly help to improve firefighting efficiency and reduce firefighting time. In order to be able to use mechanized equipment, it is necessary to know the conditions on the ground and the possibility of its application. That is why it is always good to know certain legalities and according to them to choose suitable equipment for extinguishing forest fires. Where it is possible and economically justified, it is necessary to immediately use mechanized equipment for extinguishing forest fires, as this reduces the extinguishing time and the number of people needed for extinguishing.*
Keywords: forest firefighting equipment, forest fires, fire protection

1. INTRODUCTION

Fighting forest fires is a difficult and dangerous job. The choice of fire extinguishing equipment is very important when extinguishing and has a significant impact on the effectiveness of extinguishing. The use of mechanized equipment for extinguishing forest fires is very important, where it is possible to use this equipment primarily in reducing fatigue when extinguishing with manual equipment, and also in improving the speed during extinguishing and the efficiency of extinguishing.

2. MECHANIZED EQUIPMENT FOR EXTINGUISHING FOREST FIRES AND ITS INFLUENCE ON EXTINGUISHING EFFICIENCY

The use of mechanized equipment for extinguishing forest fires facilitates and accelerates extinguishing actions and prevents the spread of forest fires. Practice shows that after two to three hours of work on extinguishing forest fires using manual equipment, the efficiency of well-trained people drops significantly due to fatigue.

[5] anitaklikovac@yahoo.com

Figure No. 1 shows the influence of fatigue on the efficiency of extinguishing using manual extinguishing equipment.

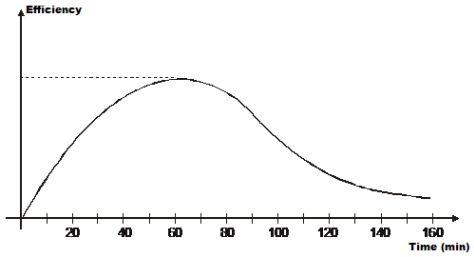

Figure 1. The influence of fatigue on the efficiency of extinguishing forest fires with manual equipment [1]

From the diagram (Figure 1), it can be seen that the efficiency drops significantly after 1.5 - 2 hours of work, so it is preferable to use mechanized equipment for extinguishing forest fires wherever possible.

The use of mechanized equipment for extinguishing forest fires can be made difficult by terrain conditions, such as: inaccessible and steep terrains, soft and unsuitable roads, unorganized and impassable forests, swampy terrains, economic reasons and the like.

The most important works that can be performed with mechanized equipment when extinguishing fires are:

- fire extinguishing with water,
- removal of combustible material in front of the fire, especially when forming fire lines,
- digging ditches, plowing and burying fuel material and the like and creating fire lines.

To extinguish and prevent the spread of forest fires, in addition to special firefighting vehicles and machines, machines for road construction, exploitation of forests, machines and tools for agricultural and other similar works are also used.

Mechanized equipment for extinguishing forest fires consists of:

- a wheeled tractor, with a simple or double plow, and a harrow for working on flat terrain,
- crawler tractor with plow,
- a grader (construction machine) on flat terrain, suitable for the construction and cleaning of fire protection lines,
- diggers and loaders for removing combustible material from the surface, transporting heavier pieces of combustible material (trees, branches, etc.).
- bulldozers for removing trees, pushing combustible material in front of the fire, laying fire lines when extinguishing fires of tall vegetation and the like,
- vehicles for water extinguishing (tanker trucks, combined vehicles, tankers with sprinklers and the like),
- vehicles for transporting personnel and equipment,
- vehicles for transporting heavy machinery to the place of intervention.

Figure 2. The creation of a blocked belt using a tractor with a plow

Table 1 shows the performance of mechanized equipment when extinguishing and preventing the spread of forest fires.

Table 1. Performance of mechanized equipment in preventing the spread and extinguishing of forest fires (1)

the name of the mechanized equipment	speed (km/h)	surface area (ha/h)	bandwidth, (m)
grader trailer: **д-20-А,д-20Б, д-165-А...** **д-241....**	 **1,0** **0,7**		 **4,5** **4,5**
auto graders: **д-144** **д-196**	 **1,0-1,25** **0,7-0,9**		 **4,5** **4,5**
bulldozers: **д-216** **д-157** **д-159**		 **0,4-0,7** **0,6-2,0** **0,6-1,2**	 **6,0** **6,0** **6,0**
tractor plows: **п-5-35, 5к-35...** **к-412-д...**		 **0,81** **0,6**	 **tractor speed** **4,8 km/h**

Setting up a barrier belt using agricultural machinery is the safest and most efficient way to stop the spread of fire along the edge. However, the application of these machines is limited by their slowness of movement, high weight, poor mobility and low maneuverability. Due to slow movement, mechanized equipment arrives late at the work area. Therefore, in order to transport these machines faster, it is necessary to provide vehicles for their quick delivery to the place of intervention (towing train, vehicle carriers, etc.).

The choice of vehicles for extinguishing forest fires cannot always be subject to some standardization, primarily because the problem of extinguishing forest fires is so diverse that common lines cannot be drawn in every case. The choice, construction and equipment of firefighting vehicles depends on terrain and topographic conditions, the type of predominant vegetation, the way and method of extinguishing and economic factors.

Terrain - topographic conditions impose the use of different types of vehicles. Tracked vehicles are more suitable for swampy, soft, uneven, rocky, hilly, and poorly accessible roads. Wheeled vehicles are more suitable for hard, flat, well-traveled terrain and with good roads.

The type of vegetation also requires the use of different types of vehicles, so lighter and faster vehicles are used for grassy terrain and maquis, and heavier and slower vehicles for forests and dense maquis.

Firefighting tactics determine the choice of vehicle, primarily depending on the application of direct or indirect firefighting methods. In the first case, more people and equipment are needed for extinguishing, so the vehicles must be adapted to those needs. In the second case, more heavy equipment and vehicles will be used for indirect extinguishing.

Figure 3 shows some dependencies when choosing a vehicle for extinguishing forest fires.

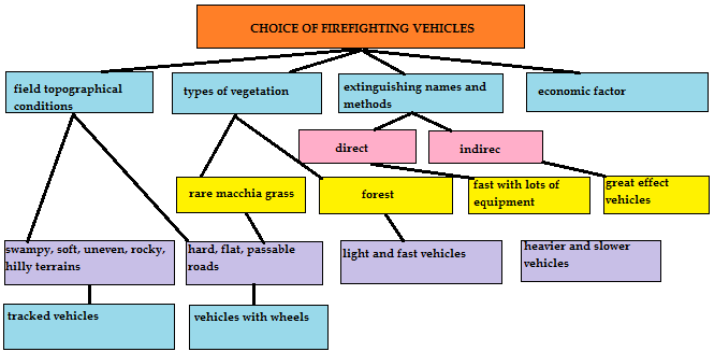

Figure 3. Scheme of selection of vehicles for extinguishing forest fires (1)

Before choosing, purchasing and equipping a vehicle, a thorough examination of the field conditions is necessary. It is necessary to work out the tactics of extinguishing forest fires in detail and include all this in the plans for suppressing and extinguishing forest fires.
Where the conditions allow it, it is necessary to use mechanized equipment when extinguishing forest fires, primarily due to the speed of extinguishing, reduction of fatigue of people, coverage of a larger area affected by the fire. By using this equipment, the risk can be reduced, and thus contribute to the increase in extinguishing efficiency. That's why in operational extinguishing plans, it is necessary to enter all the facts that are important for the use of mechanized equipment, such as the marked roads, the condition of the roads, the method of transporting the mechanized equipment, the type of vegetation, places for collecting and stationing the equipment, protective lines and the like.
Table 2 shows the time saved by using mechanized equipment compared to manual equipment for extinguishing forest fires.

Table 2. Time savings using mechanized equipment for extinguishing forest fires (1)

TYPES OF WORKS	1 man (minute)	the machine (minute)
1. Installation of a barrier belt with a width of 0.5 (m) using hand tools and machines	80 - 100	15 - 20
2. Installation of the obstacle belt using a tractor plow by five people	10 - 15	2 - 3
3. Placement of an obstacle belt using explosives at a distance of 1 m between the openings	100 - 120	
4. Installation of a barrier belt using chemicals, 1 m wide and consumption 0.5 l/m2	15 - 18	3 - 6
5. Extinguishing the edge of the fire using two jets of water with the treatment of a strip 10 m wide by six people	40	15

Table 2 shows that the time to extinguish forest fires using mechanized equipment is relatively shorter. This equipment should always be used in forest firefighting when field conditions permit.

3. EFFECTIVENESS OF APPLICATION OF FOREST FIRE EXTINGUISHING EQUIPMENT - METHODOLOGICAL APPROACH

Table 3. Efficiency of the use of mechanized equipment for extinguishing forest fires in relation to the possible area of application

Extinguishing area with mechanized equipment (%)	Extinguishing efficiency
The possibility of using mechanized equipment on 70% or more of the surface	Excellent and extremely effective
The possibility of using mechanized equipment from 50 to 70% of the surface	Extremely good
The possibility of using mechanized equipment from 30% to 50% of the area	Good
The possibility of using mechanized equipment from 10% to 30% of the area	Good as an auxiliary shutdown method
The possibility of using mechanized equipment on less than 10% of the area	Satisfactory as an additional extinguishing method

Table 4. Efficiency of the use of mechanized equipment and the choice of vehicles for extinguishing forest fires depending on the terrain and topographical conditions

Type of terrain	Choice of vehicle	Efficiency
Wetlands with softer ground, hilly terrains	Crawlers and tracked vehicles	Very good
Wetlands with softer ground, hilly terrains	Wheeled vehicles	Not recommended due to the possibility of jamming
Wetlands with softer ground, hilly terrains	Four-wheel drive vehicles	Good
Wetlands with softer ground, hilly terrains	Vehicles without four-wheel drive	Not recommended
Hard and flat, with good and passable roads	Wheeled vehicles	Very good
Hard and flat, with good and passable roads	Tracked vehicles	It can be good, it is limited by slower and heavier transport
Hard and flat, with good and passable roads	Vehicles for transporting people	Good

Table 5. Efficiency of the use of mechanized equipment and the choice of vehicles for extinguishing forest fires depending on the type of predominant vegetation

Type of predominant vegetation	Type of vehicle	Efficiency
Predominant vegetation: grass and low vegetation	Lighter and faster vehicles	Very good
Predominant vegetation: grass and low vegetation	Heavier and slower vehicles	Good but the performance is lower due to greater slowness (longer shutdown time)
Forest and dense vegetation	Lighter and faster vehicles	Good, but depends on access (good and passable roads are required)
Forest and dense vegetation	Heavier and slower vehicles	Good because of greater passability, but requires a longer extinguishing time due to slower action

Table 6. Efficiency of the use of mechanized equipment for extinguishing forest fires depending on the way and method of extinguishing

Extinguishing method	Type of vehicle	Efficiency
Indirect extinguishing method	High-speed vehicles are used with great effect in the installation of barrier belts and tracks	Very good
Indirect extinguishing method	Heavier and slower vehicles with good performance in placing barrier belts and tracks	Good
Indirect extinguishing method	A combination of high performance fast vehicles and heavier slower vehicles with good performance	Extremely good
Direct extinguishing method	Fast vehicles with more equipment	Good
Direct extinguishing method	High speed vehicles and medium speed vehicles with water fire extinguishing equipment	Extremely good
Direct extinguishing method	Fast vehicles for transporting personnel and equipment	Good

Table 7. Mechanized equipment for extinguishing forest fires with water and efficiency in relation to the intensity and speed of filling with water

Charging speed (minutes)	Efficiency
Up to 15 minutes	Very good
Up to 30 minutes	Good
Up to 60 minutes	It depends on several factors (intensity of fire, speed of spread, influence of wind, etc.)
Over 60 minutes	Not recommended

4. ECONOMIC JUSTIFICATION OF THE USE OF MECHANIZED EQUIPMENT FOR EXTINGUISHING FOREST FIRES IN RELATION TO THE AMOUNT OF MATERIAL DAMAGE CAUSED BY THE FIRE

Although this aspect is often overlooked and not taken into account, the actual costs of extinguishing forest fires are often high and exceed the damage caused by the fire itself. The question is often asked whether it is justified to make large material costs using a large amount of equipment and hiring a large number of people if this exceeds the damages caused by the fire itself, unless the fire creates a danger to people and material goods. It is often not possible to draw an exact line between all the parameters because there are many of them, and one must also take into account the environmental hazard factor, which is often immeasurable.

Table 8. shows the economic justification of using mechanized equipment for extinguishing forest fires in relation to the damage caused by the fire itself.

The amount of damage caused by the fire and the material costs of extinguishing it with mechanized equipment	Justification
If the use of mechanized equipment for extinguishing forest fires does not exceed 30% of the material damage caused by the fire	Very justified
If the use of mechanized equipment for extinguishing forest fires ranges from 30% to 50% of the material damage caused by the fire	Justified
If the use of mechanized equipment for extinguishing forest fires ranges from 50% to 80% of the material damage caused by the fire	Justified if there is a greater threat to people and material goods
If the use of mechanized equipment for extinguishing forest fires exceeds 100% of the material damage caused by the fire	It is not justified, it is necessary to use other methods

5. CONCLUSION

The use of mechanized equipment for extinguishing forest fires where possible is desirable and its application can compensate for many of the shortcomings and problems that arise from the use of manual equipment for extinguishing fires. Where the conditions allow and where the use of mechanized equipment is justified, mechanized equipment should be used because it reduces the extinguishing time and reduces the number of people needed for extinguishing, and its application can increase the efficiency of extinguishing. The very possibility of using mechanized equipment for each area should be determined based on the parameters that condition the use of this equipment and entered into the maps of applicable equipment for extinguishing forest fires.

PREVENTION OF OCCUPATIONAL RISKS IN TRANSPORT AND INSTALLATION OF CONCRETE PRESTRESSED T-GIRDERS ON PROJECT IVERAK-LAJKOVAC

Darko Marković[1], Instiute Alfapreving, Belgrade
Nebojša Ćurčić[2], The Academy of Applied Technical Studies Belgrade

Abstract: *With a gantry crane located on the plateau, the precast T-girder is lifted and loaded onto the transport vehicle. Placement of the girder in a precisely determined and pre-prepared place is done with two truck cranes with a load capacity of up to 70 tones or with one truck crane with a load capacity of up to 200 tones. Due to their size and mass, precast concrete elements pose a significant risk to everyone who works with them and persons in the immediate vicinity. The process of lifting and mounting the girders belongs to the group of high-risk jobs. Transport, lifting and installation of girders is a demanding and complex process in construction site. In the construction phase, occupational safety management is a critical segment that must be addressed in order to maintain the health and safety of employees while promoting productivity. During the preparation of technical documentation, engineers must take into account occupational safety and health as well as costs, so that the Plan of preventive measures foresees adequate preventive measures in the execution phase. In the future, alternative methods such as working with a launching gantry or working on scaffolding should be used.*
Keywords: prestressed concrete girder, truck crane, launching gantry, protective measures, technical documentation

1. INTRODUCTION

The construction of the high-speed road Iverak - Lajkovac represents a transverse link in the road network of the Republic of Serbia and connects parts of the Republic of Srpska, i.e., Bosnia and Herzegovina with the E-763 road (Belgrade - South Adriatic) and Corridor X. The technical characteristics of the terrain through which the section of the state road passes is plain. The total length of the section is 18.25 km.
Based on the hydrological analysis of the "Jaroslav Černi" Water Institute, carried out for the hydraulic calculation of the high waters of the Kolubara River for the relevant 100-year high water level, the route was placed on the bridge structure in the zone of immediate influence of the Kolubara River, in a length of 4 km. Crossing 1 has a total length of about 185 m (six fields), Crossing 2 has a length of about 930 m (33 fields) and Crossing 3 has been increased to 580 m (20 fields) [1]. Bridge constructions are semi-integral, they consist of segments with spans usually of 30 m. The upper part of the structure consists of 6 prefabricated prestressed girders connected to each other by a road plate. At Crossing 2 (the bridge over the Kolubara River), where there are 33 fields, a total of 348 prefabricated concrete girders have been prepared for installation. In the assembly phase, the girders are of the static simple beam system, and the span of the girders is 24.40 m, 29.40 m, and 35.40 m.
In the paper are presented method used for lifting and mounting T-girders, alternative methods, determination of safe methods and procedures, monitoring of the entire work process, analysis, and improvement of protection measures during the performance of work activities on the assembly of T-

[1]darkomarkovic.hse@gmail.com
[2]ncurcic@atssb.edu.rs

girders. The aim of the paper is to analyze the construction, transport, and installation methods of the ginders, identify existing hazards and circumstances that may threaten the occupational safety and health of employees. To implement adequate measures, a risk assessment is needed that includes an analysis of the current state of safety. It is important to raise awareness among all participants about the importance and role of safety, as well as the impact on the behavior of employees during the performance of work activities.

2. CONCRETE PRESTRESSED GIRDERS CONSTRUCTION PROCEDURE

Prefabricated components are previously concreted and confined on the prefabrication platform in the immediate vicinity of the building (bridge). After the concrete has hardened and the appropriate stress has been achieved in accordance with the project documentation for the construction of the bridge, they are transported as finished elements and mounted on the bearing beams. Before mounting the girders, the contractor will control the position and height of the bed on which the mounting supports will be supported and seek the approval of the supervisory authority. Installation is done with truck cranes. During assembly, the supports must be secured in terms of the designed position and secured from reaching such a position in which stress conditions occur that are unfavorable in relation to the quantity provided by the project.
After the concreting process of one girder and formwork dismantling, as well as after the completion of the first phase of the prestressing process (tighten of the lower cable), the girders are placed in the designated place for storage. Gantry cranes are used to move the girders, which are placed on the platform for the prefabrication of girders. On the plateau there are two cranes with a capacity of 60 tones, which are used for lifting the finished girders and two cranes with a capacity of 10 tones for lifting the formwork. The girders are raised three times in different stages. The first time with gantry cranes in the storage phase, when the girder is moved from the base (foundation) where it is concreted to the storage area. The second time with a gantry crane when the girder is placed on a transport vehicle that is used to transport it to the place of installation. The third time, the girders are lifted by truck cranes and placed in the intended place in the bridge structure itself (bearing beam). Figure 1 shows the method of lifting a T-girder with cables using a gantry crane [2].

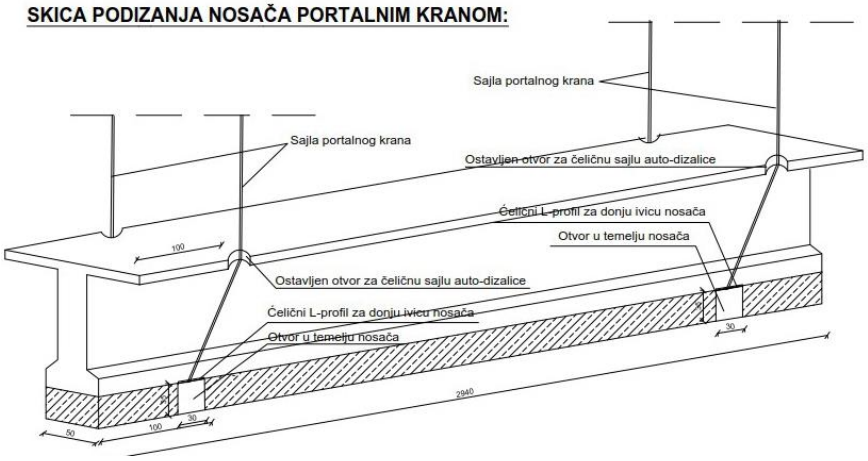

Figure 1. The method of lifting T-girders with a gantry crane with cables [2]

The gantry crane located on the plateau lifts the prefabricated T girder and loads it onto the transport vehicle with a payload of 100 t and the girder is transported to the location of the bridge. On the bridge, the longest T-girder is 35.40 m, and the weight is about 60 t. Placement of the girder in a precisely determined and pre-prepared place is done with two truck cranes with a load capacity of up to 70 t or with one truck crane with a load capacity of up to 200 t. The required number of truck cranes depends on the plan for lifting the girder in the specific field of the bridge, the access and working field of the truck cranes, the access road of the transport vehicle, the terrain conditions at the construction site, the height of the girder lifting, the presence of the river and electrical lines. Figures

2 and 3 show a graphic representation of the mounting of the girder with one truck crane of the right and left bays of the bridge.

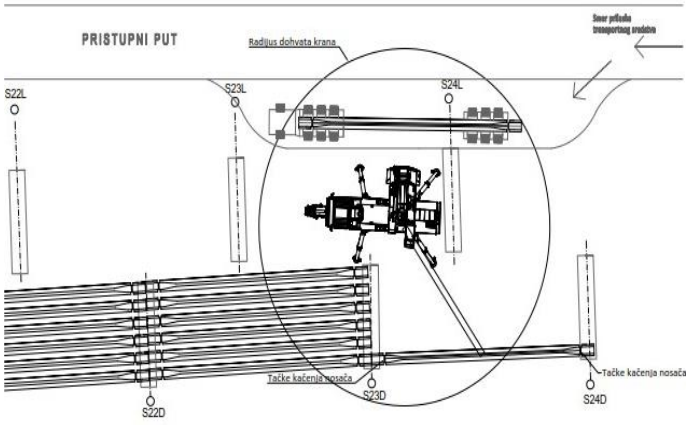

Figure 2. Mounting of the right field with one truck crane [2]

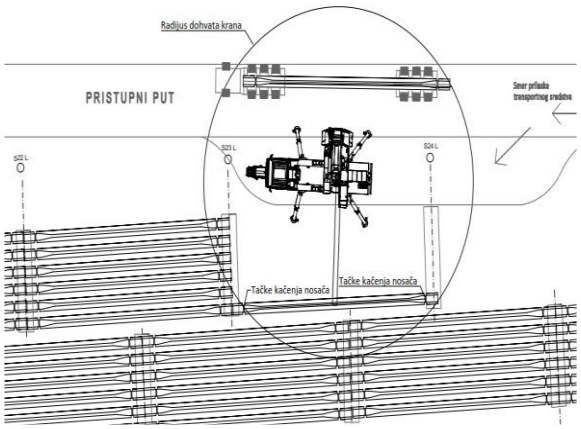

Figure 3. Mounting of the left field with one truck crane [2]

When the terrain and access is such that it is possible to place two truck cranes and a transport vehicle with a girder can approach the working field of the cranes, lifting and placing the girder is performed with two truck cranes, whose load capacity is up to 70 t. Figures 4 and 5 show a graphic representation of the mounting of the girder with two truck cranes.

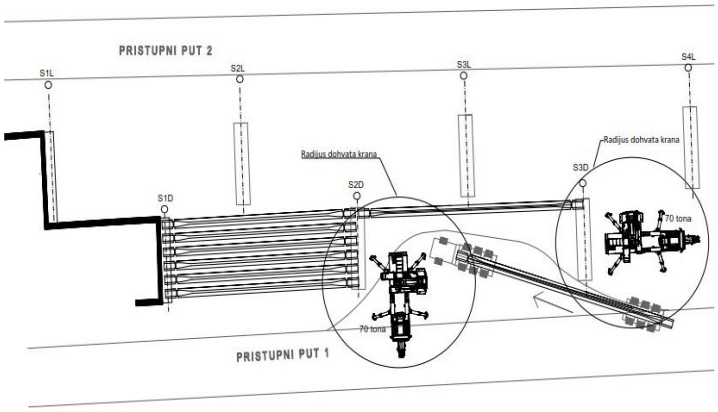

Figure 4. Mounting of the right field with two truck cranes [2]

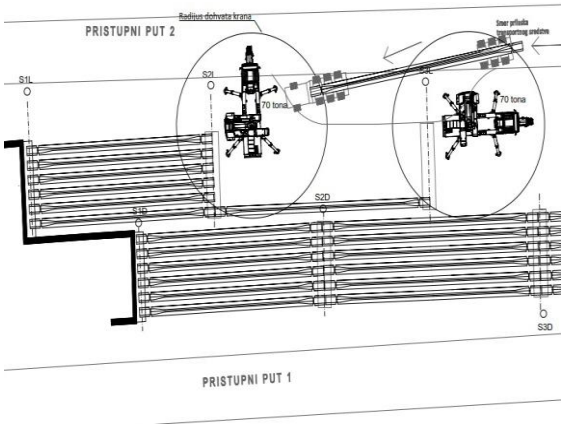

Figure 3. Mounting of the right field with two truck cranes [2]

Testing of the load bearing capacity of soil of the transport roads and platforms for lifting the girders are carried out before the start of the process of transporting prestressed concrete girders. Bearing capacity is satisfactory if it is more than 40 MPa. The test is carried out on the transport road itself, then on the platform where the girders are loaded onto the transport vehicle, as well as in the places where truck cranes are planned for lifting and mounting the girders. The examination is carried out in the presence of the supervisory authority and is carried out by an accredited laboratory.

2.1 Hazards and critical points identification

The previously described method of lifting the girders, using truck cranes, is the simplest, fastest, and cheapest method. Using this method has several disadvantages, namely critical points from the aspect of occupational safety and health. Disadvantages observed during work with truck cranes relate to compaction of the soil and stability of the cranes, access to the place of work and installation of the girders and movement after the completion of the lifting of the girders. The ground on which the stabilizers from the truck crane rest, must be adequately compacted and tested. In certain situations,

near the pillars, the material settles because the compaction guidelines are not respected in the places where the truck crane is placed in the initial lifting position. The stability of the crane is compromised, and it may tip over (Figure 6). Access to the place of work is provided so that employees can come with lifting platforms and after that they make preparations on the bed beams before lifting the girder. The work zone on the bearing beams during the assembly of the girder is narrow and the space for manipulation is narrowed also. The employees are between the reinforcements that are woven and follow the girder that is lifted with truck cranes and the installation in the designed position (bed), where even the slightest lack of concentration and movement can lead to injuries during work (Figure 7). After finishing lifting and mounting the girder on the bed, it is necessary to untie the cable and move to the next field and place yourself in the initial position. Getting out of the initial position from the bearing beam to the girder, untying the cable and moving on the girder after the installation riskier positions in the lifting and mounting phase (Figure 8).

Figure 6. Stabilizers of truck crane

Figure 7. Access and working area of mounting the girder

Figure 8. Getting out of the initial position

In addition to the mentioned method, there are other systems that can be applied when building structures from prestressed concrete, such as the method with a launching gantry or work on scaffolding and other temporary structures. A girder launch is generally a designed and built machine used for precast post-tensioned bridge structures. It consists of a lifting device and a supporting structure for lifting girders and prefabricated bridge segments into the assembled position. A launch girder usually consists of a main truss (″girders″) and lifting devices that would move horizontally along the truss when hanging/lifting the precast girder, bridge segment and/or assembly work platform [3]. The method of the launch gantry crane is divided into the shuttle method, the one-way method and the side feeding method according to the overstressed girder supply method. The construction method of the launching gantry crane enables the construction of bridges with overstressed girders in difficult conditions by delivering materials (girders) to the construction site with vehicles for transporting girders [4]. Figures 9 and 10 show the mounting methods of the carrier with the launching gantry.

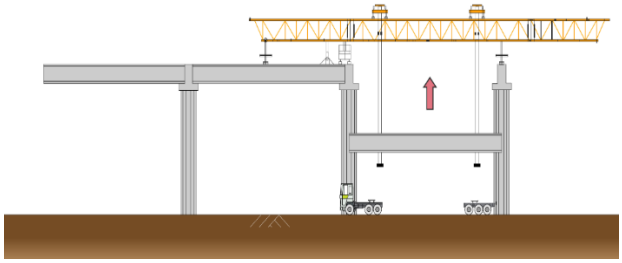

Figure 9. Installation of the carrier from the transport vehicle [4]

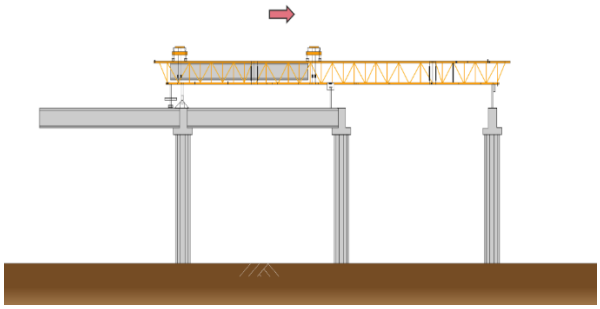

Figure 10. Installation of the carrier using lateral method [4]

From the preparatory work on the installation of the portal for the launching gantry grid method, there are hayards that require the application of protection measures during the process of mounting the elements on the bed. As with the method of lifting with cranes, it is necessary to pay special attention to the movement of employees on the girders after assembly.
Scaffolding consists of straight and angular connections (supports) that are installed and assembled from the bottom surface to the level of the bridge base (fixed scaffolding). Steel scaffolds can be formed manualy or in special forms made in factories [5]. Work on the scaffolding includes complete concreting and prestressing of one field and is done according to the "field by field" principle.

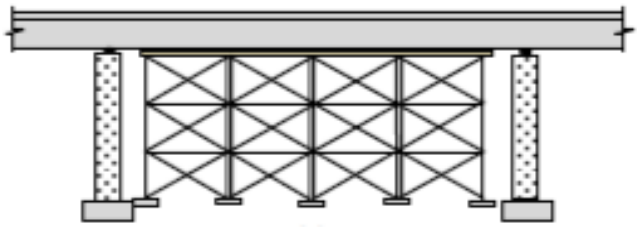

Figure 11. Method of construction on a fixed scaffold [4]

Scaffold assembly and disassembly work requires sufficient soil compaction to prevent settlement. During the preparatory work, it is necessary to comply with the requirements from the scaffolding project and the application of special protection measures when performing work at height. The scaffolding method requires a lot of time for assembly and disassembly and higher costs.
There were no reported work-related injuries on the project during the lifting and installation of the girders, but in this regard, it should be noted that the method with the launching gantry is safer compared to the method used with truck cranes.

2.3 Technical documentation, risk management and protection measures

Technical documentation contains textual, numerical, graphic attachments, technical characteristics of the object, the way, and methods of building the object and the construction works. It is created as a: general project; conceptual solution design; project design; project for building permit; project for construction work; project of the constructed object [6]. Through the justification study, the spatial, ecological, social, financial, market and economic justification of the investment is determined. During the preparation of technical documentation, designers must consider occupational safety and health, so that the Plan of preventive measures foresees adequate preventive measures of protection in the phase of construction works. In the stage of planning and preparation of technical documentation, it is necessary to anticipate costs related to safety measures. Defining and determining safety costs is very important to accurately calculate safety costs and establish a safety management system during construction.
Due to their size and mass, precast concrete elements pose a significant risk to everyone who works with them and employees in the immediate vicinity. Persons carrying out work must manage occupational safety risks, including consultation, cooperation and coordination with others. Employees and their representatives must also be involved when identifying and assessing risks and when deciding how to eliminate or minimize risks [7]. In a construction safety management system, identifying safety risks is one of the most important things to do. Risk identification is necessary to improve workplace safety, as the first step to prevent accidents by knowing the risk factors that contribute to accidents [8]. Based on the perceived dangers in the process of lifting, transporting, and mounting the girders and the analysis of the work activities performed, the works are classified as high-risk and risk control measures must be taken. Figure 12 shows the risk analysis during the lifting and mounting of the T-girders.

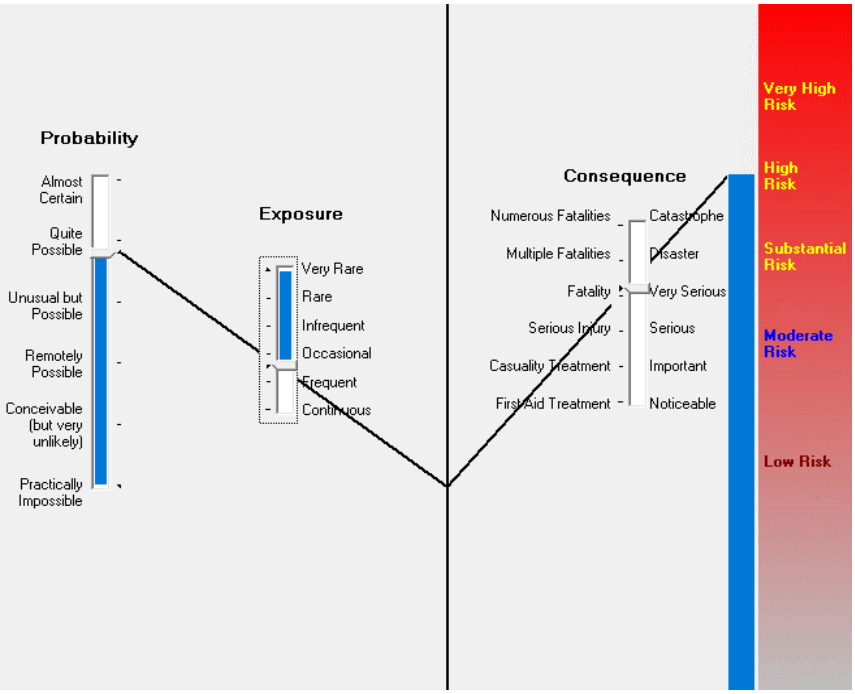

Figure 12. Lifting and installation of the T-girder risk analysis

Based on the identified and established hazards during the transport and installation of T-girders, it is necessary to apply appropriate protection measures. The goal is to eliminate/reduce recognized risks by applying measures and to reduce the possibility of accidents, to the extent that injuries at work are prevented. Figure 13. shows the hierarchy of prevention and control measures.

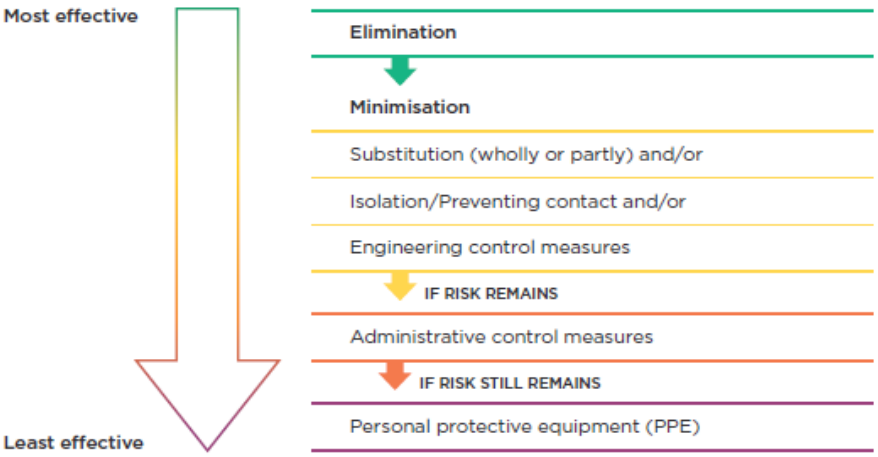

Figure 13. Hierarchy of prevention and control measures [7]

During the construction works, it is necessary to respect the safety measures that have been defined and that the participants in the project adhere to them. For access to the workplace and work zone, it is necessary to set up work platforms that will allow employees safe access to perform work activities. To prevent settlement on the platforms where the truck cranes will be installed, it is necessary to prepare the terrain and sufficiently compact the material. Respect the guidelines from the methodology and carry out continuously for each field test on the transport road itself, on the platform where the girders are loaded onto the transport vehicle and in the places where the installation of truck cranes for lifting and mounting the girders is planned. The aim is to create safe conditions for smooth operation to place the crane stabiliyers on a solid base to avoid the cranes tipping over during the lifting of the girder. A horizontal fall protection system must be provided for exiting the working position and moving on the support. By connecting a portable steel cable or reinforced nylon rope to a series of portable anchors or poles, employees can work safely and efficiently at heights without

compromising mobility or range of motion. When used in conjunction with personal protective equipment, a fall protection system can arrest a fall, limiting the amount of force transmitted to both the employee and the poles [9]. The system must be placed on a platform before being transported to the installation site. In addition to technical protection measures, it is very important to carry out additional training (education) of the direct executors of the work and familiarize them with new methods and procedures for mounting concrete girders, as well as protection measures.
The most effective measure of risk control is the elimination of danger or the replacement of a dangerous process with a less dangerous one, which is more practical, simpler, and cheaper to define in the design and planning phase than to manage risks in construction works.

3. CONCLUSION

Transport, lifting and installation of girders is a demanding and complex process in the building construction phase. The method of lifting and installation the T-girders with truck cranes carries with it dangers that may endanger the safety of employees during the work, therefore alternative methods (launching gantry or scaffolding) should be considered and used. The process of lifting and installation the girders belongs to the group of high risk works. In the construction phase of facilities, occupational safety management is a critical segment that must be addressed to maintain the health and safety of employees while promoting productivity. A well-crafted project that complies with regulations and a method that is safer can result in a significant reduction in costs, injuries, as well as improving the health and well-being of employees during the construction phase.

"NEAR MISS" EVENTS IN THE TPS ZEMUN RECONSTRUCTION PROJECT: A Research and Analysis

Milena Andrejević[1], The Academy of Applied Technical Studies Belgrade

Abstract: *The construction sector is a vast and constantly evolving field characterized by a multitude of uncertainties. All construction projects involve numerous stakeholders and a variety of risks. Effective safety management in this industry requires a tailored and flexible approach. Traditionally, efforts to improve health and safety at construction sites have focused primarily on analyzing indicators collected after work-related incidents, illnesses, or fatal accidents. However, statistical data from the Occupational Safety and Health Administration show that the number of occupational accidents in the construction industry is increasing at an alarming rate despite extensive legislative measures. The main objective of this study was to explore the potential application of corrective measures for "near miss" incidents as a proactive approach to effective safety management in construction projects. The aim was to improve outcomes and overall safety performance. The study was conducted in an organization that had implemented a system for reporting "near miss" events. The study provides a deeper understanding of real-life situations on construction sites, and the willingness and understandings of employees to report unsafe acts and conditions. This prerequisite is crucial to ensure that this tool adds significant value to the safety performance of projects.*
Keywords: Near miss, Safety, Construction

1. INTRODUCTION

The idea of collecting data that would serve to create preventive measures specific to each construction project, through the reporting of "near miss" events, is not new in the world and is part of the indicators that are rated as leading in the field of project management from the aspect of safety and health at work. This relatively free tool is important for collecting data that could not be obtained in any other way and is important for taking preventive measures adapted to the construction project being carried out, but also for the construction industry in general.
Avoided events are well known for providing a major source of useful information for security management. These events occur statistically more often than accidents, and their causes could potentially lead to an accident under slightly different circumstances. Despite the importance of this type of feedback that can be obtained by analyzing the collected data, there is little knowledge about the characteristics of avoided events and the use of this information in the management of occupational safety and health in various fields.

2. NEAR MISS CONCEPT OVERVIEW

A "near miss" refers to an unforeseen incident that, although it did not cause any harm, illness, or damage, had the potential to do so. It was only due to a fortunate chain of events that injury, death, or damage was averted. Additionally, a "near miss" encompasses any unintentional occurrence or

[1] milena.resimic.mr@gmail.com

sequence of events in which injury or damage to property, infrastructure, or equipment is avoided solely by chance.
A broader definition that encompasses not only the negative aspects of near misses, but also their positive impact on system functioning, characterizes a near miss as an occurrence, series of events, or observation of an unusual incident that has the potential to enhance the operability of a system by reducing the risk of any disruption. Some of these disruptions could result in significant damage or injury. A near miss presents an opportunity to enhance environmental, safety, and health practices, based on an incident that could have had more severe consequences. It is viewed as a chance for improvement, where positive experiences motivate employees to report such incidents rather than conceal them. This definition also includes any operational issues or disturbances, some of which may lead to serious damage, while others may cause inconvenience or downtime, resulting in inefficiencies [1].
Alternative phrases for these occurrences are often referred to as a "close call" or, when it involves objects in motion, a "near hit". Additionally, a "near miss" can be defined as any instance in which an employee perceives being in an unsafe situation due to factors such as circumstances, equipment, or their own actions that had a significant likelihood of causing harm. However, by a fortunate chance, the employee remains unharmed. The specific definitions of a "near miss" can differ and may encompass incidents resulting in damage or injury, excluding fatalities [2].
Near-miss is also defined in the literature as a chance to improve practices related to safety and health at work and environmental protection based on working conditions or an event/incident that has a high potential to produce a serious consequence [3].

3. ELEMENTS OF RESEARCH

The purpose of this study: is to examine the perspectives of the workers regarding the implementation of this tool as a means of safeguarding against workplace injuries in the construction site. Additionally, it aims to gauge their comprehension of the incidents classified as "near misses" and determine the essential elements that need to be reported to ensure the tool's effectiveness. Efficiency in this context refers to the thorough examination and collection of all relevant data about potential undesirable incidents at a construction site. These incidents may not be readily apparent to occupational safety and health professionals during their site visits or when reviewing the documentation. By being aware of potential hazards and risks that are not immediately visible, professionals can take proactive measures to prevent injuries and damages from occurring. Moreover, this practice empowers employees to actively contribute to enhancing the safety culture within the organization. They can do so by suggesting measures to improve safety and health at work based on reported "near miss" events. The ultimate objective of this practice is to engage all employees in the organization in the process of establishing a secure work environment. This, in turn, fosters the development of a robust and well-recognized safety culture within the organization. This culture is evidenced by satisfied employees, a minimal number of work-related injuries, and the absence or low incidence of professional and work-related illnesses. Employees' engagement involves actively comprehending the nature of potential incidents or hazardous practices that necessitate reporting, the reporting process, the need for timely reporting, and ultimately, the decision to report. Consequently, to arrive at a conclusive outcome, it becomes imperative to establish sound research hypotheses that align with the research subject and objectives.
The null hypothesis: H_0 - *It posits that the level of comprehension regarding the reporting of "near miss" incidents significantly influences the decision to report such incidents, consequently reducing work-related injuries.*
Technology of research: The study involved gathering questionnaires from participants and analyzing the data using Microsoft Excel software. In addition to this, descriptive and inferential statistics were employed to examine the data, and the findings were summarized using a chi-square test to evaluate the null hypothesis. The data was thoroughly analyzed, and the results were visually presented through pictures, graphs, and tables. Following an assessment of the variables at various

levels of trust, the study concluded and offered suitable recommendations to enhance the organization's management.

To gather data for our research, we opted for the survey research technique on the construction project called "TPS Zemun". Since there are no standardized research techniques available for our specific research problem, which is stated in the subject of this paper, we developed a research questionnaire. You can find the questionnaire attached as Attachment No. 1 in this paper. The research questionnaire was designed as a tool to collect data using surveying as the research technique. By analyzing the responses received from the questionnaire, we were able to uncover relevant facts about the phenomenon under investigation in this paper. Specifically, the questionnaire assessed the respondents' levels of agreement regarding the implementation of the "near miss" concept on the selected construction project, which directly relates to the subject matter of this paper.

Research sample: For this research, the survey was successfully completed by 60 employees at the "TPS Zemun" construction site. Of that, 65% are male and 35% are female. Most respondents at the construction site were men, which agrees with the data of the survey conducted by the International Labor Organization in Serbia in 2018, which was used for this survey to review and compare the data. Most survey participants fall within the age bracket of 30 to 40 years, which aligns with the findings of a study conducted by the International Labor Organization in Serbia back in 2018. This study was utilized for our research to evaluate and compare data. Among the participants included in our research sample, the highest number of respondents had accumulated work experience ranging from 15 to 30 years in the construction industry. This indicates that our sample is representative and suitable for the intended research objectives.

4. RESULTS AND DISCUSSION

The variables used in this research were divided into those that can be associated with the elements of the organization's safety culture based on the idea shown through the Bradley curve (Figure 1) and those that do not belong to those elements.

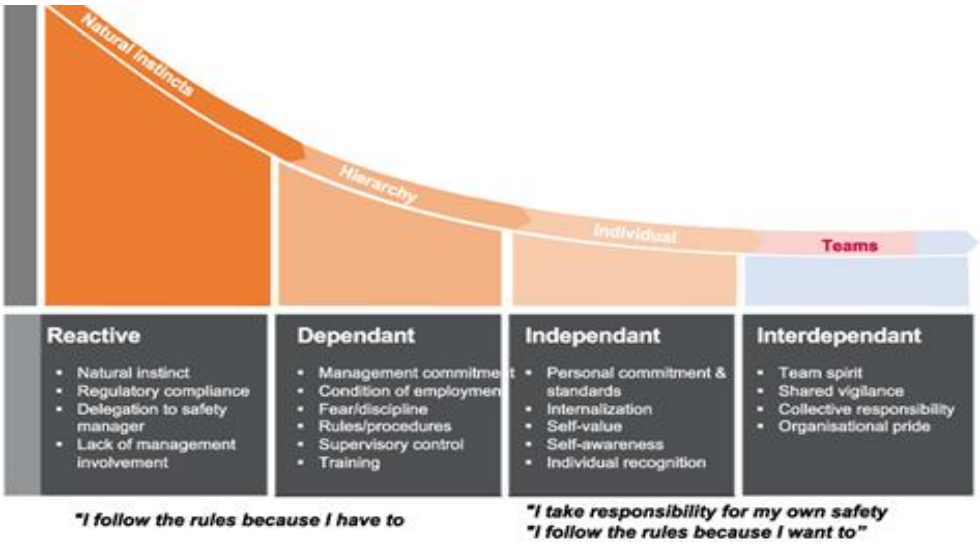

Figure 1. Bradley curve, Du Pont
Source: Du Pont official coaching material

This division was made for the purpose of giving recommendations to the employer regarding the improvement of the Safety management system. The Dupont Bradley Curve is based on DuPont's experience and expertise in safety management, which dates to 1802 when the company was founded as a gunpowder manufacturer [1]. It illustrates the relationship between accidents and corporate culture. Next figures show that the elements of corporate culture are essentially important for participation in terms of reporting and contributing to "near miss" reporting tool among the employees.

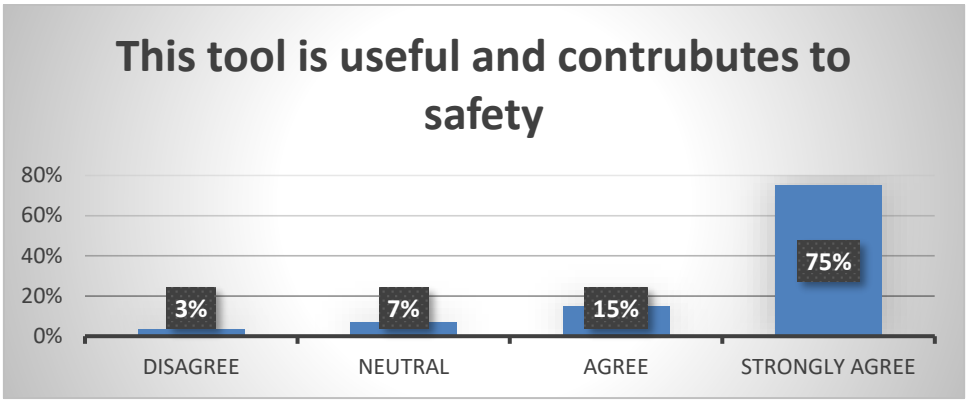

Figure 2: Questionnaire results
Source: *original author's*

To the question "I think reporting "near miss" events is useful and contributes to safety on the construction site, which was designed in the form of a Likert-type scale, as many as 75% of respondents answered that they completely agree with this statement and 15% that they mostly agree (Graph 1), which represents a significant number of respondents who have no doubt that the concept of reporting "near miss" events is something that contributes to their safety and the safety of their colleagues on the construction site.

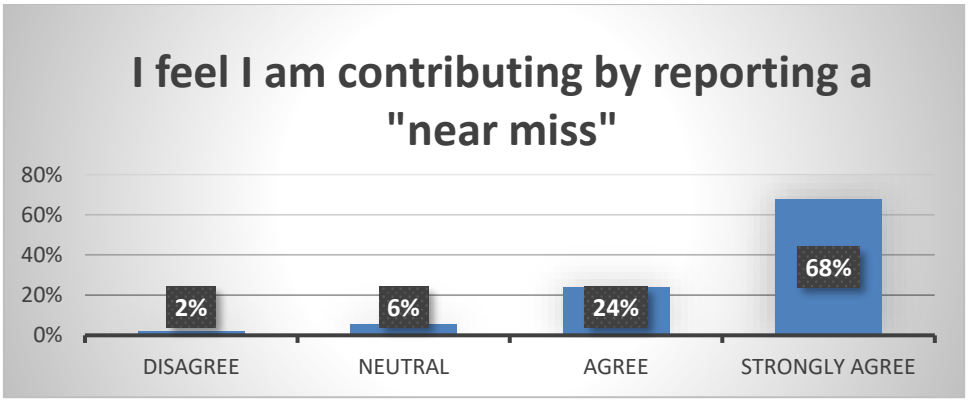

Figure 3: Questionnaire results
Source: *original author's*

To a slightly lesser extent, respondents agreed with the statement that they feel useful and as if they contributed to safety when they reported an unsafe event (Graph 2). This again indicates a very positive attitude towards the concept of reporting and recognizing "near miss" events.
The questionnaire and the whole research are available in the Master Thesis Paper available at the library of Belgrade Polytechnic [5].

In the following part it will be presented what were the results of testing the research hypotheses.

H_1 - There is a significant association between employee gender and willingness to report a near miss event.

Given that the calculated value of Chi-square is 1.68 less than the critical value of Chi-square, we can conclude that there is no statistical association between the gender of employees and the willingness to report a "near miss" event. It is therefore concluded that **H_1** is ***NOT ACCEPTED***.

H_2 - There is a significant association between the simplicity of the near miss event reporting system and the decision to report the event.
Given that the calculated Chi-square value of 8.81 is greater than the critical Chi-square value, we can conclude that there is a statistical association between the simplicity of the near miss event reporting system and the decision to report the event. It is therefore concluded that **X_2** is ***ACCEPTED***.

H_3 - There is a significant association between perceived usefulness and contribution to safety and the decision to report a near miss.
Given that the calculated Chi-square value of 5.10 is greater than the critical Chi-square value, we can conclude that there is a statistical association between the sense of usefulness and contribution to safety and the decision to report a near miss. It is therefore concluded that **H_3** is ***ACCEPTED***.

H_4 - There is an association between an employee's job loss concern and willingness to report a near miss event.
Given that the calculated value of Chi-square is 2.84 less than the critical value of Chi-square, we can conclude that there is no statistically significant relationship between the fear of job loss and the willingness to report a "near miss" event. It is therefore concluded that **H_4** is ***NOT ACCEPTED***.

H_5 - There is a statistically significant association between years of work on a construction site and willingness to report a near miss event.
Given that the calculated value of Chi-square is 2.06 less than the critical value of Chi-square, we can conclude that there is no statistically significant relationship between years of work at the construction site and willingness to report a "near miss" event. It is therefore concluded that **H_5** is ***NOT ACCEPTED***.

H_0 - It is assumed that the degree of understanding of the concept of reporting a "near miss" event has a significant impact on the decision to report a "near miss", and therefore on the reduction of injuries at work.
Given that the calculated Chi-square value of 6.59 is greater than the critical Chi-square value, we can conclude that there is a statistical association between the sense of usefulness and contribution to safety and the decision to report a near miss. It is therefore concluded that the zero hypothesis **H_0** is ***ACCEPTED***.

After thoroughly examining the relevant literature, previous studies conducted in this field, gaining valuable insights from the construction site, and concluding this research, it is concluded that: the primary objective and intention of this study were to explore the possible utilization of "near miss" incidents within an occupational health and safety management system in construction projects, to enhance outcomes and overall performance. In contrast to a conventional management system that relies on analyzing data from accidents with and without lost time, this approach offers a more comprehensive understanding of the current situation on-site in terms of risks, the safety culture among employees, and ultimately the number of work-related injuries that have transpired during project execution. The primary objective of this study is to specifically examine employees' comprehension and willingness to actively contribute their firsthand safety observations to such a management system. Notably, extensive research has demonstrated the effectiveness of this system in enhancing safety and health performance across various industries and operational frameworks. It has been demonstrated that the comprehension of the concept, the perception of usefulness, and the ease of implementation of the avoided event reporting system have a direct impact on the frequency of reported events by employees. Considering that these factors are integral to the safety culture, it becomes evident that concerted efforts must be made to enhance the overall safety culture within the organization. This will ensure that reporting avoided events becomes ingrained in the cultural practices observed at construction sites. Conversely, it is observed that variables such as gender and years of experience among employees do not influence their willingness to report a “near miss”. Hence, it becomes imperative to focus on fostering a comprehensive safety culture within

organizations and leverage all the documented information obtained through the safety protocols implemented at construction sites. This approach ensures that our precautionary measures align with the primary hazards prevalent in the environment. By employing this distinctive methodology tailored to individual construction sites, we can guarantee the identification, management, and eradication of potential hazards.

The present study possesses certain constraints associated with the fact that it solely focuses on a single endeavor pertaining to railroad reconstruction. Consequently, the outcomes cannot be extrapolated to encompass all construction projects. Moreover, the investigation primarily elucidates the safety and health protocols implemented by a foreign corporation, which cannot be directly correlated to the safety and health standards prevalent in the Republic of Serbia. In this context, it is worth noting that the adoption of such an approach is not obligatory in Serbia.

5. CONCLUSION

In the construction industry, it is crucial to take numerous preventive and proactive measures before accidents occur, while gathering valuable insights from employees who face risks daily. Encouraging employees to embrace a safety-focused mindset and actively report dangerous situations and behaviors is pivotal for the effective implementation of management systems. Rather than harboring shame, it should be ingrained in individuals as a core value they continually strive for, ultimately ensuring the success of these systems. Developing a safety culture based on each employee's independence in being aware of, contributing to and caring for a safe and healthy work environment, not only for themselves but also for others, is key to reducing work-related injuries and striving for "zero" fatalities as the highest value we strive for as a society.

To my mentor dr Marta Trninić: Accept my most sincere appreciation to you, for being a **mentor** *and a friend.*

RESEARCH AND ANALYSIS OF PROFESSIONAL STRESS ISSUES AMONG EMPLOYEES IN SECURITY ROLES

Maja Đikić[1], The Academy of Applied Technical Studies Belgrade
Novak Milošević[2], The Academy of Applied Technical Studies Belgrade

Abstract: *In today's increasingly complex work environment, professionals from various sectors face challenges related to workplace stress. This issue particularly affects security workers, whose daily responsibilities include maintaining safety and security in both public places and private organizations. The focus of this study is on identifying key stress factors among security workers and exploring their impact on stress levels and employee well-being. More precisely, this study aims to provide a deeper understanding of the stress issue among security workers, investigate the specifics of the organization in which the research was conducted, and offer guidelines for improving working conditions and stress prevention. The study presents the results of research on professional stress conducted on a sample of 70 security workers in the "Securitas Services" organization.*
Keywords: professional stress, security workers, identification of stress factors

1. INTRODUCTION

Security personnel, defined as individuals with the appropriate license for performing private security duties, often carry out their responsibilities within the premises of other employers or service users. This places them in situations that significantly impact their safety, further contributing to the existing professional stress. Service users, on the other hand, can be legal entities, entrepreneurs, or individuals who rely on private security services to protect their property interests. Understanding the specific working conditions and the relationship between security personnel and service users becomes crucial for comprehending the stress experienced by these professionals during their work routines.
Previous research indicates that working conditions such as night shifts, shift work, the risk of violence, and poor working environments (noise, inadequate lighting, etc.) are key factors contributing to professional stress among security workers. For example, the risk of violence can be present in their daily tasks, leading to psychological and emotional stress. Studies have also highlighted how night shifts and shift work can disrupt the circadian rhythm, leading to sleep disturbances and an increased risk of health issues. These specific issues have been the focus of investigation in this study.

2. METHODOLOGY

The research was conducted in August 2023 at the company Securitas Services Ltd., which employs over 4,000 individuals. All respondents are security personnel. The research employed a quantitative research method, which involves collecting quantitative (numeric) data and analyzing this data using statistical methods. The instrument used in this research is a questionnaire consisting of several sections. The first part of the questionnaire pertains to basic information about the respondents, such as gender, age, level of education, length of employment in the current company, and other relevant information, as presented in diagrams 1-6.

[1] maja.djikic92@gmail.com
[2] nmilosevic@atssb.edu.rs

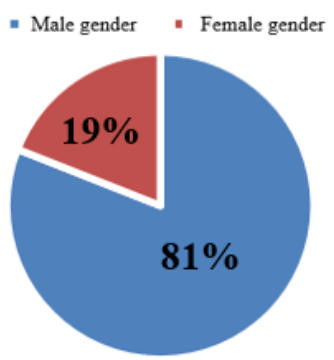

Figure 1. The structure of respondents by gender

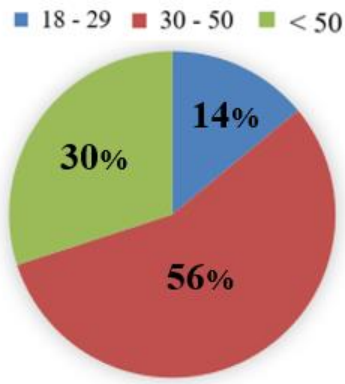

Figure 2. The structure of respondents by age

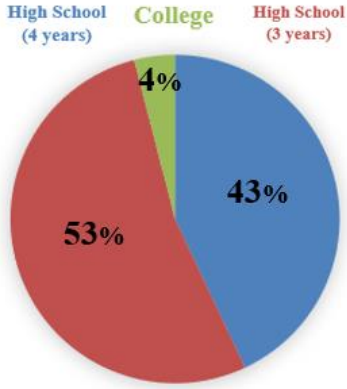

Figure 3. The structure of respondents by qualifications

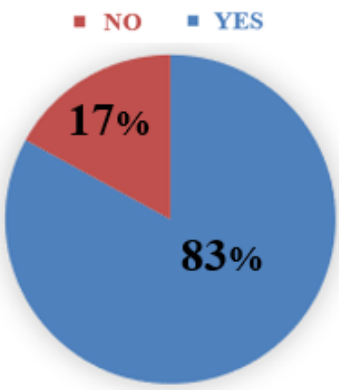

Figure 4. The structure of respondents by shift work

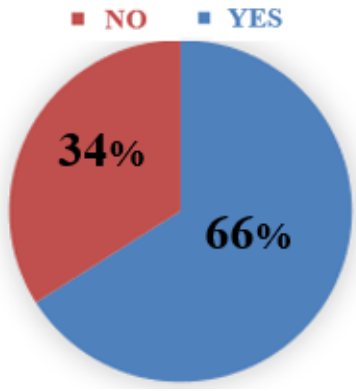

Figure 5. The structure of respondents by night shift work

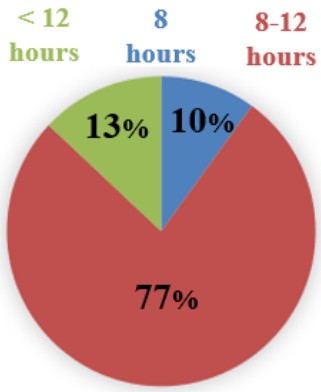

Figure 6. The structure of respondents by the length of their working hours

These data can reveal whether certain demographic groups tend to experience higher stress levels compared to others. Understanding the specific needs of different groups can help allocate resources where they are most needed.

The second part of the questionnaire contains questions about workplace conditions, workers' experiences with violence or conflicts, and the impact of working hours (shift work, night shifts) on their emotional state. The final part of the questionnaire is about workplace stressors, which consists of selected 10 stressors, and respondents' answers about their experience of each stressor were evaluated using Likert scale ratings: 1 (not stressful at all), 2 (rarely stressful), 3 (sometimes stressful), 4 (stressful), and 5 (extremely stressful). The total sample size consisted of 70 security personnel, including 57 males and 13 females, who worked in different sectors. The sample was stratified by different sectors and genders, meaning that the sample included 20 security personnel from industrial complexes, banks, and shopping centres, as well as 10 security personnel employed at the airport, who were selected by random sampling.

Data were collected using the following methods: *frequencies* (f) and *percentages* (%), which show how often certain responses occur and the percentage of workers supporting specific statements. Descriptive statistical methods were used, including measures of central tendency (mean and median), which show where the majority of workers position themselves about specific stress factors.

3. RESULTS AND DISCUSSION

Within the research on professional stress among security workers, the responses of 70 security personnel from various sectors, including banks, shopping centres, industrial complexes, and airports, were analyzed. By examining their responses to key questions, insights were gained into their

experiences and perceptions of workplace stress factors. In response to the question "Do you have enough time to rest after a night shift", 40% of the respondents claim they do not have enough time to rest after a night shift. The majority of these respondents are employed in industrial complexes and shopping centres. Indecisiveness proved significant, with 32.86% of respondents, the majority of whom work in banks. Only 20% of respondents believe they have enough time to rest after a night shift, while 7.14% strongly disagree with the statement.

Regarding the question "Shift work/night work affects the quality of your sleep and rest", the results show that 45.71% believe that shift work/night work affects the quality of their sleep and rest. Most of these respondents work in industrial complexes and shopping centres. In contrast, 37.14% of respondents claim that this is not the case, with the majority working in banks. Indecisiveness is present in 12.86% of respondents, while 4.29% believe that shift work/night work significantly affects the quality of their sleep and rest.

Regarding the question "Do you have the opportunity for professional development and education at work", 40% of respondents believe they do not have this opportunity, with the majority working in shopping centers and industrial complexes. Conversely, 24.29% agree that they have this opportunity, with banks and airports being the most significant sectors. Indecisiveness is present in 18.57% of respondents, while 17.14% believe they have complete opportunities for professional development and education. The results of these questions are presented in diagrams 7, 8, and 9.

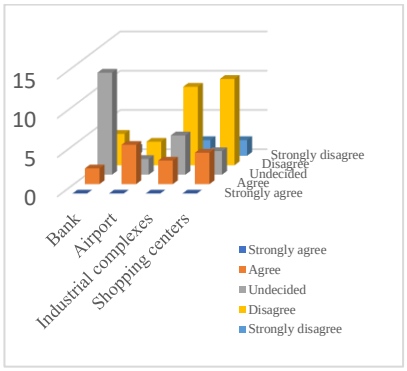

Figure 7. The structure of respondents by shift work
Source: *original author's*

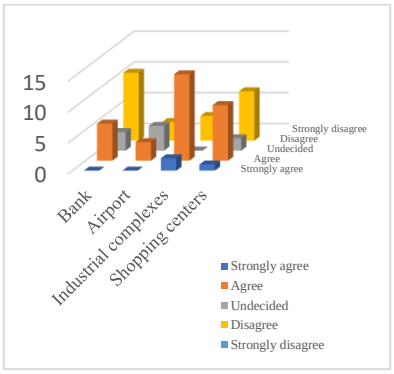

Figure 8. The structure of respondents by night shift work
Source: *original author's*

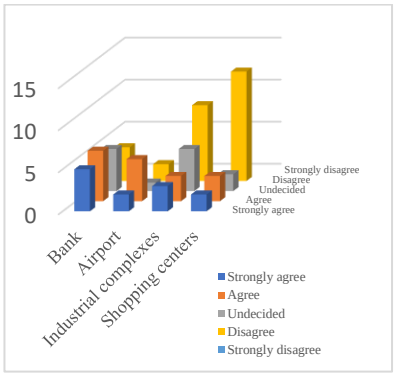

Figure 9. The structure of respondents by the length of their working hours
Source: *original author's*

These research results indicate the diversity of perceptions and experiences of security workers regarding workplace stress factors. Different groups from various sectors have different views on rest time after night shifts, the impact of shift work on sleep quality, and opportunities for professional development. These results highlight the need for further research and consideration of how working conditions for security workers can be improved, with a particular focus on sectors where issues are more pronounced.

To gain a deeper understanding of the attitudes and needs of security workers, an open-ended question was posed to the respondents: "What would be the most important change that could be implemented immediately to improve the work of your profession?". This question allowed respondents to express their personal comments and views on possible improvements in their professional environment. The results displayed in diagram 10 show that a significant number of respondents (72.86%) emphasized an increase in salary as the most important change that would improve their professional status. This may indicate that many feel inadequately compensated for their work, which can affect their job satisfaction and motivation. Additionally, the results show an interest in more days off (5.71%) and the elimination of overtime work (10%). This may indicate the importance of work-life balance for security employees. 11.43% of respondents did not provide an answer, which may suggest that respondents were not willing to share their opinions.

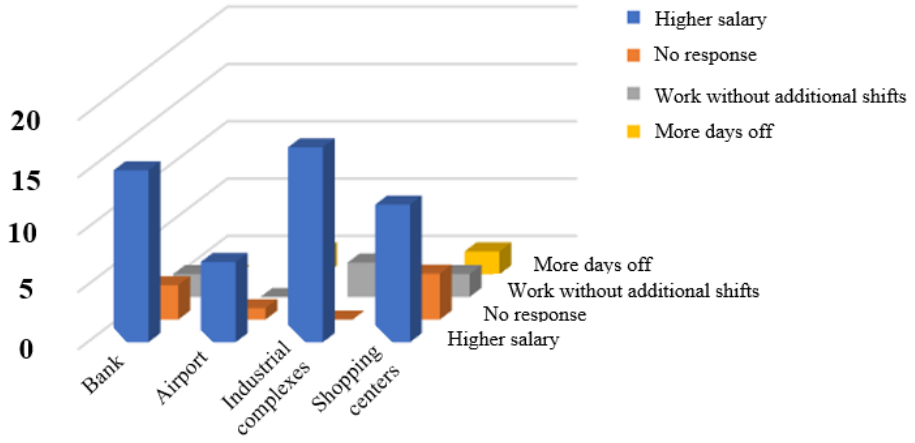

Figure 10. Analysis of the open question
Source: *original author's*

These results point to the need for further research and consideration within organizations employing security workers to explore specific measures to improve their working conditions and well-being. Salary increase is just one possible step in that direction, while considering other aspects, such as working hours and benefits, is also crucial for creating satisfaction and motivation among these workers.

To gain a deeper understanding of stress factors and highlight differences in stress perception among male and female security workers, an analysis of the stressors that workers rated as most pronounced was conducted. Through this analysis, we gain a deeper insight into the challenges faced by security workers, which will help in forming a more comprehensive understanding of their work experience.

Among male respondents, the highest values for stress factors were related to overtime work, lack of rest, and violence or threats from visitors. These factors were rated as the most stressful, while long and monotonous work activities, as well as daily unforeseen situations, were rated as less stressful.

On the other hand, among female respondents, the highest values for stress factors were related to overtime work, lack of rest, and limited advancement opportunities, and the lowest for communication with superiors. Graph 11 shows the stress factors causing the most stress in both genders to understand the difference in stress perception between the two genders.

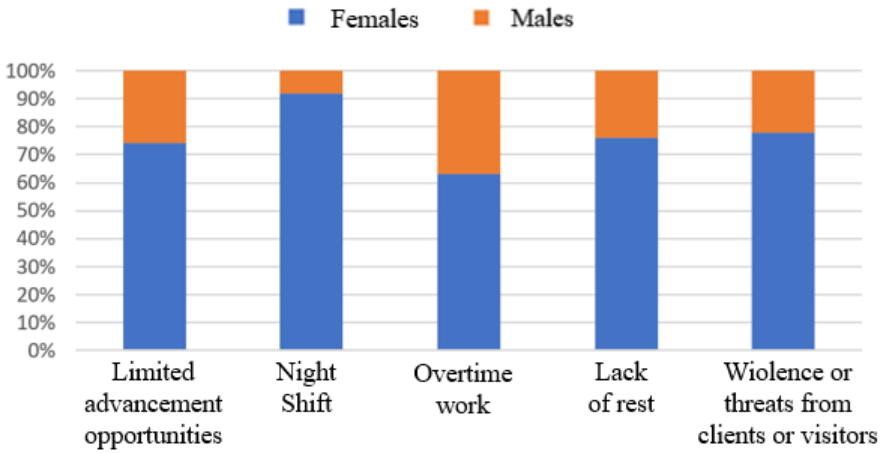

Figure 11. The Difference in stress perception between male and female workers
Source: *original author's*

So, female respondents rate the mentioned factors as more stressful compared to male respondents, with a significant difference in percentages. These results suggest the need for a targeted approach to stress management and support depending on the gender of security workers to improve their working conditions and well-being.

4. CONCLUSION

Research on stress among security officers represents an important aspect of working conditions in this professional field. The results of this study point to significant challenges that security officers face in their work environment. Stress factors such as night shifts, overtime work, and violence or conflicts with visitors are significant challenges that can impact the physical and emotional health of workers and can have important implications for managers and organisations employing security officers, emphasizing the need for the development of programs and measures to help manage stress and support a healthy work environment. The results also indicate differences in stress perception between men and women. However, the inequality in the number of participants may affect the interpretation of the results, so future research should address this imbalance in sampling to arrive at more reliable conclusions regarding stress perception among security workers. The results of this study also suggest the existence of a statistically significant relationship between stress factors and stress levels among security officers, leaving room for further research to further confirm this relationship.

In summary, this research represents an important step in understanding the issue of stress among security workers and provides a foundation for designing programs and measures to enhance the quality of work and the well-being of workers in this sector. Continuous monitoring and analysis of stress factors and stress perception in the security sector remain a necessity to ensure ongoing support and improvement of working conditions.

THE IMPACT ANALYSIS OF STRESS ACCUMULATED OUTSIDE THE WORKPLACE ON THE OCCUPATIONAL SAFETY AND HEALTH OF EMPLOYEES IN INSTITUTE OF NUCLEAR SCIENCES „VINČA"

Lazar Milićević[1], The Academy of Applied Technical Studies Belgrade
Novak Milošević[2], The Academy of Applied Technical Studies Belgrade

Abstract: *In the process of researching literature on the term, causes, effects and consequences related to professional stress, the authors noticed that vocational publications in this area primarily direct protection engineers in the field of risk assessment regarding this professional phenomenon to exclusively consider incidents that can or already have taken place in the workplace itself, without reference to the process of stress accumulation, the source of which is most likely to manifest itself outside of the workplace. The authors believe that non work related stress has equal importance for health and safety at work as much as work related stress. As proof for the previously stated position authors will include in this paper, part of the research that analyses the impact of non work related stress on health and safety at work in one of the units of the Institute of Nuclear Sciences "Vinča" (Centar Operativa 300/200).*
Keywords: professional stress, non work related stress, stress accumulation.

1. INTRODUCTION

The fast-paced lifestyle is the most common reason for often unrealistic demands, which a person sets for himself on a personal and business level. The reaction of our body to this artificially created pressure can be very different and depends on the type of stressor and its intensity. A naturally innate defence mechanism, which protects the human body from an excessive reaction to a stressor, which could have serious consequences, is called stress [1].
The phenomenon of professional stress is ubiquitous when implementing technological processes and other work tasks in the daily lives of employees. This psychological phenomenon is a direct consequence and the "price" that modern society pays due to the unfathomable and often irrational speed of technological development.
One of the major problems in the field of studying professional stress, which is currently very difficult to solve, is directly related to the "modern" way of life and the fact that workers come to work with an already significant amount of accumulated stress. Therefore, ***one of the goals of this paper is to draw the attention of the experts in the field of protection engineering to the fact that professional stress should not be seen as a source of harm, which can only manifest itself in a working place.*** It is much more likely that the manifestation of this professional phenomenon at work is only a trigger, for accumulated stress, which source is actually directly linked to the employees and the time they spend outside of the workplace.
The "battle", that protection engineers lead every day, against such currently "stronger opponents", inevitably leads to an increase in the number of incidents and accidents at work. One of the reasons for the difficulties in the fight against the observed occupational harm can be **the very approach** of the profession, which is concentrated exclusively on stressors, that are manifested in the technological processes at the workplace. In the opinion of the authors, ***this approach is***

[1] fikolaz@gmail.com
[2] nmilosevic@atssb.edu.rs

fundamentally wrong, because the process of identifying professional stress is based on actions, which are oriented towards the trigger, and not the source, of the future accident. Based on the previously stated conclusions, authors deem pure necessity to suggest change and diversification of stress through the national professional literature into "work related stress" and "non work related stress", as well as to equalize their importance, when assessing occupational risk at the workplace.

2. THE NEED TO PROBLEM RESEARCH

The starting point in stress management is the fact, that it is impossible to completely eliminate it. It is only possible to control its effects when they manifest themselves at work and take a series of preventive measures to eliminate stressogenic factors. A very important component of stress management, when eliminating risks that may arise due to the presence of stressors at work, is **the way** professional experts manage this psychological phenomenon. Stress management at the workplace is possible through interventions and activities on an organizational and individual level. The best preventive measure in the event of stress occurring in the workplace is to adapt the working conditions for employees to their individual physical and mental capabilities [2].
The results of many researches indicate that the accumulation of stress, which takes place at the workplace, is to a large extent directly related to the working conditions at the observed workplace. Similarly, people's feelings when they are not at work are largely conditioned by events that take place outside the workplace. Stress, which occurs at the workplace, as well as stress, which occurs outside the workplace, are associated with physical and mental effects on the health of employees. ***Excessive demands at work or stress in one part of private life can have a serious effect on the life of employees in another.*** Such a "conflict" between private and business works equally in both directions. When such a situation occurs, the amount of accumulated stress in the human body begins to increase, because there is a **joint effect**, which acts as an **additional source of stress**, and in this way, a **synergistic effect on the health of employees occurs**. When viewed together, both types of stress are divided according to the place of origin, it is possible to conclude that the effects and consequences of one type of stress can easily spill over to a part of life, where another type of stress from the analyzed division is present [3]. So, ***the manifested effects of stress that people feel at the workplace are not only a reflection of the problems and events that took place at work, but a very important variable in looking at the entire problem is the private life of the respondent, as well as his "personal problems".***
The practice has shown that it is not enough to adapt only the workspace and technological operations, so that they do not cause a significant increase in the accumulation of professional stress, because even after the implementation of all the foreseen "anti-stress" measures in the field of the health and safety at work, there is still a manifestation of incidents and accidents directly linked to this psychological phenomenon. **It is of the utmost importance**, based on previous conclusions, that **protection engineering implements** in the design of modern programs and tools for the promotion of health and safety at work and stress detection tools, **an idea which insists** that it is an absolute necessity, that **all types of tools for measuring professional stress** are adjusted so that they **equally detect the accumulation** of this psychological phenomenon **in the workplace** itself, **as well as outside it**. To implement this idea in the most efficient possible way, the first step is to **conceive and organise multidisciplinary research** on the topic of stress accumulated outside the workplace, to determine the starting points for the creation of professional "tools", which would help employees who work at high-risk workplaces. The second step is to implement these professional "tools" in the work process in that way, employee that works in high-risk workplaces must solve tests, before the start of their "high risk" works, which would establish the precise amount of already accumulated stress in their bodies. The employee population after the test, according to the level of risk of manifesting the effects of accumulated stress, would be divided into three groups: benign, neutral and threatening part of the population. The next step is to distribute the tested workers based on the rotation of jobs so that: the **neutral part of the population** work task starts with easier duties, the **benign part of the population** with the most difficult, while the

threatening part of the population for the day would be assigned to work tasks, where there is no risk of manifesting the effects of professional stress.

3. METHODOLOGY

Research of the impact of external stress on health and safety at work when employees are exposed to this psychological phenomenon, part of which is presented in this paper, was conducted by surveying 29 employees at the Institute of Nuclear Sciences "Vinca". It was done in the form of non-experimental research, through a survey of the population of employees in the Centar - Operativa 300/200. The research technique used is based on written communication and consists of questionnaires for the employees. When selecting the population units that will participate in the research, the random sample method was applied, which in itself guarantees that the research result is representative. Based on the number of respondents who participated in this research, it can be concluded that the results are adequate. Work assignments in the Centar - Operativa 300/200, consist of various types of maintenance work within the Institute. Due to the nature of working assignments, present in this part of the organization, it was not possible to organize group testing. Workers filled out the survey individually and at their workplaces.
The sample includes employees from several workplaces of the Centar - Operativa:

- Operation and maintenance (the sample includes two workers from the boiler room and one housekeeper),
- Design Bureau (the sample includes Institute architect and architectural technician),
- Center for engines and vehicles "CMV" (the sample included five drivers and one housekeeper),
- Product testing and certification department (two employees participated in the survey),
- HSE department (two HSE officers participated in the survey),
- Fire protection (five firefighters participated in the survey),
- Electrical services (three electricians participated in the survey) and
- Computer networks (three employees participated in the survey).

The employee questionnaire was filled out by the director, business secretary and driver from the Centar - Operativa, as well as one employee from the legal department of the "Vinča" Institute. The structure of respondents in relation to their gender, age, qualification and work experience at the current workplace is shown by descriptive statistics, that is, in the form of frequency or percentage in diagrams 1-4 [4].

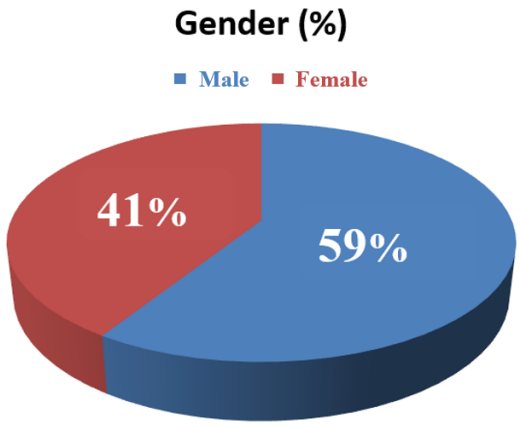

Figure 1. The structure of respondents by gender
Source: *original author's*

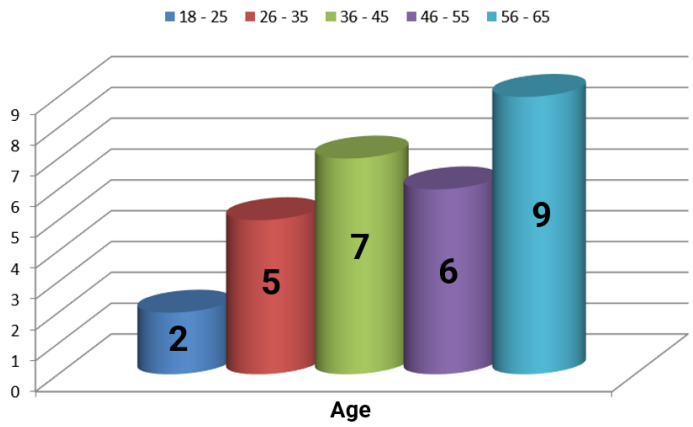

Figure 2. The structure of respondents by age
Source: *original author's*

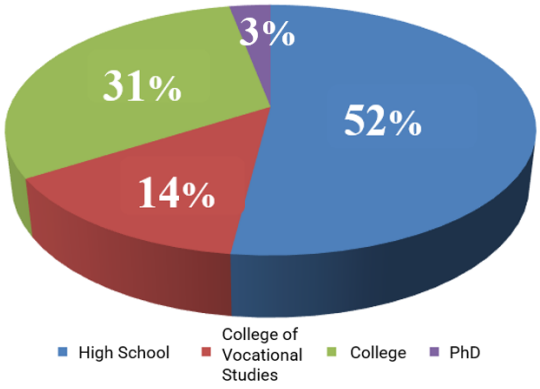

Figure 3. The structure of respondents by qualifications
Source: *original author's*

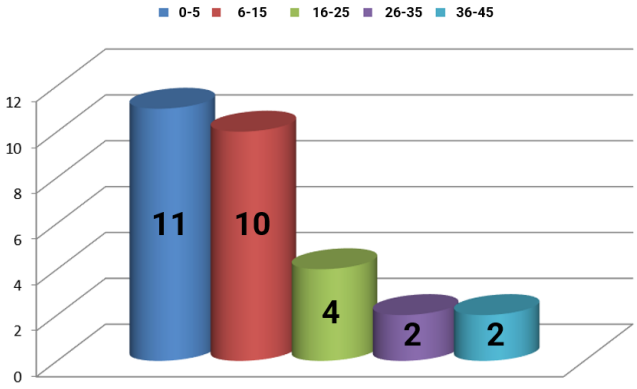

Figure 4. The structure of respondents by work experience at the workplace
Source: *original author's*

The data obtained from the questionnaire were processed with the help of descriptive statistics, i.e. using counting measures (frequency (f) and percentage (%)), to determine and analyze the impact of "external stress" on the health and safety at work of employees in the observed institution. This way of data processing enables the distribution of research results to be displayed in an overview [5].

4. RESULTS AND DISCUSSION

The most important goals of this paper are [4]:

- To devise, redefine and publish a new categorization in professional publications for psychological phenomenon - stress;
- To ensure the introduction of the concept of "external stress" in national by-laws, through amendments to the regulations;
- To precisely determine the probability of the impact of stress outside the workplace as a factor on the health and safety of employees in work organizations;
- To determine the frequency of the manifestation of stress outside the workplace, as a risk that cannot be avoided in work organizations;
- To determine the severity of the consequences that can be caused by non work related stress,
- That "external stress" and its impact on the health and safety of employees in work organizations be implemented as an unavoidable variable in the risk assessment in relation to the harms associated with the psychological phenomenon of stress;
- To design and create modern "tools", which would ensure the accurate measurement of the presence of "external stress" in the worker's body, before starting work;
- To ensure an increase in the level of health and safety at work in work organizations, through the mandatory implementation of "tools" for measuring "external stress" and corrective measures in case of the presence of this psychological phenomenon.

Table 1. shows the opinion of employees in the Centar - Operativa 300/200 and their attitude towards the manifestation of the effects of accumulated external stress at the workplace, as well as their attitude about the impact of this psychological phenomenon on health and safety at work, shown in the form of frequency and percentage. In the part of the questionnaire for employees presented in the paper, on a Likert-type scale, respondents were required to enter a + sign next to each question, depending on how they assess the level of agreement or disagreement with a certain statement, on a scale of 1-5. Whereby the level of agreement of the respondents was assessed as: **1 - I do not agree at all; 2 - I do not agree; 3 – I partially agree; 4 - I agree; 5 - I completely agree** [4].

Table 1. Results of the employees attitudes at the Institute of Nuclear Sciences „Vinča"
Source: *original author's*

QUESTION		1	2	3	4	5
Manifestation of accumulated external stress at the workplace						
It happened to you that you **"spend"** non work related stress at work.	Frequency	14	10	3	1	1
	Percentage	48	34	10	4	4
It happened to you that you **felt calm and satisfied** after **successfully completing a work task**, even though you **came to work nervous or in a bad mood**.	Frequency	3	3	6	8	9
	Percentage	10	10	21	28	31
You often **feel the need to complain to colleagues** that you are under stress because you are not satisfied with the support provided by your partner and/or family.	Frequency	20	9	/	/	/
	Percentage	69	31	/	/	/
It happened that you **experienced an unpleasant situation due to a conflict with colleagues**, which you consider to be **caused by non work related stress**.	Frequency	17	7	4	1	/
	Percentage	58,5	24	14	3,5	/
It happened that **you needed to cause a conflict with one of your colleagues**, due to a stressful situation you experienced outside the workplace.	Frequency	21	6	1	1	/
	Percentage	72	20	4	4	/
You often **feel difficulty in using work equipment,** because of the stress you have accumulated outside the workplace.	Frequency	21	6	2	/	/
	Percentage	72	20	8	/	/
It happened to you **that you forgot to apply** health and safety measures at work, due to stressful situations that happened to you outside the workplace.	Frequency	18	8	2	/	1
	Percentage	62	27,5	7	/	3,5
You feel reluctance to implement health and safety measures at work because **you often think about stressful situations**, that happened to you outside the workplace.	Frequency	19	7	2	/	1
	Percentage	65,5	24	7	/	3,5
It happened to you that **you feel that the work you do is too difficult or monotonous** because you **felt the effects of stressful situations** that you experienced outside the workplace.	Frequency	13	8	7	/	1
	Percentage	45	27,5	24	/	3,5
It has happened to you/you know that it happened to someone, **to get injured at work**, due to the **presence of non work related stress**.	Frequency	14	7	4	3	1
	Percentage	48	24	14	10	4
QUESTION		**1**	**2**	**3**	**4**	**5**
The impact of non work related stress on the health and safety at work						
In your opinion, stress accumulated outside the workplace **has an impact on the health and safety** of employees in work organizations.	Frequency	6	3	11	5	4
	Percentage	20,5	10	38	17,5	14
You believe that **it would be desirable** that one part of the **basic theoretical training in health and safety at work** be devoted to **non work related stress and its effects** on the health and safety of employees in work organizations.	Frequency	5	2	9	5	8
	Percentage	17,5	7	31	17,5	27
You feel that it would be desirable to introduce **mandatory testing of employees** for the **presence of accumulated stress**, immediately before starting work on high-risk jobs.	Frequency	1	3	11	6	8
	Percentage	4	10	38	21	27
In your opinion, **testing employees for the presence of accumulated stress** would lead to a **reduction in the number of injuries at work**.	Frequency	4	2	10	8	5
	Percentage	14	7	34,5	27	17,5
You think that **testing employees for the presence of accumulated stress would save part of the money**, which the employer spends on health and safety at work.	Frequency	4	7	7	4	7
	Percentage	14	24	24	14	24

Through this research on "external stress" in work organizations, two effects of **social significance** can be promoted. The social importance could first be presented through improving **the mental health of employees**. Preventive tests that detect the presence of external stress among workers could also improve the early detection and diagnosis of mental disorders and mental health in the earliest stages of their occurrence [4].

The next effect on the social importance of this research is reflected in the **savings of employers' resources**, which they can redistribute to some other very important parts of the work process in their organizations. This saving would be realized after the complete implementation of this research into professional streams because then the preventive nature of amendments to legal regulations and procedures related to the effects of "external stress" on work organizations would come to the fore. The money, which was once spent on preventing and eliminating the consequences of this psychological phenomenon, would now be left to employers to use to eliminate some other dangers or harms associated with the activities they are engaged in [4].

5. CONCLUSION

When analyzing the first statement from this part of the questionnaire, four fifths, or 23 respondents, believe that doing their work assignments, allows them to at least partially "spend" the stress they accumulated outside the workplace and thus improves their state of calmness and satisfaction. Respondents have an opposite opinion in the case of the statement: ***It happened that you*** *experienced an unpleasant situation due to a conflict with colleagues****, which you consider to be*** *caused by non work related stress.* The vast majority of respondents, as many as 82.5% of them, expressed a negative attitude towards the analyzed claim. A significant majority of respondents, 72% of them, **do not know that someone has been injured at work**, due to the **presence of accumulated stress**. Despite the position expressed in the previous two statements, **the employees** of the Institute of Nuclear Sciences "Vinca" still ***believe that the presence of "external stress" in the workplace has an impact on health and safety at work***. The processed and analyzed result of this conclusion is very important because it is a confirmation of the author's position on non work related stress. Respondents also believe that it would be desirable to implement a part in basic HSE training, which refers to non work related stress. An important conclusion is the affirmation of the idea that it would be desirable to introduce a mandatory test, which would preventively measure the presence and level of stress accumulated by the employees.

RESEARCHING THE HARMFUL EFFECTS OF COOLING LIQUID ON EMPLOYEES

Jelena Tintor[1], The Academy of Applied Technical Studies Belgrade
Jasmina Rajić[2], The Academy of Applied Technical Studies Belgrade
Igor Babić[3], Faculty of Mechanical Engineering East Sarajevo

Abstract: *During the processing of metals and other materials, there is a need to cool the work process. Depending on the composition of the cooling system, it can hurt humans or the environment. To reduce the negative impact, several procedures are undertaken. The work aims to determine the level of information and training of employees during work with the chemical substance. After the survey, it was concluded that the knowledge of the employees should be improved to prevent injuries or illnesses.*
Keywords: Cooling liquid, chemicals, toxicity, health and safety.

1. INTRODUCTION

With the development of metal processing, the problems of overheating of tools and workpieces appeared. In an attempt to solve that problem, the workers began to experiment using water, then water enriched with soapy water, and so even today by mixing various substances, cooling agents are obtained. These cooling agents have different chemical properties and sometimes hurt humans and the environment. The health and safety department at works to reduce such risks to the lowest possible level. Due to the use of chemical substances, accidents often occur. It is important to react properly so that they do not happen or, if they do, to reduce the consequences in the best possible way and to learn from such situations. The best way to handle a chemical is with a safety data sheet. To improve the new safety of employees who handle the chemical substance, research was carried out through a survey on the level of awareness of employees about the chemical substance they work with. Through the survey, it was concluded at what level is the knowledge of the employees about the dangers and harms they are exposed to. Based on the answers, measures were proposed to improve knowledge.

2. COOLANTS

Coolants are a type of liquids used to cool and lubricate in specific processes like metalworking [1]. Their main use is to regulate the temperature of a system and workpiece, and secondary uses are to lubricate and prevent corrosion on tools, machines, and workpieces. Use is widespread due to the constant growth of the metalworking industry.
Their main characteristic is high thermal capacity, low cost, and low viscosity, which helps with the cooling and distribution of the fluid. Ideally, they should be non-toxic, corrosion-inhibiting, and chemically inert. Their freezing point must be lower than the minimal temperature at which the fluid will be used. From a safety standpoint, they need to be non-flammable and non-explosive. Many

[1] jelenatintor0@gmail.com
[2] jrajic@atssb.edu.rs
[3] igor.babic2@gmail.com

substances fulfill the cooling and lubricating requirement, but for them to be used they must also fulfill requirements in terms of toxicity, flammability, and price. Its effect on the human environment and law regulations is also an important factor.

3. MEASURES FOR SAFE WORK WHILE USING CHEMICAL MATTERS

While working with cooling fluids proper implementation of safety measures is important. These are modern training, social, organizational, technological, ergonomic, and health measures, prescribed by the occupational health and safety law [2]. Preventive measures must call for law regulations. Preventive measures are measures that have been taken before an accident or occupational-related sickness happens. For their proper implementation, it is important to properly understand all hazards and dangers inside the workplace. If the workplace contains chemical matters it is important to note the safety data sheet content which contains identification properties of the chemical, its characteristics, way of use, preventative measures, and supplier information [3]. It is important to have the safety data sheet in the native language that the workers understand so they will be able to understand named risks and preventive procedures. The starting point for prescribing preventative measures is the eleven principles of environmental protection [4]. When assessing the risk it is important to note the presence of chemical matters and take them into account [4]. While using chemical matter designed for the cooling of the work process it is important to pay attention to specific and general limit concentration in substance so the limit concentration can be evaluated over which its use affects human health and the environment [4]. It is concluded that the risks while using this liquid are high. Measures for reducing the risk of hazards and dangers are numerous technical and organizational solutions. Both types of solutions can be individual and collective. Based on all the information presented, it is clear that ensuring safe and healthy handling of chemicals is crucial for protecting both human lives and the environment. It is the responsibility of both employers and employees to take necessary measures to ensure safe and healthy work practices are followed [5].
It is also important to adhere to the principles of prevention, where it is expected from the employer to nullify the risk from work-related illnesses and accidents or at least to reduce it to the lowest level possible. The principles are:

- Planning and organization of work;
- Providing adequate clothing and personal protection equipment for working with chemicals;
- Implementation of proper maintenance system;
- Reducing the number of exposed workers to a minimum;
- Reducing the time and intensity of exposure to workers;
- Implementation of proper hygienic measures;
- Reduction of chemical matter presence in the workplace to a minimum;
- Implementation of proper procedures including use, handling, storage, and maintenance of chemical fluids and disposal of waste fluids.

4. ACCIDENTS

Production and consumption of hazardous matters are in constant growth. Transport and storage of hazardous matters is done for the needs of production processes which exposes the environment to constant danger of accidental and unwanted contact. Every day in the world around 35 chemical accidents of different scales. Hazardous matters can pollute the environment in two ways. The first one is daily from different means of constant pollution (spills, leaks, etc.). They are hard to spot and show only after years or decades of constant pollution. The second way is sudden and happens almost instantly, then it is a chemical accident. Chemical accidents can happen due to human error, failure of various systems, breakdowns, traffic accidents, etc. The consequences in this case are the release of large amounts of chemical substances which can cause large-scale pollution over a large area. All types

of chemical accidents cause human harm, loss of lives, and often loss of livestock and material goods. Chemical accidents threaten human safety and prosperity. All these accidents need good organization, planning, evacuation, and a large amount of funds for decontamination and loss mitigation. When working with hazardous substances, it is important to implement safety measures to ensure a healthy work environment.The key to accident prevention is well-made assessments of risk and environmental protection [6].

5. DATA ABOUT THE LIQUID USED FOR COOLING IN THE PROCESS OF MANUFACTURING CASINGS

From the safety sheet for the substance can be concluded that the fluid is intended for mixing with water to create water-oil emulsions (cutting fluid), industry use, transport, handling, and disposal [7].

Table 1: Information on ingredients
Source: *Safety data sheet [8].*

Chemical name	%
Distillates (petroleum), hydrotreated light naphthenic; Baseoil - unspecified	20- <40
2-(2-butoxyethoxy)ethanol; diethylene glycol monobutyl ether	1- <5
2,2'-(methylimino)diethanol; N-methyldiethanolamine	1-<5
Alcohols, C16-18 and C18-unsatd., ethoxylated	1-<5
Amides, C12-18 and C18-unsatd., N-(hydroxyethyl), ethoxylated	1-<3
2-Pyridinethiol, 1-oxide, sodium salt	0,1-<0,25
Other components below reportable levels	60-<100

It is identified that in contact with human skin or eyes can cause damage and irritation of second category harmfulness to human health. Contact with the environment can cause environmental damage. Can cause damage to the water world of the third category if it gets into it.

Table 2: Risks and mitigations.
Source: Safety data sheet [8].

Vulnerable body part	Risk mitigation measures and PPE
Eyes	Glasses with side protection or other adequate eye protection equipment.
Hands	Adequate gloves are intended for protection against oil or chemicals.
Breathing organs	Adequate ventilation inside work and storage spaces. If ventilation is not available breathing masks with adequate filters are needed. Filters must protect against the aforementioned chemicals.
Skin	Adequate clothing.

Common ways to come into contact with chemicals:

- Breathing – prolonged inhalation of chemical vapors can cause damage to breathing organs and related illnesses;
- Skin contact – according to relevant data it is not possible to classify the type and level of possible skin damage;
- Contact with eyes – causes hard irritation and temporary or permanent damage to vision or vision loss;
- Ingestion - according to relevant data it is not possible to classify the type and level of possible damage but poisoning and esophagus and stomach damage are probable.

6. SURVEY RESULTS AND DISCUSSION

The data collected through the anonymous survey was processed. The survey contains eighteen questions, eight of which are shown in the results discussion. The survey aims to determine the level of employees' ability to work while using the cooling agent.

Table 3: Questions and answers
Source: Author

Questions	Answers:	Percent:
Are you acquainted with the safety sheet for the chemical matter with whom you come into contact every workday?	Yes	75%
	No	25%
Is there always available a copy of the safety data sheet in the Serbian language or in a language that the employee understands at the workplace?	Yes	87,5%
	No	12,5%
Are you familiar with all the dangers and harms to which you are exposed in the workplace as an operator of a machine for the production of chanchet?	Yes	50%
	No	50%
Are you informed about the data obtained based on the act on risk assessment and informed about the amendments and additions to the Act on risk assessment that are carried out if there is a significant change in the work process?	I am	62.5%
	I am not	37,5%

Based on the answers provided to the four questions, it can be concluded that employees have some knowledge of the properties, dangers, and harmful effects of the cooling agent. To minimize the risk of injuries and illnesses, it is crucial to have a safety sheet that contains all the necessary information in a language that the employees understand. It should be made available at the workplace where chemical substances are used. It is also important to educate the employees about the safety data sheet and its contents.

Table 4. examines the general knowledge of employees about the asset and how to handle it.

Table 4: Questions and answers
Source: Author

Questions:	**Answers:**	
Does the liquid meet the limit value of 8% ?	Yes	Percent:
Does the liquid meet the limit value of 8% ? Is the chemical stored at a safe distance from incompatible materials?	No	50%
	I do not know	33,3%
	Yes	16.7%
Is the chemical stored at a safe distance from incompatible materials? Are you familiar with what means of extinguishing a fire if there is a fire on that production line?	No	75%
	I do not know	25%
	Yes	0%
Are you familiar with what means of extinguishing a fire if there is a fire on that production line? To what extent do you think appropriate hygiene measures were applied? (hygienic measures include access to technical water, hand washing pastes, and availability of brooms and brushes intended for maintaining hygiene at the workplace)	No	75%
	Not at all	25%
To what extent do you think appropriate hygiene measures were applied? (hygienic measures include access to technical water, hand washing pastes, and availability of brooms and brushes intended for maintaining hygiene at the workplace)	Little bit	12,5%
	Satisfied	37,5%
	Very satisfied	25%

Based on the answers provided by employees, it has been concluded that they have varying levels of knowledge and awareness when it comes to preventing injuries or illnesses. To address this, it is important to identify the reasons behind their responses and attitudes. Once this is done, suitable training sessions should be conducted to remove any misunderstandings or doubts that employees may have, thereby minimizing the risk of injuries or illnesses in the workplace.

7. CONCLUSION

During the preparation of the paper, the topic of cooling agents and their characteristics, which are required by the market and legal regulations, was covered. It also investigated what measures should be taken for safe and healthy work, what legal regulations do they refer to and how does it look in practice. It explains how to act after various accidents and how they can occur if chemical substances are used. Through a survey, employees' knowledge of the dangers and harms of the fluid and information about how to handle the fluid were examined. Based on the processed data, it can be concluded that the employees have different levels of knowledge and training. Such results indicate to us that injuries or illnesses may occur due to a lack of information or negligence. To prevent such situations, it is necessary to talk with employees to determine inconsistencies in the answers. It is also necessary to educate employees. Education must be carried out regularly and properly to minimize the risk as much as possible.

EMPLOYEE SAFETY DURING PLASTIC DEFORMATION METAL PROCESSING

Jelena Tintor[1], The Academy of Applied Technical Studies Belgrade
Jasmina Rajić[2], The Academy of Applied Technical Studies Belgrade
Igor Babić[3], Faculty of Mechanical Engineering East Sarajevo

Abstract: *Working in the metal industry carries with it a certain risk. The level of risk is largely influenced by the human factor, which is very important. The goal of this work is to determine the level of risk for the workplace operator on the machine for the production of casings and to prescribe preventive measures for safe and healthy work. To determine measures to reduce risk, a survey of the current state of occupational safety and health at the mentioned workplace was carried out. During the observation of the work process to assess the risk, the processing of metal by plastic deformation and the technical-technological procedure of the production of casings were observed.*
Keywords: Safety, workers, plastic deformation, production line, metal

1. INTRODUCTION

It is important to always be up-to-date with the latest laws and regulations, as well as advancements in occupational safety and health, to continuously improve workplace safety. Also, it is important to implement it all in practice. The awareness of the importance of said measures has to be lifted to a high level so the workers will accept their implementation. Respecting preventive measures is mandatory in workplaces with physical and chemical hazards. When doing research on work-related accidents and their causes, work-related health issues, or after the implementation of new production techniques or production equipment 1 the human factor is often disregarded although it is one of the most important factors in the occupational safety and health sphere.

2. HUMAN FACTOR IN THE OCCUPATIONAL SAFETY AND HEALTH SPHERE

Adaptation is important in the worker–work area interaction. Work equipment and work protocols must be adapted so that errors can be brought to a minimum. Workers must be qualified for safe work, which is enabled by schooling, courses, and training so the minimization of human errors is enabled too. Single factors or personal factors that affect work health and safety can be defined as any state or characteristic of an individual that can influence a worker to act less safely. They can be of a physical, cognitive, or psychological nature. Single factors include motivation, training, attitude, and human error and their interaction with the physical, mental, and perceptive ability of an individual[1]. Typical single factors include:

- Personal interests in bonuses and pay increases;
- Bad / damaged hearing;
- Bad eyesight;
- Language barriers or problems in communication;
- Physical health;

[1] jelenatintor0@gmail.com
[2] jrajic@atssb.edu.rs
[3] igor.babic2@gmail.com

- Experience;
- Competency;
- Personality and attitude;
- Age;
- Place in the hierarchy of the organization;
- Training.

After all large problems can be caused by language and communication barriers. The presence of foreign workforce and national minorities causes them. Training must be adjusted to different groups and the ability of workers to communicate in that group should be considered [2].
Negative factors that can affect workers are:

- Low level of skill and competency;
- Psychophysical exhaustion of colleagues;
- Disinterest of colleagues;
- Personal health problems;
- Dissatisfaction with repetitive tasks and lack of training to increase work/advancement availability;
- Lack of experience, especially in young workers;
- Peer pressure to conform to a group, or to accept their views on how "work should be done".

These factors have a great influence on operational health and safety, and some of them are unchangeable because they are caused by personality traits. Changeable factors also are important as are motivation, perception, attitude, and skill, and they can be changed through training, courses, and similar measures [3].

3. METAL PROCESSING BY PLASTIC DEFORMATION

In the production of brass casings, several hazards are present during metal processing by plastic deformation. These hazards affect the level of the risk, which has to be evaluated, and safety measures prescribed for risk mitigation. Plastic deformation is a complex process that starts as a consequence of the forced and permanent displacement of atoms in the crystalline structure of metals. Plastic deformation can be cold and hot. Cold plastic deformation happens at temperatures below the temperature of recrystallization while hot deformation happens at temperatures larger than the temperature of recrystallization which decreases the resistance of metals to deformation and increases plasticity. Both hot and cold deformation are used in different types of industries to produce metal parts [4].
The benefits of processing metal by plastic deformation compared to other methods are:

- Simpler machines;
- Increase in mechanical properties of deformed part;
- Room for automatization and mechanization of processes;
- High utilization rate of material.

Some of the downsides of plastic deformation are:

- Economic justification of process only for a large number of parts;
- Large deformation forces so the machines are bulky and heavy;
- Expensive tools.

4. PREVENTIVE MEASURES

While working it is important to properly implement preventive measures. These are modern social, organizational, technological, ergonomic, and health measures prescribed by the law of health and occupational safety [5]. Preventive measures must call on law regulations. Preventive measures are measures that are taken before an injury or illness happens. Their purpose is to decrease the risk or if possible, eliminate it. For proper implementation of preventive measures, timely identification of

hazards and dangers in workplaces is important. While creating preventive measures it's important to dedicate to the content of the safety data sheet which contains identification cards of chemical matters, data about its characteristics, way of use, way of disposal, dangers and hazards, measures for risk reduction and prevention, and supplier dana [6,7]. The basis for creating preventive measures is the eleven laws of environmental protection where in industry the accent is on prevention and precaution. The safety data sheet needs to be made in the native language of workers so they can understand all dangers and safety procedure [9]. While using chemical matter designed for the cooling of the work process its important to pay attention to specific and general limit concentration in substance so the limit concentration can be evaluated over which its use affects human health and the environment[10].

5. TECHNOLOGICAL PROCESS OF CASING PRODUCTION

For the production process of creating brass casings at „Valjaonica bakra Sevojno AD“ brass sheet is used as raw material. The raw sheet is made by passing a brass block through a series of rollers which decreases its thickness increasing length and width thus creating a sheet. The sheet is then cut to a specific width needed by the machine and tools used. The sheet is transported via a console crane and with a forklift to a roll feeder. The sheet is fed into feed rollers and then into the tool inside the machine. The sheet then goes through a multi-stage tool that transforms the raw sheet into casings. The first step is the stamping of the blank workpiece, and the second step is deep drawing to form the casing. The stamping speed of the machine is 100 – 115 strokes per minute. Using 2 stage tools and having multiple nests per tool the machine can produce from 600 up to 920 casings per minute (Figure 1.). The used sheet exits the machine and is collected and recycled (Figure 2.) Formed casings are at this point collected and transported to a rotational barrel degreaser to remove coolant oils from them. They go through a series of degreasing baths followed by a hot water bath, powder degreasing, and air drying which gives clean casings of corresponding shine, cleanliness, and quality. The finished product is then packed into wooden crates lined with oil paper. In the production of these casings cooling liquid must be used, most commonly oil–water emulsions which at the same time function to cool the tools and to lubricate them. Emulsions are created in a tank capacity of 600-800 liters, with a 5% oil concentration, and its own cooling and purification system. Coolant tanks are cleaned every two to three months. Because of its properties, emulsions pose a hazard and are harmful to human health and the environment.

Figure 1. Finished product
Source: Authors gallery

Figure 1. Leftovers
Source: Authors gallery

This process of creating casings produces a lot of heat which needs to be mitigated by the use of cooling liquids (emulsions).

6. RISK ASSESSMENT

The 5×5 method is used to assess the risk level according to the current situation and prescript corrective measures. Risk assessment takes into consideration work tools, work processes, work organization, raw materials, personal protection equipment, and other elements that can increase work-related accident risk, health deterioration, and sickness of worker [12].

Table 1. Risk matrix

Risk matrix							
Formula P=L*C		Level (L)	Probability of accident (B)				
			Minimal	Low	Probable	High	Sure event
			1	2	3	4	5
Accident consequences (C)	Very unlikely	1	1	2	3	4	5
	Unlikely	2	2	4	6	8	10
	Possible	3	3	6	9	10	15
	Likely	4	4	8	12	16	20
	Very likely	5	5	10	15	20	25

Table 2. Risk assessment.
Source: Author

Code	Hazard/harm	Probability	Weight	Risk	Evaluated risk
10	Probability of slip or fall (slippery floors)	4	3	12	Medium
21	Chemical hazards	3	2	6	Low
22	Noise	4	4	16	High
22	Vibrations	2	2	4	Very low
24	High/low temperatures	4	4	16	High
28	Hazards from dangerous materials present in production, transport, storage etc.	4	4	16	High
31	Non-physiological body posture	5	3	15	Medium
32	Psychological tiredness - monotony	4	4	16	High
33	Using adequate skill/knowledge.	3	3	9	Low
34	Shift work	4	4	16	High
34	Night shifts	4	4	16	High

By the assessment of risk using the matrix 5×5 method it can be concluded that a workplace of a machine operator for a casing production machine is the workplace with considerable risk, therefore measures for risk mitigation are to be prescribed. Table 3. shows evaluated risks and measures for their mitigation.

Table 3. Safety measures
Source: Safety sheet data [11]

Hazards/harms	Measure for mitigation
Slip or fall (Slippery floors)	Non-slip shoes and slippery (wet) floor signs.
Noise	Hearing protection.
High or low-temperature	Work clothing made for high/low temperatures. Climate conditioning. Air-conditioned rest areas. Access to cool water fridges during work shifts.

Hazards of using dangerous matters in work, transport, etc.	Adequate clothing/gloves. Adequate training on specific dangers. Safety data sheets.
Non-physiological body posture (standing for long durations).	Access to chairs near the workplace for resting. Adjusted work and rest time intervals.
Psychological tiredness - monotony	/
Shift work	/
Night work	/

7. CONCLUSION

During the preparation of the paper, the current state of safety and health was processed using risk assessment for workplace "Operator on the machine for casings production". Measures for risk mitigation are prescribed. The risk assessment shows that the workplace of the "Operator on the machine for casings production" is a workplace with increased risk. Therefore, it is necessary to post a prescribed notice of danger, to increase the awareness of the employees, and to use prescribed means and equipment for personal protection to reduce the risk to a satisfactory level. To implement risk reduction measures in practice it is necessary to properly educate employees about the dangers and harms and how new preventive measures can be used to reduce the risk of accidents or illnesses at the workplace. Based on the prescribed measures, instructions for safe and healthy work were written.

CHEMICAL HAZARDS IN HORTICULTURE FROM THE ASPECT OF OCCUPATIONAL SAFETY AND HEALTH

Milica Marković[1], The Academy of Applied Technical Studies Belgrade

Abstract: *Over the years in the horticulture industry, the use and distribution of chemicals on the market have escalated more and more. The main cause of this phenomenon lies in an increasingly diverse assortment of plants, which has led to a sudden increase in the need for pesticides to ease and speed up the production process. The usage of these chemicals can be seen in the context of significant concern and difficulty from the side of occupational safety and health and the natural environment. In this paper, we analyze the application of these chemicals in horticulture, hazards, and damages, as well as the measures of protection at work during the technological process.*
Keywords: chemicals, risk, hazards, damages, protective measures

1. INTRODUCTION

Horticulture, as one of the branches of agriculture, has to do with plant cultivation and maintenance, such as flowers, fruits, vegetables, and other plants. Although this activity provides various benefits, such as aesthetic landscaping and food production, it also brings significant challenges from the aspect of occupational safety and health. In recent years, we have witnessed an expansion of interest in horticulture due to an increasingly diverse assortment that has become easily available in terms of a simpler way of importing plants from other countries. As the number of plant species arriving from other countries increases, so does the need for new technologies to create artificial environmental conditions that imitate the original environment of the plant's origin. In this regard, the increased need for the wide usage of chemicals to protect plants by controlling pests and weeds carries countless unwanted results when it comes to the safety and health of the person engaged in this activity.

2. DESCRIPTION OF THE APPLICATION OF CHEMICALS IN THE TECHNOLOGICAL PROCESS

The most demanding but also the primary job of an employee who performs plant maintenance involves treating plants with different chemicals depending on the need. Frequently used solutions to treat plants belong to a group of pesticides, i.e. fungicides, selective herbicides, and the most harmful, i.e. insecticides.

1. Within the industry, fungicide is often used to protect plants right after their delivery from any fungal diseases and conditions potentially present in the new environment. This chemical agent for suppressing the growth and destruction of fungi, i.e. for protecting plants and animals, including humans, from the causative agents of fungal diseases and disorders (mycosis), includes many effects harmful for humans and the environment, such

as flammability, acute toxicity, environmental hazard and sensitization of respiratory organs.

2. Selective herbicides are chemicals used to control a specific type of weed that prevents the plant from developing properly. Their intentional effect on the weed plant targets specific growth processes or metabolic pathways. Production-wise, it is a useful tool in agriculture and gardening because it can ensure complete control of weeds without damaging crops or other plants. Although these chemicals offer many benefits, they still contain many, in terms of occupational safety and health, harmful properties, such as flammability, corrosiveness, sensitization of respiratory organs, and danger to the environment.
3. Insecticides are chemicals used to control insects that damage plants by feeding on their leaves, flowers, fruits, or roots. Although they are used less than fungicides and herbicides, they represent far more toxic and dangerous chemical compounds for the safety and health of people and the environment. Unlike selective herbicides that control only certain weeds, insecticides not only do not kill harmful insects but can also leave a negative effect on beneficial insects such as bees that pollinate plants. Therefore, improper use can potentially reduce the population of beneficial insects and affect the ecosystem. Moreover, the improper handling and disposal of insecticides can severely contaminate the soil, water, and air and accordingly cause harmful effects on plants, animals, and people that come into contact with these natural elements. Some of the properties of insecticides include toxicity, environmental hazard, corrosivity (corrosive substance), respiratory sensitization, and flammability.

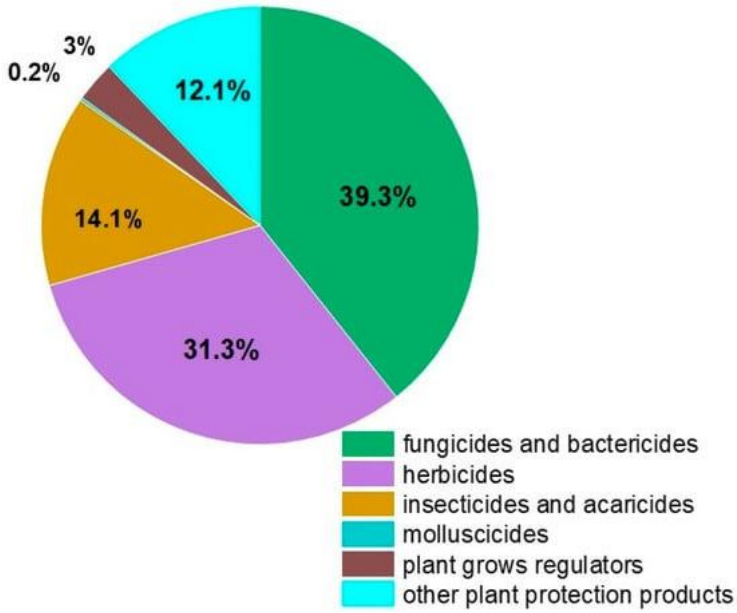

Figure 1. Categories of pesticide sales in the European Union in 2019
Source: https://shorturl.at/qxES4

3. HAZARDS WITH POSSIBLE CONSEQUENCES FOR WORKERS PERFORMING PLANT MAINTENANCE ACTIVITIES

Hazards are phenomena that endanger or may endanger employee's health and even life. Chemical hazards often take place in a short period, causing worker injuries that can be fatal, as opposed to damages that act over a longer period through long-term exposure to various harmful agents resulting from the technological process itself, causing occupational or work-related illnesses.

Depending on the type and level of exposure, exposure to chemicals can have a variety of negative health effects. The most common ones on the human body include:

1. Poisoning - chemicals such as pesticides, heavy metals, poisonous gases, and vapors originating from plants can cause acute or chronic poisoning in the body. Poisoning symptoms include nausea, vomiting, dizziness, damage to organs and nervous system, and even death.
2. Carcinogenicity - there is a wide range of carcinogenic chemicals that can cause different types of cancer such as cancer of the lungs, skin, kidneys, liver, and other organs. Susceptibility to cancer depends on many factors, such as body resistance, hereditary factors, and the length and frequency of exposure. Even so, the main risk catalyst can be still linked to the chemical exposure.
3. Respiratory problems - chemicals such as ammonia contained in artificial fertilizers or formaldehyde, also called an industrial fungicide, can cause numerous respiratory problems, such as airway irritation, allergic reactions, asthma, bronchitis, and other respiratory problems. Consequently, long-term exposure to these chemicals can lead to permanent lung damage.
4. Damage to the reproductive system - pesticides globally have very harmful effects on the reproductive system of men and women. They can cause decreased fertility, hormonal disorders, miscarriages, fetal deformities, and other reproductive health problems.
5. Neurological disorders - certain chemicals such as lead contained in insecticides, mercury used in the production of fungicides, or pesticides themselves can cause damage to the nervous system. Exposure to these chemicals leads to neurological disorders, the most common of which are memory loss, concentration disorders, depression, anxiety, tremors, epilepsy, and other problems.
6. Allergic reactions - sensitive people and people with reduced immunity are especially susceptible to allergic reactions to chemicals used in activities such as horticulture. The most common are surface reactions on the skin such as rash, itching, redness, and swelling. In addition, there are also respiratory reactions in the form of breathing difficulties, sneezing, coughing, and other allergy symptoms.

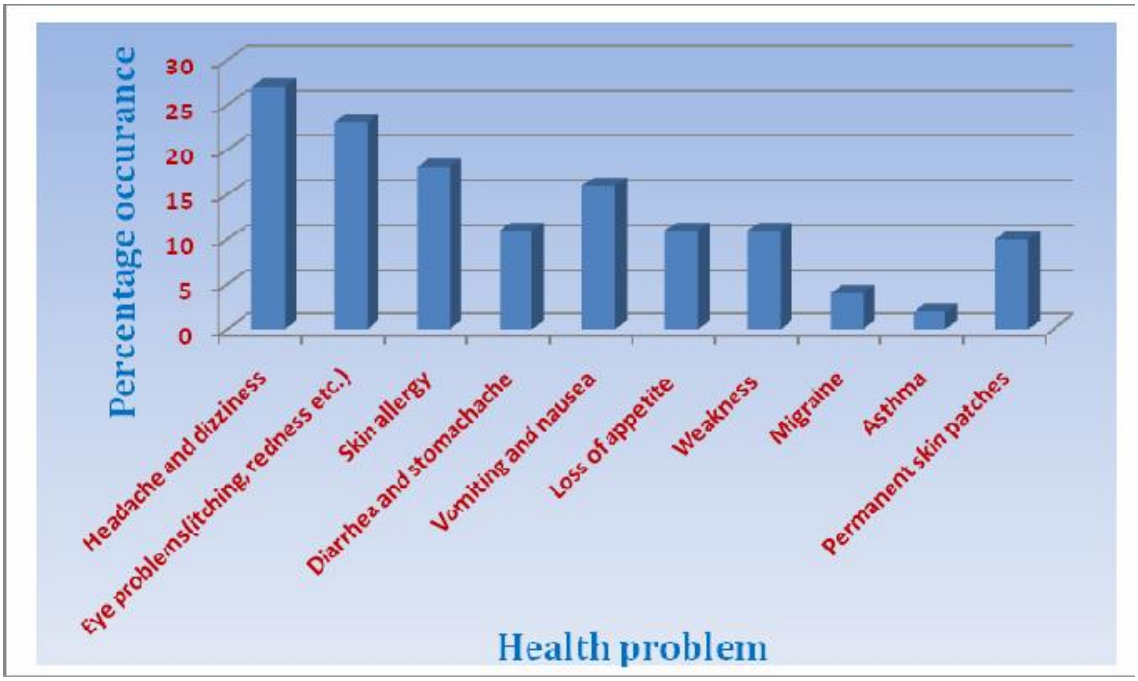

Figure 2. Negative health effects on farmers caused by pesticides
Source: https://shorturl.at/pxI37

4. PROTECTIVE MEASURES AT WORK AGAINST LONG-TERM EXPOSURE TO CHEMICALS

To precisely determine occupational protection measures against exposure to chemicals used in this activity, it is necessary to know the type of chemical, the length and method of exposure, the amount of dangerous chemicals present in the environment, and possible ways of chemical substances entering the body. There are four ways the chemical substances can reach the human body: absorption through the respiratory tract (inhalation), which is the most common case, absorption through the gastrointestinal tract (ingestion, i.e. swallowing), absorption through skin or eyes, and injection.

To avoid negative consequences for human health due to excessive exposure to chemicals, the Rulebook on preventive measures occupational safety and health when exposed to chemical substances ("Official Gazette of the Republoc of Serbia, no. 106/2009, 117/2017 and 107/2021) established occupational exposure limit value (OEL), as well as short-term exposure limit value (STEL). OEL is the average concentration of a hazardous chemical substance in the air at the workplace in the employee's breathing zone, under normal microclimatic working conditions and with light physical work. It is calculated over a certain period, in relation to the indicated reference period. According to the general opinion, it is not harmful to the employee's health, if the employee works at a concentration of a hazardous chemical substance that is lower than or equal to the limit value of a hazardous chemical substance, eight hours a day, expressed in mg/m^3 or ml/m^3 [ppm]. STEL is the concentration of a dangerous chemical substance to which an employee can be exposed for a short period of time without risking health damage. Exposure to such a concentration of a hazardous chemical should last no more than 15 minutes and should not be repeated more than four times during working hours. There should be at least 60 minutes must elapse between two periods of exposure to it. Short-term exposure values are expressed in mg/m^3 or ml/m^3 [ppm];

Occupational safety measures are organized according to a previously established hierarchy, first resorting to elimination and substitution measures, through engineering and administrative measures, all the way to the application of personal protective equipment measures. They can also be applied in combination.

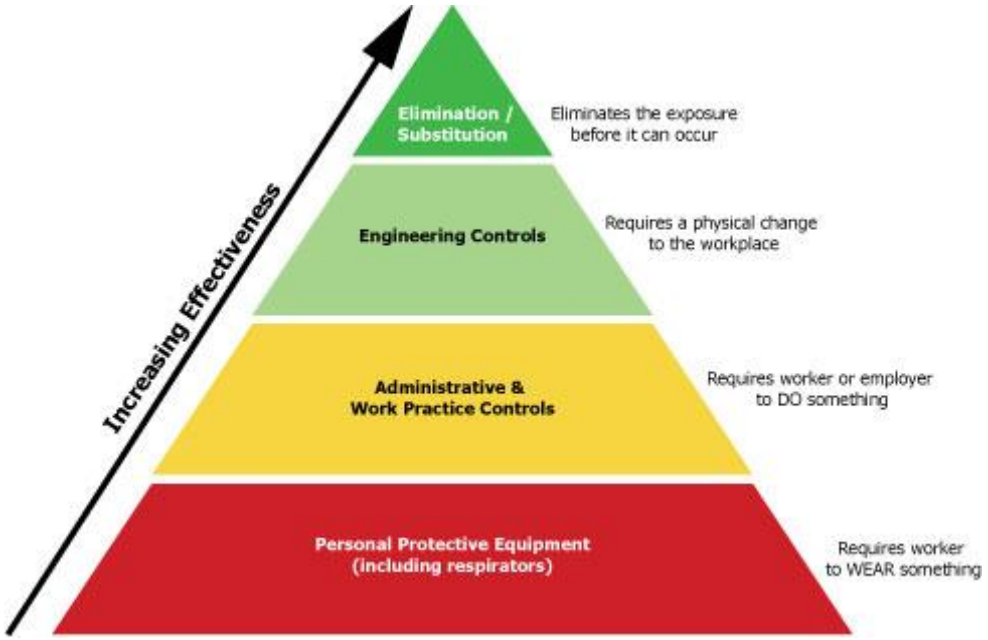

Figure 3. Hierarchy of measures for safety and health at work
Source: https://shorturl.at/ciqS1

1. Elimination and substitution refer to the elimination or replacement of hazardous chemicals by less hazardous ones. In this regard, we can mention a recent year's example of substituting the herbicide for destroying weeds called "Total 480 SL" by using completely safe agro textile mats. It is widely known how harmful the mentioned chemical is to the safety and health of both humans and animals that come into contact with it, but also how progressive and permanent the decontamination of the treated soil is, as the ban on the use of this chemical in the EU countries indicates. Nowadays, there are much safer alternatives for this type of problem, among which are agro textile mats made of woven polypropylene.
2. Engineering measures refer to physical changes in the work environment to reduce exposure to chemicals. Examples would be installing ventilation systems, establishing air drainage and filtration systems, or using closed chemical handling systems.
3. Administrative measures involve establishing organizational procedures to reduce exposure to chemicals. The most important administrative measures aimed at reducing the exposure of workers to dangerous chemicals are instructions for safe and healthy work when using hazardous substances, limiting the exposure time and rotation of workers, especially when plants are treated with insecticides and when high temperatures are present in greenhouses, providing access to safety data sheets for each dangerous chemical, monitoring the presence of dangerous chemicals using concentration detectors. They also include signs, signals and alarms to indicate permitted chemical concentration limits.
4. Personal protective equipment is used as the last line of defense when other measures are insufficient. This measure includes wearing gloves, safety glasses, face masks, respirators, protective suits, and other types of equipment that protect against exposure to chemicals. It is essential for personal protective equipment to be properly selected, used for its purpose, and regularly maintained.

5. CONCLUSION

In the field of horticulture, in addition to chemical hazards, there are also many other damages and hazards that additionally complicate finding a compromise solution. However, chemicals represent a major challenge for occupational health and safety engineers.
These are some essential measures for safe and healthy work during plant maintenance activities under exposure to chemical hazards:

1. Procurement of adequate personal protective equipment, such as disposable masks and gloves and their obligatory use during work. Non-disposable personal protective equipment must be regularly cleaned and maintained, especially after using harmful chemicals for plant treatment.
2. Using more frequent and shorter breaks when working in the greenhouse during the summer when the temperatures are above 35 °C, providing enough mineral water and air-conditioned rooms where the employee can spend time during breaks.
3. Mandatory previous and periodic medical examinations once a year.
4. Providing training courses and educating workers on how to properly use hazardous substances during plant maintenance activities.

What should represent a key aspect and good practice of every organization in the field of occupational safety and health primarily is the proper introduction of preventive measures, since they can significantly reduce the possibility of injuries, illnesses, and occupational diseases in the workplace. Preventive protection measures can bring the best results primarily through the direct cooperation of employees, employers, and persons in charge of occupational safety and health. Only a healthy and satisfied worker can ensure his maximum in the work process and contribute to himself and his employer accordingly.

POTENTIALLY EXPLOSIVE ATMOSPHERES IN FLOUR PRODUCTION

Marijana Drakulić[1], The Academy of Applied Technical Studies Belgrade

Abstract: *Dusts of organic origin often appear in processes in the food industry. In addition to other hazards related to potential damage to the health of employees, there are also risks of creating explosive atmospheres of organic dust and air. The paper analyses the possibility of creation of an explosive atmosphere because of flour dust that is occur in the technological process of flour production. Important factors influencing the creation of an explosive atmosphere were studied.*
Keywords: flour production, dust, explosive atmosphere, explosive limits

1. INTRODUCTION

In the current practice of explosion protection, the greatest attention is paid to the analysis of electrical devices as a source of ignition of an explosive atmosphere. However, in addition to the creation of an electric spark, a spark can also occur due to other causes such as a mechanical spark (impact, friction), hot surfaces, hot gases and flames, static electricity, ionized radiation, ultrasound, shock waves, self-ignition of dust, etc. Flour dust is a common by-product in the production process, consisting of fine particles of flour and bran. As such, when it is found in a higher concentration, it represents a danger of explosion because there is enough oxygen for combustion, and in combination with certain factors, it represents a potential risk for explosion.

2. EXPLOSIVE ATMOSPHERES

An explosive atmosphere is a mixture of air and flammable substances in the form of gases, steam, fog, or dust, under atmospheric conditions in which, after ignition, combustion spreads to the entire unburned mixture [1]. An explosive atmosphere can be caused by:

- Inadequate ventilation resulting in the accumulation and deposition of flour dust and a truly explosive atmosphere.
- Equipment that generates heat, static electricity, or friction (this can create sparks that can ignite flour dust).
- The human factor (due to improper maintenance and non-observance of safety procedures can also increase the risk of flour dust exposure).

The hazard of explosions and fires from combustible dust is present in industrial plants where materials are crushed and/or there is present of finely divided solid particles. A characteristic of a dust cloud explosion is the high speed of the flame front. The strength of a dust explosion is influenced by the following factors:

- maximum explosion pressure (P_{max}) - the greatest amount of pressure and maximum amount of damage that dust can cause in an confined space;
- maximum rate of pressure rise $(dP/dt)_{max}$ - maximum rate of pressure rise, before an explosion runs out of oxygen and fuel.

[1]mdrakulic2023.13037@atssb.edu.rs

The product of the volume of test vessel (V) and the maximum rate of pressure rise (dP/dt) is expressed through the relation:

$$K_{st} = (dP/dt)_{\max} \times V^{1/3} \text{ [barms}^{-1}\text{]}$$

K_{st} (dust deflagration index) is a dust constant, therefore normalising maximum rate of pressure rise in a 1 m^3 vessel. K_{st} is characteristic of the material not the test vessel size [2]. Depending on the K_{st} classes, the classification of dust is given in Table 1.

Table 1. Classification of dust [2]

Dust class	**K_{st} (barms^{-1})**	
St0	0	Does not explode
St1	1-200	Weak explosion
St2	201-300	Strong explosion
St3	>300	Very strong explosion

3. COMBUSTIBLE DUST EXPLOSION

The term explosion means a rapid chemical reaction of oxidation or decomposition of an explosive substance, followed by a significant release of energy in a very short period, which causes shock waves in the surrounding space. Detonation and deflagration are distinguished according to the method and speed of propagation of this phenomenon through the reducing material. Deflagration is defined as a very rapid burning of material from the surface to the interior. Burning speeds are in the so-called subsonic range (burning speed is lower than the speed of sound - less than 340 m/s). Detonation is an almost instantaneous combustion explosion followed by the formation of high pressure and temperature. The speed of the explosion can reach 10 km/h [3].

If the right conditions are created, an explosion of very high intensity can occur. For the burning process to occur and take place, three conditions are necessary: fuel, enough thermal energy needed to heat the fuel to a certain temperature, ignition, and the presence of oxygen. Dust explosion needs two additional elements – confined space and dispersion of dust particles in right concentration, as shown in Figure 1. A dust explosion is often the result of the swirling of accumulated explosive dust, which, together with oxygen from the atmosphere, creates an explosive environment. Its initial ignition leads to the transfer of heat from particle to particle (when one grain burns, it lights up nearby grains like a chain reaction), and with the influence of dust turbulence, a primary explosion occurs, which is generally of lower intensity. It represents the main shock wave that promotes the further swirling of deposited dust, because the pressure lifts the deposited dust, which triggers a secondary explosion that is far more intense and far more dangerous. Accordingly, it is understood that all the bigger explosions are the result of a chain reaction - a domino effect (Figure 2).

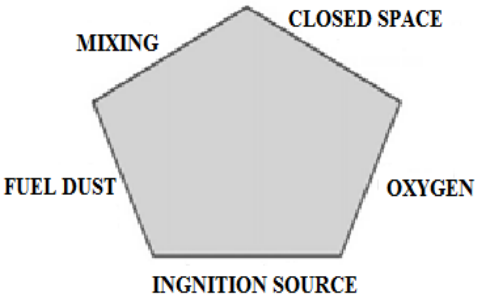

Figure 1. Dust explosion pentagon [4]

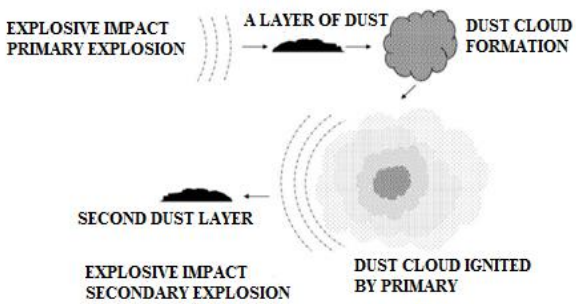

Figure 2. Dust explosion domino effect [4]

The explosive nature of flour is based on the fact that its particles are so small that they burn instantly. The energy thus released in the form of a flame can flash through the dust cloud with explosive force. When flour particles are suspended in the air and when the substance is present in powder form it offers a greater surface area exposed to oxygen per unit weight, compared to bulk materials, therefore flour dust clouds are much more flammable than bulk material, they can ignite in the presence of heat, burn instantly and transfer heat relatively quickly to nearby particles.
Flour and wheat, although are not classified as dangerous substances, under certain circumstances can exhibit dangerous properties. Flour is highly flammable as well as explosive in nature. This is because its main component is starch, a type of carbohydrate. Any hydrocarbon when it meets oxygen and heat undergoes combustion and burns to produce carbon dioxide gas and release water.
Flour and other sugar particles, when suspended in the air as dust, become explosive. Even a very small amount, is sufficient to ignite in the presence of a heat source. Almost all flour mills have flour handling systems such as transfer bins, bucket elevators, hammer mills, and bags. They provide the necessary containment and pressure, and ultimately, increase the risk of explosion. This type of explosion is known as a dust explosion [5].
Dust is defined "a small solid particle in the atmosphere that settles due to its weight but remains in the atmosphere as a dust/air mixture". The appearance of dust in industry is a consequence of the presence of raw materials and products (e.g. flour) or as a waste product (e.g. iron dust). Another definition of dust from the aspect of fire protection is that dust is a dispersed system in which one dispersed phase consists of particles of solid matter, and the other is air or another gas - the carrier gas [3].
The explosiveness of dust is primarily influenced by its chemical composition. Accordingly, dust can be defined in the following groups:

- organic (food dust, grain dust, cotton, wool, wood, coal, plastic and rubber dust, pharmaceutical and cosmetic dust, etc.);
- unbranched (dust from metals and various alloys, carbides, oxides, etc.);
  mixed (their composition can be different, and various dust mixtures occur in various ratios, eg calcium - carbonate, graphite - aluminium, polyester, etc.) [3].

In Table 2., the values of the lower explosive limit (LEL) for certain types of dust are given.

Table 2. Lower explosive limit for various dust [3]

The name of the dust	**LEL u g/m^3**
Al in powder	58
Potato starch	40,3
Tea	32,8
Flour	**30,2 – 63,00**
Hay	20,2

Ignition and combustion of dust take place within the explosive limits. Certain gases, vapours, and dust together with air can form explosive mixtures that explode under certain conditions. The minimum amount of flammable gases, vapours, or dust at which such a mixture can explode in contact with an ignition source is called the lower explosive limit. Above this limit value, the mixture is still explosive, but up to a certain concentration, when it stops being explosive. This limit value is called the upper explosive limit.
For many dusts, it is not possible to precisely determine the upper limit of explosiveness. For many dusts, the lower limit of explosiveness ranges between 20 and 60 g/m^3, while the upper limit of explosiveness ranges from 2 to 6 kg/m^3. The most favourable size for explosive combustion of dust is of the order of molecular size. As the particle diameter increases, the value for the lower explosive limit decreases. Table 3. shows the characteristics of some of the food dusts [3].

Table 3. Examples of combustible food dusts [6]

Product	Explosible?	P_{max} (bar)	K_{st} (barm/s)	MIE (mJ)	MIT_{cloud} (ºC)	MEC (g/m^3)
Corn	Yes	6.5	112	45-100	390-400	73
Wheat	Yes	7.4	87	50-100	370-380	67
Oats	Yes	7.2	43	> 500	420-430	30
Barley	Yes	6.3	100	50-100	360-370	73
Soy Beans	Yes	9.2	110	50-100	600-620	80
Starch (rice)	Yes	10.0	220	> 30	460-470	60
Starch (wheat)	Yes	9.1	156	10-30	470-480	30
Sugar	Yes	9.0	138	< 30	470-480	60

MIE - indicating the lowest electrical energy stored in a capacitor which upon discharge is sufficient to effect ignition on a dust cloud
MIT_{cloud} - lowest temperature of a hot surface capable of igniting a combustible dust cloud;
MEC - indicating the minimum amount of dust, dispersed in air, required to spread an explosion

4. FACTORS AFFECTING DUST EXPLOSION

Numerous factors affect the dust explosiveness, and to assess the risk of explosion, it is necessary to determine these factors, namely:

- dust concentration,
- oxygen concentration,
- size of dust particles,
- dust ignition temperature,
- minimum ignition energy,
- dust turbulence,
- presence of flammable gases,
- dust ignition source.

Dust concentration. A dust explosion occurs if the appropriate concentration of dust in the atmosphere is established. There is a range of dust concentrations. The lower explosive limit for most combustible dusts ranges from 50 g/m^3 to 100 g/m^3. The explosive concentration range of a dust cloud is not only a function of the chemical composition of the dust, but the limits vary depending on the size and shape of the particles in the dust cloud [4].
Oxygen concentration. As oxygen is a key factor in the triangle of fire (Figure 3), there is a limit to the minimum concentration required to cause an explosion (known as the threshold oxygen concentration). As stated in the dust explosion pentagon, the necessity of oxygen appears, which is characterized by the presence of air and its content of 21% oxygen. An oxygen concentration above 21% tends to increase the rate of the combustion reaction, but for a concentration lower than 21%, the rate of combustion decreases.
The consequence is that the rate of dust combustion decreases with the decrease of oxygen content in the atmosphere, thus the combustion may decrease or if an explosion occurs, it will be of lower intensity and the probability of a domino effect is very small. Burning is maintained only if the concentration of oxygen in the air is greater than 10% [3].

Figure 3. Fire trianle

Size of dust particles. The size of the dust usual ranges from 0.1 to 500 μm. [4] From the aspect of explosion protection, the most dangerous are dust particles smaller than 10 μm, the so-called floating - respirable dust. One of the most important properties of dust is that the smaller size of the dust particles means that they have a larger surface area in relation to the weight of the particle itself, thus enabling the speed of the particle's reaction with free oxygen in the air [3], Figure 4.

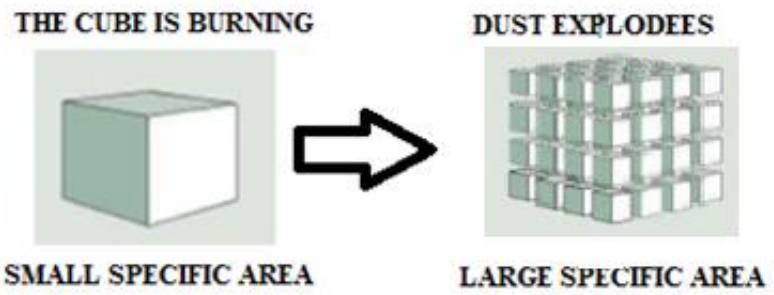

Figure 4. The surface of a dust particle

Dust ignition temperature. The ignition temperature represents the lowest temperature at which matter in the form of an aerosol or dust mixed with air can ignite. In the case of combustible dust, it is important to know:

- The minimum ignition temperature, ie the lowest temperature at which a certain thickness of the dust layer can be ignited on the heated surface;
- The ignition temperature of deposited dust, which represents the lowest temperature of the surface of the heated substrate leads to the ignition of a 5 mm thick layer of deposited dust. The ignition temperature decreases with the increase in the thickness of the dust deposits;
- Minimum temperatures of swirling dust, which is defined as the temperature at which the swirling dust of the most flammable concentration ignites.

The ignition temperature decreases with increasing dust fineness, in normal conditions of grain size of 50 to 100 mesh, the ignition temperature is 650°C, while with dust fineness over 270 mesh, the ignition temperature is 400°C [3].

Minimum ignition energy. The minimum ignition energy is the smallest energy of an electric spark, which can ignite finely distributed dust particles in the air. This energy depends on the concentration of the oxidizing agent in the combustible mixture, the type of combustible material, and the concentration of flying dust. A dust with a fineness of 50 μm can be ignited by a spark of energy 10-50 μJ, while dust with a fineness of 5000 μm only ignites when the energy reaches the level of 1.3 to 2.5 μJ [3].

5. REDUCING DUST EXPLOSION RISKS IN FLOUR PRODUCTION

The possibility of the creation of explosive atmospheres in the flour production process depends on many factors, primarily on the physical and chemical characteristics of the dust that is created and on the effectiveness of protective measures. Particularly important characteristics of dust refer to the size of the particles in the air of the work area. The distribution of the particles has a significant impact on the parameters of the wheat flour dust samples - smaller particles exhibit higher explosion parameters [7].

The aim of the protective measures is to minimize the creation of dangerous concentrations of flour dust in the air as much as possible, that is, to prevent the creation of high dust concentrations. The most effective way is to change the technological process so that the generation of flour dust is reduced to the smallest possible extent. Sufficient capacity ventilation and dust removal systems should be designed in accordance with the specifics of each technological process, as well as in accordance with the characteristics of the working space (space volume, equipment arrangement,

etc.). Maintaining the hygiene of process equipment and space through appropriate cleaning practices, preventive equipment maintenance are mandatory protection measures.

5. CONCLUSION

A organic dust explosion can be expected in almost all branches of industry, but the greatest risk is in the food and wood industries. The flour production process can create an environment where all these elements come together. Under such conditions, flour dust acts as a fuel source when mixed with oxygen, which can cause a fire when confined in a confined space. Due to the occurrence of disturbances during technological processes (high vibrations, dynamic imbalance, belt slippage, bearing damage, bent blades, rough handling, changes in environmental conditions, dust deposition, occurrence of static electricity, etc.), the creation of a spark and the ignition of an explosive atmosphere can occur.

INFORMATION SECURITY MANAGEMENT STANDARD AND PERSONAL DATA PROTECTION – PRACTICAL EXPERIENCES

Radoslav Raković[1], *Engineering Academy of Serbia*

Abstract: *The basic standard for information security ISO 27001 declares the need to preserve the basic properties of information - confidentiality, integrity and availability - and defines a certain number of controls oriented towards technical, organizational and combined actions that should ensure this. A special issue relates to the protection of personal data, which is the subject of a special General Data Protection Regulation (GDPR), which was applied in the EU on May 25, 2018. and the special Law for the Protection of Personal Data of the Republic of Serbia, which came into effect on August 22, 2019. After a brief presentation of the new revision of the ISO 27001 standard, GDPR and the relevant law, the paper discusses practical experiences and challenges in the application of personal data protection.*

Keywords: Information Security, Personal data protection, General Data Protection Regulative (GDPR), Law on personal data protection

1. INTRODUCTION

Modern technologies have greatly facilitated our daily activities, but they have faced us with a problem that was present before, but not to that extent - information security. A particularly delicate component of information security is the personal data protection (PDP), because we are all sensitive to information about ourselves that we do not want to share with a large number of people.

In order to solve the problem of information security in a comprehensive and systematic way, the International Organization for Standardization (ISO) adopted the family of standards ISO 27000, which refers to information security management systems (ISMS). The main standard in this family, ISO/IEC 27001 [1] is a standard with ISMS requirements that are oriented towards preserving the basic properties of information - confidentiality, integrity and availability - with a set of controls of an organizational, technological or combined nature that should ensure this.

The issue of personal data protection is only partially regulated by the ISO/IEC 27001 standard, because at the European level it is the subject of a special General Data Protection Regulation (GDPR) [2], which began to be applied in the EU on May 25, 2018. and the special Law for the Protection of Personal Data of the Republic of Serbia, which began to be applied on August 22, 2019 [3]. That is why the paper presents the key elements of the ISO/IEC 27001 standard related to the protection of personal data, the essence of the provisions of the GDPR regulation and the Law on Personal Data Protection in the Republic of Serbia. Also, some practical experiences and challenges in the application of these documents are considered.

2. INFORMATION SECURITY MANAGEMENT STANDARD ISO/IEC 27001 AND PDP

The ISO/IEC 27001 standard represents a global framework for ISMS, because it systematically provides an overview of all the elements that need to be taken into account if we want to protect information and thus reduce the business risk that can arise if that information gets into the hands of

[1] rrakovic@ep-entel.com

those who are not favorable to us as an organization. The basic properties of information are protected - confidentiality, so that the information is available only to those who have the right to it, integrity, so that the information is complete and not changed without authorization, and availability, so that the information is available to those who has the right to it when he needs it. Among the other properties of information that are protected in practice, the most interesting is non-repudiation, so that the recipient cannot deny that he has received the information, especially if some of its obligations arise from it.

The standard itself was issued under the designation 27001 in 2005, the second revision was published in 2013, and the third in 2022 [1]. This standard is specific in relation to other management system standards in that the basic part of the standard is relatively small in scope, but it contains Annex A which is normative (mandatory) with a multitude of controls that more precisely define certain elements related to information security. Revision 3 of the subject standard [1] defines a total of 93 controls (in version 1 there were 133, and in revision 2 there were 114) which are grouped into 4 categories - organizational controls (37), people-related controls (8), physical controls (14) and technological controls (34). The number in parentheses represents the number of those controls. It should be noted that despite the trend of reducing the number of controls, they were not omitted, but were only regrouped in order to facilitate their operational application. A more detailed description of these controls is given in the standard ISO/IEC 27002:2022 [4].

Revision 3 of the ISO/IEC 27001:2022 standard [1] already in the name change expanded the emphasis from information security to cyber security and privacy protection, because part of the name "Information technology - Security Techniques ... " was replaced by "Information security, cybersecurity and privacy protection ...". When it comes to controls, the topic of personal data protection is most directly dealt with by organizational control A.5.34, which refers to privacy and protection of information that identifies a person (Personal Identifiable Information - PII). A certain number of other controls deal with this topic indirectly. Of the organizational controls, these are management of information assets - human information assets (controls A.5.9, A.5.10), access control - authentication (controls A.5.17, A.5.18), incident management for information security (controls A.5.25 to A.5.28) and ensuring business continuity (control A.5.29), as well as most people-related controls (controls A.6.1 to A.6.5 and A.6.8).

3. GDPR REGULATION

The General Data Protection Regulation 2016/679 (GDPR) [2] was adopted by the European Parliament and the Council on 27.04.2016, published on 04.05.2016, and began to be applied on 25.05.2018. The period of two years from the adoption to the application of the GDPR was filled with many doubts about its content and the possibility of its application, which is still present today. The regulation itself has a total of 88 pages, the first 31 of which contain a preamble with 173 items, which explains the basic elements contained in the regulation. Paragraph (7) of the Preamble, which states that "natural persons should have control over their personal data", should be especially emphasized, and this can be considered an essential reason for adopting the regulation. The regulation itself is presented on the remaining 57 pages, it contains a total of 99 articles that are grouped into 11 chapters, some of which have sections.

It is important to note that together with this regulation, directive 2016/680 [5] was adopted, which limits the application of the GDPR in cases related to the processing of personal data by competent authorities for the purposes of prevention, investigation, detection and prosecution of criminal offenses. The bottom line is clear - those who engage in criminal activities cannot invoke the protection of personal data in order to prevent investigations related to their crimes!

A more detail overview of GDPR is given in the literature [6]. In accordance with the GDPR, the key participants in the processing of personal data are the "Controller" and the "Processor" - the "Controller" determines the purpose and means of personal data processing, while the "Processor" processes personal data on behalf of the controller. One of the key institutions is the "consent" of the data subject to the processing of personal data, as any form of freely expressed will of the data subject

by which he or she, by statement or clearly affirmative action, approves the processing of personal data related to him or her. A key problem that arises in the processing of personal data is "Personal Data Breach", which is a breach of security that leads to the accidental or illegal destruction, loss, alteration, unauthorized disclosure or access to personal data that is transmitted, stored or processed on another way.

According to the GDPR, the processing of personal data takes place in accordance with seven principles - legality, fairness and transparency, purpose limitation, data minimization, accuracy, storage limitation, integrity and confidentiality and accountability ([2],[6]). The essence is clear - personal data can be collected and processed only in accordance with the purpose for which they are intended and in the smallest possible scope, while they must be protected from all forms of abuse. In simple words, we need to "find the right measure" in the processing of personal data, and we know how difficult this is in many areas of life. In addition, the GDPR regulation defines eight key rights of data subjects ([2],[6]) - the right to be informed about the processing of their personal data, the right to receive confirmation from the controller as to whether or not personal data has been processed, the right to correction, the right to erasure ("right to be forgotten"), the right to ask the controller to limit processing, the right to data portability, the right to object and the right not to be the subject of decisions based solely on automatic processing, including profiling.

Within the GDPR, very high penalties are foreseen for breach of the personal data security, in two levels [2] - an administrative fine of up to €20 million, or up to 4% of the annual income in the previous financial year, i.e. €10 million, or up to 2% of the total annual income in the previous financial year, which is more unfavorable for the perpetrator! In the first two years, there were several cases of fining operators (Google, British Airways, Facebook, Post in Austria, real estate company Deutche Wohnen in Germany, etc.) mainly for the loss of personal data or their unauthorized use for marketing purposes, with fines ranging from 565 thousand to 205 million € [6]. Recently, the most attention has been attracted by fines for Twitter in the USA of $150 million (end of May 2022) for providing data to advertisers, as well as for the company META (formerly Facebook) in Ireland (end of May 2023) of as much as 1.2 billion € due to the delivery of data on EU citizens to the USA.

It is interesting to analyze the relationship of the GDPR to the information security management standard ISO 27001. The analysis shows [6] that a correctly implemented information security management system according to the ISO 27001 standard is still not sufficient for compliance with the GDPR. Although there are many similarities between these documents, there are also significant differences. First of all, these documents differ in their character - the GDPR is a legally binding document, the non-implementation of which entails certain penalties, while the implementation of the standard is voluntary, until the organization opts for it.

In addition, many institutions that exist in the GDPR do not exist within the ISO 27001 standard. This primarily refers to consent to the processing of personal data (Articles 7 and 8 GDPR), the right to erasure, i.e. "to be forgotten" (Art. 17 GDPR), the right to limit processing (Art. 18 GDPR), data portability (Art. 20 GDPR) and the right to object (Art. 21 GDPR), while the international transfer of personal data from Art. 46 of the GDPR partially exists in the ISO 27001 standard, but primarily refers to business data. On the other hand, the standard contains details on maintaining the level of information protection, which do not exist in the GDPR.

4. THE LAW ON PERSONAL DATA PROTECTION OF THE REPUBLIC OF SERBIA

In November 2018, a new Law on Personal Data protection of the Republic of Serbia - LPDP [3] was adopted. The constitutional basis for passing the Law in question is contained in Art. 42 of the Constitution of the Republic of Serbia, which proclaims that the protection of personal data is guaranteed, that the collection, storage, processing and use of personal data are regulated by a separate law, that everyone has the right to be informed about the collected personal data and has the right to judicial protection in case of their abuse. The reasons for the adoption of the new LPDP lie both in internal needs and in the context of joining the European Union. In the first segment, it refers to the need to upgrade the legal system to better ensure the protection of personal data, because the previous

law was passed in 2008 and was not able to fulfill what is required in this area. In the second segment, the adoption of this Law represents part of the state's international obligations and obligations to comply with EU legislation in the process of European integration. The need to amend this Law was stated in 2016 as part of the report on Serbia's progress in the EU accession process.

Table 1. LPDP structure vs GDPR
Source: *Raković R: Personal Data Protection – Framework and Challenges [6]*

Part	Part Title	Articles	GDPR Part
I	General provisions	1-4	I
II	Principles	5-20	II
III	Rights of the data subject	21-40	III
IV	Controller and processor	41-62	IV
V	Transfers of personal data to the thrd countries and international organizations	63-72	V
VI	Commissioner (Independent supervisory authority)	73-81	VI
VII	Remedies, liability and penalties	82-87	VIII
VIII	Specific processing situations	88-94	IX
IX	Penalty provisions	95	VIII
X	Transitional and final provisions	96-102	XI

The Table 1 shows the structure of LPDP [6]. The law essentially combines Regulation 679/2016 - GDPR [2] and Directive 680/2016 [5]. In comparison with the structure of the GDPR, sections VII "Cooperation and consistency" and X "Acts of delegation and implementation" are missing, which is a consequence of the fact that Serbia is not yet a member of the EU. Basically, the principles of LPDP and the rights of data subjects overlap to a significant extent in both documents. Nevertheless, there are certain additional differences between these documents, which are summarized in the literature [6] based on the wider literature:

- From the point of view of applicability, the GDPR has a significant advantage over the LPDP because it contains an extensive Preamble that accompanies the regulation itself and significantly contributes to its understanding through examples, explanations and the context of its adoption. The provisions from the Preamble were not included in the LPDP, and direct application of the GDPR is not possible because we are not a member of the EU, so in practice the provisions of the LPDP remain to be implemented in the spirit of other legislation.
- The law provides for the right to "complain" to the Commissioner, which is taken from the Law on Inspection Supervision, even though the GDPR provides for the right to lodge an objection - appeal. Lawyers are united in their opinion that the legal effect of a complaint and an objection - appeal is not the same.
- Violations of the Law are subject to fines ranging from 50 thousand to 2 million RSD for 32 cases, as well as 6 cases with a fixed fine of 100 thousand RSD. It is drastically different from the GDPR because the range of fines is from €430 to €17,000, which in a certain way contradicts the view that the penal policy should have a disincentive effect on the perpetrators. In the case of the Law, the amount of the fine is far below the damage that can be caused by violating the Law and the profit that can be made in that way, so the violators calculate it as a "cost" of doing business!

5. PRACTICAL EXPERIENCES AND CHALLENGES

In the practical application of the Law, there are many dilemmas, inconsistencies and challenges, of which only the most significant ones are listed below, summarized from the extensive literature in the reference [6]:

- The law imposed new obligations on the authorities and the Commissioner, but left a very short interval of 9 months from the entry into force of the LPDP until its implementation. In the case of GDPR, that interval was 2 years! The Commissioner asked for a postponement of the implementation of the LPDP, but this was not accepted.
- There is still insufficient awareness among people about the importance of personal data, people think that they are not important, that they have nothing to hide, etc. so they themselves in various forms (social networks, street polls, public places and public transport, etc.) give their personal data to others without any need.
- In the course of 2021 alone, more than 200 complaints about the violation of personal data were sent to the Commissioner, and 303 inspections were carried out [6].
- In the period from January 2015 to July 2020, the activities of the public prosecutor's office and the courts related to Art. 146 of the Criminal Code, which refers to the unauthorized collection of personal data. The results show [6] that in 14 of the 66 courts, there were a total of 28 cases related to that article, 4 acquittals, 2 convictions (both conditional), and the other 22 cases were rejected as unfounded, dismissed or suspended. In the same period, the Commissioner submitted 17 criminal reports, but none of them received an epilogue.
- Banks or hotels often ask for an ID card, which, instead of basic identification, is read, printed and placed in some binders without any need, or kept at the reception desk during the guest's stay with the explanation that they are being asked to do so by the Ministry of Interior Affairs. Similarly, during the registration and de-registration of employees, copies of identity cards are requested, in addition to the documents provided by the provisions of the law.
- By-laws did not resolve the issue of video surveillance in open and/or closed spaces (facial recognition technology), nor the use of photos on social networks.
- Within the unified IS in education and IS in health, there is a series of data in the form of a register of pupils/students, their parents or guardians, a register of teachers, etc. as well as an electronic diary system, as well as, patients, doctors, health records, laboratory results, etc. In practice, it happens that information leaks from these systems to the public, which should not be disclosed publicly under any circumstances.
- Companies carry out their activities based on the legal obligation to record the employment relationship, for the purpose of realizing the rights of employees and their family members or for the purpose of realizing the business and legitimate interest of the organization (eg employee references). In this sense, the principles of minimization (collecting only as much data as is necessary, no more and no less) and expediency, ie. that for each of the data there is a clear purpose for which it is collected and processed.
- In practice, there are many cases of abuse of personal data in order to discriminate against sensitive groups, e.g. women for whom, during employment, the employer asks for information that is not of interest to the job, such as information on marital status and family planning, etc.

Practical experiences of the application of personal data protection are illustrated by the example of the company Energoprojekt Entel p.l.c. from Belgrade, whose activity is design, consulting and engineering in the fields of energy, water, telecommunications and environmental protection. The organization has implemented an integrated management system (IMS) with five management standards ([6],[7]) – quality, environmental protection, occupational health and safety, information security and energy management, in accordance with the relevant ISO standards. The organization expanded its ISMS (defined by procedure EN-27P-01) with a special procedure EN-27P-02, which is dedicated to the issue of personal data protection. The subject procedure regulates the analysis (mapping) of personal data (data description, category, basis of processing, storage period, medium/location of storage, transfer to a third party, controller, processor and a more detailed description of the purpose of processing), assessment of the impact on the security of personal data, procedure in the case of endangering the security of personal data, giving and revoking consent to the processing of personal data, obtaining an employee's insight into the personal data that is collected and processed about him/her and deleting personal data. In addition to employees, this procedure

includes the collection and processing of personal data of potential employees (who apply for a job through the organization's website) and suppliers and other business partners.

6. CONCLUSION

The topic related to the protection of personal data is still new in our conditions. It is crucial to take measures of a preventive nature, and not to treat the consequences when problems arise. In practical application, there are many difficulties, considering that many elements are not defined by secondary legislation (use of unified number of citizens, video surveillance outdoors - traffic, parks, and indoors - shopping centers, etc.). The fact is that there is a lot of space for improvement.

DEFICIENCIES AND ADVANCEMENT IN ORGANIZATIONAL STRATEGIC DECISION-MAKING

Miloš Jelić[1], Foundation for Quality Culture and Excellence - FQCE
Ana Aksentijević Jelić, Academy of Applied Technical-Artistic Studies

Abstract: *Any organization is susceptible to make misperceptions which may bias own judgment and lead to weak strategic decision. This issue appears to be of a paramount importance for organizations striving excellence where the strategy is to be based on understanding needs of both stakeholders and external environment. Strategic decisions are never simple to make, and they sometimes go wrong due to human shortcomings. The prevalence of biases in company decisions is to some extent a function of habit, training, executive selection or organizational culture. However, biases are highly pervasive owing to human nature which is predominantly resistant to feedback. The paper is aimed to make an inventory of vices that are rather common in organizations of various sectors. At the same time, it proposes actions which are not only based on efforts to limit biases of personnel but also on organizing a decision making process that will confront different biases and restrict their impact.*
Keywords: strategy, excellence, organizational culture, quality

1. INTRODUCTION

Most top managers in companies would agree that skill to define strategy is the attribute of major importance for successful performance of their job. Following such position, a huge number of organizations spend a lot of time and resources in a formal and regular strategic-planning process which results in a series of business reviews with remarkable participation of top manager and his team. However, in real, a substantial minority of them truly accept that such time-consuming process pays off since they regard it to be fraught with politics offering a small amount of ideas. Instead to prepare management team to face strategic challenges ahead or to incite creative thinking about the vision of the organization or the route the organization is heading, the planning process frequently appears to be a mere ritual where no one is exactly sure why it is conducted but still nurturing a sort of mystical hope that something good will come out of it, [1].
Large organizations predominantly tend to separate operative work from strategic thinking ("hands" from "minds"). By doing so, they often sever the vital feedback between the two. For example, the person from the organization who identifies the customer with unmet need may gain the most strategic information in the whole organization. However, such information becomes useless if he is not in position to create a strategy in response or he cannot convey information to the person who is in such position or such transfer is meaningless since the response has already been formulated. [2]. Therefore, real strategies are rarely developed in paneled conference room. They are more likely to be cooked up in informal situations like: casual working groups, conversations in lobbies or even own reflections.

2. STRATEGIC DECISION-MAKING: DISTORTIONS AND DECEPTIONS IN ORGANIZATIONAL SETTING

Whichever approach in strategy defining an organization inclines to, the organization is vulnerable to misconceptions and biases. The prevalence of biases in brought decisions is partly a function of habit, training, selection of managers, and organizational culture. But most fundamentally, biases are pervasive because they are a product of human nature – hard-wired and highly resistant to feedback, [3]. A group of wide-spread biases are cognitive biases we all possess as human beings. This sort of biases distort the way humans collect and process information and they may arise from interactions in organizational settings where judgement may be influenced by proper interest leading humans to commit (un)concious deceptions. One of frequent distorsion is overoptimism where people build their high expectation on something vague or unknown, what may result in underestimating technical chalenges in large projects or total time to complete them. However, humans that experienced losses more than gains in the past are susceptible to loss aversion which lead them to rather be inactive than to face even acceptable risks. Such an distortion have effects in scarcity of investment projects. Finally a distortion that is usually met among ambitious people is their overconfidence where excessive goal focus pulls to underestimation of challanges.

Also, strategic decisions made within an organizations result from interactions among senior executives. Usually, a manager proposes a decision (for some investment) and an executive committtee makes evaluation. In such an array, a conflict of interest between the manager, acting as an »agent«, and the organization (»principal«) on behaf of which he acts, may arise. Principally, this problem takes place when agent's intentions are not quite aligned with the interest of the organization what leads to intentional deceptions – conveying misleading information to other actors. When organizations make review and evaluation of proposed strategic decisions, three main conditions generating »agency problem« are encountered. One is the misalignment of time horizon between individuals and organizations where individuals are focused solely for time period for their curent position within organizational setting. Conflict of interest is avoided only if both parties are happy with short term impact.

Another problem that may result in harmful deception appears when career risks are perceived by individual and organization in different way. Very often managers are reluctant to risky project if they consider that if the project fails it wil ruin their reputation and have adverse effect to their future career. In such an consideration they rather incline not to propose an attractive investment (for the organization) particularly in situation when no penalty is expected for such an omission. The asymmetry between results based on action and inaction is refered to as »omission bias« which explains loss aversion behavior of managers.

Third sort of agency problem is encountered in situations where a subordinate is significantly more competent than his superior for a certain issue. Consquently, the manager doesn't make judgement on the ground of proposal merits but rather putting trust in the person (subordinate) who promotes it. At first glance, it is quite natural when managers believe to his closest associates. However, this leads to the tendency where the decision is grounded too much on a subordinates reputation, what in turn increases susceptibility to deception. This type of deception is known as the »champion bias«.

Almost opposite problem, but also grounded on exessive trust, may be encountered in large organization with authoritarian leadership. It is called »sunflower management« and denotes the inclination of people in organization to align themselves with leader's announced or even assumed viewpoint. If the readiness to pursue lider's decision is not based on personal attitudes but on pure obedience and supression of proper opinion the decision will be brouht under deception.

3. MANAGER'S FLAWS IN STRATEGIC DECISION-MAKING

Majority of top managers are reluctant to spend time on developing strategy for own organization. Out of many two reasons may be highlighted. First they see this job rather difficult in spite of the fact that most successful strategies have been created and led by pragmatic leaders who are capable

to consider alternative futures for their organizations, top managers are predominantly insecure on proper capability to generate credible and sustainable strategy. The other reason lies in perception that strategy development shall be in fade of their daily and most pressing issues. However, such attitude is not caused by personal misperception and shall be regarded rather as the result how the strategy is managed and developed in many organizations.

At the same time, classic term "strategic planning" should cover activities aimed to create opportunities for future organization growth. However, many have thought of endless form filling, request for additional information and fight to protect own budgets. Under a planning-led system top management team tends to initiate process with pre-defined growth that shall be attained in a certain period of future. Such process is usually led by finance department and performance trends are defined in terms of current trends with minor fluctuations. In such an approach top management discussions are limited to detailed budgetary issues. On the other hand, a strategy-led approach starts with a question what kind of business an organization is striving. The focus is on clarifications which are the best ways to win in the future and to determine what organization structure and size will be adequate to make it happen. Only upon such an alignment it is possible to determine key steps that will enable organization to move from the current position to the strategic future.

Generally, strategic planning and developing strategy approach are distinctly different. While strategy development is trying to find ways how to win on chosen market, planning seeks to identify best ways to achieve defined objectives within defined resource constraints. Planning requires a predefined timetable for proper allocation of resources, while strategy responds to the market issues and opportunities once they emerge. When metrics is concerned, planning deals with profit and loss, cash-flow budget and market share projections, whereas strategy development pays attention to innovation, customer satisfaction, brand strength etc. Finally, annual planning requires a central planning team, while strategy development needs the active involvement of business leaders. Therefore, to safeguard strategy development and increase chance for new opportunities an organization shall separate strategy development from annual planning process.

Planning-led approach provides incremental gains to an organization. However, if the changeover to strategy-led approach is conducted the success of such process will not be certain unless mindset of top managers is changed. Fleeing from risk to be wrong or even to be seen wrong in decision-making immobilizes top managers to propose some radical solutions that are directed to change existing business model or current strategy. The shift in mindset shall include declining from mere profit targets and moving towards a long-term goal that drive to new thinking and higher commitment to organizational ongoing success. The key issue for a top manager in setting goals is to be successful in suppressing ego and to have clear understanding on what are feasible options for the company once the top management team conducts necessary strategic and organization changes.

To be successful in strategic-led approach one should refrain from putting financial issues ahead of ideas due to the fact that developing business strategy relies on creativity and idea generation to higher extent than it is driven by analysis. Most business development successes emerged from small groups or individuals who possessed a strong will to change surrounding in some way. So far many books on business strategy have put stress on application of analytical methods and tools. No doubt that a certain level of analysis is inevitable to make business strategy successful. However, in the absence of fresh the efforts will result in very good understanding of the position an organization currently has on the market but with no guidelines how to drive new profitable growth in future. The table of comparison between analytical and creative approaches to strategy is given on Table 1, [4].

Many managers, even on senior level, do not feel the distinction between a vision and a strategy. Sometimes it is expected that once a vision defined it is a routine work to set out a strategy growth. Such expectations are ungrounded since a vision can merely inspire executives and employees but in fact the vision can not provide supportive information on where to focus their efforts in order to make your strategy embedded across the organization. In that regard, vision shall be understood as an inspirational overarching long term goal of an organization whereas strategy represents a

framework for directing decisions and actions across the organization to provide superior performance of the organization and the vision accomplishment.
Omission of top management to determine which are the key issues for an organization and which ones are of lower importance is the frequent reason for strategy failure. Once an organization fails to make proactive trade-offs it is quite unlikely that it will have a winning strategy or attain a leading position on the market. Very often top managers rely on competitive benchmarking excessively what results in trials to become a (pale) imitation of the leading organization on a particular market. The problem for such (imitating) organization lies in the fact that only market leaders can occupy the biggest part of customer's attention thus it is unlikely that new aspirants will be noticed addressing to the market in a repeated way. In other words, an organization should head in a way to identify what characteristics make it distinctive in its business environment, to ascertain whether there is something unique that would immediately be noticed by customers and last, but not least, to what extent the proposed business model will be difficult to be copied by rivals.

Table 1. Analytical vs. Creative Approaches to Strategy
Source: [4]

Analytical approaches	**Creative Approaches**
Focus on analysis of markets and performance	Focus on new ideas
Desktop assessments	Real-life experience
Follower	Leader
Problem solving	Innovation
What's happening	What if?
Dealing with the past	Focused on the future
Financial proof before action	Action before financial proof
Forecasts and long-term plans	Rapid learning action plans
Strategy teams staffed with analytical experts	*Ad hoc* strategy teams staffed with a mix of "thinkers" and "doers"

During strategy implementation almost no strategy can remain unchanged. By pursuing main organization objectives, implementing initial plans and taking actions, it is quite likely that some direction changes will take place. The results from the actions, as a feedback, will drive the strategy and rectify the way of future organization success. This is the core of Action-based Approach. In Traditional Approach many assumptions are made at planning stage and the plans are implemented regardless the assumptions were confirmed while in Action–based Approach a permanent trial-and-error and learning process yields opportunity for continuous strategy correction. Traditional Approach includes planning how to plan for months, whereas Action-based Approach means - act from day one, [5].

4. STRATEGY ISSUES IN ORGANIZATIONS PURSUING EXCELLENCE

Vision and mission in excellent organizations are implemented by developing a stakeholder focused strategy. Strategy is based on understanding both of needs and expectation of organization stakeholders, and internal performance and capabilities of organization. In gathering stakeholders' needs and expectation for the development of their strategy an organization striving excellence remains constantly alert to any changes. They also identify, understand and anticipate threats and opportunities based feedback from stakeholders and other external sources. To better define position in market environment they compare their performance with relevant benchmarks to understand own strength among competitors and areas for improvements, [6]. Such approach in excellent organizations principally reduces their vulnerability to misconceptions and biases, and particularly reduces susceptibility to deceptions due to intensive interrelation with key organization stakeholders.

Strategy and policies established for strategy implementation are regularly reviewed and updated. Organizations tending excellence identify and introduce key results to evaluate accomplished progress towards the vision and strategic goals. They also adopt mechanisms to create future scenarios on market and to manage organizational strategic risk. These mechanisms significantly contribute that risk aversion of their top managers is diminished. Regular keeping track of key results and key performance indicators enable such organization to identify advantages of its rivals thus to learn about the areas where the organization might excel, i.e. items that are supposed to draw significant customer attention that will result in future leading position of the organization on the market, [7].

Regular monitoring of business environment landscape furnishes relevant information to conduct analysis and understand external indicators and timely feedback from stakeholders thus creating a ground to establish a cycle of idea generation – action, learning and refinement. The critical aspect in this cycle is to learn as quickly as possible. It means that the ability of an organization pursuing excellence to generate its competitive advantage is directly proportional to its capacity to operate this cycle faster, more efficiently and more effectively.

5. BETTERMENT IN DECISION-MAKING PROCESS

Being aware of the fact that human nature may lead to some hardly explained decision, wise leaders in ambitious organizations will fortify their judgment when making important decisions. To cope successfully with this problem, they have to identify which sort of bias is most likely to affect decision. Predominantly large organizations suffer from excessive optimism, whereas excessive risk aversion is inherent to small organization where the decision-makers fear for potential losses to a higher extent.

Leaders in organizations play crucial role both in identification of prevalent biases and in use of adequate tools to create productive decision-making culture. At first place, they should consider which decisions are really strategic and where they are made. After targeting the crucial decision making processes, leaders shall examine them with two objectives: determining susceptibility of organization to human error and real problem assertion. It should be taken into account that a decision-making safeguard that appears useful in one setting may be counter productive in another.

Once an organization tackles the diagnostic process, it can introduce tools that limit risk of distortions and deceptions. To temper optimism it is useful to track the expectation of individuals against actual outcomes in order to examine process that support strategic decision. Once forecasts and results show strong departure, the organization shall review these processes.

Another way of avoiding overoptimistic decision is to provide an additional assessment from independent second source. It is usually done by assigning important decisions to committees. However, the effectiveness of such approach depends on willingness of committee members to challenge proposals and on validity of facts that are in front of them.

Loss aversion along with career induced self-censorship find roots in explicit and implicit organizational censorship. Regularly, lower-level managers are typically faced with more but smaller risks. To mitigate the problem, an organization can embed higher tolerance for them, for instance by using different criteria for the financial analysis of larger and smaller projects. Another technique is to request from managers that their investment recommendation include alternatives (second and third option). The approach yields two benefits: organization may calibrate the manager's risk aversion level and uncovers opportunities that a manager might consider insufficiently safe to present, [8].

Another approach to solve distortion and deception problem lies in fostering a culture of open debate within an organization. It should be noted that ultimate effectiveness is proportional to quality of the resulting discussions, and they may be effective only if organization already has a culture of open and objective debate. It is commendable to initiate constructive debate among top

manager and management team in order to reflect collectively on past decisions. A willingness to ask how the decisions emerged demonstrates that the organization is able to learn from mistakes.
Once it is decided that a group will be the decision-maker, the key prerequisite for good strategic decision-making is to "frame" conversation thus to ensure that right questions and answers are on the table. When a meeting has been called to reach a decision, framing the discussion includes understanding the criteria to reach it and being aware to what extent options can be expanded, particularly when the decision is important and unusual. In this way, a well-framed debate includes a set of proposed criteria for making the decision and, if applicable, an effort to demonstrate their relevance though examples and analogies.

6. CONCLUSION

Organizations that are deliberate to pursue successful strategy shall not lose from sight the influence of human factor in the process of making strategic decisions. Such organizations can greatly enhance their chances to make right decisions by raising awareness of the way cognitive biases can mislead them, by performing review of their decision-making processes and last, but not least by nurturing the culture of open and objective debate.

CIVIL PROTECTION MANAGEMENT MODEL AT THE LOCAL GOVERNMENT LEVEL

Igor Milić[1], University of Applied Science Velika Gorica, Slovenia

Abstract: *Resilience to crisis situations is built at the local level of the civil protection system. In the Republic of Croatia, 127 cities and 428 municipalities participate in the civil protection system at the local level, which represents many participants who have the obligation to develop capacities for prevention, preparedness, and response to crisis situations. Bearing in mind the available capacities and especially the crisis situation caused by the COVID-19 pandemic and the mitigation of the consequences of the earthquake in Zagreb, Sisak-Moslavina, Zagreb, Karlovac, and Krapina-Zagorje counties, local government units cannot carry out their duties independently. The existing Civil Protection System Act prescribes numerous obligations (prevention, planning, operational, financial) for local government units, and it is obvious that local government is faced with great challenges. The aim of the paper is to present a new civil protection management model that is based on research conducted with the purpose of collecting data from the level of local government units on the topic of the civil protection system. The civil protection model should be based on three main elements: citizens, operational forces, and local administration, and focuses on citizen education, prevention, and the development of a safety culture.*
Keywords: civil protection, local government, management.

1. INTRODUCTION REMARKS

Civil protection in the Republic of Croatia, as well as in other countries of Europe and around the world, represents the most complex subsystem of national security and connects together the planning, prevention, and operational capacities of a large number of participants from the national, regional, and local levels. The experience of the member states of the European Union shows the need to build risk management capabilities, develop a system of early warning and preventive action, and propose and implement risk reduction measures to avoid new risks and especially reduce existing ones. The civil protection system in the Republic of Croatia is organized on three levels (state, regional - counties and the City of Zagreb, and local including cities and municipalities). Cities and municipalities are obliged by the Civil Protection System Act to participate in the implementation of civil protection measures and activities, but in this process, they face numerous challenges (personnel, organizational, financial, etc.). Civil protection tasks represent the important obligation of local government that is also prescribed by the Constitution.

In 2022, the University of Applied Sciences Velika Gorica conducted research entitled "Civil protection in the local community". The goal of the research was to collect data on the challenges faced by local government units in the civil protection system and to propose improvements to the legislative framework and guidelines for the development of the civil protection system at the local level. The research technique used was an online questionnaire with 17 questions that were grouped by thematic areas (planning, preparedness, operations, and development). Out of 555 local self-government units (127 cities and 428 municipalities), 110 units filled out the questionnaire, which represents about 20 percent of the respondents. This tells us that the local government want to be an

[1] igor.milic@vvg.hr

active participant in the process of revising the civil protection system and emphasis the problems they are facing and to propose improvements to make civil protection at the local level even better and more efficient.
The results of the research offered a basis for creating new proposals for the improvement of the civil protection system. The civil protection management model, which is presented in this paper, represents one of the proposals based on the conducted research, which aims to improve and connect all available capacities for civil protection management at the local level.
The main hypothesis of this paper is that all crisis situations begin and finish at the local level of the civil protection system.

2. BEST PRACTICES OF THE CIVIL PROTECTION SYSTEM

The civil protection system should be determined on clear and acceptable principles, agreeing with the political system, the material possibilities of the state and local communities, and the real needs to respond to existing and possible risks from sources that have the consequences of a crisis situation [1]. Civil protection is an important element of the national security system for action in crisis situations. The civil protection system in the Republic of Croatia is regulated by the Civil Protection System Act. The Act defines all segments of the system (participants, operational forces and citizens) with the aim of protecting and rescuing people, animals, cultural assets and the environment in major accidents and disasters.
The greatest advantage of the civil protection system, compared to other components of national/homeland security, is that it provides a coordination platform for the inclusion of all necessary participants throughout the country, and has the great advantage that it operates at all levels (state, regional and local). This enables all participants and operational forces to coordinate the implementation of civil protection measures (i.e. search and rescue, shelter, first aid, etc.) and other activities in crisis situations.
Organization of the civil protection system is based on risks that pose significant threats to the population, property, and environment. The principles of the civil protection system are humanity, prohibition of discrimination, sustainable development, solidarity, subsidiarity, and continuity of action. Subsidiarity principle is important to have in mind at the local level. It described the way to activate the system from the lowest to the highest hierarchical level by making decisions and implementing civil protection measures and activities by engaging a higher level, only when all the available resources of the lower level are exhausted. The first response to crisis situations occurs precisely at the local level with all available operational capacities (firefighters, police, emergency medical service, Red Cross, civil protection units, etc.) [3].
Civil protection headquarters play a very important role in the civil protection system as a professional, operational, and coordinating body for the implementation of civil protection measures and activities in crisis situations. The civil protection headquarters is established at all levels of the system (state, regional, and local) and manages the response of the civil protection system to crisis situations in its area. Civil protection headquarters of municipalities and cities in crisis situations are the first to be activated and start implementing the necessary measures and activities with the aim of mitigating the consequences of a specific crisis situation.
The mayor (city-level) and head (municipality level) play a very important role as the primary responders for the civil protection system in their area of responsibility. According to the Civil Protection System Act, the mayor and head of the municipality are required to undergo training within six months of assuming office and familiarize themselves with their rights and obligations in crisis situations [3].

3. MAIN CHALLENGES AND OPPORTUNITIES

In order to facilitate and operationally speed up the operation of the civil protection system, certain powers and responsibilities of administrative structures at the national level in most countries are

dispersed to local government, while respecting the specificities of the area covered by each local government, i.e. it is necessary to create an analysis of real threats which are characteristic of that local community [2].

Analysis and research play a crucial role in understanding complex systems like civil protection. Thorough analysis and research we can understand the nature, scope, and potential impact of the crisis. This understanding is fundamental in formulating an effective development strategy to implement best practices for the civil protection system.

Research conducted in 2022 by the University of Applied Sciences of Velika Gorica has shown that the biggest challenge at the local level is the lack of professional staff and the big obligations in the part of creating planning documents. 60% of those surveyed believe that the area of preparation of planning documents should be revised, that is, the obligations of local government should be reduced in that area. The challenge of lack of financial resources, as well as citizens' lack of interest in the issue of civil protection, is always relevant. Opportunity for development, except through the support of the state and the county through budget funds (30% of respondents), as many as 26.4 respondents believe that connecting with neighboring local government can improve civil protection capacities at the local level.

It is interesting feedback that in the part of investment in operational capacities, in addition to firefighting capacities, the largest investments should be made for the development of capacities for managing crisis situations (technical-tactical support) in the field.

Research has also identified the following areas for improvement:

- Reduce the burden on the level of local government in the part of obligations to prepare planning documents.
- Conduct trainings for the preparation of planning documents.
- Digitization of planning documents, application of documents in trainings, exercises, and real situations.
- Education of children through compulsory teaching programs in schools.
- Emphasize the creation of digital platforms for information management.
- Further investment is required: digital innovation for early warning systems, creation of strategic documents, education, and infrastructure.

Implementing above mentioned areas will enable local governments to make informed and better decisions, allocate resources wisely, communicate effectively (both internally and externally), and continuously improve their resilience, ultimately enhancing their ability to mitigate the impact of crises.

4. LOCAL MANAGEMENT MODEL 3x3

A simple and effective management model that covers various stages of the civil protection system: planning, prevention, preparedness, response, and recovery, is a must for local government. The model should be based on principles, priorities, and values that will ensure the implementation of civil protection activities at local level. We need to keep in mind that the model should be implemented to 555 local management units and therefore it should be developed like a “toolbox” where the local government will pick and implement solutions that are relevant for them, having in mind topography, demography, history aspect, identified threats, etc.

4.1. Cornerstones of management model

Three *cornerstones* of the management model are identified principles, priorities, and values of the civil protection. For each, three actions are identified as most relevant:

Principles

- *Flexibility*: refers to the ability of civil protection systems to adapt and respond effectively to a wide range of crisis situations. Given the unpredictable nature of the crisis, having flexible plans and frameworks in place is crucial for a successful response.
- *Self-sufficiency*: capacity of the necessary material and technical means (personal and collective equipment, including vehicles, water, food, etc.) with which the local level operates independently

at the location of the intervention in the response with the aim of achieving continuity of action and to have, as least possible, logistical requirements to regional and/or national civil protection authority.
- "*Light and fast*": refers to a strategy in crisis response that emphasizes swift, agile, and efficient actions to quickly provide aid and support to affected communities. This approach is particularly important in the initial stages of a crisis when rapid response on the local level can save lives and reduce the impact of the crisis.

Priorities
- *Prevention*: refers to the actions implemented to avoid or minimize the negative impacts of potential crises or disasters. It involves identifying potential risks, vulnerabilities, and hazards and taking proactive measures to mitigate these risks.
- *Education and exercises*: educate the public and operational forces about potential risks and how to prepare for crisis situations. This includes school programs, public service announcements, and community workshops. It is necessary to conduct regular exercises to ensure that the population and operations forces know what to do in case of the crisis situation.
- *New technologies*: digital solutions can facilitate and speed up the decision-making process in crisis situations through the establishment of interactive databases on risks and operational forces, modern early warning systems, and tools for reviewing the situation on the ground in real-time.

Values
- *Knowledge*: expertise and skill of methods for involving communities in crisis preparedness, response, and recovery efforts. Building community resilience through education, awareness, and participation.
- *Partnership*: essential for creating a collaborative and coordinated approach to crisis preparedness, response, and recovery. These partnerships involve various stakeholders, including local administration, operational forces, and citizens, working together to enhance the overall resilience of communities.
- *Trust:* crucial for ensuring the effectiveness of civil protection efforts and maintaining the well-being of communities during crises. Trust fosters cooperation and encourages compliance with directives and promotes a sense of safety in the public from actions taken by local administration and operational forces.

4.2. Main stakeholders of management model

In the context of civil protection, various stakeholders are involved to ensure the safety and well-being of communities during crisis situations. The main stakeholders of civil protection at the local level are local administration, operational forces, and citizens. For each, three actions are identified as most relevant:

Local administration
- *Infrastructure:* essential for responding to crisis situations effectively are local operations centre, communication systems, fire stations and firefighting/rescue equipment, police station, and medical facility, shelters, warehouses, and training facilities.
- *Early warning system:* establish systems that can provide early warnings to the population. This could be through sirens, text alerts, social media, or other communication channels that will provide in the fast way alerts and instructions to the population.
- *Legal persons:* who have the capacity to quickly and efficiently provide accommodation services (hotels and schools), transport in case of evacuation (transport companies), water and food (restaurants and hotels), sanitary support, and other types of services for the affected population.

Operational forces
- *Digital database*: A robust but single system to manage and organize critical information about risks, resources, and their capabilities. Such a database can significantly enhance the efficiency of civil protection activities and support decision-making process.

- *Single communication system:* involves integrating various communication technologies and channels into a unified platform. Such a system aims to facilitate communication and coordination among operational forces (firefighters, police, emergency medical service, civil protection units, Red Cross, etc.) involved in civil protection activities.
- *Modular equipment:* refers to an approach where equipment and vehicles are designed in a modular fashion, allowing them to be compatible and easily assembled, disassembled, replaced, or upgraded based on specific requirements or changing needs during civil protection operations.

Citizens

- *Safety culture:* collective awareness, attitudes, and behaviours of citizens within a community regarding safety measures and practices. A strong safety culture among citizens is essential for building resilient communities and mitigating the risks associated with the local community.
- *Vulnerable groups:* individuals or communities that are at higher risk during crisis situations due to various factors such as age, disability, socioeconomic status, health conditions, or limited access to resources and information. It is crucial to identify and address the specific needs of these groups to ensure their safety and well-being during crisis situations.
- *Commissioners of civil protection*: operate in their area (street, neighborhood, etc.) in preparing citizens for personal and mutual protection, provide information to citizens about the timely undertaking of civil protection measures, participate in the organization and implementation of evacuation, shelter, disposal, organize protection and rescue of members of vulnerable groups [3].

Effective collaboration and communication among these stakeholders are essential for a coordinated and efficient civil protection system at the local level. Each stakeholder group contributes with unique expertise and resources to ensure the safety and resilience in the crisis situations. Within the local administration office is necessary to have at least one employed person/expert that will cover the portfolio of civil protection that could be combined with wide security aspects like environmental protection, local infrastructure, urban security, etc.

Management model 3x3 that is appropriate for certain local administration units should be defined in detail in the local Civil Protection Response Plan that is adopted by the local administration council, and it is obligations defined by the Civil Protection Act.

5. CONCLUSION

The civil protection system ensures the implementation of measures and activities in complex crisis situations of interest to national security. The civil protection system should be flexible, logistically self-sufficient at the local level, the capacities of civil protection units should be strengthened. It is necessary to better define the role of legal entities/private companies from the local level that have capacities for transportation, nutrition, accommodation, sanitary support, etc., which proved to be crucial in caring for people during crisis situations. Further research can offer an objective picture of the current situation of civil protection and their results should be taken into account when thinking about improving the civil protection system. The paper confirmed the main hypothesis.

Abstract: *Quality 4.0 is a paradigm that focuses on the integration of advanced digital technologies, including Artificial Intelligence (AI), into quality management systems. AI has the potential to improve product quality, reduce defects, and optimize production processes. This paper provides a comprehensive review of the current applications of AI in Quality 4.0, including predictive maintenance, quality control, and data analysis. It also discusses future directions for the use of AI in quality management, such as the integration of AI with the Internet of Things (IoT) and blockchain technologies. This paper reviews the current applications of AI in Quality 4.0 and discusses future directions for research and development.*
Keywords: Quality 4.0, AI, Predictive Maintenance, Quality Control and Data Analysis.

1. INTRODUCTION

The journey of digital transformation has led us from Quality 1.0 to Quality 4.0 (Figure 1.). With each phase, advancements in technology have revolutionized quality management. From manual processes and inspection in Quality 1.0 to the integration of AI, IoT, and blockchain in Quality 4.0, organizations now have the tools to optimize quality, achieve operational excellence, and thrive in the era of the fourth industrial revolution [4,11,21].

Quality 4.0 is a transformative paradigm that emphasizes the incorporation of advanced digital technologies, particularly AI, into quality management systems. This paper presents a comprehensive review of the current applications of AI within Quality 4.0, highlighting its potential to enhance product quality, minimize defects, and optimize production processes [2,6]. Additionally, it explores future directions for leveraging AI in quality management, such as integrating AI with the IoT and blockchain technologies [20].

In the era of Industry 4.0, organizations across various industries are actively seeking innovative approaches to optimize their operations and improve product quality. Quality 4.0 emerges as a promising paradigm, leveraging advanced digital technologies to revolutionize quality management systems [3]. Among these technologies, AI stands out as a transformative force with its ability to analyze vast amounts of data, extract meaningful insights, and facilitate intelligent decision-making [8].

This paper explores the current applications of AI in Quality 4.0, highlighting its potential to drive advancements in predictive maintenance, quality control, and data analysis. Moreover, it delves into the future directions for AI in quality management, envisioning the integration of AI with the IoT and blockchain technologies.

2. RESEARCH METHODOLOGY

This research aims to provide a comprehensive review of the current applications of AI in Quality 4.0 and discuss future directions for research and development. To achieve this objective, the following research methodology is utilized:

- Literature Review
- Data Collection
- Analysis and Synthesis
- Future Directions

It is important to note that this research is based on a comprehensive review of existing literature and does not involve primary data collection or empirical studies. The primary focus is to synthesize and present the current state of AI applications in Quality 4.0 and provide insights for future research and development in this field.

2.1. Literature Review

A systematic and extensive review of existing literature is conducted to gather relevant information on the current applications of AI in Quality 4.0. This involves searching scholarly databases, journals, conference proceedings, and relevant industry reports to identify studies, articles, and case studies that focus on AI in quality management systems.

2.2. Data Collection

The collected literature is analyzed and synthesized to extract key findings, applications, and insights regarding the integration of AI in Quality 4.0. The data collection process involves extracting relevant information such as the types of AI technologies used, their application areas (e.g., predictive maintenance, quality control, data analysis), and the benefits and challenges associated with their implementation.

2.3. Analysis and Synthesis

The collected data are analyzed and synthesized to identify patterns, trends, and common themes related to the current applications of AI in Quality 4.0. This analysis will help in understanding the impact of AI on product quality improvement, defect reduction, and production process optimization.

2.4. Future Directions

In addition to reviewing the current state of AI applications in Quality 4.0, this research explores future directions and potential areas of research and development. This involves identifying emerging technologies, such as the integration of AI with the IoT and blockchain, and discussing their potential implications for quality management systems.

3. KEY FINDINGS

This study provides a comprehensive review of the current applications of AI in Quality 4.0 and also highlights the need for further research and development in this field. Also, the study summarizes the key findings derived from the review and outlines the implications for future research and development.

3.1 Improved Product Quality

AI plays a crucial role in augmenting product quality within Quality 4.0. Through advanced analytics and machine learning algorithms, AI enables proactive defect detection, early identification of quality issues, and real-time quality monitoring. By harnessing AI's capabilities, organizations can achieve higher levels of precision, consistency, and reliability in their products [13,16,18].

3.2 Defect Reduction

AI empowers quality control efforts by automating and streamlining defect detection processes. It can analyze vast amounts of data, identifying patterns and anomalies that may indicate potential defects. With AI-driven quality control systems, organizations can proactively identify and rectify defects, minimizing rework, waste, and production disruptions [10,14].

3.3 Optimized Production Processes

AI's integration into Quality 4.0 enables the optimization of production processes. Machine learning algorithms can analyze historical production data, identifying opportunities for process improvement, efficiency enhancement, and waste reduction [9]. By leveraging AI, organizations can achieve leaner, more agile manufacturing processes, leading to cost savings and improved productivity [15,19].

3.4 Predictive Maintenance

AI is a powerful tool for predictive maintenance, which involves monitoring and predicting the maintenance needs of equipment and machinery. By analyzing sensor data, performance indicators, and historical patterns, AI can anticipate equipment failures, allowing for timely maintenance interventions. This proactive approach reduces unplanned downtime, extends equipment lifespan, and enhances overall operational efficiency [11,14,17].

3.5 Data Analysis and Insights

AI enhances data analysis capabilities within Quality 4.0. Through sophisticated algorithms, AI can extract valuable insights from vast amounts of structured and unstructured data, enabling

organizations to make data-driven decisions and quality control (Figure 2.). By leveraging AI-powered analytics, organizations can uncover hidden patterns, detect emerging trends, and identify areas for continuous improvement [5,7,10].

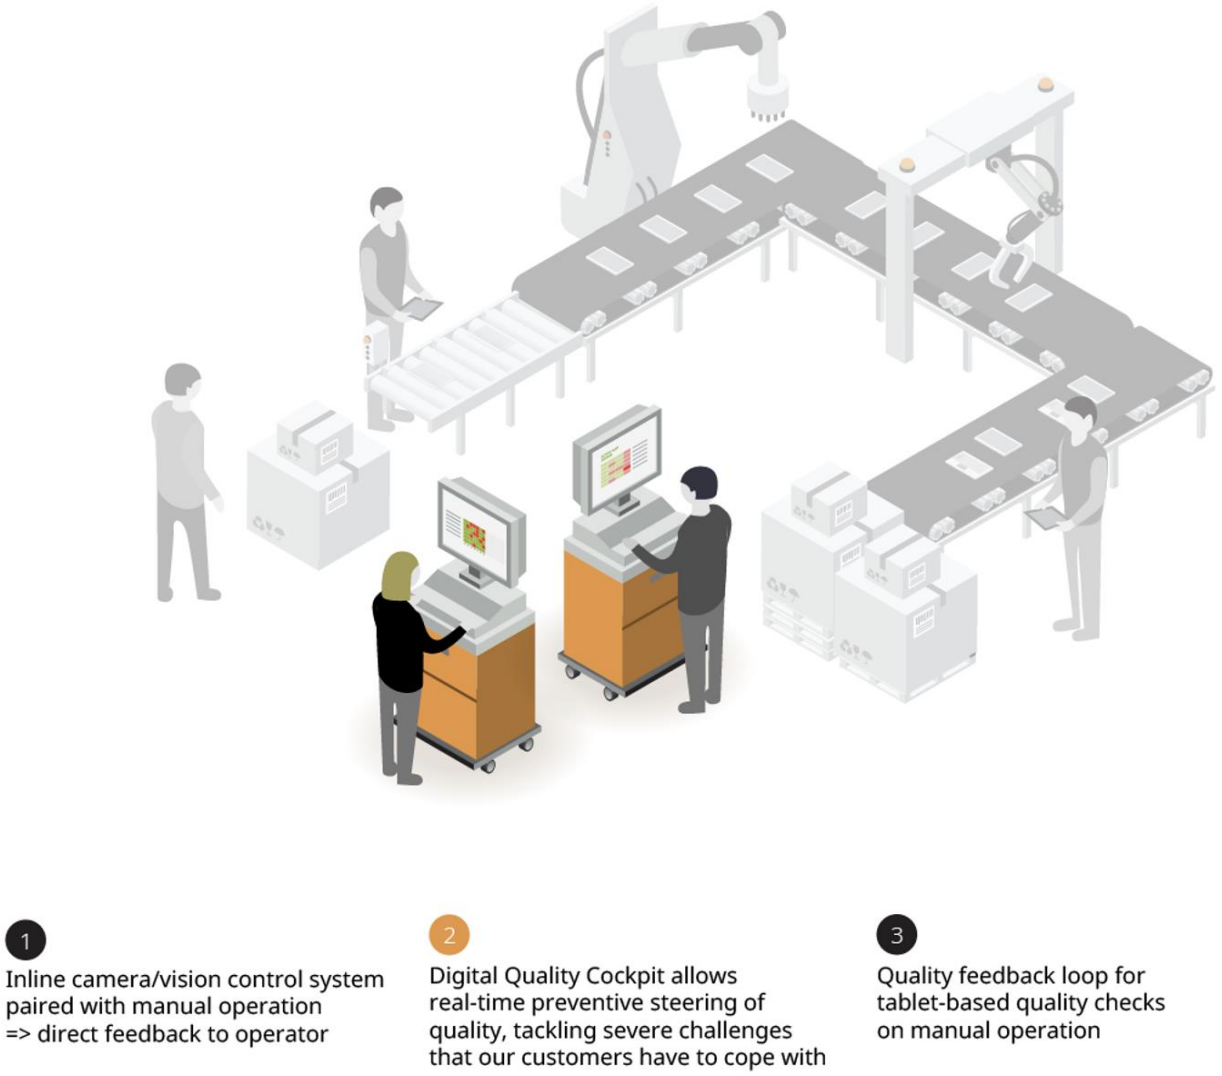

Figure 2. Quality control tower application interfaces
Source: [10]

4. DISCUTIONS AND FUTURE RESEARCH DIRECTIONS

The integration of AI with the IoT is a promising future research direction for AI in quality management. By connecting AI systems with IoT devices and sensors, organizations can leverage real-time data streams to improve quality control, enable predictive maintenance, and enhance decision-making processes.

Another future direction is the integration of AI with blockchain technology. Blockchain has the potential to enhance transparency, traceability, and trust within quality management systems. By utilizing the distributed ledger of blockchain, organizations can ensure immutable records of product quality, facilitate transparency across the supply chain, and streamline recalls, audits, and compliance procedures.

However, it is important to note the limitations of this study. The scope was limited by the databases examined, and the analysis focused only on English publications, excluding articles published in other languages. Future research should consider a broader range of databases and languages to provide a more comprehensive understanding of the topic.

The findings of this study offer valuable insights for organizations looking to harness the potential of Quality 4.0. By effectively implementing Quality 4.0 strategies based on these insights, organizations can align with their strategic objectives and gain a competitive advantage in the market. The incorporation of advanced digital technologies, particularly AI, into quality management systems is a key aspect of Quality 4.0, offering opportunities to enhance product quality, reduce defects, and optimize production processes.
So, the future directions for AI in quality management involve further exploration of its integration with emerging technologies such as the IoT and blockchain. This will enable organizations to unlock new levels of efficiency, transparency, and quality in their operations.

5. CONCLUSION

AI plays a crucial role in the realization of Quality 4.0, providing organizations with the capability to optimize their quality management processes and achieve exceptional product quality. The current applications of AI, including predictive maintenance, quality control, and data analysis, have already demonstrated their potential in driving substantial improvements. Looking towards the future, the integration of AI with the IoT and blockchain technologies, along with the emergence of autonomous quality management systems, holds immense promise for revolutionizing quality management practices [1, 3, 12]. As organizations embrace these advancements, they position themselves at the forefront of innovation, enabling them to adapt and thrive in the dynamic landscape of the fourth industrial revolution. Therefore, this study holds significant importance as it pioneers the examination of the impact of Quality 4.0 on organizational performance, achieved through the utilization of an integrative literature review.

ADULT EDUCATION IN SERBIA AND COUNTRIES OF THE REGION

Koviljka Banjević[1], The Academy of Applied Technical Studies Belgrade
Jovana Femić[2], The Academy of Applied Technical Studies Belgrade

Abstract: *Adult education is not new practice in education, but under the influence of contemporary environment it has gained importance over the last years. It prepares individuals for present and future jobs and roles in the society; has positive effect on health and well-being; reduces differences and diversities*; *improves productivity, innovation and creativity; raises the awareness about the importance of democracy; and it is necessary for implementation of national and international policies. Based on this importance, the paper explores the state of adult education in Sebia and countries of the region. Statistical data were collected from national sources of mentioned countries, as well as from European sources. By applying descriptive statistics actual situation is systematically presented. The findings could be interesting for individuals, educators, policy makers and present and future studies.*
Keywords: Adult Learning, Statistical Data, Croatia, Slovenia, Montenegro, North Macedonia

1. INTRODUCTION

Globalization, technological developments and demographic change have caused numerous challenges in the lives of individuals, organizations, governments and society. The ‘’new’’ context of working and living has required transformations in the way people work, new approaches to utilization of talents and diversity, better social protection for workers, update education, investments in workforce through training and learning [1, 2]. For these issues one thing is common – the necessity of continual ‘’adult skilling, reskilling and upskilling throughout person`s career’’ [3, pp.1]. In addition to previous, contemporary findings refer to the following: globally, 60% of the total employees were in informal employment in 2019 [5]; in 2020, 7.2% of workers lived in extreme poverty [5]; 1.3 billion people are overeducated or undereducated, and by 2030 this number will be increased to 1.4 billion [4]; 203 million persons have been unemployed in 2023 [5]; great number of organizations recognize the skills gap as the main barrier to business transformation, as well as the 44% of workers` core skills will be changed in the next five years [6]; ‘’600 million new jobs need to be created by 2030’’ [7]; differences have still existed in employment rate by gender, age and education level [6]; inflation and cost-of-living crisis have affected the most vulnerable groups [6]; the fastest growing jobs are technology-related roles, while the ‘’fastest declining roles are clerical or secretarial roles’’ [6].

Based on the previous data, it is clear that current knowledge and skill needs differ from those that will be demanded in the very close future. Besides the other actions, adult education could have a crucial role in overcoming these differences. The main idea of this paper is to present actual situation of adult education in Serbia and countries of the region. This is a review paper and it is based on the descriptive approach. This paper is structured as follows: the first part of the paper is devoted to consideration the concept of adult education and its context in Serbia and countries of the region (Montenegro, Croatia, North Macedonia and Slovenia). Bosnia and Herzegovina was excluded because the authors could not find statistical data within its national and European sources. The

[1]kbanjevic@atssb.edu.rs
[2]jovanafemic0@gmail.com

second part of the paper presents statistical data on the state of adult education for different demographic groups within the period of last five years. Data were collected from national and European sources and processed by Excel tools. Some data for Montenegro and North Macedonia were not available and it is the main limitation of this study.

2. THEORETICAL BACKGROUND

2.1 Concept and importance of adult education

Adult education (AE) is not a new practice of upgrading competences, but over the last decade it has gained importance. Initial form was related to learning after completing formal education. During the time, different terms were used to describe learning during the person`s life [8]. Nowadays, lifelong learning (LLL) and adult learning (AL) are the terms that are more commonly used. Explanations of LLL and AL have been revised over time [9]. European Commission (2001) defined ''lifelong learning as all learning activities undertaken throughout life, with the aim of improving knowledge, skills and competences within a personal, civic, social and/or employment-related perspective'' [10, pp.3]. ''Adult learning means the participation of adults in lifelong learning. It usually refers to learning activities after the end of initial education and it covers participation in formal and non-formal education and training'' [11]. According to UNESCO ''adult learning and education encompasses formal, non-formal and informal learning and education for a broad spectrum of the adult population. It covers learning and education across the life course and has a special focus on adults and young people who are marginalized or disadvantaged'' [9, pp.28]. By exploring literature there are other institutions and authors who defined AL in very similar way. For the purpose of this paper the authors use the term ''adult education'' that covers all learning activities after the end or after leaving formal education (primary, secondary and tertiary). In this sense, population aged 25-64 was observed. Adult education encompasses various target groups and can differ in terms of objectives, contents, quality and learning outcomes. Furthermore, it can be performed in institutions of formal education, as well as in other institutions and organizations. [12]. Generally, there are three modalities of adult education – formal, non-formal and informal learning [13]. Formal learning occurs in all types of educational institutions and it results in diploma or certificate [12]. Non-formal learning refers to different workshops and trainings that can take place in different organizations and institutions that not belong to formal educational system [12, 14]. Informal learning results from everyday activities, it is not structured [12] and it includes ''learning from others, learning by doing and learning new things at work'' [14]. Globally, adult education has important role because it prepares individuals for present and future transformations in society, economy and the labour market [15]. European Education Area has recognised adult education as strategic priority for the period 2021-2030 [15]. Its significant role is noticeable in the 2030 Agenda for Sustainable Development adopted by the United Nations [16]. Furthermore, the importance of adult education has been recognized by many organisations and institutions worldwide (for example: ILO, OECD, BCG, WEF), as well as numerous institutes and associations of adult education and lifelong learning have been founded. The European Association for the Education of Adults (EAEA) identified adult education as a key instrument in overcoming the challenges facing the EU [17]. In this sense, adult education ''influenced the development of democratic societies in Europe'' (pp. 5), as well as it enhances participation of adults in social activities. Improvement of knowledge, skills, attitudes and behaviours has positive effect on health and well-being. Adult education ensures ''life skills'' (pp. 9) necessary in the 21st century, that provide new opportunities for individuals` careers and lives. Adult education brings people together and intensifies ''social cohesion, equity and equality'' (pp. 11). At organizational level, continual learning improves productivity, innovation and creativity. Acquiring the digital competences is important activity of adult education for today`s society. Migration and demographic change have caused challenges in communication and need for better understanding of different cultures. Adult education helps to close this gap. Finally, ''adult education is necessary to implement most European and international policies'' (pp. 21) [17].

2.2 Context of adult education in Serbia and countries of the region

In the Republic of Serbia adult education has been recognised as a part of unified educational system. There are two forms of adult learning – adult education and short cycle of study. Adult education occurs as formal, non-formal and informal learning, and it can be directed to general, vocational and/professional education. Adults imply to individuals over the 15 years old who have not completed primary education i.e., over the age of 17 who have not completed secondary education and persons over the age of 18 who want to improve their competences [18]. Promoters of adult education can be institutions of primary and secondary education, as well as other organizations within their registered activity. The area of adult education is regulated by the Law on adult education (adopted in 2013) and the Law on National Qualifications Framework in Serbia (adopted in 2018). According to Ministry of Education 453 institutions offer 635 different programmes of adult education [19].
Short cycle of study is organized at tertiary level of education. The main objective is related to acquiring competences for specific job in accordance with the labour market requirements. Short cycle of study is intended for persons who obtained secondary education, students, graduates and employees [20]. Furthermore, Serbia has been a part of the EPALE (Electronic Platform for Adult Learning in Europe) network since 2017 [21], and few organizations for adult learning are the members of EAEA [22]. Recognition of qualifications, acquired through adult education and short cycle of study, is regulated by the Law on National Qualifications Framework in Serbia [23].
The contexts of adult education in countries of the region (Montenegro, Croatia, North Macedonia and Slovenia) are very similar to the one in Serbia. All mentioned countries have recognized the importance of adult education for achieving lifelong learning objectives, and consequently Sustainable Development Goals. Adult education is intended for all persons over the age of 15 who do not participate in regular education. Unlike the other countries, Croatia established separated system of adult education at primary and secondary level, and higher education is not part of this system. Besides formal, non-formal and informal learning, Montenegro and Croatia identified self-directed learning. All countries adopted strategies for adult education, as well as a comprehensive body of legislation. The distribution of responsibilities is clearly defined, and recognition of qualifications is regulated by national qualifications framework [24]. All countries are the members of EPALE and EAEA.

3. THE STATE OF ADULT EDUCATION IN SERBIA AND COUNTRIES OF THE REGION

For the purpose of better understanding the state of adult education in mentioned countries, in Table 1 some demographic data are presented.

Table 1. Population size aged 25-64 by gender and educational attainment level

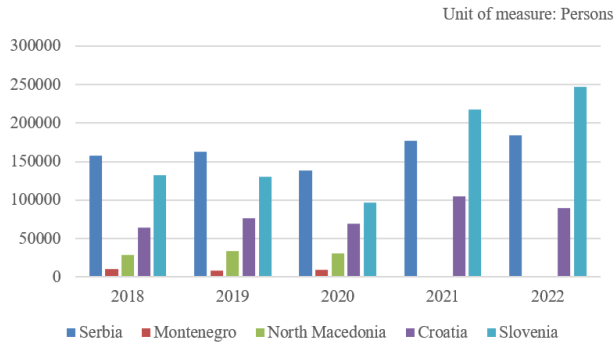
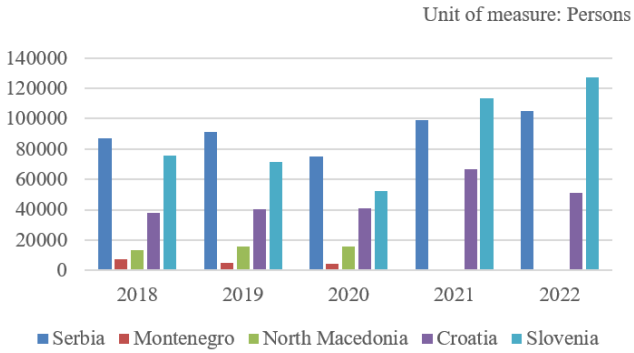
NA - not available
ISCED 2011: 0-2 levels- Less than primary, primary and lower secondary education; 3 and 4 levels-Upper secondary and post-secondary non-tertiary education; 5-8 levels- Tertiary education

Data in Table 1 indicate that the most people have obtained secondary education in all mentioned countries. Over the last five years, in Serbia, the number of people who acquired tertiary level of education has been increased, and consequently the number of those with primary and secondary education has been decreased. The situation is similar in other countries, except in Croatia where values have been varied or decreased during the observed years. In Slovenia, the differences in values between people who obtained secondary and tertiary education are smaller than in other countries, as well as Slovenia notes a greater increase in the number of people who obtained tertiary level of education.

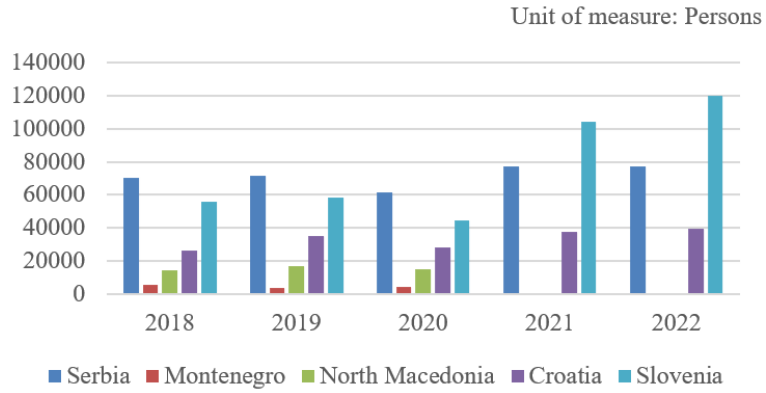
According to main idea of this paper, the following graphics present the participation of adults in education and training by age, gender and educational attainment level.



Graphic 1. Participation of adults aged 25-64 in education and training
Source: [31]

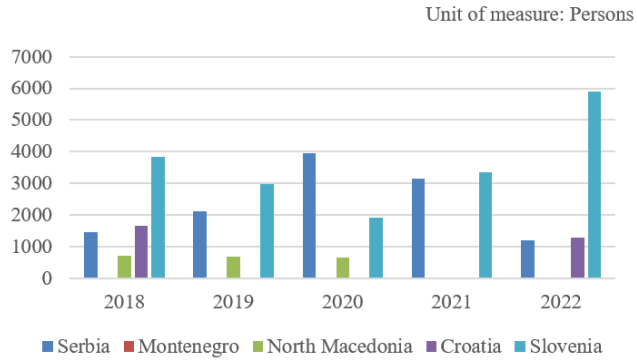


Graphic 2. Participation of females aged 25-64 in education and training
Source: [31]

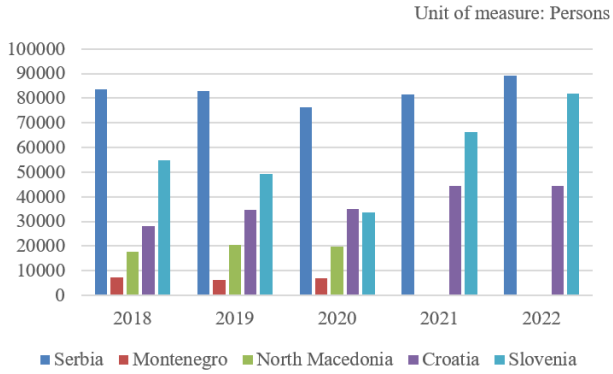


Graphic 3. Participation of males aged 25-64 in education and training
Source: [31]

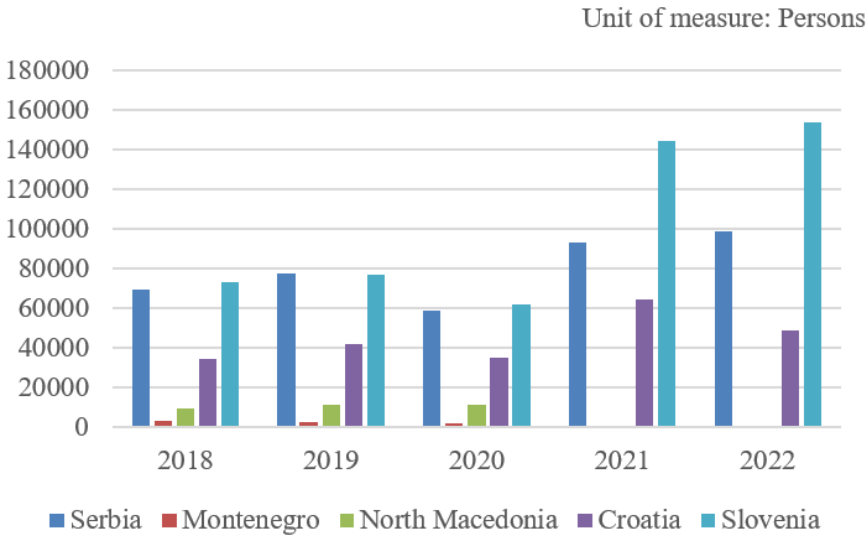
From the Graphic 1 to Graphic 3 it can be concluded that Slovenia has the largest participation of adults in education and training. If the numbers were to be converted into percentages (Graphic 1), participation rates in Slovenia were 11,4%, 11,2%, 8.4%, 18.9% and 21.6%, respectively. Since 2018 to 2022, in Serbia, participation rates were 4.1%, 4.3%, 3.7%, 4.8% and 5.2%. In other countries, the participation rates were at similar levels, but less than in Serbia. Generally, participation of women in adult education is greater than participation of men in all mentioned countries (Graphic 2 and Graphic 3).



Graphic 4. Participation of adults in education and training – aged 25-64 and who attained 0-2 educational levels
Source: [32]



Graphic 5. Participation of adults in education and training – aged 25-64 and who attained 3 and 4 educational levels
Source: [32]



Graphic 6. Participation of adults in education and training – aged 25-64 and who attained 5-8 educational levels
Source: [32]

In relation to educational attainment level (Graphic 4 to Graphic 6) the participation rate of adults in education is the lowest for the persons who have less than primary, primary and lower secondary education in all mentioned countries. Except Slovenia, in other countries these rates are less than 1%. In Serbia, the largest number of adults who participate in education and training are those who obtained secondary educational level, except in 2022 (Graphic 5). The same situations are in Montenegro and North Macedonia in the years of 2018, 2019 and 2020. Unlike these countries, in Croatia and Slovenia people who obtained higher education participate the most in adult education.
Besides previous presented data, the authors explored participation rate of adults in education for other age groups (25-34, 35-44, 45-54 and 55-64) [see: 31] and it appears that Slovenia is the most successful in adult education comparing to other countries of the region. Furthermore, in all mentioned cases Slovenia achieved better results than EU average levels and even more it was more successful than most European countries [31, 32].

4. CONCLUSION

In the age of technological revolution, rapid population ageing, efforts to environmental protection and the recovery from the Covid-19 pandemic, adult education has become increasingly important. Simply put, adult education includes all learning activities after the end or after leaving formal education. It appears in different forms, like formal, non-formal and informal learning, and it can be performed in educational, as well as in other institutions and organizations. The main objective of this paper was to explore the state of adult education in Serbia and countries of the region. The findings show that all mentioned countries have recognized the importance of adult education, and they have adopted strategies and necessary legislative framework. Despite the contexts of mentioned countries have been very similar, Slovenia was more successful than other countries over the last five years. Thus, the new question arises – why Slovenia achieved better results i.e., what made it different from the other countries, that could be the subject of future research.

APPLICATION OF THE PARETO ANALYSIS IN QUALITY CONTROL

Dragana Gardašević[1], The Academy of Applied Technical Studies Belgrade
Dragana Rošulj[2], The Academy of Applied Technical Studies Belgrade
Mina Radišić[3], The Academy of Applied Technical Studies Belgrade
Koviljka Banjević[4], The Academy of Applied Technical Studies Belgrade

Abstract: *In the production process, operational waste is generated due to various causes. The quality control department, among other activities, deals with monitoring and analyzing the frequency of nonconforming products and the causes of nonconformities in order to reduce them. In this context, several statistical methods and techniques are used. The focus of this paper is on the application of Pareto, a simple, but very effective method for determining the most significant causes of nonconformities. Using this technique, it is possible to perform further analyses and to determine the trend of the occurrence of nonconformities. As a result, corrective measures can be planned and implemented.* T*he aim of this paper is to present the application of Pareto analysis in the production of micro-switches. The data are collected from one Division of the company that wanted to stay anonymous.*
Keywords: Pareto chart, Statistical Quality Control, Quality.

1. INTRODUCTION

In today's market environment, quality, among others, is ''the crucial factor of competitiveness, which determines the direct relationship between quality and production efficiency'' (Dunchenko, cited in [1], p1). Quality control, failure analysis, and improvement are central elements in manufacturing [2]. Improving quality contributes to improving production efficiency. Continuous improvement, as one of the eight quality management principles, is a set of repetitive actions, which are designed to increase the capacity to meet the requirements [3]. As one of the main objectives of each organization, quality is focused on continual improvements of the total performance [4]. In that context, the quality of a product is the highest interest of an organization. Therefore, one of the tasks for quality management is to apply appropriate tools and techniques [5].
Planning and operating the production are complex. Controlling and maintaining quality of production are important topics for manufacturing companies. In order to improve the production results, a number of techniques, methods or tools can be applied to increase production capacity, the volume of manufactured products, and the quality of semi-finished and finished products respectively. Most of them are focused on the technological processes, production machinery, and equipment, and less on human resources [6]. In each process, excessive variations and errors can cause nonconformities, that consequently may cause undesirable consequences - scrapped or wasted resources and "contamination" from undetected nonconformities. These consequences reduce the value of the product to the customer. The goals of quality control in every production system are to (*a*) eliminate nonconformities and their consequences, (*b*) eliminate rework and wasted resources, and (*c*) achieve these goals at the lowest possible cost [7].

[1]dgardasevic@atssb.edu.rs
[2]drosulj@atssb.edu.rs
[3]mradisic228.2017@politehnika.edu.rs
[4]kbanjevic@atssb.edu.rs

For achieving the previous goals, a number of methods and techniques could be used. Quality tools and techniques offer a variety of methods to visualize and control process data [2]. The most used methods in the practice are: the Pareto chart, Cause-and-Defect diagram, Control carts, Failure Mode, Check Sheet, Histogram and Scatter plot [1, 2, 5, 8]. With the help of Pareto diagram, which is mostly used to identify critical areas, the manufacturing defects in each stage of the production chain have been prioritized by arranging them in decreasing order of importance. Then cause and effect diagram is being applied to explore possible causes/factors of defects and to determine the causes/factors that have the greatest effect [9]. Pareto analysis is used to separate the "vital few" from the "trivial many" [10]. It serves as the tool for sorting different defects with their relative significance to the total rejection [9].

The goal of this paper is to present the application of Pareto analysis in the production of micro-switch parts in the company that wanted to stay anonymous. In the text below the authors will use *XZY* as the name of the organization. XYZ is a technological organization that produces systems for passenger and commercial vehicles, as well as industrial technology [11]. This organization has several divisions in Serbia, but the *D* division (not its original name) deals with the production of micro-switches. Its products are installed in basic household appliances (electric motors and generators for hybrids and electric drives, gear levers, and microswitches) [11]. Within this organization, the quality department deals with the analysis, monitoring, and control of the production process and product quality.

2. THEORETICAL BACKGROUND

The interest in research on quality management exists because decision-makers are aware of the importance of high-quality production in achieving a competitive advantage in the global market [12]. Quality performance is defined through eight dimensions:

1) performance (that refers to primary operating characteristics of a product);
2) features (refers to characteristics that support the basic functioning of the product);
3) reliability (refers to the probability of the product malfunctioning or failing within a specified period);
4) conformance (refers to the degree to which the product's design and operating characteristics meet standards);
5) durability (the amount of use the customer gets from the product before replacement is preferable to continued repair);
6) serviceability (refers to speed, courtesy, competence, and ease of repair);
7) aesthetics (based on individual preference for how the product looks, feels, sounds, tastes or smells);
8) perceived quality (based on image, brand name, and advertising that makes inferences about quality) (Cole, cited in [14]).

To achieve High quality production performance, the process of control has to be well planned and carried out after the completion of each stage of the production process. Statistical process control (SPC) methods may be used to make sure that the rate of produced defective products occurs in a stable and predictable manner (the process is in control) [15]. Among various methods applied in monitoring the production, descriptive statistics is used for the simple data presentation (scatter plots, histograms, etc), while Pareto is used to help the identification of different defects and their classification in relation to their significance [9].

Monitoring of nonconformities provides useful information about the processes and the operations of production lines. Montgomery, in [17, p 190], claims that clear data presentation is ''essential to good statistical thinking because of the important features they provide and the insight about the type of model that should be used in solving the problem''.

Among known methods, the Pareto chart is used for the causal analysis of phenomena (factors, nonconformities, causes, causative agents, quantitative, value, and other characteristic measures of the work process). This diagram shows, in descending order, the relative influence of an observed quantity or group of quantities in the set of quantities being analyzed. This is an effective tool for ranking quantities by degree of importance and identifying basic problems that require a solution. The application of the Pareto chart is found in a variety of industries. For example, it was applied in the pharmaceutical industry for identifying and analysing defects in products (Paul and Azeem, 2009) and in the lamp production process for minimization of defects (Ahmed and Ahmad, 2011). From the literature, it is clear that Pareto analysis is one of the essential tools to analyze and identify the causes of defects in industry [16]. To conduct Pareto analysis, needed data must be sorted in descending order, i.e. it is necessary for a checklist to be created. In this check-list, the frequency of defects is noted and then the accumulated frequency and corresponding accumulated percentage of defects are calculated. The reason for the wide application of Pareto is that it serves as a simple way to get the answer about the causes of defects that must be paid attention to and that must be eliminated [18].

3. THE APPLICATION OF PARETO ANALYSIS IN QUALITY CONTROL

The quality department of the *D* division of *XYZ* organization deals with product control and monitoring the production process on manual lines and automatic machines. The quality of micro-switch parts is monitored and controlled in each phase of the production, as well as their merging into one product. Data (number of nonconforming manufactured parts, error codes, shift number, and other relevant data) are entered into checklist called *Mistake collection,* according to the Inspection Plan and manipulated in the internal program, where the permissible limits of the qualitative and quantitative characteristics of the product are adjusted.

The Pareto method is used in the *D* division for a simplified presentation of the number of nonconformant products and the causes of nonconformities. Products produced on manual lines and automatic machines (per shift on a daily basis) are taken in consideration. The production and product control on manual lines is carried out in accordance with *the Control plan, Escalation plan and Instruction in case of non-conformance.* The Control of products produced on automatic machines is performed after setting up the machine and approving the production order. Then, the detection of nonconformities is performed by verifying the quality of the product. On the other hand, the control on manual lines is performed after each phase of the production.

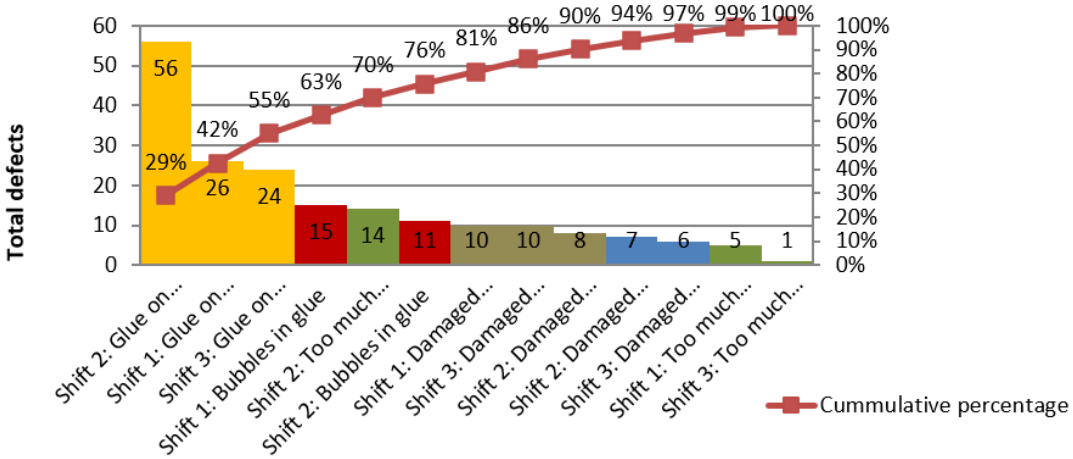

Figure 1. Pareto chart for the manual line
Source: XYZ organization

Figure 1 presents the Pareto chart of defects on manual lines in all three shifts per day. In total, operators produced about 1500 pieces of switches per day, and the total scrap was 56 pieces in the first, 96 pieces in the second, and 41 pieces in the third shift of the observed day.

Figure 1 indicates that the most frequent causes of nonconformities in total (on the manual line) are "Glue on isolation" in all shifts (29%, 13%, and 13% of the total number of nonconformities, respectively), "Bubbles in glue" in shift 1 (8%) and "Too much solder on the terminals" in shift 2 (7%). These are the first five nonconformity causes that make up 70% of all nonconformities in the observed period. Further analysis showed that the operator who was gluing the switches was a new worker on training, therefore the scrap in the third shift was twice as large as in the first and the second shifts.

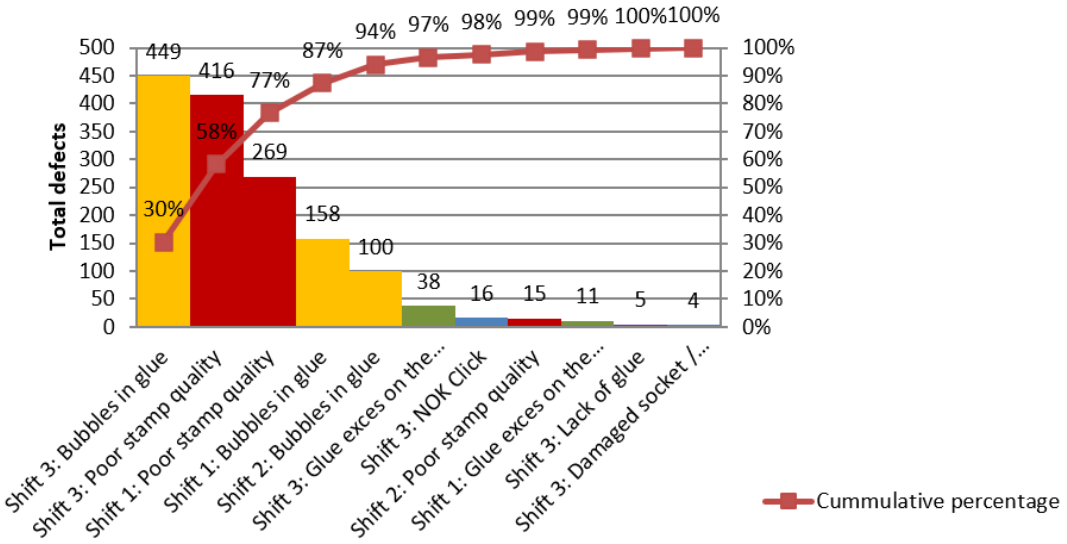

Figure 2. Pareto chart for the mashine line
Source: XYZ organization

Figure 2 shows the Pareto chart for the five most frequent nonconformities induced during the production process on the machine. These non-conformities are detected on a machine that produces 3000-4000 pieces per shift. The total number of nonconformant pieces per shift was 1476, where 438 were in the first, 115 in the second, and 923 in the third shift (see Figure 2). The most significant nonconformities in the observed period were: ‘’Bubbles in the glue’’ in shift 3 (30%), ‘’Poor stamp quality’’ in shift 3 and 1 (28% and 19%, respectively). These causes made up approximately 80% of the nonconformities in the observed period.
Subsequent analysis showed that the problems on the machine were in the vent pipe that was leaking glue, and the poor print (bad ink mixture) on the matrix. After that, the problems were solved.
In addition to the Pareto diagram, descriptive statistics and polygons are used to monitor the frequency and types of nonconformities trends.

4. CONCLUSION

It is well-known that quality management ensures continual quality improvements of processes, products, and overall business. Like the other systems, production processes have to be well planned, monitored, controlled, and continuously improved in order to ensure product quality. For this purpose, many statistical and engineering methods and techniques can be used. In the processes of monitoring and controlling, methods and techniques enable detecting defects and their causes in effective and efficient manner. With no neglecting the importance of other methods, this paper presents an example of the application of Pareto analysis in production quality control.
The Pareto method is a simple, but very effective quality tool that helps in underlining few crucial causes of the observed problem. By the Pareto diagram, which is mostly used to identify critical areas, the manufacturing defects in each stage of the production can be prioritized according to the decreasing order of importance.
D division of *XYZ* organization uses various statistical and engineering methods as a base for monitoring and controlling its processes. These methods are useful to minimize the risk of errors or

weaknesses in procedures or systems or in raw materials. Process flow management and statistical control feedback contribute to the physical quality of the product. Among various methods that are used in *D* division, the Pareto method is used as a simplified presentation of the number of nonconforming products and types of nonconformities produced on manual lines and machines, per shift on a daily basis.

ACKNOWLEDGMENT

Data presented in the text, Figure 1 and Figure 2 are collected from XYZ company.

Abstract: *Digital transformation is fundamentally changing how organizations manage their relationships with stakeholders, operate, and deliver added value to customers. Customers become more connected, informed, empowered, and active, expecting customized products or services. To meet customers' high standards and expectations, organizations have to be agile, constantly innovate, and change themselves by embracing new technologies, but first of all, organizations must have understanding and empathy for customers. This paper provides an overview of the influence of digital transformation on customer perception using standards as tools for achieving better performances.*
Keywords: digital transformation, customers, standards

1. INTRODUCTION

The world is facing numerous risks and challenges: inflation, cost-of-living crises, trade wars, capital outflows from emerging markets, widespread social unrest, geopolitical confrontation, and the spectre of nuclear warfare [1, p. 6]. These affect organizations and their stakeholders. In addition to all of the above, organizations cannot continue to do things in the same old ways, due to disruptive digital technologies that are becoming the new standard and challenging traditional business rules [2, p. 891]. Digital transformation occurs in response to changes in digital technologies, increasing digital competition and resulting in fundamentally altered customer preferences [2, p. 895]. Customers, as one of the stakeholders, have changed and become more sophisticated. They value the whole experience, not just product or service quality and price. In such circumstances, agility becomes a hallmark across the organization, as it permits speed and flexibility without loss of product or service quality [3; 4, p. 28]. The aim of this paper is to discuss the influence of digital transformation on customer perceptions, as well as the benefits of ISO standards implementation in the digital economy.

2. DIGITAL TRANSFORMATION OF ORGANIZATION

Digital transformation, the integration of digital technology into business, is fundamentally changing how organizations manage their relationships with the stakeholders, operate, and deliver added value to customers [5]. Digital transformation accelerated across all industries at an unprecedented pace throughout the coronavirus pandemic, which was critical for business success. Digital transformation is multidisciplinary, involving changes in strategy, organization, information technology, supply chains, and marketing [2, p. 890]. It is a way to efficiently meet changing customer demands, enable remote work, enhance product or service development, production, and delivery, reduce costs, assess

[1] anastasic@atssb.edu.rs
[2] drosulj@atssb.edu.rs
[3] kbanjevic@atssb.edu.rs
[4] apavlovic@atssb.edu.rs

realistic benefits, etc. The impact of digital transformation on business performance depends on internal (organizational size, age, board composition, organizational structure, and organizational culture, digital growth strategies, digital assets, products vs. services, development of digital networking or big data analytics capabilities) and external factors (legal, technological, market, cultural, social, and economic environments, whether international, national, regional, or local), as the competitive landscape is changing drastically and moving the interests of customers to relatively new digital businesses. [2, p. 896]

Modern technology, digitalization, flexible data management, and highly agile processes help organizations achieve an intelligent and highly agile digital environment that predicts and responds to changes in the ecosystem to capitalize on new opportunities [5]. Since the launch of the World Wide Web and its global dissemination, more and more supporting technologies (e.g., broadband Internet, smartphones, Web 2.0, Web 3.0, SEO, cloud computing, voice recognition, online payment systems, and cryptocurrencies) have strengthened the development of e-commerce. Also, the prevalence of big data and disruptive digital technologies (artificial intelligence (AI), blockchain, Internet of Things (IoT), robotics, autonomous vehicles (AV), augmented or virtual reality (AR/VR), digital traceability, and 3D printing) have a significant effect on the economy [2, p. 890; 3, p. 4]. Also, new digital technologies impact the cost structure by replacing human labour in the provision of services with robots or virtual agents, optimizing logistic flows, and reducing supply chain costs through the use of AI and blockchains [2, p. 890].

The biggest challenges for organizations are ensuring accelerated transformation progress and creating digital innovations that lead to sustainable business values [6, p. 1]. The digital organization has digital products and services and powers core business processes and operations with technology [5]. Such an organization needs digital assets and acquires or develops capabilities related to digital agility, digital networking, and big data analytics. The organization should develop agile structures with low levels of hierarchy, internalize IT and analytical functional skills, and lead platform-based market development, customer co-creation, and platform diversification [2, p. 896]. New agile business models enable business continuity [5] and digital resilience as organizations compete with (new) digital players and absorb exogenous shocks from disruptive digital technologies [2, p. 896].

Businesses cannot digitally transform unless or until people transform. Therefore, digital transformation needs a change from organizational culture to digital culture and a radical rethinking of people, processes, and technologies [7]. Organizations should focus on reimagining work to fight change fatigue, building digital acumen across the enterprise, and deepening human connections between colleagues and teams [6, p. 1]. Digital transformation includes tectonic changes in human interactions within the ecosystem, as well as changes in tasks, rights, responsibilities, and obligations [5]. Accelerating digital transformation requires new digital skills, not just in IT but across all organizational functions. Training, reskilling, and upskilling keep the workforce prepared and optimized in an environment of digital transformation [4, p. 32].

Organizations with a digital culture use digital tools and data-powered insights to drive decisions and customer-centricity while innovating and collaborating across the organization. Digital culture drives sustainable action and creates value for all stakeholders. It is about being flexible and having a workforce that can respond to new challenges, effectively using technology, and having the right tools, structures, incentives, and mindsets to integrate new technologies into work. The organization develops innovative products and services to meet changing customer needs with tech and data-enabled delivery channels. Also, the organization fulfills ESG goals (circular economy) and develops integrated initiatives that transform business and have an impact on stakeholders, rather than implementing performative campaigns (“greenwashing”). [7, p. 8]

Digital transformation is essential for all businesses, from small to large. Therefore, the Center for Digital Transformation (CDT), in cooperation with the Ministry of Economy of the Republic of Serbia, sent out a public invitation in October 2023 for the new “Digital Transformation Support Program for Micro, Small, and Medium Enterprises 2023” to improve business, successfully adapt,

actively participate, and make progress in the digital age through the introduction of modern digital tools into the organization [8].
Digital transformation is blurring market boundaries and changing the roles of players (e.g., customers becoming co-producers, competitors becoming collaborators, and organizations integrating or bypassing stakeholders) [2, p. 890]. Consequently, organizations must know as much as possible about their customers and stakeholders.

3. CUSTOMER PERCEPTION IN THE DIGITAL ERA

A customer is an individual or business that purchases goods or services from another organization. Customers are the most important because they generate revenue. Without them, organizations can neither survive nor thrive. The organization should meet customer requirements and strive to exceed their expectations by understanding their current and future needs. Sustainable success is achieved when an organization attracts and retains the confidence of customers and other relevant interested parties so that every aspect of customer interaction provides an opportunity to create more value for the customer. [9, p. 13] Organizations compete to attract or retain customers by aggressively promoting their products or services, lowering prices to expand their customer base, or developing unique products, services, processes, and experiences that customers like.
Customer behaviour is changing in response to digital transformation. Customers have access to more information than ever before. The Forbes study showed that 90% of customers read online reviews before visiting a store and that these reviews influence 67% of purchase decisions [10]; 50% intend to increase their online spending in the next six months; 63% of customers have purchased products directly from a brand's website; 80% of customers said they would pay up to 5% more for sustainably produced goods; 40% would pay up to 10% more than average; 10% would go up to 30%; and nearly 7% say they would pay even higher prices [11]. Spending more on sustainability is most likely coming from Millennials and Generation Z, who are generally more conscious of social justice and environmental issues [11].
With the help of new search and social media tools, customers become more connected, informed, empowered, and active. Their criteria change. They look closely at what a brand says, does, and stands for. Customers often co-create value by designing and customizing products or services, taking over last-mile distribution, and helping other customers by sharing product or service reviews. Many customers don't make decisions based only on product or service price. [2, p. 890; 5] Lately, for the customers the most important is the experience (45,9%), then the quality of the product or service (33,6%), and price (20,5%) [12].
The COVID pandemic has permanently changed customer preferences. Hence, organizations must ensure their survival by implementing the four most important customer trends [13]:

1. Socio-political values are diversifying and increasingly influencing customer choices.
2. Customers are willing to use technology to optimize themselves and have virtual experiences that can overtake real-life experiences.
3. Brands are expected to offer more comprehensive services, use customer data, and promote well-being.
4. Customers are recognizing and appreciating distinctly human traits as the world becomes increasingly influenced by other forms of intelligence.

Organizations should better understand and strongly interact with hyper-connected customers. Cost, choice, and convenience are still relevant, but experience is more important. Globally, customers have access to more than 1 billion different products offered by traditional competitors and dynamic new entrants experimenting with new business models and methods of customer engagement. With increasing choice, loyalty is weakening, and customers are becoming more empowered. To meet customers' high standards and expectations, organizations have to remain agile, constantly innovate, and change themselves by embracing new technologies. [3, p. 2]

4. INFLUENCE OF DIGITAL TRANSFORMATION ON CUSTOMER PERCEPTION

Digital transformation occurs in response to changes in digital technologies, increasing digital competition and resulting in fundamentally altered customer preferences. Such disruptions force all businesses to engage their target customers in new ways using digital technology [2, p. 895]. Organizations understand the imperative to respond to customers evolving needs for customized products or services. To achieve this, organizations prioritize the innovation of all business processes, promote transparency in buying behaviors and customer choices, deliver tailored products or services to market at unprecedented speeds, and respond to unexpected disruptions related to supply issues, distribution channels, or facility closures. [3, p. 28] The proactive organizations use technologies such as generative AI and chatbots; invest in customer relationship management (CRM), mobile apps, and social media; build direct-to-consumer (D2C) and subscription capabilities; meet customer demands in terms of environmental, social, and governance (ESG) and sustainability; and only then expect to capitalize on growth in customer spending in the coming period [11]. Therefore, organizations strive for competitive advantages and empower customers by providing the necessary tools, information, technology, and support to make decisions [11].

Customers look like they believe in apps and new AI-based technologies. Creating the most appealing advanced experiences, physical or digital or both, starts with an outstanding understanding and empathy for the customer requirements, needs, and expectations, and brings to increased customer value, increased customer satisfaction, improved customer loyalty, enhanced repeat business, enhanced organizational reputation, expanded customer base, and increased revenue and market share [9, p. 15]. Regretfully, most organizations start with technology before understanding the customers they serve. The problem for organizations is that, in their never-ending attempt to increase operational effectiveness, digital transformation has become more crucial than customer empathy. Without a compelling comprehension of customer requirements, engaging digital experiences are impossible to create. If efforts focus on what motivates customers to click and switch, organizations don't achieve the desired results and long-term satisfaction, loyalty, and retention. To satisfy customer expectations, organizations should improve their customer initiatives, and measure customer satisfaction, customer loyalty, customer relationship, and employee engagement in customer experience [14]. Here are some good examples [12]: customer experience is the number one brand differentiator in recent years; 1 in 3 customers will leave a brand they love after just one bad experience; 49% of customers have made impulse purchases after receiving a more personalized customer experience; customers that rate the organization with a high customer experience score (i.e. 10/10) spend 140% more and remain loyal for up to 6 years; 64% of customers are more likely to recommend a brand to others if it offers simpler experiences and communications; 71% of customers recommend a product or service because they received a "great experience"; 65% of all customers find a positive experience with a brand to be more influential than great advertising.

Organizations that cannot adapt to these changes become less attractive to customers and are likely to be replaced by ones that use such technologies [2, p. 891]. ISO standards provide organizations with tools to improve their performance.

5. BENEFITS OF ISO STANDARDS IMPLEMENTATION IN THE DIGITAL ECONOMY

ISO has published more than 22.000 international standards and related documents that represent globally recognized guidelines and frameworks based on international collaboration to help governments, industry, and customers [15]. ISO standards define what great looks like, setting consistent benchmarks for businesses and customers, ensuring reliability, building trust, and simplifying choices. They guide businesses in adopting sustainable and ethical practices, creating excellent customer purchases, and safeguarding our planet. In essence, standards seamlessly blend quality with conscience, enhancing customer everyday experiences and choices [16]. ISO standards apply to all organizations, regardless of size, industry, or nature of business. Each of these standards can be efficiently implemented independently, but their integrated application is more effective.

The UN Guidelines for Consumer Protection outline that the right to informed choice and to redress where expectations are not met is fundamental to effective relations with customers and is a basic right [17]. Therefore, ISO has a range of standards that help organizations address every aspect of customer satisfaction, from codes of conduct to handling complaints and disputes. These standards bring together the best international practices for customer satisfaction [18]:

1. ISO 10001, Quality management – Customer satisfaction – Guidelines for codes of conduct for organizations;
2. ISO 10002, Quality management – Customer satisfaction – Guidelines for complaints handling in organizations;
3. ISO 10003, Quality management – Customer satisfaction – Guidelines for dispute resolution external to organizations;
4. ISO 10004, Quality management – Customer satisfaction – Guidelines for monitoring and measuring.

In addition, standard *ISO/PC 317:2018 Consumer protection: privacy by design for consumer goods and services* assists organizations in dealing with customer protection in the digital economy in areas such as data protection, artificial intelligence, the sharing economy, and legislation on the online consumer experience. This standard enables organizations to comply with regulations and generates greater customer trust at a time when it is needed most [19]. Implementation of ISO standards helps organizations to ensure that their products and services perform as expected and continuously improve: quality and reliability, consistency in the delivery of services, choice, and fair competition; transparency in production information, suitability of products for vulnerable populations; and standards have the credibility to support consumer protection laws [18].

6. CONCLUSION

Modern technology, digitalization, flexible data management, and highly agile processes help organizations achieve an intelligent and highly agile digital environment that predicts and responds to changes in the ecosystem to capitalize on new opportunities [5]. Customers look like they believe in apps and new AI-based technologies, so organizations strive for competitive advantages and empower customers by providing the necessary tools, information, technology, and support to make decisions [5]. But it seems that for many organizations, digital transformation has become more crucial than customer understanding and empathy [14]. The survival, growth, development, and sustainable success of an organization mean achieving the desired results, as well as customer satisfaction means long-term loyalty, retention, increasing the number of customers, and repeat purchases offline or online. This implies increasing the availability of products and services, improving the total customer experience, providing customized value and impact for customers, focusing on their incentives and recognition, and educating customers through a stronger focus on product credibility and environmental, social, and governance (ESG) awareness and sustainability [20]. The Government of Serbia is giving support programs for micro, small, and medium enterprises to improve business, successfully adapt, actively participate, and make progress in the digital age through the introduction of modern digital tools into the organization [8]. Also, implementing ISO standards benefits organizations in fulfilling customer satisfaction and protection.

THE EFFECTIVENESS OF ENVIRONMENTAL SOCIAL AND GOVERNANCE DUE DILIGENCE IN DRIVING SUSTAINABLE OUTCOMES IN THE OUTDOOR APPAREL INDUSTRY

Ana Maksimovic[1], Independent corporate sustainability consultant

Abstract: *Due diligence in the areas of environmental, social, and governance (ESG) has grown to be a crucial tool for assessing and enhancing business practises. The study investigates the qualitative assessment of how ESG due diligence encourages sustainable performance inside organisations. Using a combination of case studies, data analysis, and theoretical frameworks, the study explores best practises for attaining tangible progress across several industries. The report also shows links between improved resource efficiency, worker wellbeing, risk reduction, stakeholder involvement, and successful ESG due diligence. It highlights the opportunity for data analytics and technology to improve impact assessment precision. The report explains how ESG due diligence leads to sustainable outcomes by giving organisations a path for assessing and publicising their sustainability successes. It helps businesses to better comprehend the importance of their ESG due diligence efforts and to take defensible actions to improve their sustainability performance.*
Keywords: ESG due diligence, corporate sustainability, impact measurement, investor perspective

1. INTRODUCTION

The complex aspect of sustainability in the outdoor apparel industry is the main topic of this article. It's becoming more and more clear in today's corporate environment that businesses need to give social and environmental responsibilities equal weight with financial goals. More than 90% of S&P 500 businesses and over 70% of Russell 1000 businesses publish ESG reports [26]. This indicates that stakeholders, consumers, investors, and regulators - are calling for increased openness and a dedication to sustainable business practices. Through an examination of supply chain procedures, labour conditions, and environmental effects, this article seeks to disentangle the complex web of possibilities and problems that the garment industry faces as it makes its way toward sustainability. In doing so, it hopes to clarify how companies may satisfy the demands of a worldwide consumer base that is becoming more and more aware of social and environmental issues while balancing profit with social and environmental well-being.

In order to fully investigate these concerns, this article takes a multimodal approach. It draws from a variety of sources, including academic literature, industry publications, case studies, and sustainability efforts within the garment sector, and blends qualitative and quantitative research approaches. As a result, it presents an analysis that combines academic research, field data, and empirical evidence to give a comprehensive view of the possibilities and problems that enterprises in the garment industry confront. It also makes use of the OECD's Due Diligence Guidance for Responsible Supply Chains in the Garment and Footwear Sector and the United Nations Guiding Principles on Business and Human Rights (UNGP) to offer a workable framework for resolving environmental and human rights issues. The content of the paper is organised so that it gradually examines important topics. It starts with a focus on labour conditions and modern slavery in the apparel supply chain, moves on to the role of HRDD in reducing human rights violations, and ends

[1] hi@anamaksimovic.com

with a thorough analysis of the environmental effects of clothing over its whole life cycle. In doing so, it hopes to offer insightful analysis and practical suggestions for businesses attempting to balance profit with social and environmental responsibility in the competitive corporate world of today.

2. THE RISING NEED FOR ESG DUE DILLIGENCE

Due to market pressures, it is now crucial to focus on sustainability and integrate ESGs into business operations [25, 27]. According to Banerjee et al. [2], using corporate resources in socially responsible ways may improve a company's reputation and foster stakeholder involvement. Freeman and Dmytriyev [12] assert that a commitment to ethical operations not only helps businesses develop a sustainable strategy by generating economic value through social benefits, but also boosts their competitiveness and profitability by attending to social needs.

Despite the fact that modern slavery and forced labour are pervasive in many facets of the economy, apparel imports into G20 countries at risk for modern slavery ranked second [21]. The supply chain workforce is severely impacted by short lead times and low price requirements, which frequently results in forced labour or underpayment of wages [1]. While businesses are aware of the need to educate their suppliers and staff about the risk of modern slavery, a study revealed that they typically ignore the influence that their purchasing policies have on the supply chain employees [22].

The UN developed the Guiding Principles on Business and Human Rights as a framework to aid companies in conducting human rights due diligence (HRDD) in order to avoid, contribute to, or at the very least mitigate negative effects on human rights, such as those seen in the supply chains for clothing. Concerns over human rights in enterprises throughout the world led to the publication of the United Nations Guiding Principles on Business and Human Rights (UNGP) in 2011. In order to detect, avoid, reduce, and repair any negative human rights repercussions associated with their operations and supply chains, businesses should follow the human rights due diligence (HRDD) framework [23]. Fashion companies of all sizes may execute due diligence procedures at each level of the UNGP HRDD framework according to their capabilities and resources. The OECD's Due Diligence Guidance for Responsible Supply Chains in the Garment and Footwear Sector provides this advice [20].

The whole supply chain has an influence on the environmental sustainability of a specific manufacturer, hence it is essential to incorporate the emphasis on economic sustainability into business models. The findings of Cai and Choi [5] may suggest that less effort is put into mitigating human rights risk in supply chains than is put into mitigating environmental risk. The analysis of the environmental effects of garments over the full product life cycle shows that the stages of manufacturing, processing, and consumer use outweigh those of transport and product end-of-life [17].

3. MEASURING ESG IMPACTS IN THE OUTDOOR APPAREIL INDUSTRY

In recent years, there has been an increase in the implementation of sustainability measures due to increased awareness of the environmental and social problems surrounding the apparel sectors and customers [16]. Environmental and social risks are becoming a major focus of due diligence, an approach to lowering commercial and financial risks. The process involves a thorough investigation, often carried out by one firm against another, to look into any potential wrongdoing or area of non-conformity that does not meet the expected level of conduct. Performing due diligence is a way to foresee potential future social, environmental, and ethical issues that might have an impact on the business [6].

Consumers are particularly interested in and concerned about sustainable practices in the outdoor apparel industry, which is supported by initiatives of brands such as REI, Patagonia, Nike, and Black Diamond [8]. Two significant players in the outdoor apparel market, Patagonia and REI, have adopted practices that include recycling clothes, accepting old clothing back for resale, and giving customers instructions on how to maintain their own equipment [17]. Although many businesses in the outdoor

sector are thought of by the public as being transparent in practicing environmental care, this is not always the case. Only five (5) of the fourteen (14) firms studied publicly demonstrated a full sustainability plan, according to the study, and the majority of outdoor brands did not even publicly announce their attempts to produce sustainable clothes [4].

3.1 Social performance: Working conditions and supply chain health

The Fair Wear Brand Performance Check is a tool used to evaluate how much business practices enhance working conditions throughout the company's supply chain and promote more open and trustworthy relationships with its manufacturing partners. Every year, Fair Wear evaluates its operations by examining how successfully the firm has located, assessed, and resolved problems with its suppliers. To guarantee accountability and openness, the audit results are made available to the general public. For the objectives of the study, three brands at random from the FairWear website were selected: Equip, Dynafit, and Jack Wolfskin[2]. Best practices and suggestions to enhance working conditions and supply chain sustainability were looked for in their reports.

The major goal of the sourcing strategy should be maintaining long-term partnerships. Implement stringent supplier onboarding procedures and extensive supplier due diligence procedures. Create a policy for onboarding new suppliers. Create a risk analysis in accordance with the OECD's guidelines. Conduct a supplier-level risk assessment and risk scoping. During the process, include all eight labour standards and use the gender analysis lens. Apply a gender perspective to all improvement activities as they are implemented. Use Fair Wear nation studies and other outside sources to pinpoint country risks and evaluate their likelihood and gravity. Consolidate the supply chain to be able to demand better working conditions at major production sites. Analyse the expenses of funding pay raises across the supply chain. To assist the supplier's transition to living wages, pay additional costs to the manufacturer for a set length of time. Increase your understanding of the cost breakdowns for all product categories, but refrain from making one-time charity donations. Calculate the labour minute costs of the goods to be able to determine the precise expenses of labour and connect this to the price of your purchases. Provide purchasers with cost breakdown training, utilising tools such as the Fair Price app[3]. Create a fair contract using the Common Framework of Responsible Purchasing Practises (CFRPP). Prefer to source from nations where employees are allowed to establish or join a union and/or engage in collective bargaining. Include feedback from employees, vendors, and other stakeholders in the risk-scoping process. Promote the complaints mechanism helpline. In addition to feedback from stakeholders and workers, audits should also monitor other third-party audits. Make sure supplier-level monitoring is in place to evaluate and comprehend supplier risk. Analyze the compliance with human rights of suppliers' subcontractors.

After each season, evaluate the manufacturing process with the supplier and make any necessary adjustments for future planning. Establish order timescales as early as feasible to provide the supplier with some sense of certainty. Take proactive action against excessive overtime by planning ahead for capacity and raw materials, and exploring the underlying reasons for excessive overtime with suppliers. Follow the development of yearly audits. Participate actively in discussions with suppliers for living wages. During pricing discussions, take into account changes in the legal minimum wage as well as salary levels, desired wage increases, and other relevant information. Implement a wage structure that pays the higher of the worker's hourly and piece rate rates. Every year, compare the salaries paid to suppliers to the estimated living wages in the country. Check to see if the required minimum wage was paid. Include the Global Living Wage Coalition's standard[4]. Strive for greater pay and create a systematic, time-bound strategy.

Examine whether the factories have anti-harassment committees or policies. Encourage businesses to elect workers' representatives. Encourage vendors to use posters and team meetings to spread the word about worker representatives. Establish independent worker representation in factories, and

[2] Equip Source, Dynafit Source, Jack Wolfskin Source
[3] Source: https://app.fair-price.org
[4] Source: https://globallivingwage.org

include these representatives in monitoring and correcting issues. Ensure the workers can complain. Provide assistance to vendors who scored poorly on the human rights due diligence requirements so they may correct any violations. Assist in organizing or financing training for suppliers on social dialogue and Freedom of Association. Find the source of complaints to stop them from reoccurring. All factories where this is a risk should implement training.
Include employee and supplier feedback in the assessment process. Suppliers and worker representatives should always be included in the evaluation of the internal grievance process. The results of the evaluation should be shared with the aforementioned parties and discussed about ways to improve. Suppliers and employee representatives should be informed of the corrective action plans. Support the development of capability, and put internal grievance procedures into practise at suppliers. Establish improvement schedules as soon as possible.

3. 2 Environmental performance: Environmental impact and product life-cycle assessment

Throughout the whole lifespan of the product, textile, and garment items have a substantial environmental impact [11], and understandably so since the industry employs 9.3% of the global workforce and accounts for 4% of global exports [24]. Various producers, such as fabric mills, dyeing facilities, and finished products facilities, are a part of the intricate worldwide networks that make up apparel supply chains. Before reaching a retailer and a customer's hands, a pair of shoes may pass through multiple distinct facilities in five different nations. If a business cannot find a method to overcome these obstacles and build strong relationships with its partners along the global value chain, it will be impossible to track and manage the various impacts all the facilities have.
The five tools that make up the Higg Index evaluate the social and environmental performance[5] of the value chain as well as the effects of products on the environment. They are the Higg Facility Environmental Module (FEM), Higg Facility Social & Labour Module (FSLM), Higg Brand & Retail Module (BRM), Higg Materials Sustainability Index (MSI), and Higg Product Module (PM). It gives businesses verifiable data to analyse, improve, and share performance. The Higg Index for Materials, the most popular sustainability grading system for the apparel industry, evaluates materials from "cradle to gate" while taking into account the effects of chemicals, fossil fuel use, water scarcity, excessive eutrophication, and the effects of global warming. However, after greenwashing claims in 2022, it moved away from producing consumer-facing reports [10].
The need for positive environmental practises in the clothes sector is expanding, but little study has been done on how to help apparel designers, producers, merchandisers, and customers incorporate environmental concerns into their products [16]. These decisions include how the materials are used, how much waste is produced by the forms they choose, how products are made and packaged, where they will be made and sold, how much energy is used in transportation, and how customers will use and dispose of the product [13]. Retailers may wrongly promote specific materials as being more ecologically friendly than others because the Higg MSI assessment methodology favours synthetic materials generated from fossilised carbon over bio-based textiles like wool, silk, and leather. Because it uses a "cradle-to-gate" strategy rather than a "cradle-to-grave" or "soil-to-soil" strategy, the Higg MSI is flawed in a number of ways. In order to determine sustainable impact, it only looks at the environmental impact of an item rather than its environmental, economic, and social costs of production. Animal fiber products like wool, silk, and alpaca rate lower than the preferred materials used by the majority of apparel manufacturers, such as cotton and synthetics, as a result of differences in how different fiber types are scored. There is yet no one system that incorporates all sustainability measures and ranks the best materials and manufacturing techniques, therefore the only thing to do is to wait for the Higgs index to develop. Before evaluating and making a decision, the companies are forced to take the more time-consuming route: understand each stage of their product lifecycle, each production phase’s emissions data, energy inputs, and associated emissions, pollution, and environmental impacts directly attributable to each stage of processing and use for a specific weight of the fabric, and the impacts on water pollution [9]. The paper analyzed the best practices in the

[5] Source: https://apparelcoalition.org/higg-facility-tools/

outdoor industry looking at websites, sustainability reports, and commentary on top-ranked sustainable outdoor brands. The following is the best practice approach towards improvement of environmental impact in phases of design, production, consumption, consumer care, and garment afterlife. Find out what garment characteristics and what issues are most essential to you. Learn the performance standards for your fabric. In contrast to typical fibers, consider alternate fibers with comparable performance. On technical equipment, apply a coating that is PFC-free and water-repellent. Despite making technical textiles water-resistant, PFC coating may be dangerous for both human and animal health. As a result of a longer life cycle, Bédat [18] claims that increasing a product's lifespan by twofold leads to a 44% decrease in greenhouse gas emissions. While developing a product, the entire lifespan of the product should be considered. Make products that will last for as long as possible. Give a lifelong repair warranty to encourage consumers to modify their consumption patterns [7].

Change to completely biodegradable, reusable, or recyclable packaging, and make an effort to get rid of virgin petroleum fibers. Remove single-use plastics from the supply chain. Keep as much operating waste out of landfills as you can. By using only one material in the item's creation, the lifespan of the original material may be enhanced by up to ten times, making it easier to recycle and transform into another useful product. In November 2019, Salomon[6] presented a novel shoe design that could be completely converted into ski boots. To prevent the Forte sleeping bag from ending up in landfills, NEMO made it totally recyclable[7]. For years, as a part of the ScrapMeUp programme, Houdini has been upcycling and has used manufacturing excess fabric to make limited-edition clothes. Foster a culture of sharing above owning. Clients were able to rent shell apparel from Houdini's retail outlets by using an access economy strategy[8]. Avoid deforestation by adopting bio-based materials, such as polyester made from sugarcane waste, and ensure that no slash-and-burn farmlands are a part of the project. Create a supply chain map. Picture[9] is a good example of supply chain transparency. Work on locating and reducing the carbon footprint of value chain operations. Avoid using carbon offsets. Instead, encourage suppliers to switch to sustainable energy sources.

4. CONCLUSION

In order to maintain sustainable development and competitive advantage, it is becoming more and more important for businesses to prioritise non-financial performance, such as ESG due diligence, as we navigate this changing terrain. It is clear that businesses with an emphasis on sustainability are drawing long-term investor interest, which benefits their standing, employee happiness, and innovation. The study presented in this paper is consistent with the conclusions drawn by a number of authors [14, 19, 15], however, it is important to recognise that different rating and scoring services use different methodologies, which leads to different ESG ratings. This disparity underscores how industry-wide ESG measures must be standardised. The ESG ratings indicate a significantly larger range of correlations, from 38 to 71 percent, whereas credit scores from agencies such as S&P and Moody's show a substantial correlation. While credit scores from agencies like S&P and Moody's exhibit a strong correlation, the ESG ratings show a much wider range of correlations, from 38 to 71 percent [3]. Moreover, organizations such as the Sustainability Accounting Standards Board (SASB) and the Global Reporting Initiative (GRI) employ different metrics, further complicating the landscape. It is obvious that further study is required in the future to improve ESG measuring techniques and determine their wider effects on sustainability, business performance, and innovation. The intricacy of ESG due diligence demands continuous research endeavours to cultivate a more profound comprehension of its function in promoting sustainability. Future developments for sustainable business practises will be largely shaped by the industry's dedication to ESG efforts and a more standardised approach to measurement in the years to come.

QMS & EMS IMPLEMENTATION IN SERBIAN ORGANIZATIONS – A DRIVING FACTOR FOR SUSTAINABLE DEVELOPMENT

Aleksandra Pavlović[1], The Academy of Applied Technical Studies Belgrade
Aleksandra Nastasić[2], The Academy of Applied Technical Studies Belgrade
Andrea Ivanišević[3], Faculty of Technical Sciences, University of Novi Sad

Abstract: *In the last few years, the development of management system standardization has been accelerating. A special focus is placed on QMS and EMS implementation in organizations, given that it is very important for the sustainable development of the country. As Serbia is still a developing country that strives for sustainable development and economic prosperity, it is very important to raise awareness of the importance of implementing the mentioned management systems in organizations. This paper provides an overview of the state related to standardization in Serbia, especially the ISO 9001 and ISO 14001 standards, as well as an overview of the value of certificated Management Systems in accordance with the requirements of the ISO standards in Serbia in the last decade. Organizations that own the aforementioned certificates are safe and attractive for both domestic and foreign products and services customers, but they are also socially responsible because, in addition to profit maximization, they also take into account the ecological side of the business. Unfortunately, there is a scarce number of studies on this topic in Serbia and the region, so the recommendation for future researchers in this field is to pay more attention to this important issue.*
Keywords: QMS, EMS, Standardization, Sustainable Development

1. INTRODUCTION

The business of every organization, regardless of the economic sector in which it operates, consists of a series of tasks that need to be performed on a daily, weekly, monthly, or annual basis, in order to ensure a normal and smooth business process. All these tasks require rules that define the scope, quality, methods, and techniques that should be followed during their performance, in order to ensure quality and reduce the possibility of business errors. If there were no clearly defined rules in business, operational chaos would occur. Thus, that is why clearly defined rules are implemented into the organization's business process, and the most prominent type of such rules are ISO standards. ISO standards are internationally agreed by experts and it can be said that they are a formula that describes the best way of doing something [1]. The internationally recognized organization that develops and publishes ISO standards is the International Organization for Standardization (ISO).
The Institute for Standardization of Serbia (ISS) is the only national standardization body of the Republic of Serbia that has the status of a legal entity and operates in accordance with the regulations governing the legal position of public services. ISS is founded by the Government of the Republic of Serbia [2]. Serbian standards can be created as original standards, or as standards based on national, international, European, or regional standards or related documents of other countries, in accordance with the agreements concluded with the standardization bodies of those countries [2]. Nowadays, ISO is an independent and non-governmental international organization whose portfolio includes 24997 international standards (covering almost all aspects of technology, management, and production), 169

[1]apavlovic@atssb.edu.rs
[2]anastasic@atssb.edu.rs
[3]andreai@uns.ac.rs

national standardization bodies with membership in it (one member per country), and 824 technical committees and subcommittees (take care of the standards development) [3].
The preparation of the Serbian standard takes place in four steps, respecting the principles and rules established by international and European organizations for standardization [2]:

1. Involvement of all interested parties in the Serbian standard's adoption process;
2. Preparation of the preliminary Serbian standard draft;
3. Draft of the Serbian Standard's Commission;
4. Public discussion on the Serbian standard's draft.

It has been revealed that both management systems, Quality Management System (QMS) and Environmental Management System (EMS), significantly contribute to the improvement of the organization's performance. The implementation of requirements of the ISO 14000 standard in the organization is the second step after the implementation of requirements of the ISO 9000 standard, i.e. most of the organizations that implemented EMS implemented the QMS earlier [4]. Today, the most important and applied standards are ISO 9001 - QMS, ISO 14001 - EMS, and ISO 22000 - FSMS, which represent a framework for business standardization around the world [5].
"Sustainable development (SD) is development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (p. 16), thus, "future generations do not vote; they have no political or financial power; they cannot challenge our decisions" (pp. 16) [6]. The concept of SD can be complete only if all three of its components are respected: economic, ecological, and social. However, usually the ecological component remains unrealized, thus, future generations cannot experience well-being in the true sense of the word if they live and work in degraded environmental conditions. The connection between QMS, EMS, and SD is very strong, which is indicated by a large number of scientific papers [7, 8, 9, 10, 11]. ISO contributes to all of the SD goals [1]: 1) no poverty; 2) zero hunger; 3) good health and well-being; 4) quality education; 5) gender equality; 6) clean water and sanitation; 7) affordable and clean energy; 8) decent work and economic growth; 9) industry, innovation, and infrastructure; 10) reduced inequalities; 11) sustainable cities and communities; 12) responsible consumption and production; 13) climate action; 14) life below water; 15) life on land; 16) peace, justice and strong institutions; 17) partnerships for the goals.
This manuscript is structured as follows: section 2 – previous research; section 3 – general participation of standards in sustainable development - a brief review; section 4 – participation of standards in Serbian sustainable development; section 5 – a conclusion and recommendation for future research are given.

The aim of this paper is to discuss the state related to standardization in Serbia, especially the ISO 9001 and ISO 14001 standards, as well as to give an overview of the value of certificated Management Systems in accordance with the requirements of the ISO standards in Serbia in the last decade.

2. PREVIOUS RESEARCH

A large number of scientific works testify to the important connection between QMS, EMS and SD. Unfortunately, in our region, the number of such works is scarce.
Thus, one of such works in our region is the work of Professor Majstorović and others [5], which deals with the issue of business standardization in Serbia and the world. The authors concluded that business standardization entered a new era with the adoption of Annex SL[4] and the release of new models of QMS and EMS: 2015, as well as that these documents laid new basics for the development and application of other standardized management systems (SMS), and in such a way this will be significant for users, as they will be able to easily integrate two or more SMS.

[4] According to ISO, Anex SL is normative or harmonized structure (identical clause numbers, clause titles, text and common terms and core definitions) for Management System Standard (MSS).

Afterwards, a group of authors from the University of Novi Sad [14] in one of their papers dealt with the issue of key competence factors of organizations in Serbia with certified management systems. The authors based the study on The European Manufacturing Survey questionnaire and analyzed the competence of Serbian companies through the implementation of the ISO 9001 standard. The study revealed a significant difference between certified and non-certified companies, in terms of the quality of products and services, as well as that the implementation of QMS in business is of great importance for SD.

A group of authors [7] investigated the connection between SD, QMS, and EMS on the example of Slovakia. The authors concluded that environmental labeling is of great importance for SD within EMS and that ISO 9001 is particularly relevant to organizations that tend to label their products as CE[5]. Another paper [8] testifies to the importance of QMS for SD. In other words, there is a need to define activities in the field of QMS that have to be implemented in the organization, and which will serve as a source of inspiration in creating value for interested parties. As well, QMS has to be integrative, inclusive, and adaptable in order to respond to SD challenges and support companies in their business challenges.

Another group of authors [9] dealt with the issue of EMS in the field of architecture, engineering, and construction, as well as with the issue of SD in that context. Their study generated a wide range of benefits to support the implementation of ISO 14001 in AEC sectors[6], while using ISO 14001 as a framework would certainly help companies to focus on achieving SD goals.

3. GENERAL PARTICIPATION OF STANDARDS IN SUSTAINABLE DEVELOPMENT – A BRIEF REVIEW

The following table (table 1) shows the number of ISO standards participating in each of the SD goals.

Table 1. The number of ISO standards that apply to each SD goal
Source: International Organization for Standardization, [1]

SD goal		Number of ISO standards
1.	No powerty	393
2.	Zero hunger	604
3.	Good health and well-being	3559
4.	Quality education	639
5.	Gender equality	238
6.	Clean water and sanitation	712
7.	Affordable and clean energy	1109
8.	Decent work and economic growth	2838
9.	Industry, innovation and infrastructure	14407
10.	Reduced inequalities	656
11.	Sustainable cities and communities	2810
12.	Responsible consumption and production	3179
13.	Climate action	1423
14.	Life below water	393
15.	Life on land	1206
16.	Peace, justice and strong institutions	243
17.	Partnerships for the goals	16

It can be concluded that the largest number of ISO standards participate in the 9th SD goal – Industry, innovation, and Infrastructure (14407), while the lowest number of ISO standards participate in the last SD goal – Partnerships for the goals (16). Some of the most significant examples of ISO standards that participate in the 9th goal of SD are: ISO 44001 – Collaborative business relationship management systems, and ISO 56002 – Innovation management systems.

As QMS and EMS are of key interest for this work, the following figures (figure 1 and figure 2) show which SD goals the ISO 9001 and ISO 14001 standards participate in.

[5] CE marking i.e. the presence of the CE logo means that the manufacturer/importer confirms the conformity of the goods with EU standards of health, safety and environmental protection, and it is not a quality indicator or a certification mark.

[6] Architecture, Engineering and Construction sector.

Figure 1. Participation of ISO 9001 in the goals of SD
Source: International Organization for Standardization [1], Author's creation

The life cycle of the ISO 9001 standard began in 1987 (ISO 9001:1987), and the last version was published in 2015 (ISO 9001:2015). The standard is revised every five years. The ISO 14001 standard participates in the 1st, 9th, 12th, and 14th goals of SD. The ISO 9001 standard is based on seven quality management principles (QMP) [12]:

1. QMP 1 – Customer focus;
2. QMP 2 – Leadership;
3. QMP 3 – Engagement of people;
4. QMP 4 – Process approach;
5. QMP 5 – Improvement;
6. QMP 6 – Evidence-based decision making;
7. QMP 7 – Relationship management.

Together, these principles can form the basis for performance improvement and organizational excellence, likewise, the implementation of QMS brings numerous benefits to the organization, such as: clear goal setting and identifying new business opportunities, working in a more efficient way, meeting the necessary statutory and regulatory requirements, expand into new markets, identifying and addressing business risks, etc. [12, 13].

Figure 2. Participation of ISO 14001 in the goals of SD
Source: International Organization for Standardization [1], Author's creation

The life cycle of the ISO 14001 standard began in 1997 (ISO 14001:1997), and the last version was published in 2015 (ISO 14001:2015). The standard is also revised every five years. As well as the ISO 9001 standard, the ISO 14001 standard participates in the 1st, 9th, 12th, and 14th goals of SD. However, this standard also participates in the 2nd, 3rd, 4th, 6th, 7th, 8th, 13th, and 15th SD goals. It can be concluded that EMS is in almost every goal of SD and that is why its implementation in the organization's management system is of great importance for the successful business process.

4. PARTICIPATION OF STANDARDS IN SERBIAN SUSTAINABLE DEVELOPMENT

Serbia is still in the transition process, aspiring to join the European Union and accelerate its economic growth, therefore, Serbian companies are forced to implement QMS in their business because the quality of products and services is the most important factor of competitiveness nowadays [14]. There is also a need to implement EMS in the business process, because today foreign capital prefers to go to socially responsible locations, and the time when only cheap workforce was the main attraction factor for foreign investors is passing. Thus, figure 3 shows the number of certificates (ISO 9001 and ISO 14001) in Serbia in the last decade.

	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022
ISO 9001	2366	2637	2512	3017	2213	2427	2707	3092	3461	3541
ISO 14001	762	901	1120	1139	887	1169	1275	1629	1794	1921

Figure 3. The number of certificates in Serbia in the period from 2013 - 2022
Source: International Organization for Standardization [15], Author's creation

It can be concluded that the number of ISO 9001 certificates is significantly higher compared to the number of ISO 14001 certificates, which points to the fact that it is necessary to raise awareness in Serbian companies about the implementation of EMS, regardless of the fact tha implementation of this standard is voluntary, i.e. it is not required by law, but organizations have to become aware of the importance of environmental protection and socially responsible business. Also, it can be seen that the number of both certificates dropped significantly in 2017. The reason for that could be the introduction of a new global financial crisis, similar to the crisis of 2007/2008. Back in 2017, economic experts warned of an inevitable new global economic crisis, which could also begin with the bursting of the so-called financial bubble, as well as the previous crisis (unrealistically high values of certain parts of assets in the area of securities, real estate, etc.). Hereafter, the growth of public and private debt with insufficient economic growth almost always represents a serious problem for the economy of a country. Deteriorated business conditions, tensions, and the trade war between the United States and China have disrupted global trade flows by raising tariffs and other barriers to trade [16]. On the other hand, it is encouraging that, in recent years, there has been a constant increase in the number of both certificates, thus, even the COVID-19 pandemic did not disrupt that flow.
Table 2 shows the value of certificated EMS and QMS in accordance with the requirements of the ISO standards.

Table 2. The value of certificated EMS and QMS in accordance with the requirements of the ISO standards in the period from 2013 - 2022
Source: Cornell University, INSEAD[7], and WIPO[8], [17 - 26]

Year	Value of certificated EMS and QMS (bn PPP$ GDP)	
	ISO 9001	ISO 14001
2013	36.40	6.60
2014	39.40	10.50
2015	24.70	7.90
2016	27.50	9.40
2017	25.70	11.50
2018	29.70	11.20
2019	27.00	11.10
2020	19.80	10.10
2021	21.40	10.10
2022	24.40	12.80

[7] The Business School for the World
[8] World Intellectual Property Organization

It is noticeable that the value of the ISO 9001 is higher than the value of the ISO 14001. Also, the lowest value of the ISO 9001 was recorded in 2020, and the highest in 2014, while the lowest value of the ISO 14001 was recorded in 2013, and the highest in 2017. The low value of the QMS in 2020 may be the outbreak of the COVID-19 pandemic.
The next figures (figure 4 and figure 5) show annual variation of the total of the data reported by the providers that took part in both the ISO surveys 2020 and 2021, and ISO surveys 2021 and 2022.

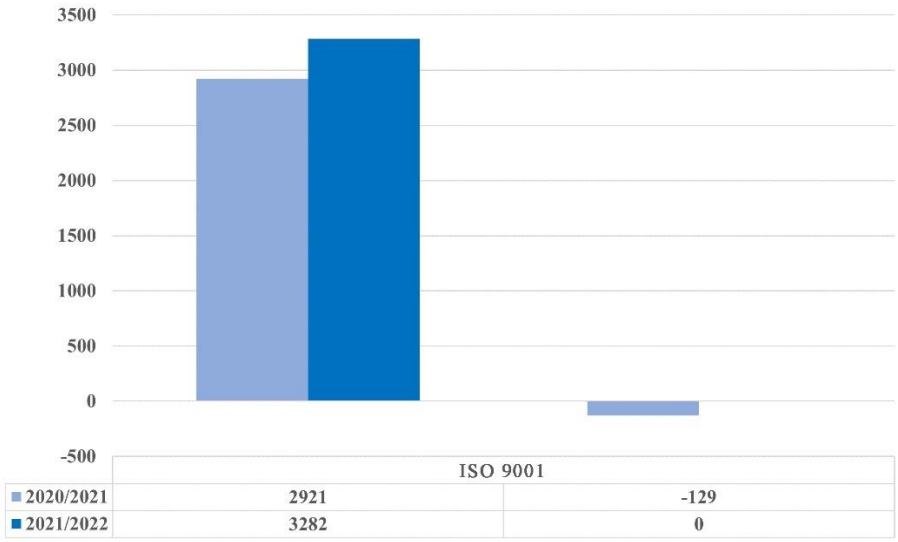

Figure 4. Annual variation of the total of the data reported by the providers that took part in ISO 9001 surveys 2020. and 2021, and 2021 and 2022.

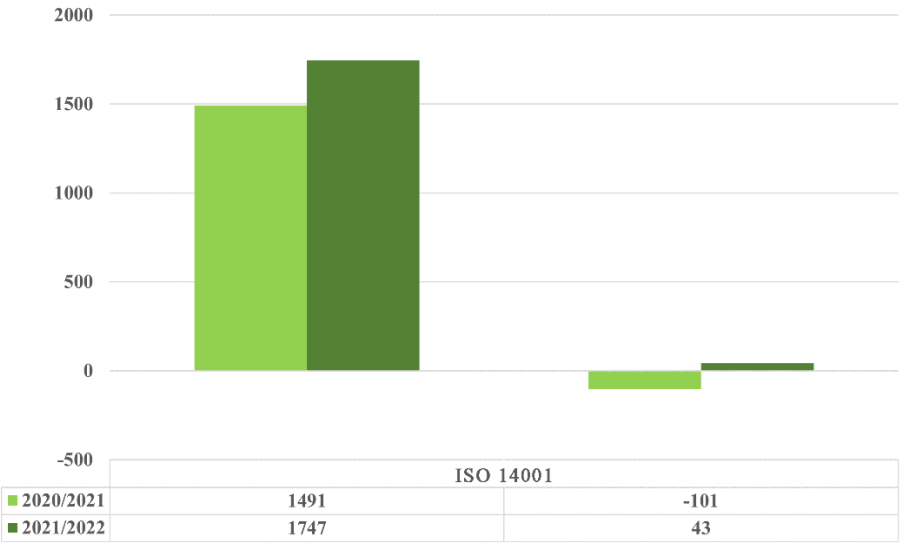

Figure 5. Annual variation of the total of the data reported by the providers that took part in ISO 14001 surveys 2020. and 2021, and 2021 and 2022.
Source: International Organization for Standardization, [15]

The difference between the number of ISO 9001 certificates in 2021 compared to 2020 is a negative number (-129), which means that the number of certificates in 2021 decreased, while the difference is zero when it comes to 2022 compared to 2021, i.e. the certificate number remained unchanged. On the other hand, when it comes to ISO 14001 certificates, in 2021 compared to 2020, a negative number of certificates was detected i.e. also decreased (-101), while in 2022 compared to 2021 that number is positive (43), which means that the number of certificates in 2022 has increased.

5. CONCLUSION

The concept of SD is based on its three pillars – economic, environmental, and social. However, the fact is that the greatest importance is tacitly given to the environmental pillar. The reason for that lies in the long-term neglect of the ecological component of SD. By implementing QMS and EMS in businesses, current generations will protect the rights of future generations to an environment that is safe for their life and health. In the world, there are a large number of those who exploit natural resources excessively, leaving little for future generations, but there is a much larger number of those who consume insufficiently natural resources and live on the edge of existence (poverty, hunger, disease, etc.) [6]. Therefore, it is important to preserve a healthy environment and not to consume natural resources excessively. Standardization in the field of product and service quality and the environment significantly helps countries on their way to achieving healthy SD.

When it comes to Serbia, it is still necessary to raise awareness about the importance of environmental protection and encourage companies to implement EMS in their operations. The complete system of ISO standards is based on principles that allow the company to establish a vigorous relationship with customers, suppliers and employees, as well as to stand out on the market for the quality of products and services, as well as environmental responsibility.

Compared to the rest of the world, Serbia and the region do not stand out in the terms of the number of scientific works in the field of standardization and SD, therefore, the recommendation for future researchers from these areas would be to deal more with this issue.

SOCIALLY RESPONSIBLE CHAINS: INVESTIGATING THE SOCIAL IMPLICATIONS OF SUPPLY CHAIN DUE DILIGENCE IN CORPORATE SUSTAINABILITY

Ana Maksimović[1], independent corporate sustainability consultant

Abstract: *As businesses increasingly recognize the interconnectedness of social responsibility and corporate sustainability, the role of supply chain due diligence in shaping socially responsible chains gains prominence. The aim of this paper is to investigate the social implications of supply chain due diligence and its contribution to fostering corporate sustainability with a strong emphasis on social welfare. The study investigates how supply chain due diligence affects social dimensions within organizations and across their supply chains. Through case studies and qualitative analysis, the paper examines how due diligence practices contribute to fair labour practices, human rights protection, and community engagement. The study emphasises the transition from transactional supplier relationships to collaborative partnerships that prioritise ethical and social factors. Finally, this research contributes to the discussion of corporate sustainability by shedding light on the social consequences of supply chain due diligence. It emphasises the critical importance of due diligence in developing socially responsible chains, where ethical issues are as important as environmental ones. By providing insights into best practices and potential challenges, the paper contributes to developing strategies that align supply chain due diligence with broader corporate sustainability goals.*
Keywords: *supply chain due diligence, corporate sustainability, fair labour practices, socially responsible supply chains*

1. INTRODUCTION TO SUPPLY CHAIN DUE DILIGENCE

Bad labour practices in the textile industry sparked intense discussions on the responsibility of multinational corporations for the working conditions and environmental effects of their supply chains. They were fueled by tragedies such as the Rana Plaza collapse (2013) and the Tazreen Fashion factory fire (2013) [27], as well as unveiling the state-sponsored forced labour system [9] in 2020 in Xinjiang, China [11]. They clarified the necessity for regulation to hold companies accountable for supply chain practices. According to Gustafsson et al. [21], the focal subject of these discussions is foreign corporate responsibility (FCA), which is the obligation of corporations to have adverse effects brought about overseas by their suppliers or subsidiaries. Multinational corporations have responded to the need to "clean up" their supply chains with a variety of voluntary corporate governance initiatives [3]. These private governance systems are critiqued for a variety of well-documented shortcomings, such as insufficient coverage, a lack of publicly disclosed accountability mechanisms, a lack of sufficient independent oversight, and ineffective implementation [8].
Multinational corporations traditionally relied on voluntary actions for due diligence. However, key issues like the gender pay gap, biodiversity, environmental conservation, and more remain underreported globally. Some countries now mandate due diligence to address these concerns. The European Commission has led sustainability and transparency efforts, from the European Green Deal [16, 17] to the Corporate Social Responsibility Directive (CSRD) [19]. France, the Netherlands, the UK, Australia, and Germany (2021) have adopted national due diligence regulations. African nations, including the Democratic Republic of the Congo and Rwanda, mandate supply chain management

[1] hi@anamaksimovic.com

for conflict minerals [15]. Initially voluntary, the German Supply Chain Act (2023) resulted from inadequate voluntary measures. The European Commission's draft directive (2022) extends binding duties to major European corporations [20]. However, no regulation offers a comprehensive human rights due diligence framework. Effective regulation should clarify due diligence components and empower affected individuals and communities.

2 THREATS IN EUROPEAN SUPPLY CHAINS

More consumer goods are imported from developing countries by the European Union (EU), than by the combined imports of the United States, Canada, Japan, and China [18]. Due to its low or absent domestic production of soybeans, palm oil, coffee, and cocoa and their consequently high consumption, the EU has emerged as a significant worldwide consumer of deforestation manifested in trade [22]. When it comes to the apparel sector, numerous accounts of abusive working conditions, including unpaid overtime wages, long hours, hazardous working conditions, harassment, and discrimination in the factories and fields characterise the EU’s Asian-based suppliers [23]. The likelihood of employee exploitation increases with increasing demand for quicker production periods and more products [2].

Ethical Trading Initiative [12] has defined the major areas of human rights risk for workers in global supply chains: forced labour, child labour, discrimination, freedom of association and the right to collective bargaining, living wages, irregular employment, occupational health and safety, working hours, and harsh or inhumane treatment. As a company's supply chain is typically international, it is necessary to be aware of the most important risk factors. Poor laws, rules, and oversight systems in authoritarian nations are to blame for the lack of government protection of employment rights. Lack of transparency and indirect employment are caused by the existence of subcontractors and intermediary employment agencies in the supply chains. The ability, resources, and political will of the supplier's state to determine if there is a lack of labour inspection and monitoring.

Supply chains that are overly lengthy or intransparent might result from complex production processes that include a single product that is obtained from several locations. High unemployment and poverty rates, unstable states, and armed conflict can describe the dynamics of some labour markets. Due to exorbitant fees charged by recruiters, hiring practices can be dishonest and entail holding employees in debt as bondsmen.

According to the Ethical Trading Initiative [13], social auditing, a growing $50 billion business, may account for up to 80% of expenses for ethical sourcing. It often entails a physical examination of a facility (such as a factory, farm, mine, or vessel), as well as a documented review and interviews with management and sometimes personnel. It is often not detailed enough to pick up on hidden crimes such as child work or modern slavery nor assess the risk of future violations. Furthermore, different brands inspect certain factories more than once in a single month. This leads to audit fatigue and an overall lack of interest. Despite the fact that a number of brand firms and retailers label their audits as "comprehensive," in practice, they usually only look at a tiny subset of top-tier suppliers.

Prior to the catastrophic events, the Tazreen Fashion factory and the Rana Plaza building's clothing factories underwent social assessments. According to the audits' findings, the workplaces were legally compliant [23, 24]. Audit programmes are still used as a primary compliance tool [23, 25] despite the fact that there is little evidence that audit programmes have improved social performance issues. More than 20 years of research demonstrate that audits frequently fail to identify serious labour violations in supply chains such as working hours, overtime, salary levels, freedom of association, and modern slavery.

3 POTENTIAL CHALLENGES

In supply chain production, codes of conduct, typically supported by social audits, are frequently employed as a framework for monitoring business compliance with human rights regulations. Such codes rely on corporate engagement, but their credibility and potential longevity are dependent on

how businesses engage with other stakeholders (trade unions, civil society, and workers) in their development and enforcement [31]. However, many research studies demonstrate that social audits should not be employed as a substitute for human rights due diligence [4, 26, 10].
Social audits frequently focus on the effects of labour breaches rather than their causes, therefore often overlooking the impact that a company's business strategy and procurement policies play in exploitative labour practices farther down the supply chain [1]. A checklist approach to social compliance characterised by the superficial Yes/No audit procedure is inadequate for identifying the root causes of issues. Labour infractions in the garment industry, for instance, are not just a factory-level issue that can be resolved by better compliance monitoring, but rather a widespread and predictable result of the broader business model [29].
Despite their inadequacies, most companies continue to rely on audits and compliance-based strategies to manage and mitigate human rights risks given their limited resources, abilities, and increasingly competitive marketplaces [12]. Businesses rather outsource and delegate risk management to their suppliers, auditors, and other professionals in order to inform them of what they need to know and do. As a result, the companies' relationships with their suppliers suffer, as does their sense of ownership and responsibility for potential human rights issues. Compliance audits assert that they provide exhaustive *data* and unbiased verification of the social and environmental conditions at supplier factories using defined metrics. In reality, audit data is politicised, incomplete, and typically kept secret. When retailers add supplier improvement requirements, certain information categories get points while others with egregious violations go unpunished. Audits provide a perception of transparency and accountability, yet they frequently conceal the worst business practices from view [24].

3.1 Positive effects of supply chain due diligence

For companies to raise the level of their due diligence and successfully manage both internal and external risks, they must approach environmental and social problems in a more honest and effective manner [7]. Because it involves a wide variety of stakeholders for data collection, supply chain due diligence produces superior analyses of risks and repercussions. Better decision-making is made possible because individuals who are most directly impacted can identify the issues and the best ways to solve them. It leads to increased productivity, decreased staff turnover, improved hiring and training, improved reputation and credibility, and improved visibility of and intelligence on supply chains. It also helps supply security by lowering the risk of disruption due to labour unrest [14].

3.2 Best practices

According to the Ethical Trading Initiative [12], for businesses to manage and mitigate risks more efficiently, they should perform better risk assessment and detailed analysis of human rights risks, impacts, and causes. Companies should also implement internal reviews of approaches, policies, and practices to determine which of these directly or indirectly contribute to human rights risks instead of performing audits and outsourcing due diligence assessments. In the long-term, effective internal stakeholder relationships internally, with other companies, suppliers, trade unions, government agencies, civil society groups, experts, and multi-stakeholder initiatives are shown to be a far more successful and less expensive approach.
To ensure thorough due diligence, companies employ a mix of different methods, including human rights impact assessment, social impact assessment with an integrated human rights approach, and/or human rights risk assessment [5]. Various human rights assessments indicated that the commitment of senior management was a key element in the process. Cultural awareness aided interactions with workers and other stakeholder groups that were involved [28].
Companies should pursue fewer, more committed supplier relationships. Knowing where the items are created and confirming that they are made decently becomes easier to accomplish when the number of suppliers the company deals with decreases. In addition, when the supply chain of a

business is independently verified by a third party, it gives the business a better understanding of what actually occurs at the manufacturing sites [5].

3.2.1. DeFacto, Turkey: apparel industry

About 60% of the workforce in the Turkish textile industry is unregistered, and many of these individuals are employed by small subcontractors. With so many unregistered workers, it is challenging to guarantee their human rights as they are not officially recognised as employees. In the past several years it is estimated that three million individuals applied for refuge in Turkey. Some of them work at apparel factories. DeFacto first tracked the clothing they produced before collaborating with suppliers to enhance the conditions in their facilities. Follow-up and effective communication are crucial in building confidence with suppliers after the baseline audit evaluation. Suppliers become cooperative when they feel comfortable doing business with the company and believe that the partnership enables them to improve. Instead of feeling obliged to just address audit findings and then be done with the process, they start addressing the company proactively. DeFacto requires that its vendors disclose the names of the companies whom they subcontract so that the company can trace their supply chain. This step also encourages a sense of shared accountability among supply chain actors [6].

3.2.2. AkzoNobel, the Netherlands: chemicals industry

Akzo Nobel employs the supplier support visits (SSV) programme to mentor suppliers and assist them as they gradually adapt to the needs of the company. Through this supplier management tool, the company can build long-term relationships focused on tackling systemic issues. Rather than an audit programme, the SSV programme aims to improve the capabilities and performance of local suppliers in emerging markets so they become long-term partners. Supportive visits are planned in advance and executed by teams from the health, safety, procurement, and environmental departments. AkzoNobel’s suppliers believe that being members of the project helps them gain market awareness and commercial prospects [6].

3.2.3. UPM Raflatac, Finland: paper industry

Self-adhesive label manufacturer UPM Raflatac has a database of more than 5,000 foreign vendors. To increase awareness in 2015, the heads of the sourcing and sustainability divisions of UPM Raflatac launched a rather inventive campaign. They created a film with the sourcing team and other departments in order to include the purchasing staff in educating suppliers about the criteria for ethical sourcing. By using straightforward language and including their own, culturally diverse staff across all levels of hierarchy in their regular work environments, the video was successful in communicating to its suppliers the company's commitment to responsible sourcing, banning child labour, and forced labour [30].

3.2.4. Nestlé, Switzerland: consumer goods industry

In Ghana and Côte d'Ivoire, the cocoa industry employs an estimated two million children in child labour. Being the key ingredient in Nestlé products, the company's decision on cocoa suppliers has a direct impact on both its capacity to perform commercially and how it affects society. In 2012, Nestlé and the International Cocoa Initiative (ICI) worked on establishing the Child Labour Monitoring and Remediation System in Côte d'Ivoire. The system's objective is to identify young people who could be engaged in child work and to take corrective measures. The system has also significantly helped to reduce child labour occurrences. The reduction reached 55% according to 2019 statistics [30].

3.2.5. Total, France: energy and gas industry

Total is one of the biggest energy firms in the world, with operations in more than 130 nations and more than 100,000 suppliers around the globe. Effectively identifying and human rights risks of such a vast supply chain offers a significant challenge. Since 2012, Total has mapped its supply chain's human rights concerns and identified high-risk nations as well as product and service categories. However, further action was hindered by a lack of internal support from the larger procurement department, especially in relation to supplier social audits. In 2019, the previous conclusions from the mapping process were used to develop a sustainable procurement mapping tool that would provide procurement teams with access to a list of the core risks related to each category. The instrument provided a set of recommendations that might be implemented in addition to the risk-mitigation measures to further minimise the risks [30].

4 CONCLUSION

The paper underscores the shift from transactional supplier relationships to collaborative partnerships that prioritise ethical and social considerations. It explores good practices that companies use to leverage supply chain due diligence, ensure the fair treatment of workers, prevent human rights violations, and support local communities. It also highlights the challenges and opportunities associated with incorporating social criteria into supplier evaluation. It emphasises the crucial role that due diligence plays in creating socially responsible chains, where ethical issues are just as important as environmental problems. Future research may focus on impact assessments, comparative analyses, stakeholder engagement, transparency effects, regulatory frameworks, technological advancements, cross-sector collaboration, standardised metrics, human-centered approaches, and the outcomes of initiatives to improve education and capacity. Further research will expand our knowledge of morally upstanding supply networks that value social and environmental responsibility.

Abstract: *Project management, as a specific management field, faces numerous challenges nowadays. Those challenges are related to meeting project deadlines, simultaneous work on several projects, unplanned risks, economic instability, lack of resources or knowledge, legal barriers, etc. When it comes to the economic development of the country, special attention is given to public-private partnership (PPP) projects, because they are the driving force of economic growth. At the same time, these projects represent the most complex form of financing economic growth. A large number of factors affect the implementation of PPP projects in the country, thus, in this paper, the focus is on the legal aspect, as well as the analysis of the state of these projects in Serbia, in the terms of projects approved by the authorities, foreign investors – donors, i.e. origin of that capital, etc. Attention is also set on the impact of investments in PPP projects on economic growth in Serbia, in a theoretical sense, while the proposal for future researchers of this issue is the beginning of a model in the region that would both quantitatively express and measure this important impact.*
Keywords: PPP, PPP projects, Economic growth

1. INTRODUCTION

Public–private partnership (PPP) can be defined as an approach that aims to increase the economic value of infrastructure outputs, and it includes a wide spectrum of public sector infrastructure [1]. There is a positive trend in the development of PPP in Serbia, both in the terms of the number of projects and the quality of projects [2]. The Commission for PPP (CPPP) of Serbia invested a lot of effort in promoting this financing model to invite all local governments to propose projects within which they will supervise the provision of services and have a control mechanism, and not, as in the previous traditional model, be a service provider [2]. So far, a total of 272 projects have been approved in the field of PPP, both PPP project proposals and concession act proposals, which is a great success compared to, for example 2019, when the total number of such projects was 134 [3]. The essence of PPP is cooperation between the public and private sector, where the private sector is the investor, which ensures the allocation of risk to the partner that has better performance in the terms of control and management of unpredictable events [4].
A PPP project *("Sl. glasnik RS", br. 88/2011, 15/2016 i 104/2016)* is a project that is developed, proposed, approved and implemented according to one of the PPP models and consists of a series of interconnected activities, which take place in a certain order, in order to achieve defined goals within a certain period of time and certain financial resources, which in accordance with this law was

[1]apavlovic@atssb.edu.rs
[2]anastasic@atssb.edu.rs
[3]pdrobnjak@atssb.edu.rs
[4] alangovicmilicevic@gmail.com
[5] andreai@uns.ac.rs
[6] ivana.katic@uns.ac.rs

approved as a PPP project, with or without concession elements. In PPP projects, the degree of involvement of the private sector is proportional to the degree of allocated risk, thus, the lower the participation of the private sector in PPP, the lower the risk, and vice versa [4]. In other words, privatization allocates the entire risk to the private sector, and in the conditions of traditional financing, all risks are the expense of the public sector, i.e. citizens as taxpayers [4].
On the other hand, when it comes to economic growth, PPP are of great importance. Economic growth is closely related to the wealth of the nation because it is of the greatest importance for the living standard and, in general, the quality of life of a country. Economic growth is the main indicator of the quality of the functioning of the national economy, and it refers to the continuous increase in the value of the production of a country over time, and is basically a long-term and slow process [5]. PPP and economic growth nexus is strong, i.e. the development of PPPs has a general tendency to reflect the changes of economic growth of a country expressed by the growth of the Gross Domestic Product (GDP) [6].

This paper is structured as follows: section 2 – previous research; section 3 – a brief overview of the project evaluation tools; 4 – an overview of PPP projects in Serbia; section 5 – conclusion and recommendation for future research.

The aim of this paper is to observe the nexus between PPP projects and Economic Growth in Serbia, as well as to discuss the state related to PPP projects in Serbia.

2. PREVIOUS RESEARCH

There is a large number of works by foreign authors dealing with the issue of PPP projects and economic growth. As well, the number of domestic works shows a growing trend in recent years. Depending on the observed sample, different authors revealed different connections between PPP projects and economic growth, and some of these connections are positive, some are negative, and there are also those with mixed research results.

Thus, according to Zangoueinezhad and Azar [7] there are three key factors by which PPP projects stimulate the economic growth of the country: the number of PPP projects under way; the value of PPP projects; and the ideal type of PPP contracts in use.
A group of authors [8] investigated the macroeconomic benefits of PPP projects on the example of developing Asia. The results revealed that increasing the ratio of PPP project investments to GDP improves quality of infrastructure services and increase economic growth.
Another group of authors [9] dealt with the analysis of PPP and economic growth on the example of sectoral analysis of developing countries. The authors used GMM estimation technique and concluded that aggregate PPP investments and energy investments have a positive impact on economic growth.
A group of domestic authors from the University of Belgrade [10] investigated the question of feasibility of PPP in Local Government in Serbia. The authors concluded that there are quite low human capital and technical capacities in Local Government about realizing and understanding the concept of PPP.
Another group of authors [11] analyzed PPP projects for infrastructural development as the key to promoting intergovernmental corporation during the Covid-19 pandemic. The research revealed that the implementation of PPPs is the basis for boosting intergovernmental companies globally during the Covid-19 pandemic, thus, countries around the world should use PPPs to strengthen intergovernmental companies to successfully address a number of issues related to the pandemic, as well as similar issues that could arise in crisis situations in the future.

3. A BRIEF OVERVIEW OF THE PROJECT EVALUATION TOOLS

There are two groups of methods for project evaluation [12]:

1. *Static (non-discounting) tools* are based on the account of nominal values from the representative i.e. base year, thus, these tools neglect the time value of money. These include the following:
   - Return on Investment (ROI), and
   - Static payback period;
2. *Dynamic (discounting) tools* are based on the calculation of discount values, therefore, these tools respect the time value of money and start from the assumption that the net cash flow is reinvested every year, during the lifetime of the project's exploitation. These include the following:
   - Net Present Value (NPV),
   - Internal Rate of Return (IRR), and
   - Dynamic payback period.

It would be useful if the growing number of scientific research dealing with PPP issues could include the evaluation of PPP projects, especially dynamic methods because they give a more realistic picture of which project should be prioritized, given that they are based on the concept of the time value of money, i.e. they take into account discounting (reducing the future value to the present value of the project). However, it is very often the case that the priority of the PPP project is not determined using the above-mentioned methods, where the emphasis is on the financial effect of the project itself. In such situations a combined evaluation is used, where a broader aspect of the project's impact is considered – the secondary impact of the project on economic activities that generate GDP.

4. AN OVERVIEW OF PPP PROJECTS IN SERBIA

In recent years, an upward trend in the number of approved PPPs has been noticeable in Serbia, and therefore the need to involve citizens and civil society organizations in these projects is growing, because PPP projects that include them are more effective. In order to strengthen cooperation between the public and private sector, it is necessary to adopt appropriate regulations that will encourage civil organizations and citizens to get involved in these projects in the future.

The following, table 1 shows the list of approved projects in Serbia by The Commission for Public-Private Partnership of Serbia (CPPP). So far, a total of 272 projects have been approved by this Commission, and the table below shows only some of them, in the form of project proposal or concession.

Table 1. List of approved projects in Serbia by CPPP, either in the form of a project proposal or a concession act, until 2023

Source: The Commission for Public-Private Partnership of Serbia [3]

1. Road infrastructure	
PPP project proposal	**Proposal of the concession act**
"Direkcija za izgradnju Apatin" - Municipality of Apatin; Municipality of Stara Pazova; The city of Smederevo; The city of Vršac; The city of Pančevo; The city of Sremska Mitrovica; The city of Kruševac; Municipality of Krupanj; Municipality of Srbobran; Municipality of Mali Zvornik; The city of Sombor; Municipality of Veliko Gradište; Municipality of Babušnica; Municipality of Ada; Municipality of Brus; Municipality of Trstenik; The city of Zrenjanin.	"JP Putevi Beograd" – The city of Belgrade.
Description: - Construction of a port and a road terminal; - Financing, construction and maintenance of local road infrastructure;	Description: - Financing the purchase, installation and maintenance of escalators and elevators for the disabled people, reconstruction and maintenance of parts of underground passages and the purchase, installation and connection of

- Financing, design, reconstruction, i.e. rehabilitation and maintenance of local road infrastructure.	digital cameras that provide "motorized remote position and zoom control", and equipment for recording and collecting traffic information and software for traffic management; - Financing of regular maintenance of horizontal traffic signalling in school zones in seven city municipalities of the city of Belgrade (Barajevo, Grocka, Lazarevac, Mladenovac, Obrenovac, Sopot, and Surčin).
2. Telecommunications	
PPP project proposal	**Proposal of the concession act**
"JKP Informatika Novi Sad" – The city of Novi Sad.	
Description: - Realization of the project of construction and extension of the existing open type optical telecommunication network according to the principle of FTTH (fibre to the home - optical fibre to the end user).	
3. Passenger transport	
PPP project proposal	**Proposal of the concession act**
The city of Belgrade; The city of Jagodina; "Javno komunalno preduzeće Direkcija za javni prevoz grada Niša" – The city of Niš; The city of Požarevac; The city of Užice; The city of Bor; The city of Kragujevac.	The city of Loznica; Municipality of Topola; Municipality of Srbobran; The city of Niš; The city of Jagodina; The city of Šabac; Municipality of Negotin; Municipality of Paraćin; The city of Belgrade; Municipality of Kanjiža; Municipality of Ruma; The city of Valjevo; Municipality of Lajkovac; Municipality of Koceljeva; The city of Pirot; Municipality of Bačka Palanka; Municipality of Ćuprija; Municipality of Knjaževac; Municipality of Kovin; The city of Smederevo; The city of Zaječar; The city of Kraljevo; Municipality of Sokobanja; The city of Novi Pazar; The city of Sremska Mitrovica; The city of Pančevo; Municipality of Šid; Municipality of Vladimirci; Municipality of Mali Zvornik; Municipality of Ljig; The city of Prokuplje; Municipality of Prijepolje; Municipality of Bačka Topola; Municipality of Bogatić; Municipality of Veliko Gradište; The city of Užice; Municipality of Kula; Municipality of Aleksinac; Municipality of Kuršumlija; Municipality of Medveđa; Municipality of Žagubica; The city of Kruševac; Municipality of Inđija; The city of Leskovac; Municipality of Kladovo; Municipality of Blace; Municipality of Kučevo; Highway E-763 Beograd-Požega.
Description: - Performance of communal activities of public urban and suburban passenger transportation.	Description: - Entrusting the performance of city-suburban passenger transportation activities; - Proposal for a concession act with an analysis of the financial and economic effects of granting a concession on the E-763 highway Belgrade-Požega.
4. Public lighting	
PPP project proposal	**Proposal of the concession act**
The city of Sremska Mitrovica; Municipality of Majdanpek; Municipality of Sremski Karlovci; Municipality of Sečanj; Municipality of Plandište; Municipality of Bor.	
Description: - Reconstruction of part of the public lighting system; - Reconstruction, replacement and installation of LED lamps, maintenance and management of the public lighting system; - Replacement of existing public lighting lamps with economical "LED" lamps in the zone of streets, parks, promenades, on public areas, external decorative lighting of public buildings and monuments in settlements.	
5. Energy consumption	

PPP project proposal	Proposal of the concession act
"Zdravstveni centar Negotin" - Municipality of Negotin; The city of Leskovac; The city of Vršac; The city of Subotica; "Javno komunalno preduzeće Standard Vrbas" – The city of Vrbas; The city of Zaječar; The city of Sombor; Municipality of Opovo; "JKP Gornji Milanovac" – Municipality of Gornji Milanovac; Municipality of Kula; The city of Vranje; The city of Bor; Municipality of Bačka Palanka; The city of Niš;	
Description: - Proposal for a PPP project for contractual delivery of thermal energy to the Negotin Health Center with the construction of a new biomass-fired boiler room and renovation of exterior carpentry; - Contractual supply of heat energy with the reconstruction of the heat production system; - PPP project proposal submitted by "JKP Gornji Milanovac", which proposes long-term delivery of thermal energy to the district heating system of "JKP Gornji Milanovac" from newly installed wood biomass boilers and hot water gas boilers; - PPP project proposal, proposing long-term delivery of thermal energy from newly installed gas-fired condensing boilers for ten public buildings in the municipality of Kula; - Contract delivery of heat energy with the construction of new boiler houses from renewable energy sources - wood biomass and natural gas; - Entrusting the performance of communal activities of production and distribution of thermal energy, with mandatory reconstruction of the district heating system; - Substitution of part of the production of thermal energy from fossil fuels (natural gas, heating oil and fuel oil), with contractual delivery of thermal energy from wood biomass.	

It can be concluded that, in the field of road infrastructure, the largest number of approved projects are in the form of PPP project proposals, while "JP Putevi Beograd" of the city of Belgrade are in the form of concession act proposal. Likewise, the largest number of approved projects in the form of concession act proposal is in the field of passenger transport (a total of 48 projects).

The fact that a large part of Serbian capital is foreign should not be overlooked, because Serbia like many other countries in development and transition, finds the key to economic development in foreign capital, or Foreign Direct Investments (FDI). Serbia has benefited significantly from trade and economic integration with the EU. The EU has traditionally been Serbia's key trade partner, accounting for more than 54% of Serbia's total trade in goods, in 2022 [13]. Thus, table 2 shows the largest foreign investors – donors in Serbia in 2022.

Table 2. The largest foreign investors – donors in Serbia in 2022

Source: EU u Srbiji [13]

EU	CEFTA[7]	China	Russia	SAD	Other countries
Total trade (billion EUR)	Total trade (billion EUR)	Total trade (billion EUR)	Total trade (billion EUR)	Total trade (billion EUR)	Total trade (billion EUR)
39.08	6.40	5.80	4.03	1.19	10.00

It can be concluded that, by far, the largest capital inflow comes from the EU (39.08 billion EUR).

[7] Central European Free Trade Agreement.

The following table (table 3) shows some of the PPPs and their estimated values in Serbia.

Table 3. Some of the PPPs in Serbia
Source: Public procurement portal of Serbia [14]

Purchaser	Procurement name	Type	Procedure	Estimated value	Publication date	Submission deadline
"Elektroprivreda Srbije" The city of Belgrade	Ventilation and air conditioning maintenance services	Services	Open	500.000,00	09.11.2023	01.12.2023
"Opštinska uprava opštine Apatin" The city of Apatin	Selection of private partner for implementation of PPP project for long-term delivery of heat energy for heating of 11 public facilities with reconstruction of production systems in the municipality of Apatin	Services	Open	590.709.451,00	25.10.2023	18.12.2023
Municipality of Šid	The selection of a private partner and the award of a PPP contract for the long-term supply of thermal energy for heating 24 public buildings with the reconstruction of the thermal energy production system in the municipality of Šid	Services	Open	660.147.206,00	21.10.2023	12.12.2023

	of a sports and recreational complex					
"Gradska uprava Pirot" The city of Pirot	Entrusting the performance of urban and suburban scheduled passenger transportation in the territory of the city of Pirot, PPP with concession elements	Services	Open	755.136.000,00	13.11.2020	12.01.2021

5. CONCLUSION

PPP implies long-term cooperation between the public and private sector to ensure financing, construction, reconstruction, management, or maintenance of infrastructural and other facilities of public importance and provision of services of public importance, which can be contractual or institutional [15]. The public and private partners invest in cooperation to ensure the reconstruction, financing, construction, maintenance of infrastructure or other facilities of public importance, etc. Nowadays, in Serbia, good practice in the terms of PPP projects is becoming increasingly stronger, which is a great success after twelve years since the adoption of the Law on Public-Private Partnership, in December 2011. As many as 272 PPP projects have been approved until 2023 by the CPPP, as in in the form of a PPP project proposal, as well as in the form of a concession act proposal. The largest number of projects are from the service sector, and they are open type projects. However, it is necessary to increase the number of these projects in the field of public lighting and road infrastructure in Serbia. A recommendation for future researchers would be a greater emphasis exclusively on the connection between PPP projects and economic growth on the example of Serbia and countries in the region.

THE THREATS AND OPPORTUNITIES IN MODERN FORWARDING BUSINESS

Marija Marčetić[1], Toplica Academy of Applied studies
Danijela Milošoska [2], Fakultet za turizam i ugostiteljstvo, University Sv. Kliment Ohridski
Bojan Kocić[3], Toplica Academy of Applied studies

Abstract: *It's important for forwarding businesses to stay informed about industry trends and adapt to changing conditions. A robust business strategy that addresses both threats and opportunities is essential for long-term success in this competitive field. In this paper, the items that threaten the business of the forwarding company and those items that open up new opportunities are systematically defined. The paper enables forwarding companies to more easily orient themselves towards successful business in this complex environment.*
Key words: forwarding business, logistics, international economy

1. INTRODUCTION

Modern forwarding businesses, also known as modern freight forwarding or logistics companies, are entities that specialize in facilitating the efficient movement of goods from one location to another, often across international borders [1]. These businesses have evolved to meet the demands of an increasingly globalized and technologically advanced world.
Modern forwarding businesses heavily rely on advanced digital technologies and software solutions. They use sophisticated logistics management systems, transportation tracking software, and communication tools to streamline operations, provide real-time visibility, and enhance efficiency.
Modern forwarding business leverage data analytics to optimize routing, improve supply chain visibility, and make informed decisions. Predictive analytics may be used to anticipate demand fluctuations and optimize resource allocation. Modern forwarders have a global presence and often operate in multiple countries. They have an extensive network of partners, agents, and carriers worldwide, allowing them to provide comprehensive shipping solutions. Offering a variety of transportation modes, including air freight, sea freight, road freight, and rail freight, they can seamlessly combine these modes to create efficient multimodal shipping solutions. [2].
Modern forwarders have a deep understanding of customs regulations and international trade compliance. They help clients navigate complex customs procedures, documentation, and tariff classification. Many modern forwarding businesses prioritize sustainability and implement eco-friendly practices in their operations. This includes optimizing routes to reduce emissions, using energy-efficient vehicles, and exploring alternative fuels [3]. They focus on providing exceptional customer service. Modern forwarders offer online booking and tracking systems, 24/7 customer support, and personalized solutions to meet the unique needs of each client. They offer end-to-end visibility into the supply chain, allowing clients to monitor the status and location of their shipments in real-time. This transparency helps clients make informed decisions and plan efficiently. Also modern forwarding businesses understand the importance of risk management, offering insurance solutions to protect shipments against loss or damage and have contingency plans in place for supply

[1] neimar.marija@gmail.com
[2] danijelamiloshoska@uklo.edu.mk
[3] bojankocic@yahoo.com

chain disruptions. These companies are committed to ongoing improvement and innovation. They invest in technology upgrades, process optimization, and employee training to stay competitive and provide top-notch service Very often they form strategic partnerships with carriers, customs brokers, and other logistics service providers to enhance their capabilities and offer a broader range of services. Modern forwarders offer flexible pricing models, including transparent pricing structures and customizable solutions, allowing clients to choose the services that best meet their needs and budget. In summary, modern forwarding businesses are at the forefront of the logistics industry, leveraging technology, global networks, and customer-centric approaches to provide efficient and reliable shipping and supply chain solutions in a rapidly changing world.

2. THE MAIN THREATS FOR FORWARDING BUSINESS

Running a forwarding business, also known as a freight forwarding or logistics business, can be lucrative, but it also comes with its fair share of challenges and problems. Here are some common problems in the forwarding business:

1. Regulatory Compliance: The logistics industry is heavily regulated, and forwarding businesses must navigate a complex web of rules and regulations, both domestically and internationally. Ensuring compliance with customs, import/export laws, and safety regulations can be challenging [4].
2. Fluctuating Freight Rates: Freight rates can be highly volatile, influenced by factors like fuel prices, demand-supply imbalances, and geopolitical events. These fluctuations can impact profitability and make it difficult to plan for the future [5].
3. Competition: The forwarding industry is highly competitive, with many players offering similar services. To stand out, businesses need to differentiate themselves through pricing, service quality, technology, and other means.
4. Infrastructure and Technology: Keeping up with the latest technology and infrastructure improvements is crucial. This includes modernizing warehousing, transportation, and communication systems to stay competitive and efficient.
5. Global Supply Chain Disruptions: Events such as natural disasters, pandemics, and geopolitical tensions can disrupt global supply chains. Forwarding companies must have contingency plans in place to deal with these disruptions and ensure the timely delivery of goods .
6. Cybersecurity Threats: As businesses rely more on digital systems for tracking and managing shipments, they become susceptible to cyberattacks. Protecting sensitive customer and shipment data is vital [6].
7. Environmental Concerns: With growing awareness of environmental issues, there is increasing pressure on the logistics industry to reduce its carbon footprint. Forwarding companies may face challenges in adopting more eco-friendly practices.
8. Customer Expectations: Customers expect real-time visibility into their shipments and efficient tracking systems. Meeting these expectations requires investment in advanced tracking technology and 24/7 customer support.
9. Talent Shortage: Finding and retaining skilled employees, such as logistics experts and drivers, can be a challenge. The labor shortage can affect the quality of service and overall operations.
10. Currency Fluctuations: International forwarding businesses are often affected by currency fluctuations, which can impact pricing and profit margins. Hedging strategies may be necessary to mitigate this risk.
11. Insurance Costs: The cost of insuring shipments can be significant, and it's essential to find the right balance between adequate coverage and cost control.
12. Customs and Documentation: Navigating customs requirements and handling documentation accurately and efficiently is crucial for international shipments. Errors or delays in this area can result in fines and shipment disruptions [7].

13. Supply Chain Complexity: As supply chains become more complex, with multiple suppliers and distribution points, managing the flow of goods can be challenging. Visibility and coordination are key issues. [8].
14. To succeed in the forwarding business, companies must be adaptable, technologically savvy, and capable of providing excellent customer service while navigating these challenges effectively. Staying informed about industry trends and continuously improving operations is vital for long-term success.

3. OPPORTUNITIES FOR MODERN FORWARDING BUSINESS

The forwarding business, like many industries, is continually evolving to adapt to changing global dynamics, technological advancements, and customer expectations. Several key trends are shaping the development of forwarding businesses:

1. Digital Transformation: Embracing digital technology is a fundamental trend. Forwarders are increasingly investing in advanced logistics management systems, data analytics, and automation to enhance efficiency, provide real-time tracking, and improve customer experiences. Digital technologies have automated various aspects of the forwarding process, from order processing to document management. This has reduced manual workloads, minimized errors, and improved overall efficiency. The digitization of documents such as bills of lading, invoices, and customs declarations has streamlined administrative tasks. It has also made it easier to share and access important documents in real time [9].
2. Advanced tracking and monitoring systems powered by GPS, RFID, and IoT (Internet of Things) devices allow forwarders and their clients to track the location and status of shipments in real time. This visibility enhances customer satisfaction and helps prevent delays.
3. Data Analytics: Data analytics tools enable forwarders to gain insights from vast amounts of data. They can use this information to optimize routes, improve inventory management, and make data-driven decisions for cost reduction and process optimization [10].
4. Supply Chain Visibility: Digital technology provides end-to-end visibility into the supply chain. Forwarders can track goods from the point of origin to the final destination, ensuring better control and the ability to address any issues promptly [11].
5. Warehouse Management Systems (WMS): WMS software helps forwarders efficiently manage inventory in warehouses. It provides features such as real-time stock tracking, order fulfillment automation, and demand forecasting [12].
6. Transportation Management Systems (TMS): TMS software helps optimize transportation logistics by assisting with route planning, carrier selection, load optimization, and real-time tracking. It can reduce transportation costs and improve delivery times. [13]
7. Customer Portals: Many forwarders offer customer portals or apps that provide clients with real-time access to shipment information, documentation, and analytics. This enhances transparency and customer satisfaction.
8. Artificial Intelligence (AI): AI and machine learning are being used to optimize routing, predict demand, and improve supply chain decision-making. Chat bots and virtual assistants also help provide quicker responses to customer inquiries. Digital technology allows forwarders to remotely monitor and control various aspects of the supply chain, including temperature-sensitive cargo, security systems, and equipment maintenance. It can help forwarders reduce their carbon footprint by optimizing routes for fuel efficiency, using electric vehicles, and implementing sustainable practices throughout the supply chain [14].
1. Blockchain for Transparency: Blockchain technology is gaining traction for enhancing transparency and security in supply chain transactions. It can be used to create unchangeable records of shipments, reducing fraud and errors. While blockchain offers many advantages, its widespread adoption in the forwarding business is still in progress. Challenges related to standardization, integration with existing systems, and regulatory acceptance need to be addressed (Ahmad2021). Nonetheless, forward-thinking companies are exploring blockchain

solutions to improve their operations, increase efficiency, and enhance the overall customer experience in the logistics and supply chain industry [15].

2. Sustainability and Eco-Friendly Practices: With growing environmental concerns, forwarders are adopting sustainable practices such as optimizing routes to reduce emissions, using alternative fuels, and implementing green packaging solutions.
3. Customized Solutions: Forwarders are offering more personalized and flexible solutions to meet the unique needs of their clients. This includes tailored shipping options, pricing models, and value-added services.
4. End-to-End Visibility: Providing complete supply chain visibility is crucial. Forwarders are using IoT (Internet of Things) devices and sensors to track shipments in real-time and offer clients greater control and transparency [16].
5. Predictive Analytics: Predictive analytics helps forwarders anticipate demand fluctuations, capacity constraints, and potential disruptions in the supply chain. This proactive approach can lead to better decision-making and cost savings [17].
6. Last-Mile Delivery Solutions: Innovations in last-mile delivery, including autonomous vehicles and drones, are being explored to improve the efficiency of delivering goods to the final destination.
7. E-commerce Integration: The growth of e-commerce has led to an increased demand for efficient logistics and forwarding services tailored to online retailers. Forwarders are integrating their systems with e-commerce platforms to provide seamless order fulfillment [18].
8. Regulatory Compliance: Forwarders are keeping a close eye on changing trade regulations and tariffs. Ensuring compliance with customs and trade regulations is essential to avoid delays and fines.
9. Collaborative Platforms: Collaborative platforms and marketplaces are emerging, allowing forwarders, carriers, and shippers to connect and transact more efficiently.
10. Alternative Energy Solutions: The exploration of alternative energy sources for transportation, such as electric and hydrogen-powered vehicles, is becoming more prominent as forwarders seek to reduce their carbon footprint.
11. Customer-Centric Approach: Customer expectations for convenience and transparency are driving forwarders to adopt a customer-centric approach. Online booking, real-time communication, and 24/7 support are becoming standard. [19].
12. Geopolitical Considerations: Forwarders are closely monitoring geopolitical developments that can impact trade routes, tariffs, and logistics operations.

To thrive in the forwarding business, companies need to stay agile, adapt to these trends, and continue to innovate in response to the evolving needs of their clients and the broader global logistics landscape. In summary, digital technology has revolutionized the forwarding business by improving efficiency, visibility, and customer service. As technology continues to advance, forwarders that embrace and adapt to these innovations will be better positioned to meet the evolving demands of the global logistics and supply chain industry.

4. CONCLUSION

The forwarding business, also known as freight forwarding or logistics, involves coordinating the shipment of goods from one location to another on behalf of clients. It plays a crucial role in global trade and commerce. In summary, the forwarding business offers a range of opportunities, from embracing technology and sustainability to specializing in specific industries or regions. Success in this industry often comes down to staying adaptable, customer-focused, and informed about industry trends and regulations. There is a huge range of threats in forwarding business, from regulatory compliance to global chain disruption. The sources of a forwarding company depends on navigating these challenges effectively.

CONTEMPORARY APPROACHES TO LEADERSHIP, MANAGEMENT, KNOWLEDGE AND INNOVATION

Jelena Pavlović[1], The Academy of Applied Technical Studies Belgrade
Dragica Stanković[2], Belgrade Banking Academy

Abstract: *In the highly dynamic contemporary business environment, it is crucial to keep up with and implement new technological processes. The traditional concept of business has become inadequate in the pursuit of gaining a competitive advantage in the market. Understanding digitalization has become vital for productivity and efficiency in achieving company goals. It significantly simplifies and improves performance in various fields, including business, education, project management, communication, and many other areas. This paper emphasizes the importance of a good leader-manager relationship as key to business success and corporate management. Leaders and managers perform different roles and have different qualities, as well as approaches in leading employees and achieving goals. A modern approach to business encompasses various aspects related to changes in how business is conducted, resulting from technological advancements, social changes, and market evolution. A contemporary approach to business implies dynamism, rapid changes, and openness to new ideas and strategies. Companies that successfully implement these principles are usually competitive and prepared to face potential future challenges.*
Keywords: leader, management, governance, organization, artificial intelligence

1. INTRODUCTION

Contemporary approaches to leadership and management require an open and flexible mind, a willingness to change, and the ability to efficiently manage resources and people in a dynamic business environment. Modern leadership is regarded as a process different from management. It is perceived as a process in which individuals other than managers can be leaders, with a focus on leader-follower interaction. This is a relationship that aims at the mutual achievement of a common purpose, not just the leader's purpose. Leadership is a process that seeks to bring about significant change, instead of solely achieving a current primary goal [1]. In the ever-changing modern business environment, a contemporary approach to leadership encompasses a range of new strategies to effectively lead organizations. Therefore, the leader's role and abilities are of great significance for the development of an organization and the attainment of a competitive advantage. Monitoring trends, continuous leader development and improvement, and acquiring new skills and knowledge, are integral parts of modern and effective organizational leadership. Technology and management are closely linked and both are essential aspects of any type of organization. Management deals with people, resources, and processes, while the implementation of emerging technologies results in improved productivity, efficiency, and faster goal achievement. Therefore, these are two inseparable aspects of modern business that bring about an organization's competitive advantage.
This paper will highlight some of the general characteristics of a good leader, as well as the importance of management, tracking, and implementing emerging technologies to ensure the success of company operations. In order to elevate the position of an organization, it is necessary to invest in research and development, the management of which is based on fundamental knowledge and

[1] jpavlovic@atssb.edu.rs
[2] dragica.stankovic@gmail.com

management principles [2]. The leader defines and guides the organization's strategy. They are responsible for shaping the vision, long-term goals, and action plans that will ensure the organization achieves its strategic purpose and objectives [3].

2. LEADERSHIP AND POWER

Leadership and the use of power are closely linked. Employees expect leaders to use power in order to achieve above-average performance. Leaders at all levels in the organizational structure must utilize power as employee loyalty is not assured [1]. There is no leadership without authority and influence.

As influence is a key element in the leadership process, power is an important capacity of leadership. Power is the ability to influence or shape the behavior of another social actor. Power is the "force" that drives the social system, or an organization [4]. By influencing someone's behavior, and often their attitudes, they are encouraged to perform the necessary activities accurately and in accordance with the company's needs and objectives. Leadership is also defined as the relationship between an individual and a group based on the influence gained through authority and power. Leaders who use their power responsibly and ethically can contribute to the development of an organization and its members. We will list a few key aspects of leaders' power and influence.

1) Legitimate Power: This type of power is derived from the leader's formal position or title within the organization. For example, a director, president, or manager holds a certain authority based on their position. Legitimate power is often the basis for decision-making and resource management.
2) Power of Reward: Leaders have the power to reward their followers, whether through financial incentives, promotions, recognition, or other forms of encouragement. This type of power can motivate and inspire employees to achieve their goals.
3) Coercive Power: Similar to Power of Reward, leaders have the power to punish employees for failure or disobedience. This type of power can be used to maintain order and discipline in the organization.
4) Charismatic Power: Charismatic leaders have a pronounced ability to inspire and attract their followers. Their influence stems from their personal qualities, charisma, and the ability to articulate their vision [4].
5) Expert Power: Leaders who possess exceptional knowledge, skills, or expertise in a particular field have Expert Power. Their influence stems from their ability to solve problems and make expert decisions.
6) Referent Power: This type of power is derived from the respect and esteem that leaders command among their followers. Leaders who are principled, ethical, and represent desired behavior acquire Referent Power [5].
7) Power of Influence and Persuasion: Leaders use their communication skills and argumentation to influence the thoughts and behaviors of others. The power of persuasion is often crucial for decision-making and achieving consensus within an organization [5].
8) Power of Networking and Social Connections: Leaders with strong connections and contacts in society or industry can leverage this networking power to attain support, resources, or information.

Leaders who use their power responsibly and ethically can contribute to the development of an organization and its members. However, the abuse of power may have negative consequences for organizational culture and employee motivation. It is important for leaders to be aware of their power and how they use it, in order to achieve positive results in the organization.

3. LEADERSHIP AND MANAGEMENT

Companies need both leaders and managers to achieve predetermined and planned goals. Leaders and managers perform different roles within organizations and have different qualities and approaches to

leading people and achieving goals. According to Kotter [5], leadership is comprised of three processes: conducting activities by developing the organization's vision, adjusting to the organization's vision through effective communication, and motivating and inspiring employees by empowering their activities despite potential barriers. In contrast to leadership, management consists of qualitatively different processes such as: planning and budgeting focused on establishing short-term goals, organizing and staffing by creating an organizational structure and allocating resources, controlling and problem-solving by monitoring the alignment of achieved results with previous plans [4,5].

Figure 1. The difference between a manager and a leader [6]
Source: https://liderioo.blogspot.com

It's important to emphasize that leadership and management are not the same concept, despite the fact that leadership is often associated with management and is crucial for management. A person can be a successful manager - a good planner and a fair, organized administrator - but lacks the motivational abilities of a leader. On the other hand, some may be successful leaders - capable of inspiring enthusiasm and loyalty - but lack the managerial skills to channel the energy they generate into others. In the modern world, many organizations consider it vital for managers to possess leadership skills [6].

4. INNOVATION AND ENTREPRENEURSHIP IN THE DIGITAL ERA

In the 21st century, the only certainty is that everything is uncertain. Furthermore, conducting business in such conditions, while dealing with increased risk and uncertainty, is a primary characteristic of entrepreneurial individuals [7]. Innovation requires introducing something new. This can entail products, technological processes, new organizational models, market offers, and so on. We often hear that we are living in the digital era. Digital innovations represent the application of emerging technologies and digital resources to enhance existing products, services, and business processes, or to create entirely new products and business models. These innovations play a crucial

role in modern business and society and can be applied across various sectors. We will provide a few examples of digital innovations and how their implementation affects a variety of areas.

a) E-commerce and M-commerce: Digital innovations are crucial in the development of e-commerce and mobile commerce. Online stores, digital shopping platforms, and mobile applications enable users to purchase products and services via the Internet and mobile devices. This has transformed the way retailers operate and consumers shop.
b) Financial Technology (Fintech): Digital innovations in finance encompass new payment methods, financial management, loans, and insurance. Fintech companies utilize technologies like blockchain, artificial intelligence, and mobile applications to enhance financial services and make them more accessible [8].
c) Healthcare: Digital innovations have led to the development of telemedicine services, mobile health tracking applications, electronic health records, and artificial intelligence for medical diagnosis. This has improved access to healthcare and facilitated health monitoring.
d) Education: Digital innovations have led to the development of online education, e-learning, and mobile learning applications. Learning Management Systems (LMS) make it easier for teachers and students to track and assess progress.
e) Transportation and Logistics: Smart cities, autonomous transportation, cargo tracking technologies, and route optimization are all outcomes of digital innovations. This can improve transportation efficiency and reduce environmental impact.
f) Artificial Intelligence and Machine Learning: These technologies enable computers to learn and improve their performance in various tasks. They are used in data analysis, pattern recognition, service personalization, and many other applications.
g) Blockchain Technology: This technology enables a secure and transparent way to store and exchange data. Its most well-known application is in cryptocurrencies, but it is also used for creating secure supply chains and data management.
h) Internet of Things (IoT): IoT refers to physical device networking with the aim of exchanging data and information. This technology is used in smart homes, smart cities, manufacturing, and other sectors.
i) 3D Printing: A digital innovation that enables the creation of physical objects layer by layer. It is used in manufacturing, medicine, and many other fields.

Companies and entrepreneurs who can leverage the advantages of these innovations are often more successful in the modern digital age. The digital era requires entrepreneurs to be flexible and quickly adapt to changes in technology and the market. Digitalization enables the creation of new business models, such as subscription services, freemium models, and other revenue-generation methods. Entrepreneurs face competition from around the world and must also be cautious about data security and the privacy of their clients.

5. APPLICATION OF ARTIFICIAL INTELLIGENCE (AI)

When it comes to the application of artificial intelligence in business, opinions are divided. Artificial intelligence facilitates work and life in many areas, but its rapid development, advancement, and implementation raise numerous security and ethical issues. The fact remains that its application can be a great help to leaders and managers in various ways. AI can analyze large amounts of data faster and more accurately than humans. Leaders can use AI to make better data-driven decisions, which contributes to efficiency and success. Routine and time-consuming tasks can be automated in favor of AI, freeing up time for leaders to think creatively and strategically. AI is used for resume analysis and identifying candidates that best fit specific positions, thereby streamlining the recruitment and selection process. It can also be used for developing personalized training and education for employees. Leaders can ensure that team members acquire relevant skills and knowledge. Through the use of virtual assistants, performance monitoring, and evaluation, AI can identify possible risks

and alert leaders to potential threats, allowing them to prepare for crisis situations in advance. Chatbots and conversational AI systems can enhance leaders' internal and external communication.
AI can assist leaders, but it cannot completely replace the human element in leadership, such as empathy, moral leadership, and creativity. AI should be used as a tool to support leaders in their activities and decision-making.
The primary modern trends for the development of AI systems include expert systems development and neural network development. Expert systems attempt to replicate human thinking patterns through symbols, while neural networks do so from a biological perspective, mimicking the structure of the human brain with the help of genetic algorithms. Many scientists are skeptical about the possibility of developing true AI. The functioning of human thought patterns is still not entirely understood, which is why the computer design of intelligent systems will remain fundamentally incapable of representing these unknown and complex processes for a long time to come [9].

6. CONCLUSION

With this paper, we have observed that the modern approach to leadership, management, knowledge, and innovation is deeply rooted in rapid technological changes. While technology plays the main role in this changing landscape, the human factor is irreplaceable in leadership and management. Empathy, communication, and moral leadership remain essential aspects of successful leadership. Rapid changes require leaders and managers to be continuously educated and ready to adapt to new situations and challenges. This includes developing skills in problem-solving, creativity, and decision-making. Keeping up with technological trends and innovations is crucial for the survival and growth of organizations in the modern business world. Leaders should encourage a culture of innovation and knowledge management to create a competitive advantage. Organizational structures are shifting towards greater horizontal communication and collaboration. Although leaders and managers have different roles and responsibilities, their collaboration and cooperation play a crucial role in achieving organizational goals. The link between leadership and management is essential for the organization's success.
Essentially, leaders and managers together form the "dream team" for managing an organization. Their close collaboration enables a balance between inspiration and execution, long-term goals, and day-to-day operations, which is the key to the success of an organization in today's complex business environment.

STYDY ON THE ATTITUDES OF ELECTRONIC BANKING USERS IN SERBIA

Marko Pavlović[1], The Academy of Applied Technical Studies Belgrade
Ana Petrović[2], The Academy of Applied Technical Studies Belgrade
Đorđe Pavlović[3], Western Serbia Academy, Valjevo Department, Valjevo

Abstract: *Global changes in the sphere of business as well as the development of technology create great opportunities in the banking sector and in this way banks improve their services, reduce business costs and improve their operating efficiency. The first development of new electronic banking services in Serbia took place in 2003, and until today they have experienced major transformations in terms of improving electronic banking platforms. However, since its inception, the development trend was very slow when compared to developed countries. These limitations are reflected in information illiteracy and the population`s lack of interest in the changes offered by the bank in the market for services. In recent years, and especially during the corona virus pandemic, the use of electronic and mobile banking has increased greatly. Banks have made some progress in terms of customer trust and promotion of new electronic services, all in order to have a positive impact on their users. In this paper, the authors described the history, development and use of electronic banking, and they conducted a research on the territory of Serbia with the aim of finding out what are the further directions of the development of electronic banking services.*
Keywords: electronic banking, development, research, bank and Serbia.

1. INTRODUCTION

The development of IT technology has had a positive effect on the expansion of business in all spheres of business. With the application of computer processing as well as the use of modern means of communication, changes have taken place in the world of business in all major companies. Electronic business developed slowly. The traditional form of business as well as paper documentation has been replaced by a new type of business. Today`s business is based on a contemporary modern digital platform that allows business transactions to be carried out electronically, which is called e-business [1]. Electronic business has proven to be applicable in practice and it is certainly preceded by the emergence of the Internet. The Internet represents the most developed global medium that has enabled faster, more accessible, affordable and mass communication. Internet technology has led to the fact that certain products and services on the basis of which the business operates are on the market, and thus they have acquired the element of information. Thus, electronic business represents the use of technological solutions both for the exchange of business information, as well as maintaining business contracts and conducting transactions with the use of modern devices. As evidence that electronic business affects business, we can see that hundreds of billions of sales and financial transactions are made in the world annually. That is why electronic business is a term that is recognizable in many different economic and state entities. Today there is e-commerce, e-government, e-banking, e-learning, e-health, etc. Electronic business is a process that is carried out with the help of a computer network and refers to a broader concept than electronic commerce, while electronic banking is only one area of electronic business [2]. New digital technologies allow banks to enter the market with the

[1] markopavlovic25101982@gmail.com
[2] apetrovic@atssb.edu.rs
[3] djordje.pavlovic@vipos.edu.rs

help of an electronic platform and thus move their business from their branches to the clients` premises that suit them best. Banking services are provided with the help of new distribution channels, i.e. the Internet [3]. Electronic banking is a system that provides clients with access from their computers and therefore general information about the services offered by the bank via the Internet [4]. Electronic banking represents the use of technology by the bank to connect with its clients and enables the provision of financial services [5]. Hence, electronic banking represents a set of several ways of performing financial transactions using information and telecommunication technologies. The most frequently used synonyms for electronic banking are internet banking, PC banking, online banking and home banking [6]. The most commonly used means for performing financial transactions in electronic banking are smart cards, payment cards, QR code, electronic wallet and digital money. U istraživanju autora In the research of the authors Vehapi et al., based on the values shown, it can be established that the respondents have the most favorable attitudes regarding the statement Using internet banking saves my time (AS = 4.53), while the most unfavorable views are expressed regarding the statement Internet banking enables quick response to customer complaints (AS = 3.72) [12]. While, Đekić and his colleagues point out that the use of the Internet in the Republic Serbia is showing increasingly intense growth, the domestic market has good initial characteristics for a more successful implementation of electronic banking [13]. The structure of this paper is as follows: in the second section, a literature review is presented. The third section provides information on the methodology used in this paper as well as the results obtained in this research. At the end of the paper, the authors proposed further research directions and guidelines that the management of the banking sector could use.

2. DEVELOPMENT OF ELECTRONIC BANKING IN SERBIA

Beginning in 2000, countries in transition are slowly starting to achieve growth in the use of electronic banking services [7]. The change in the banking sector began in 1992, but major changes began after 2000, when Serbia became ready for the arrival of foreign banks [8]. With the adoption of the Law on Payment Services on January 1st, 2003, and with the Decision on the electronic method of making payment transactions, which is contained in the Law, and the institutional conditions for the beginning of the development of electronic banking are enabled. All payment transactions were then transferred from the state to the banking [9]. In the last twenty years, a large number of reforms have been implemented in the financial sector in Serbia, and a significant reform was the development of electronic banking and the reform of the payment systems. The new Law on Payment Services was passed by the National Assembly of the Republic of Serbia, and its implementation began on October 8th, 2015 and this Law defines payment via the Internet and mobile applications. It has been completely modified according to the standards that are regulated in the countries of the European Union, so that Serbia has an efficient and modern payment system. The Law was adopted with the aim of improving and modernizing payment transactions in Serbia and establishing cooperation with foreign countries with the aim of introducing electronic money institutions. This Law introduced greater competition in the field of payment services, it introduced payment institutions and electronic money institution, regulated three areas: the payment system of Serbia, electronic money and payment transactions, and it also adopted the protection of financial services consumers and competitive market.

The development of electronic banking in Serbia is reflected in the installation of a greater number of ATMs, POS terminals, as well as the introduction of new payment instruments. The following cards are in use: VISA, Master, as well as the national DinaCard. Payment cards are starting to be used mostly when paying for goods and services and at ATMs. Every client has access to the bank and its services throughout the day, which is made possible by the electronic banking service. Banks have joined the new interbank settlement systems based on world principles, where they use RTGS systems, better known in our country as the SVP system for priority and large payments. For small payments in Serbia, the Clearing or SMP Small Payment System is applied.

3. RESEARCH METHODOLOGY AND RESULTS

The aim of the research is to examine the existing secondary sources on electronic banking and to indicate which elements are used the most. The primary aim of the research is to examine the presence of electronic banking in Serbia based on the users` opinions, as well as what are the advantages and disadvantages of electronic banking. Based on the report of the National Bank of Serbia, the indicator is that the number of card transactions and electronic money transactions which were used for purchasing goods and services online, has increased. Thus, in the first trimester of 2023, a total of 12,489,426 transactions of goods and services were made online with cards and electronic money in all currencies, which is 25.42% more than in the first trimester of 2022 [10]. In the research of Todić et al. (2018), it was concluded that 62% of respondents use mobile banking services, while 74% are satisfied with mobile banking services [11]. The initial hypothesis is: H_0 A large number of respondents use e-banking. H1 The e-banking users have full confidence in this system. H2 Users believe that the technical part of the application should be improved in the future.

The total sample consists of 150 respondents. The survey was conducted online in the period from the beginning of January to the end of February 2023. Below is a tabular representation of the structure of the sample in relation to the gender of the respondents.

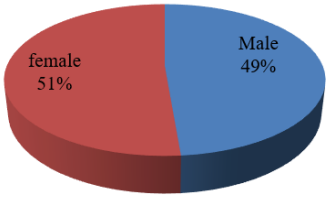

Figure 1 Sample structure with regard to the gender of the respondents
Source: Authors

With regard to the gender of the respondents, the highest response was among female respondents, but this difference was not significant. The following figure shows the structure of the respondents in relation to the age structure.

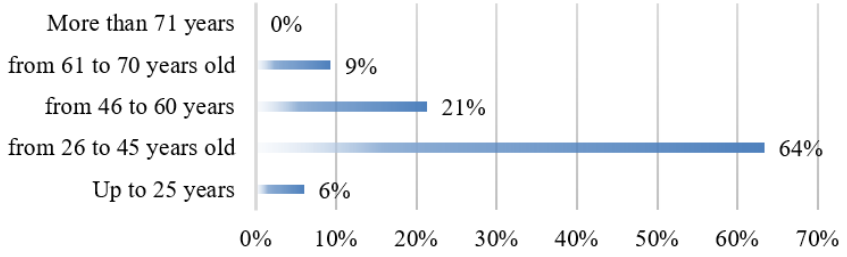

Figure 2 Sample structure with regard to the age of the respondents
Source: Authors

As far as the age population is concerned, the highest response was among respondents in the 26 to 45 age range. Figure 3 shows the structure of the respondents in relation to the educational level of the respondents.

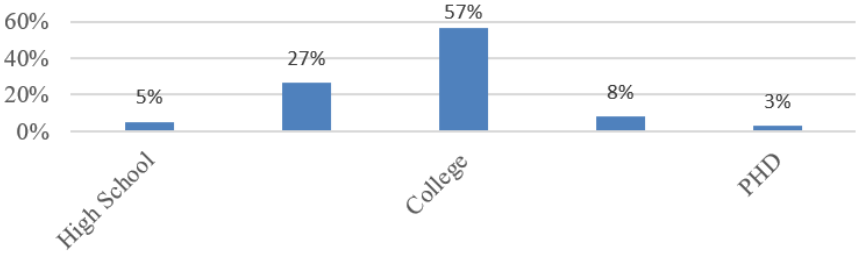

Figure 3 Sample structure with regard to the educational level
Source: Authors

From the aforementioned reseach, we can conclude that college graduates use electronic banking services most often. Educated respondents mostly use electronic banking. Figure number 4 shows the structure of the respondents in relation to the place of residence of the respondents.

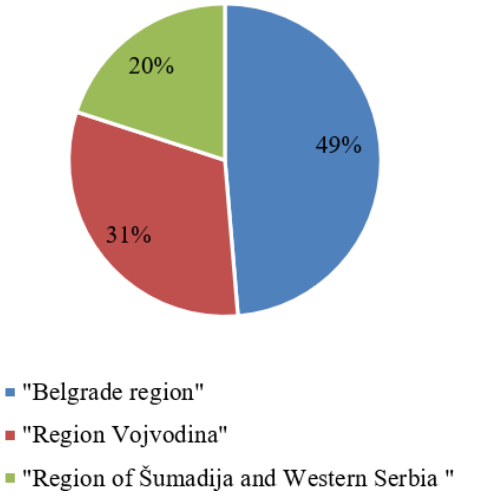

Figure 4 Sample structure with regard to the respondents` places of residence
Source: Authors

In relation to the place of residence, the largest number of respondents were from the capital which is also the main financial centre. The following figure 5 shows the structure of the sample in relation to the height of the monthly peaks.

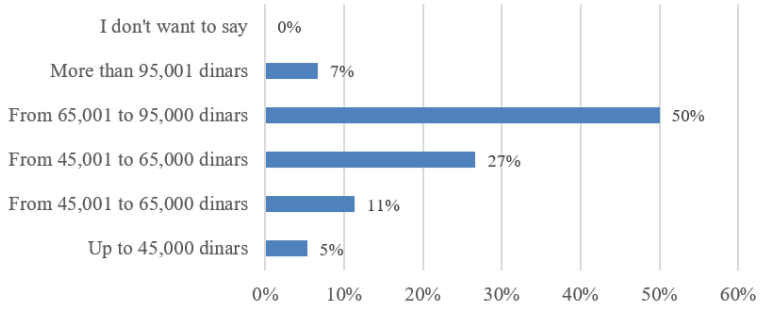

Figure 5 Sample structure with regard to the amount of monthly income
Source: Authors

The obtained results show that most respondents have incomes from 65,001 to 95,000.00 dinars. The following figure number 6 shows the structure of the respondents in relation to the working status of the respondents.

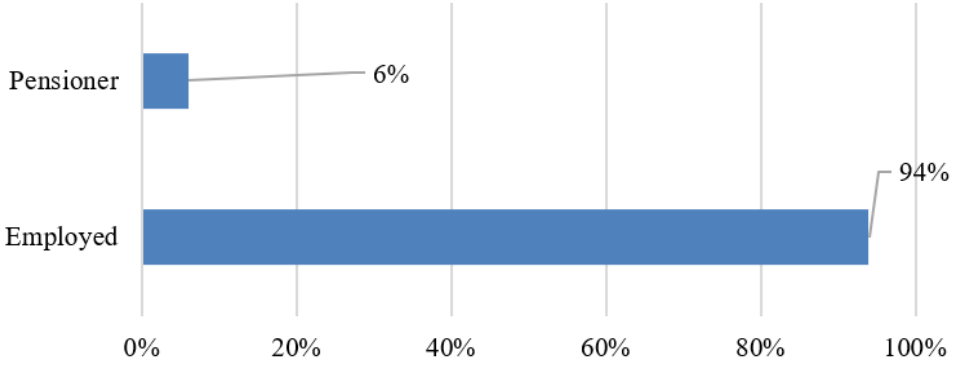

Figure 6 Sample structure with regard to the employment status of the respondents
Source: Authors

When we analyse the employment status, the majority of the respondents are employed. Figure 7 shows the percentage of respondents who have a bank account.

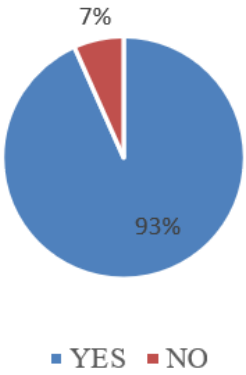

Figure 7 Do you have a bank account?
Source: Authors

We came to the result, after the analysis, that almost all respondents have bank accounts. The following 8 shows the structure of respondents who use electronic banking services.

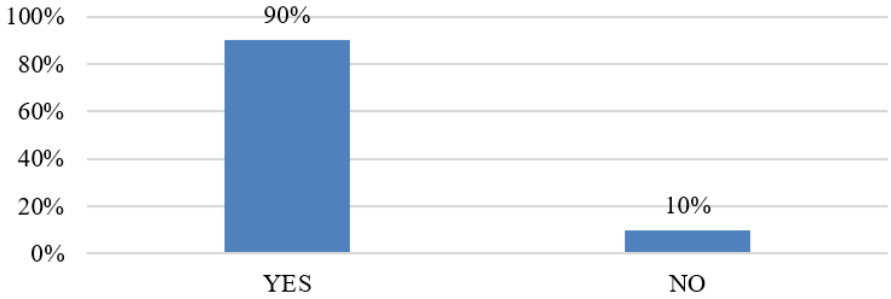

Figure 8 Do you use electronic banking?
Source: Authors

Based on the answers to this question, over 90% use e-banking. Figure 9 shows the structure of respondents in relation to the lack of electronic banking.

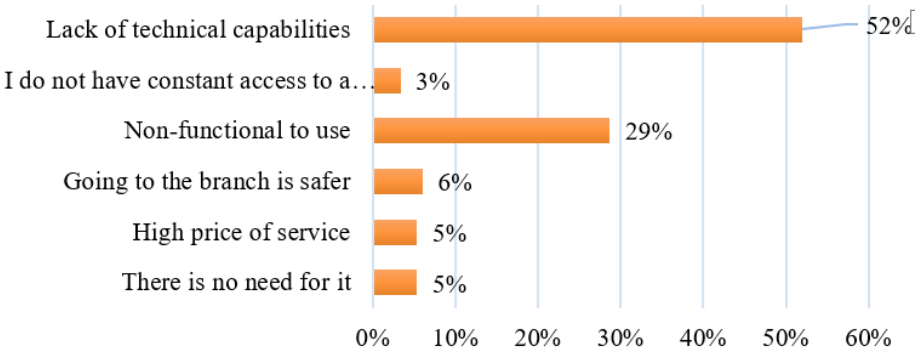

Figure 9 What do you consider to be the biggest disadvantage of e-banking?
Source: Authors

The majority of respondents believe that in the coming period banks could improve the technical characteristics of electronic banking, as they are considered as shortcomings. They include ease of use, privacy, execution of payment orders. The biggest problem is that temporary employees cannot use all electronic banking services. Many banks have merged in Serbia. For this reason, most transactions made through electronic banking are not stored.
The largest number of respondents, 32%, use electronic banking services two to three times a month, and 29% use it once a month. The following figure number 10 shows the structure of the sample in relation to the respondents' opinion as the most important element of electronic banking.

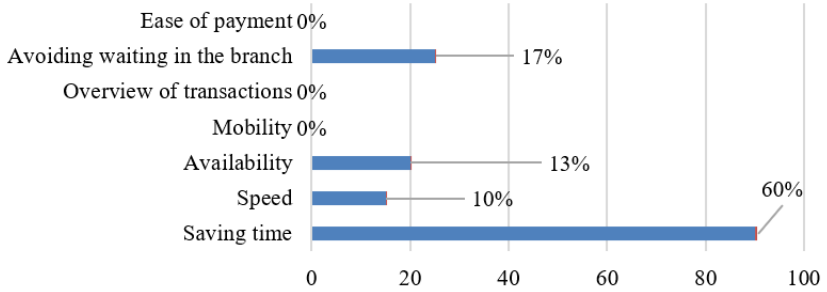

Figure 10 What is the most important element of electronic banking for you?
Source: Authors

The most important element of e-banking is saving time. Analysing the extent to which the respondents are satisfied with the e-banking service, 73% of respondents gave it the highest rating. When asked in which bank they have accounts, the largest number of respondents have accounts in the following banks: Intesa 39.2%, Postal Savings Bank 32.9%, Raiffeisen Bank 18.1%, while slightly less than 10% have accounts in other banks. When asked if they have paid for services by e-banking, almost 95% of respondents answered affirmatively. To the question related to security, trust and data protection, 59.3% of respondents expressed satisfaction, 22.5% respondents were satisfied with data protection, and 18.2% of respondents are in the middle and are not sure if their banks keep information about them. When asked whether they think that e-banking will replace traditional banking, 72.1% of respondents answered affirmatively. When asked if they would recommend e-banking, 52.6% of respondents answered affirmatively.
H_0 A large number of respondents use e-banking wass confirmed in the research. H1 The e-banking users have full confidence in this system was confirmed in the research. H2 Users believe that the technical part of the application should be improved in the future the same is confirmed in table number 9. In the coming period, banks will adapt and introduce new electronic services. Traditional banking will exist to a minimal extent.

4 CONCLUSION

The practice of using internet banking services has become an immanent part of the everyday life of the average banking client in developed countries. Although with some delay, similar trends are also noticeable in developing countries. The improvement of the range, quality, level and convenience of using banking services are the consequences of the introduction and development of internet banking and the key reasons for the growth of its market share. Clients of electronic banking are becoming more aware of the benefits it provides. This is indicated by the growth indicators of the number of users. We should not ignore the fact that electronic banking is still not sufficiently implemented in an adequate manner in Serbia. This refers to certain services that most banks do not currently provide. With the epidemiological situation that affected the world and Serbia, the population quickly adapted to the new ways of bank operations. Even before the corona virus, banks were ready for this type of business and relationship with their clients. Today, e-banking is becoming a synonym and is applied in all spheres of banking business. Based on primary and secondary sources, we can conclude that the young population uses e-banking, but not to the extent that banks expect. In Serbia, electronic banking is expanding and its maximum has not been reached yet. Only some banks in Serbia operate online (these are Yettel and Pro Credit Bank). Other banks tend towards online business. Certainly, in Serbia and the neighbouring countries, it is impossible to imagine bank operations without traditional banking for the time being. In the coming period, a large number of banks will merge, and banks should improve and simplify e-banking platforms. Further research, as well as marketing activities, should be focused on young people so that they animate older population to adapt as much as possible to today`s needs. Also, it is necessary to examine the legal regulation of electronic banking. When it comes to the limitations of the conducted research, it should be emphasized that the research sample was relatively small, and future research should include a larger sample of

respondents. It is a convenience sample in which respondents of all age groups participated and all regions of Serbia were included.

NEW TECHNOLOGIES, LABOR MARKET AND HUMAN RESOURCES

Jelena Pavlović[1], The Academy of Applied Technical Studies Belgrade
Dragica Stanković[2], Belgrade Banking Academy

Abstract: *Continuous adaptation of company size and internal configuration to the demands of social, technical, technological, and market factors is conditioned by dynamic changes in their external environment, which leads to endless alteration of a company's existing position. A company can enhance its position by actively influencing external environmental factors through an appropriate response to challenges and opportunities from its environment. As a result of such behavior, the company enters a process of growth and development. Company growth is the process of increasing the size of an enterprise and can manifest as an increase in: the number of employees, strength and installed capacity, total revenue, market share, profit, and so on. The process of company growth, as an uncertain consequence of its efforts to improve its position, often leads to diversification of the company's activities, changes in its organizational structure, and other adaptive changes.*
Keywords: emerging technologies, labor market, human resources, manager

1. INTRODUCTION

Emerging technologies bring significant challenges and have a profound impact on the global labor market. One of the greatest contemporary challenges is the need for the development of new skills and knowledge of employees. Managers play a crucial role in management and organization, and should therefore be prepared for change and having to adapt to new challenges. Developing a strategy with an innovative approach to hiring and candidate selection facilitates the identification of talents that can contribute to the success of an organization in the modern business environment. Additionally, the challenges brought about by automation and artificial intelligence in terms of employment should be taken into consideration. These technologies may lead to increased productivity and efficiency, but may also lead to workplace redundancy. In the modern business environment, company growth and development are directly linked to technological advancements and changes in the labor market. Companies that adapt to emerging technologies and market demands can achieve long-term vitality and competitiveness in their respective industry. In this regard, managers play a crucial role in the development and implementation of emerging technologies in business. They must be ready to recognize and seize new opportunities while developing new skills and competencies for managing employees in the modern business environment [1]. As a result, the growth and development of a company must be observed together, while taking into consideration their mutual interaction and synergistic effects. In this context, the analysis of a company's growth and development processes, in addition to their relationship with technological advancements and the labor market, is crucial for devising effective company development strategies and success in modern business. Companies that aim for long-term digitalization should consider their organizational structure, accumulation capacity, and size as part of the growth and development process. There are two elementary forms of growth and development [1]: directed development, which is the result of a company adapting to market changes, and autonomous development, which entails a proactive response to market changes and adopting innovation. However, in the real world, the distinction

[1] jpavlovic@atssb.edu.rs
[2] dragica.stankovic90@gmail.com

between these two forms of development is often unclear, as there are numerous transitional forms. Companies should analyze the functionality of development factors when forming their development policies and strategies. In this regard, the role of the technology market is crucial in shaping the company's development strategy.

2. PREREQUISITES FOR THE PREPARATION AND LAUNCH OF MODERN APPROACHES TO EMERGING TECHNOLOGIES

In order to prepare and implement modern approaches to emerging technologies, certain prerequisites must be met. This includes, first and foremost, understanding and assessing market needs, as well as identifying industry trends that can be utilized to enhance existing products and services. It is also necessary to secure financial resources for the implementation of emerging technologies, as well as skilled personnel responsible for the aforementioned implementation and maintenance. Additionally, it is vital to have a clearly defined development strategy focused on the company's long-term goals and building relationships with key partners and suppliers in order to achieve synergistic effects. All of these prerequisites must be carefully planned and calibrated to ensure the successful adoption of emerging technologies and the creation of a competitive advantage in the market. A company conducts various activities during its business operations to maintain and improve its market position. These activities are a result of the company’s need to adjust to the demands of its environment, primarily the market, and they manifest as changes in the type and scope of operations, product range, organizational structure, and technological foundation. Company development is a process of adaptation to changes and environmental requirements. To make this process efficient, the company must identify the factors influencing its development, as well as the key characteristics of these factors [1]. Taking this into consideration, the company conducts suitable activities in accordance with its capabilities, needs, and business objectives. It is important to differentiate between factors depending on their impact on the company's business operations. One group of factors may pose a challenge and, if adopted, an opportunity for development and prosperity. Another group may include factors that, if not accordingly taken into account, could pose a threat to the company's business operations and lead to its cessation. However, the same factor can be both an opportunity and a threat to the company's business operations. Should a company fail to monitor contemporary technological trends in its field of business, it will jeopardize its competitive position and survival.

A series of activities should be conducted in order to maintain and enhance the market position of a company. These activities arise as a result of the company's response to the demands of its environment, primarily the market, and are manifested through changes in the type and scope of operations, product range, organizational structure, and technical and technological foundation. The aforementioned changes reflect the company's ability to adapt and change according to the demands of its environment and depending on its capabilities and conditions for survival, alongside market position improvement. Company development represents the process of approaching modifications and environmental requirements. For this process to be effective, the company must identify the factors influencing its development, as well as the fundamental characteristics of these factors.

3. THE IMPACT OF EMERGING TECHNOLOGIES ON THE LABOR MARKET

Emerging technologies such as artificial intelligence, automation, blockchain, etc. have had a significant impact on the labor market and the way employees prepare for new jobs and challenges. The impact of emerging technologies on both unemployment and employment rates can differ depending on the industry sector and areas of business. Automation and artificial intelligence can have a significant impact on unemployment rates in sectors where jobs are repetitive and require manual labor. Such jobs are prone to a reduction in the human workforce in favor of machines. On the other hand, the use of new technologies also creates new jobs that require different skills and qualifications, which in turn leads to changes in the qualifications sought after in the labor market. For example, increased use of artificial intelligence, data analysis, and machine learning is driving up

demand for experts in these fields. Additionally, blockchain technology has the potential to affect unemployment rates in the finance sector, as it can automate many processes and reduce the need for human labor. Emerging technologies also affect different sectors in different ways. For example, the manufacturing sector has already undergone significant changes with the use of automation in production lines, while the education and healthcare sectors are still undergoing changes due to the increased implementation of emerging technologies. In any case, the impact and introduction of emerging technologies to the labor market and employment will vary depending on the industrial sector. Therefore, managers must be prepared to adapt to new technological trends and develop new skills to successfully manage employees in a new business environment.

In the late 1970s, the emergence and introduction of information and communication technologies caused a change in the way many organizations conducted their business. The development of the first communication media, such as the telephone and the fax machine, was followed by the advancement of computers and sophisticated forms of high technology, such as computer network systems, optical technology, satellites, and wireless technologies. Electronic business and the Internet have become indispensable in today's globally interconnected business world, altering the very concept of business. Nearly every major organization today has developed its own intranet, an internal organizational communication network that uses Internet technology and is accessible only to employees. Not only does this significantly contribute to the collection and distribution of knowledge, but it also facilitates and accelerates the decision-making process in business. The use of information and communication technology and modern information systems in business can be observed at three levels: at the production level, at the organizational level including management, and at the general level, which refers to broader global application. Management Information Systems (MIS) provide the information that organizations require for efficient and effective management. These are computer systems used for the analysis and facilitation of strategic and operational activities, providing managers with the data required to make decisions and solve problems. The Enterprise Resource Planning (ERP) system is a business management software that a company can use to store and manage data from every phase of its operations.

Technology has a significant impact on organizational behavior, and management must keep pace with and adopt technological changes while simultaneously aligning technological and sociological aspects. People, both employees and customers, should be regarded as crucial organizational resources, and management should not prioritize technology over them. Technological development and new forms of business that may emerge in the future could significantly change the existing forms of many organizations. Small, technologically advanced organizations boast organic structures and work in teams of highly skilled professionals who create new products and improve existing ones through better communication and collaboration among employees. It is imperative to monitor technological changes and align them with the needs of both employees and customers, in order to enable the organization to successfully adapt to new challenges and remain competitive in the market.

4. NEW ORGANIZATIONAL STRUCTURES THAT HAVE APPEARED IN THE MARKET DUE TO EMERGING TECHNOLOGIES

Lately, technological progress has led to the creation of new organizational structures. Rapid technological changes, international trade, and competition have put pressure on organizations' ability to keep up with new and often unpredictable competitors. Therefore, senior managers in many organizations are engaged in the development of new structural possibilities. New organizational structures arise from technological innovations that lead to "creative destruction of the industry" or technological advancement that replaces existing competencies. There are two outcomes of the search for new competitive approaches [2]:

1. The creation of a new organizational structure that requires a unique combination of strategy, composition, and management processes, i.e., a dynamic network. This new structure is both the cause and the consequence of the competitive modern environment, as the "same competitive

beast" that some companies do not understand serves as a solution to the competitive challenges of other companies.

2. The new organizational structure necessitates the development of new concepts that explain the meaning and functions within this process while providing fresh insights into the functioning of existing strategies and structures. In the future, many organizations will be designed using concepts such as vertical disintegration, internal and external intermediation, complete information system transparency, and market failures against administrative mechanisms.

The new organizational structure is both the cause and effect of the changing competitive nature; therefore, many organizations believe that their structure and management require modification for the organization to formulate new strategies that would meet the latest competitive conditions [3]. In this chapter, various new structural designs are typically described, such as: team-based organizational structure, network organizational structure, digital organizational structure, and T-shaped organizational structure.

4.1 Team-based organizational structure

The team-based organization is one of the latest approaches to creating an organization. It places teams at the center of the organization, leading to increased organizational dynamism. Team-based organization breaks down the barriers between certain organizational units or parts of the organization and makes the organizational structure more flexible [4]. Team structures are often used to eliminate possible weaknesses in organizational functioning, and many globally recognized companies incorporate them into their preexisting structure. The need to strengthen horizontal connections within the organization and create greater flexibility leads to the formation of various types of teams focused on solving different problems. In a team-based organization, the teams are important for achieving a joint work result, while bringing together people with different ideas and knowledge to solve a specific problem. Teams provide the organization with the necessary flexibility to respond more quickly and efficiently to the demands of a constantly changing environment, while simultaneously serving as a mechanism that gathers the knowledge and skills needed to solve complex work tasks. A team's success requires a joint purpose, a shared approach, mutual accountability, as well as complementary knowledge and skills [5]. The team-based organization is one of the latest approaches to creating organizations. In such an arrangement, teams take center stage, contributing to the company's dynamism. Team organization allows for the removal of boundaries between individual organizational units and makes the organizational structure more flexible. Team structure is most commonly used to eliminate functional structure weaknesses by introducing organic structure elements into existing organizational models. For a team to operate successfully, team members must share a common purpose and approach. Additionally, a team should practice mutual accountability and possess complementary knowledge and skills. The size of the team is also important, with an optimal range of two to ten members. Teams can be formed at different levels and in various parts of the organization. The most common types include advisory, action, project, cross-functional, production, self-managing, and virtual teams [4]. Based on the provided information, it can be concluded that teamwork is being increasingly used in many modern organizations. The team-based organizational structure typically consists of various teams that coordinate their activities and collaborate directly with partners and customers with the aim of achieving objectives [5]. In this organizational model, the hierarchy is notably flat (Figure 1).

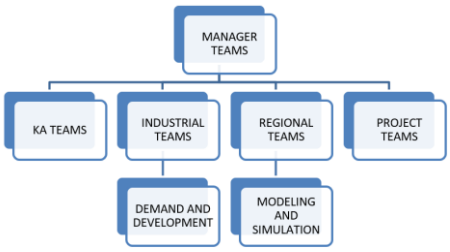

Figure 1. Global team organizational structure
Source: https://shorturl.at/nBLU9, (Accessed: 1 Apr. 2023)

In team-based organizations, as in all other modern forms of organization, information technologies play a significant role in team member relationships and performance [5].

4.2. Digital organizational structure

There are various definitions and descriptions of digital organizations that differ from one another, but they all use terms such as the absence of a physical structure, reliance on information and communication technology, transcending traditional boundaries, networks, mobility, and flexibility. A digital organization is considered to be a temporary network of participants (which can include entire organizations, parts of organizations, teams, or specific individuals) connected by information and communication technology, who flexibly coordinate their activities and combine their knowledge and resources to achieve common goals, without relying on traditional hierarchical structures of centralized direction and control. The coordinating entity in a digital organization is the organization itself, by using information and communication systems to synchronize all activities in the digital network. Both in practice and in the business world, we encounter several types of digitalization, ranging from long-distance outsourcing to employees using only the phone and email for global communication. Significant types of digital organization that are most commonly observed include digital products and services, remote work, mobility, and digital teams [6].

4.3 Network organizational structure

Outsourcing has led to organizations retaining solely their core activities while forming networks with their outsourcing partners to better respond to customer demands for a comprehensive product or service. Networking is the way a virtual organization is realized. It emerges as a response to the more complex business conditions and the increasing speed of change in business operations. Given the progressively complex and unpredictable environment in which modern enterprises operate, a growing number of companies are resorting to networks or a network organizational structure, whereby they find protection from market uncertainty. The network organizational structure is regarded as the most modern 21st-century organizational form; it is rapidly expanding, and due to the unlimited possibilities of entering and exiting the network, it is considered an organization without borders [7]. As a rule, a network organization lacks structure, while members of the network typically operate in a flat organizational structure. Enterprises connect in various ways, which is why there are networks with chain, networking, or multi-channel network forms. In a chain network form, only a certain number of network members have direct connections, while others have only indirect ones. In a networking network form, there is a key member who plays a crucial role in the network and is connected to the other members (Figure 2). A multi-channel network form is modular and flexible, making it a dynamic organization with open membership which, although imperceptible, connects all its members via computers. The biggest advantage of this network form is its adaptability, which allows gathering an amount of knowledge otherwise impossible in any individual enterprise.

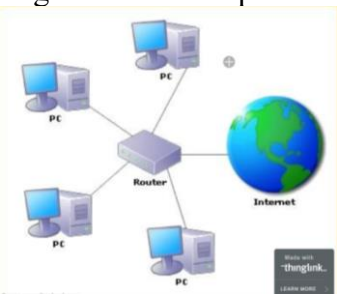

Figure 2. Network organizational form - networking
Source: https://shorturl.at/axzNT (Accessed: 2 Apr. 2023)

Organizational networking is considered one of the most important trends in the modern business environment, and its primary purpose is to reduce uncertainty and risks that are increasingly present in the organizational environment [7].

4.4 T-shaped organizational structure

The T-shaped organizational structure represents a fusion of traditional physical organization and digital components that include customers, suppliers, competitors, strategic agreements, and other partners. By establishing a digital organization structure, everything that was once handled with traditional paperwork is replaced with digital records and electronic connections. This enables a connection between customers and suppliers, ensuring the delivery of goods to the customer on a "Just in Time" basis [8]. The key characteristics and advantages of the T-shaped organizational form, or technological organization, include a high degree of managerial freedom in shaping the organizational structure, the ability for management to communicate with a much larger number of associates, significant organizational flexibility, electronic (digital) connections between customers and suppliers, trust-based rather than control-based supervision, replacement of functional units in favor of project teams, comprehensive education, and a focus on customer satisfaction [5]. The matrix organizational structure, which was temporarily neglected due to conflicts between line and project management, has been reintroduced as a result of information technologies providing it with positive change and flexibility [5]. Along with the advantages offered by the T-shaped organizational structure, such as project teamwork, merging organizations in strategic clusters, the establishment of digital departments, and remote work, internal organizational conditions are developed. Furthermore, digital communication and remote employee supervision are established. However, a key disadvantage of the T-shaped organizational form is its dependence on external partners.

5. CONCLUSION

The previous chapters of this paper discussed new technologies, and touched upon various descriptions of organizational structures and networked organizations, along with the impact of information and communication technologies on organizations and employees. It is evident that modern technologies have created not only new challenges, but also new opportunities for employees, and that managers are a key factor in motivating and retaining quality employees in the modern business environment. Additionally, through examples of different organizational structures, this paper has observed the different ways in which emerging technologies are used in business organizations and how they can affect organization efficiency and flexibility. In the modern business era, the implementation of new technologies can help automate routine tasks, freeing up space for innovation and creativity. Managers must keep up with innovation development and adopt the latest digital tools. In order to increase productivity and maintain adequate productivity levels, managers must be sufficiently tech-savvy to effectively apply emerging technologies, work with digital tools, and understand the development of a digital strategy. Additionally, emerging technologies enable enhanced collaboration and communication on a global scale, the development and presentation of the latest products, and networking with business partners on a global scale.

THE IMPACT OF THE KELVIN REDEFINITION WITHIN THE SI SYSTEM ON THE IMPROVEMENT OF TEMPERATURE MEASUREMENT TECHNOLOGIES

Zorica Baroš[1], The Academy of Applied Technical Studies Belgrade

Abstract: *In May 2019, four of the seven base units of the International System of Units (the SI): the kilogram, the ampere, the kelvin and the mol, were redefined in terms of fundamental physical constants. The SI unit of thermodynamic temperature, the kelvin, symbol K, is no longer based on an exact value for the temperature of the triple point of water (T_{TPW} = 273.16 K), but instead on a fixed value of the Boltzmann constant ($k = 1.380\ 649 \times 10^{-23}$ J K^{-1}).*
The kelvin redefinition led to the development of primary-thermometry methods and the realization of first practical thermometers linked to the redefined kelvin. An early version of such thermometers are the so-called Johnson noise thermometers. It is predicted that with the development of Johnson noise thermometry (JNT), the need to calibrate conventional temperature sensors, such as thermocouples or platinum resistance thermometers, will eventually become unnecessary due to the fact that this primary temperature measurement technique is not subject to sensor drift. Therefore, in this paper, advances in Johnson noise thermometry and its perspective both for metrological measurements and for practical application in industry, were discussed.
Keywords: kelvin redefinition, triple point of water, energy of molecular motion, thermodynamic temperature scale, Johnson-noise thermometry

1. INTRODUCTION

Temperature, a fundamental physical quantity, plays a significant role in various aspects of our lives, from scientific researches and medical diagnosis to industrial processes and everyday comfort [1]. For example, in industrial production processes, accurate temperature measurements are necessary to control product quality, optimize production and ensure product consistency.
Measuring temperature has a long history. In the 3rd century BC, the ancient Greek engineer Philo of Byzantium (c. 280–c. 230 BC) came up with what may be the first thermometer-like device: a hollow sphere filled with air and water, connected by tube to an open-air pitcher. The idea was that the air inside the sphere would expand as it was heated (e.g. if the sphere is exposed to the sun) and bubbles will be released, pushing water into the tube. Conversely, when the sphere is moved into shade, the air inside the sphere would contract due to cooling and water rises in the tube. It was later noticed that the air contracted in volume by about one third as the sphere was cooled from the boiling temperature of water to the ice point. This caused scientists to speculate on what would happen if one could keep cooling the sphere [2,3]. In the middle of the 19th century, British physicist William Thomson, 1st Baron Kelvin (1824–1907), also became interested in the idea of „infinite cold“, a state we now call the absolute zero of temperature. He estimated that absolute zero was approximately –273 degrees on the Celsius scale (–273 °C). In honor of his research, the unit of absolute temperature scale, the kelvin, is named after him [2]. Likewise, the Kelvin scale or absolute temperature scale is recognized as the international standard for scientific temperature measurement. The null point of the Kelvin scale (0 K) is absolute zero temperature, known as the lowest possible temperature in universe. This is the point at which the particles in a substance stop moving

[1] zbaros@atssb.edu.rs

entirely and all disorder disappears. Thus, nothing can be colder than absolute zero on the Kelvin temperature scale.
When Lord Kelvin carried out his research, the kinetic molecular theory, according to which all substances were made of extremely small particles called molecules in ceaseless motion, was not yet universally accepted. Nowadays, it is well known that temperature is a measure of the average kinetic energy of the molecules in a substance, and absolute zero corresponds to the lowest possible temperature, a state in which the thermal movement of molecules has stopped [2]. After the revision of the SI basic units, starting from May 20th, 2019, the temperature is defined in terms of the molecular motion energy, also called thermal energy (kT), where k is the Boltzmann constant. This way, the implemented redefinition of the SI base unit kelvin provided the possibility of using modern technologies for measuring temperature in a wide range. Furthermore, new approaches for realization of the measuring unit of the thermodynamic temperature scale, the kelvin, are now mainly based on quantum effects with the highest accuracy.

2. NEW DEFINITION OF THE KELVIN AND ITS PRACTICAL REALIZATION

2.1 Redefinition of the SI base unit kelvin and its impact on temperature scales in practical use

At the 10th General Conference on Weights and Measures (*Conférence Générale des Poids et Mesures*, or shortly, CGPM), in 1954, the thermodynamic temperature scale is defined by choosing the triple point of water (TPW) as the fundamental fixed point, and assigning to it the temperature T_{TPW} = 273.16 K, exactly [4]. Later, at the 13th CGPM in 1967, the kelvin, unit of thermodynamic temperature is defined as „*the fraction 1/273.16 of the thermodynamic temperature of the triple point of water*“ [4,5].
The TPW is the unique physical state of water in which all three phases (solid, liquid and vapour) coexist at thermodynamic equilibrium [6]. In practice, it is realized by using TPW cells [7] (see **Figure 1**), in sealed borosilicate glass or fused-silica-envelopes containing approximately half a liter of high-purity water having approximately the isotopic composition of the so-called Vienna Standard Mean Ocean Water (VSMOW): 0.00015576 mole of ^{2}H per mole of ^{1}H, 0.0003799 mole of ^{17}O per mole of ^{16}O and 0.0020052 mole of ^{18}O per mole of ^{16}O' [4]. When a fraction of the liquid is frozen by cooling the cell and the cell is accommodated in a thermostat bath controlled at a temperature close to 273.16 K, the equilibrium between the three phases is automatically established within the cell and can be maintained for many months. The kelvin definition thus is not linked to a specific artefact, in the sense that there is no international prototype of the kelvin since any laboratory can realize the kelvin by manufacturing its own TPW cell [6].

Figure 1. Triple point of water cell – National Institute of Standards and Technology (NIST)
Source: https://t.ly/wnMM_

The following definition of the kelvin was adopted at the 26th CGPM in 2018 [8]:
The kelvin, symbol K, is the SI unit of thermodynamic temperature. It is defined by taking the fixed numerical value of the Boltzmann constant k to be 1.380 649 × 10^{-23} when expressed in the unit J K^{-1}, which is equal to kg m^2 s^{-2} K^{-1}, where the kilogram, metre and second are defined

in terms of *h*, *c* and Δv_{Cs}, where *h* is the Planck constant, *c* is the speed of light in vacuum and Δv_{Cs} is the caesium frequency corresponding to the transition between the two hyperfine levels of the unperturbed ground state of the ^{133}Cs atom.
This definition implies the exact value of the Boltzmann constant $k = 1.380\ 649 \times 10^{-23}$ J K^{-1}. By fixing the value of *k*, the kelvin is now defined in terms of the SI derived unit of energy, the joule (symbol J), which is the proportionality constant between thermodynamic temperature and the associated thermal energy *kT*. The new definition has its origin in statistical mechanics, where thermodynamic temperature is a measure of the average thermal energy per degree of freedom in the system. Its effect is that one kelvin is equal to the change of thermodynamic temperature *T* that results in a change of thermal energy *kT* by $1.380\ 649 \times 10^{-23}$ J [4]. Therefore, the advantage of the new kelvin's definition is that thermodynamic temperature can be realized directly at any point in the scale without referring to the singular temperature of the TPW [9].
The value of *k* adopted for the new definition (the CODATA 2017 value by D. B. Newell *et al*. [10]) ensures that the best estimate of the value of T_{TPW} remains 273.16 K. One consequence of the new kelvin's definition is that the former relative uncertainty in the determination of *k*, 3.7×10^{-7}, is transferred to the temperature of the triple point of water, T_{TPW}. The standard uncertainty of T_{TPW} is hence now approximately 0.1 mK. The common practice to call the difference "$T - 273.15$ K" Celsius temperature, symbol *t*, remains the same. The unit of Celsius temperature is the degree Celsius, symbol °C, which is, by definition, equal in magnitude to the kelvin [4,9,11].
It is important to point out that the redefinition of the kelvin in terms of the Boltzmann constant has no effect on the temperature values or realization uncertainties of the present two defined scales: the International Temperature Scale of 1990 from 0.65 K and above (ITS-90, [12]), and the Provisional Low Temperature Scale of 2000 from 0.9 mK to 1 K (PLTS-2000, [13]), which are used in practical measurements of temperature. This is caused by the fact that the fixed-point temperatures assigned in all of the defined scales are exact (there is no assigned uncertainty) and fixed (the value remains unchanged throughout the life of the scale). In particular, the status of the TPW as a fixed point, with a defined temperature value on the ITS-90, will remain unchanged. Thus, the uncertainty of realization of the TPW on the ITS-90 will not acquire any additional uncertainty due to the change in definition of the kelvin [4].

2.2 Principles and advantages of Johnson noise thermometry in practical use

The redefinition of the SI base unit the kelvin has opened new possibilities for realizing and disseminating temperature through different approaches, with direct traceability to the redefined kelvin [9,14]. More precisely, the creation of an extended *mise en pratique* ("practical realization") of the definition of the kelvin (*MeP*-K[2]), incorporates both of the defined International Temperature Scales (ITS-90 and PLTS-2000) in current use and approved primary-thermometry methods for determining thermodynamic temperature values [4].
The following primary-thermometry methods are recommended for practical use: acoustic gas thermometry (AGT), spectral-band radiometric thermometry, polarizing gas thermometry (PGT), dielectric-constant gas thermometry (DCGT), refractive-index gas thermometry (RIGT) and Johnson noise thermometry (JNT) [11]. Primary thermometry implies direct measurement of thermodynamic temperature, without calibration against a more accurate thermometer. It is performed using a thermometer based on a well-understood physical system, for which the equation of state describing the relation between thermodynamic temperature (*T*) and other independent quantities can be expressed explicitly without unknown or significantly temperature-dependent constants. Thermodynamic temperature can be obtained by measuring or otherwise determining values of the independent quantities. Furthermore, no reference is made to any temperature fixed point [4,11]. In the long term, primary thermometers are predicted to become competitive with practical thermometers traceable to ITS-90 and PLTS-2000, as future advances in techniques will improve their repeatability, uncertainty and ease of use [9]. They will become more widely used and will completely

[2] The *MeP*-K is a guide that makes reference to the information needed to perform measurements of temperature in accord with the SI at the highest level.

replace conventional thermometers eventually [4,11]. Because of many advantages they provide when measuring temperature in various aspects of our lives, compared to conventional thermometers, the working principle of the currently most promising Johnson noise thermometers is explained below.

Conventional temperature sensors, such as thermocouples or resistance thermometers, are known to be used for temperature monitoring and control in a wide range of processes. However, they don't measure the temperature directly, instead they typically possess some property, such as voltage or resistance, which varies with temperature and can be measured. Therefore, they need to be calibrated regularly, so that users can have confidence in the measurements, which can be expensive and time-consuming. For various practical applications any improvement in confidence that can be achieved is crucial to support innovation. To overcome the need for calibration, the thermometer must measure temperature directly, as in the case of a Johnson noise thermometer [15].

Johnson noise thermometry is a primary temperature measurement technique based on the fundamental properties of thermal fluctuations in conductors. More precisely, Johnson noise (also: *thermal noise*, *Johnson-Nyquist noise*, *white noise*) is the electronic noise generated by the thermal agitation of the charge carriers (usually the electrons) inside an electrical conductor, which happens regardless of any applied voltage. The most important aspect of Johnson noise is that the power of the Johnson noise is directly proportional to the absolute temperature. There is no material property or calibration requirement to derive the absolute temperature, just electrical measurements. The accuracy of a Johnson noise thermometer can't drift over time. Therefore, a significant advantage of this technique is that it isn't subject to sensor drift [15]. By measuring the tiny electrical fluctuations associated with the random thermal motion of charge carriers (the Johnson noise), *the Johnson-Nyquist equation*[3] can be used to determine true thermodynamic temperature of the sensor, even if the sensor material degrades during exposure in harsh environments, such as high temperatures or ionizing radiation. Accordingly, by practical application of primary Johnson noise thermometry all properties that affect the temperature measurement can be measured continuously, so that the Johnson-noise thermometer always yields the correct temperature [15].

Johnson noise is usually characterized by its mean square of a noise voltage (v_n), conventionally called the noise power. For frequencies below 1 MHz and temperatures above 25 K, it is approximated to better than 1 part in 10^6 by Johnson-Nyquist equation [17]:

$$\left\langle v_n^{\,2} \right\rangle = 4kTR\Delta f \tag{1}$$

where Δf is the bandwidth in hertz over which the noise voltage is measured, T is the resistor's absolute temperature in kelvins, R is the sensor resistance in ohms (Ω) and k is the Boltzmann constant in joules per kelvin.

It is interesting to note that the noise power in a conductor (resistor) is independent of the resistance. Re-arranging the previous equation gives the thermodynamic temperature:

$$T = \frac{1}{4k} \cdot \left\{ \frac{v_n^{\,2}}{R\Delta f} \right\} \tag{2}$$

In conventional JNT systems, one measures the noise power from a sensor at a known temperature (usually at the triple-point temperature of water, which has a conveniently defined value in the International System of Units: T_{TPW} = 273.16 K), and the noise power of a second sensor at the unknown temperature. The unknown temperature is inferred using equation (1) from the ratio of the measured noise powers and the ratio of the sensing resistances [17].

The Johnson noise thermometry offers huge advantages over conventional practical sensors which exhibit progressive loss of accuracy in harsh environments. The practical Johnson noise thermometer is independent of any calibration and it can measure with confidence all parameters which are needed to

[3] In 1927, John Bertrand Johnson (1887–1970), conducted a series of experiments that showed that electrical noise exists in all conductors and that this noise is inherent and is not the result of poor component design. Johnson also provided a formula for the noise. Later, in 1928, Harry Nyquist (1889–1976), applied the principles of quantum and statistical mechanics and derived on a theoretical basis Johnson's formula [16].

yield the true temperature for prolonged periods. This results in improved process control and better efficiency, in terms of energy use, product yield and reduced process downtime [15].
The Johnson noise thermometry system is in use at the Physical Measurement Laboratory in National Institute of Standards and Technology (NIST), in support of work aimed at reducing uncertainty in temperature measurements and improving the understanding of the international temperature scale, as well the development of a novel electronic method for determining the Boltzmann constant. Within the JNT project, conducted by NIST, quantum-based synthesis of the voltage waveform is applied to the precise measurement of the Boltzmann constant by developing the primary temperature standard based on the electrical measurement of the Johnson-Nyquist voltage noise of a resistor at the triple-point temperature of water. The NIST Johnson noise thermometer may eventually replace the large collection of temperature fixed points (temperature artifact standards) that define the ITS-90 thermodynamic temperature scale, providing a unique electronic measurement of the Boltzmann constant, which is important for the New International System of Units [18].
Although Johnson noise thermometry is well established in certain laboratories and used in primary thermometry and Boltzmann's constant determinations, it hasn't been used for practical devices in industrial environments. The world's first practical Johnson noise thermometer (**Figure 2**) has been made as a result of the collaboration between the National Physical Laboratory UK and Metrosol Limited. It has achieved accuracy of temperature measurement better than 1 °C and could eventually be commercialized in future [15].

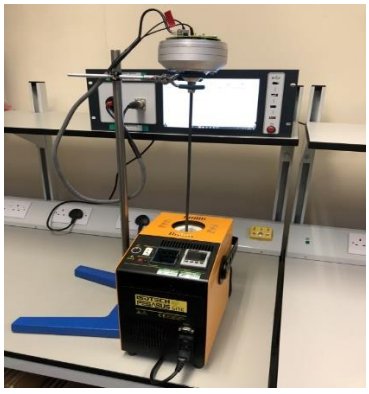

Figure 2. The first practical Johnson noise thermometer
Source: https://t.ly/QkZ1E

3. CONCLUSION

The redefinition of the kelvin will allow the accuracy of temperature measurements to gradually improve without limitations associated with the manufacture and use of water triple point cells, nor with limitations of the present temperature scales. Within a variety of alternatives, laboratories can realize a temperature standard by choosing the experimental method which is best suited to their available equipment. The aforementioned primary-thermometry methods which are recommended for the direct realization and dissemination of thermodynamic temperature are expected to eventually replace the International Temperature Scales (ITS-90 and PLTS-2000) in practical use. The most promising of them, Johnson noise thermometry, represents a breakthrough in temperature sensing, particularly in harsh environments, with the perspective of being commercialized for the needs of industrial and other measurements. By applying this method, the temperature sensor, unlike today, will no longer need calibration to ensure traceability.

ANALYSIS AND VISUALIZATION OF COVID-19 DATA SET IN PYTHON PROGRAMMING LANGUAGE

Ana Đokić[1], Information Technology School ITS Comtrade, Belgrade
Hana Stefanović[2], Information Technology School ITS Comtrade, Belgrade

Abstract: *This paper presents some of the ways to process and visualize data from a given data set in order to prepare data for further analysis. For this purpose, Python programming language with its libraries Pandas, Matplotlib and Plotly was used. The free Anaconda distribution is used for processing and visualization, as one of the most used programming environments for data analysis. The program editor in which the program codes of the tasks are written is Visual Studio Code.*
Keywords: Data Analysis, Data Visualization, Python Programming Language

1. INTRODUCTION

To understand the dominant role of Python programming language in data science, it is necessary to compare it with other programming languages used in this field [1]. Compared to the programming language R, which can be considered one of the main alternatives, Python is a multipurpose language and is more practical. Writing code is simple and significantly faster than in Java and C++. The languages Ruby and JavaScript are similar in nature to Python in terms of flexibility, but not in terms of open-source support. The development of Python programming language is supported by large user communities and has a huge number of libraries and tools with ready-made solutions available to the user. It is suitable for performing many operations, from data preparation, visualization, and analysis to the application of artificial intelligence and machine learning algorithms [2]. According to the programming language popularity index [3] for the year 2023, Python programming language is ranked first.

A tool that manages open-source packages for installing Python programming language [4] (in the context of data processing and visualization) and allows the isolation of different projects is the Anaconda virtual environment [5]. The advantage of Anaconda is that it allows the use of different versions of Python on different platforms and has many preinstalled packages with compatible versions, which greatly facilitates the use and avoidance of conflicts.

There are more than 700 libraries available in Anaconda. The Pandas, Matplotlib, and Plotly libraries are presented in the code examples in the paper. The Pandas library enables simple and efficient loading of tabular data, to process the data. It is built on the Numpy library and is compatible with the Scikit Learn machine learning library [6].

Libraies Matplotlib [7] and Plotly [8] enable the creation of different types of graphs, i.e., visualizations in Python programming language. Many commands can be used to create standard line charts, histograms, bar, and pie charts. To adjust the appearance of the graph, formatting is applied, which refers to the choice of colour, thickness and type of line, addition of titles and legends.

2. ANALYSIS AND VISUALIZATION OF COVID 19 DATA SET

2.1 Data analysis and processing

The paper used data on the COVID-19 corona virus, from March 15, 2020, which was processed and analysed. The data can be found in the data set [9].
Descriptions of column names from the data set are shown in Table 1.

Table 1. Descriptions of column names from the data set
Source: *Author's paper*

The name of column	Description
Province/State	The name of province or state
Country/Region	The name of country or region
Last Update	MM/DD/YYYY HH:mm (24-hour format, in UTC)
Confirmed	The number of confirmed cases
Deaths	The number of deaths
Recovered	The number of recovered cases
Latitude	Latitude of country/region or province/state
Longitude	Longitude of country/region or province/state

For data processing and analysis, a program was written that displays the first 5 rows from the data set, prints information about the data and checks for missing values, prints the number of confirmed, deaths, recovered and active cases in relation to the country they are from, prints information about 7 countries with the highest number of confirmed cases.
The printout of the first 5 lines is shown in Figure 1.

	Province/State	Country/Region	Last Update	Confirmed	Deaths	Recovered	Latitude	Longitude

2.2 Data visualization

Data visualization is very useful and necessary to display data. The choice of graph type is preceded by data analysis, based on which the most suitable type of visualization is chosen.

To visualize data for a given data set, a program code was written to create a line chart that visualizes data on deaths, confirmed, recovered and active cases, in countries with more than 100 deaths, which is shown in Figure 6. To obtain the graph the Matplotlib library is imported.

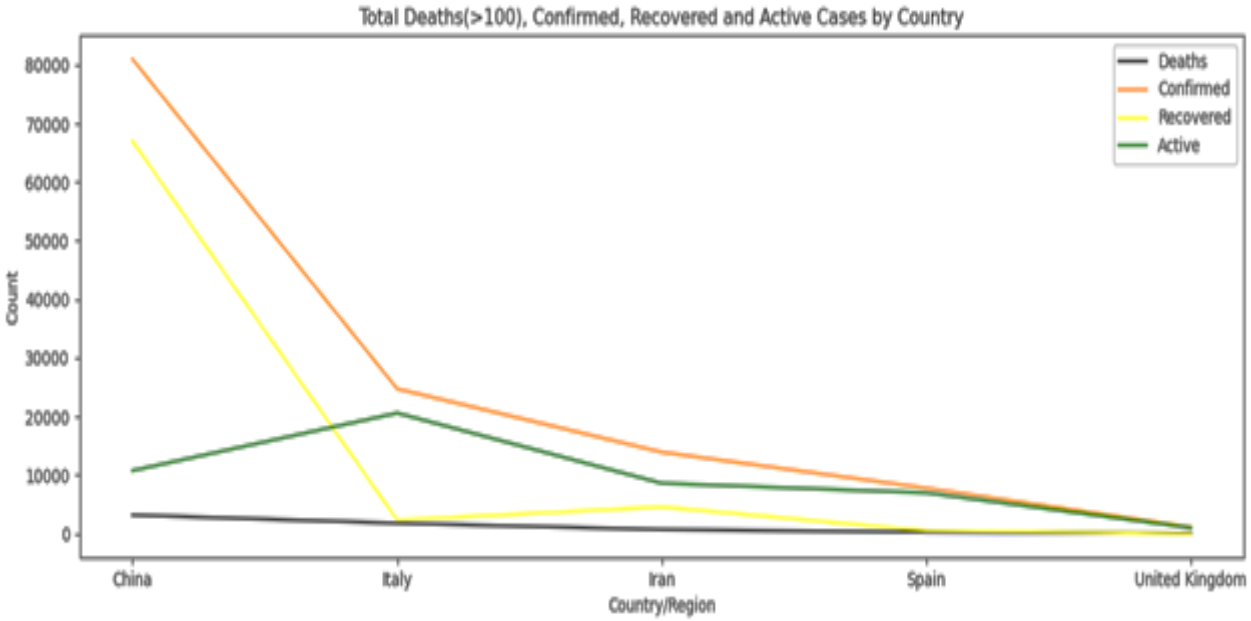

Figure 6. Line graph from COVID-19 data set

Figure 7 shows a bar graph showing the frequency of different cases of the corona virus in Australians by area. On the x axis, the categories of attributive features (confirmed, deaths, recovered, active) are applied, while on the y axis, the frequency of the observed category, a numerical variable (Count), is applied. The Plotly library is imported to create graphs.

3. CONCLUSION

There are more and more programmers and researchers in the field of computer science who look at their professional development through the prism of data science. To solve practical problems, it is necessary to understand the very concept of data analysis and master at least one programming language that supports data analysis and visualization. Due to its simplicity and great programming possibilities, Python programming language is a good choice.
This paper presents the results of data processing and analysis and visualization, with the aim of adopting the skills and techniques of data visualization and processing, to illustrate the approach to problem solving in the field of data analysis. The choice of programming language is an important step in data analysis, which is also illustrated in this paper.

EXAMINING THE ROLE OF DRONES AS EDUCATIONAL TOOLS: AN PRACTICAL TEACHING EXAMPLE IN ENHANCING LEARNING EXPERIENCES IN STEM EDUCATION

Sanja Pavlović[1], College of Applied Studies Aviation Academy
Dejan Crnoglavac[2], College of Applied Studies Aviation Academy
Starčević Aleksandar[3], College of Applied Studies Aviation Academy

Abstract: *In recent years, drone technology has revolutionized various industries, from photography and filmmaking to agriculture and disaster response. Now, educators are harnessing the potential of drones to enhance science and technical education. Aviation Academy in Belgrade has also recognized and introduced drones as a powerful tool in both theoretical and practical educational methods, of acquiring high-quality knowledge in aviation educational field, aiming to improve the knowledge of its students. The students of Aviation Academy learn how to observe and record the terrain situation using a drone for various agriculture purposes. Students can also learn about various drone operation technologies, including aerodynamics, aviation, programming, and data analysis, by working with drones. This article presents concrete teaching examples and students' achievements in the practical applications of drones in teaching at Aviation Academy, discussing their benefits and potential impact on student engagement, critical thinking, and problem-solving skills particularly in the fields of science, technology, engineering, and mathematics (STEM).*
Keywords: drones, education, hands-on learning, problem-solving, teacher support.

1. INTRODUCTION

With the rapid advancement of technology, educational institutions are constantly seeking innovative methods to enhance teaching and learning experiences. Drones, also known as unmanned aerial vehicles (UAVs) initially developed for military and commercial application [1], have found a niche in the realm of education. From kinematics, fluids and aerodynamics to electromagnetism, electronics, programming and data collection and analysis, drones provide an exciting and engaging platform for students to grasp abstract principles while inspiring curiosity and creativity in the world of science, technology, engineering, and mathematics (STEM) [2].
Integrating drones in STEM education contributes to better student's knowledge and has benefits in many areas of science, technology and education methods such as:

a) **Physics principle and laws**: Kinematics, Newtons laws, Bernoulli principle in flight, aerodynamics, observe and analyses drone flights, measure distances, calculate velocities, and explore motion graph, examine the effects of thrust, drag, lift, and weight on the drones' flight, balanced and unbalanced forces (**Figure 1**). Students also can learn about basic circuit concepts like voltage, current, resistance, and how they relate to drone operation, etc.
b) **Sensors:** Understand the working principle of various sensor types such as multispectral, thermal imaging, and LiDAR sensors.
c) **Drone software systems to control the flight operations and capture data efficiently:** Popular open-source platforms like ArduPilot and PX4 allow customization and integration of various

[3]starcevic.a@vakademija.edu.rs

sensors. Learn how to program the drones for autonomous flights, image processing, and data analysis using languages like C++ or Python. Fine-tune flight controls, stabilize drone stability, optimize power consumption, and integrate sensor data into actionable insights; d) **Hands-on learning and real-world application**: Students can actively engage in building, programming, optimizing and piloting drones, giving them a tangible connection to the principles they learn in the classroom, study the various components required to build a drone: flight controllers, motors, propellers, batteries, GPS modules, and sensors, research reputable drone manufacturers and their product offerings, learn how to assemble and solder drone components together [3,4]. There are numerous online resources and tutorials available that provide step-by-step guides to building drones [5,6]. They can also explore the effects of different components and configurations on the drone's performance and test drone in real-life agricultural settings, etc.

d) **Data collection and analysis**: Research their applications in agriculture for example, data collection methods, and data interpretation techniques; f) **Problem-solving and critical thinking**: Assignments involving drone missions encourage critical thinking and creativity, as students must strategize flight paths, calculate power requirements, and optimize payload distribution, all while considering the laws of physics that govern the drone's flight.

e) **Safety precautions and legal guidelines for flying drones**, including understanding airspace restrictions, privacy concerns, and proper maintenance practices.

2. EXAMPLES

2.1 Drone flight time

In order to use drones for student education and enhance student's understanding of drone operations, teachers can, for example, assign a task to students to investigate the relationship between drone payload, battery capacity and flight duration.

In this task, students will be required to: a) demonstrate basic knowledge in physics, such as Newton's dynamics; b) apply some simpler formulas; c) think how to increase lift force; d) use an existing online calculator for drone parameters calculation [6,7]; e) think how to optimize relation between payload weight and flight time.

It can be assumed that adding payload decreases flight time. For the purpose of this article, it is also assumed that the payload is increased while the drone's components stay the same. Student need to be able to conclude that to overcome a higher weight, more thrust is required from the propellers, which requires higher RPM (rotation speed), which draws more power from the battery, thus decreasing the available battery life and flight time.

Adding mass to a UAV, the amount of thrust required to lift it off the ground is increased.

When a drone is hovering, it is in equilibrium so the thrust is equal to the weight:

$$\text{Hover thrust} = \text{Drone weigh} = \text{mass} \times \text{gravity } (9.82\ \text{m/s}^2) \qquad (1)$$

For most drones, it is necessary that their max thrust be about twice as much as is required to hover, which allows them to take-off, climb, and operate smoothly. Ultimately, greater mass means greater thrust requirements. There are a few ways to calculate thrust, but it is generally dependent on several factors, including propeller diameter and pitch, air density, velocity, and rotation speed (RPM), as demonstrated by this equation for dynamic propeller thrust [8]:

$$Thrust = 4.329 \times 10^{-8}\, RPM \frac{d^{3.5}}{\sqrt{pitch}} (4.233 \times 10^{-4} \cdot pitch - V_0) \quad (2)$$

Where: d-propeller diameter (m), V_0-propeller forward airspeed(m), pitch- displacement a propeller makes in a complete spin of 360° degree usually in inches (propeller of 40 pitch will advance 40 inches for every complete spin).

According to eq. (2), there are a couple ways we can increase thrust: we can change the dimensions of the propeller, or we can increase the RPM. Since propellers are constant, it will therefore have to increase the RPM.

So, the question for the student are how to increase RPM. To increase the RPM, we have to draw more electrical power from the battery, specifically more voltage. The more power drawn, the shorter the life of the battery. Since it will be drawing higher voltage (and therefore greater power) to reach a higher RPM, the battery life will deplete faster, and our flight time will be lower.

Students could be given the task to calculate: Flight-time vs battery capacity and flight-time vs total weight relations using some of the flight time calculators and to plot the correspondent graphs.

The simple equation below shows how battery capacity and power draw relate to the flight time of the drone. The more power you draw, the shorter the flight time will be:

$$Fligt\ time(h) = \frac{Battery\ capacity(Wh)}{Power(W)} \quad (3)$$

The battery capacity ($E_{battery}$) is equal to the weight of the battery ($W_{battery}$ in grams) multiplied by the energy density ($\sigma_{battery}$ in Wh/g).

$$E_{battery}(Wh) = \sigma_{battery}\left(\frac{Wh}{g}\right) \cdot W_{battery}(g) \quad (4)$$

The total power (Power in Watt) is equal to the weight of the drone (Wdrone (g) = W_{frame} (g) + $W_{battery}$ (g)) divided by the propeller's efficiency (propefficiency in g/W).

$$Power(W) = \frac{W_{drone}(g)}{prop_{efficiency}(\frac{g}{W})} \quad (5)$$

By combining the eqs. (3), (4) and (5) , it can be obtained that the flight time is :

$$FT = \frac{\sigma_{battery}\left(\frac{Wh}{g}\right) \cdot W_{battery}(g)}{W_{frame} + W_{battery}} \cdot prop_{efficiency}\left(\frac{g}{W}\right) \quad (6)$$

$prop_{efficiency}\left(\frac{g}{W}\right)\left(\frac{W_{frame}+W_{battery}}{Number\ of\ propellers}\right)$ - propeller efficiency is a function of total weight of the drone divided by the number of propellers on drone. From eq. (6) students should conclude that increase in the weight of the battery increases the division term in the equation above and reduces the propeller efficiency. In this way, the battery can influence the flight time in both directions. Larger batteries have a higher capacity, which can increase flight time, but they also have a higher weight, which increases the thrust required for operation, thus decreasing the flight time. Those formulas are implemented in the various existing flight time online calculators which uses the following drone parameters: weight and capacity of drone battery, total weight of your quad (without the battery), and

the number of propellers, it combines this information with propulsion data and estimates flight time [5,6].
In the previously described example, the students obtained the following results that are shown on the **Figure 2** and **Figure 3**. On **Figure 2**, students can observe the effect of varying the battery capacity on the flight time at constant drone weight . As it can be seen, increasing the battery capacity above 250 Wh increases the flight time by a few minutes, but reduces the control authority as the weight to thrust ratio decreases.

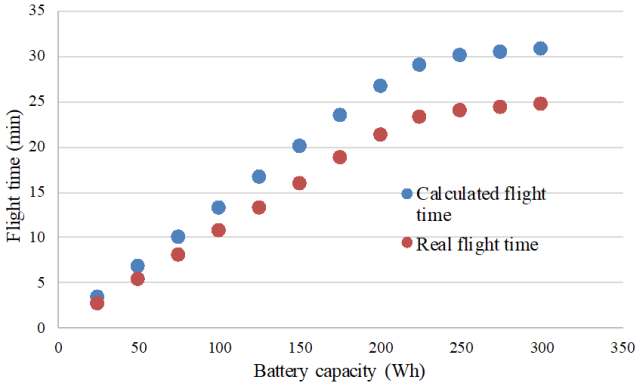

Figure 2. Calculated vs real drone flight time as a function of battery capacity.

Further increase (above 250 Wh) shows very little contribution in terms of flight time, but increases noise and reduces controllability. So, it is very important for various drone applications to optimize battery capacity in relation to required payload and flight time.
It should be noticed that time calculated with flight time calculators differ from the real flight time because they assumed that drone mostly hovers in the air – every time it performs some elaborate maneuvers, one of the motors has to work faster and hence uses up more current. If drone only moves around slightly – for example, during aerial photography – the flight time will time will be about 75% of the calculated time, or if drone flies in strong wind or moves around a lot, the flight time will decrease to around 50%, etc. On **Figure 3**, it can be noticed that with zero payload and the mass of the drone at 1.6 kg (battery included), we get a flight time of 26,6 minutes, giving more than enough time to shoot a 20-minute video. As we increase the payload by 0.2 kg increments, watch what happens to the flight time: As payload is gradually increased, flight time decreases.

2.2. Students' achievement in practical application of drones

The second task for the students was to observe, record and analyze drone images of the terrain situation [9,10]. The specific thing about the drone was a built-in multispectral camera that recorded the whole range of visible spectrum, including those outside of the visible spectrum, such as red band, near infrared, infrared and ultra-violet. (RED, NIR,IR,UV) [11]. The recording could be used in numerous multispectral analyses and a specially designed software was used for its decoding.

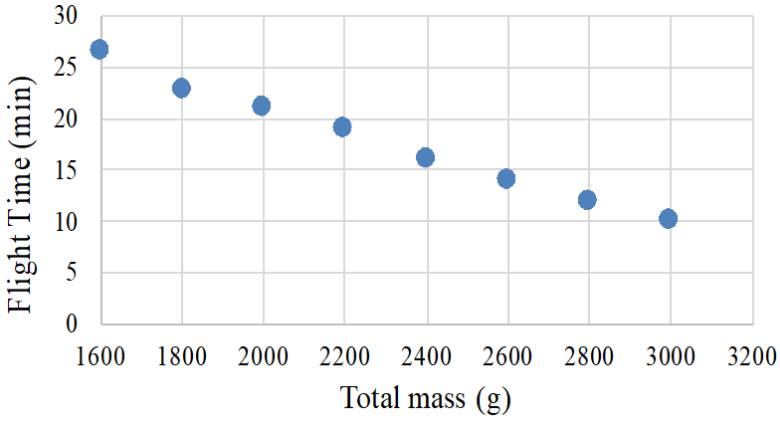

Figure 3. Drone Flight time vs. payload in hovering mode

In practice, the students were assigned an orchard as a recording terrain and they had to examine those plants general condition and target the ones that needed special treatment. The analysis of colour tracking provided information on plants (if the leaves had become dry, if they have enough water, if they suffer from certain disease or if they are damaged). The most well-known and used index map produced from multispectral imagery is NDVI (Normalized Difference Vegetation Index).
The pigment in plant leaves, chlorophyll, strongly absorbs visible light (from 0.4 to 0.7 μm). The cell structure of leaves, on the other hand, strongly reflects near-infrared light (from 0.7 to 1.1 μm).
Healthy plants reflect a smaller quantity of red light but a larger amount of near-infrared light (which humans can't detect, but multispectral imaging can), whereas the opposite is true for stressed or dead plants. The difference between damaged and undamaged planted areas, can be seen on multispectral camera image NDVI analysis (**Figure 4**).

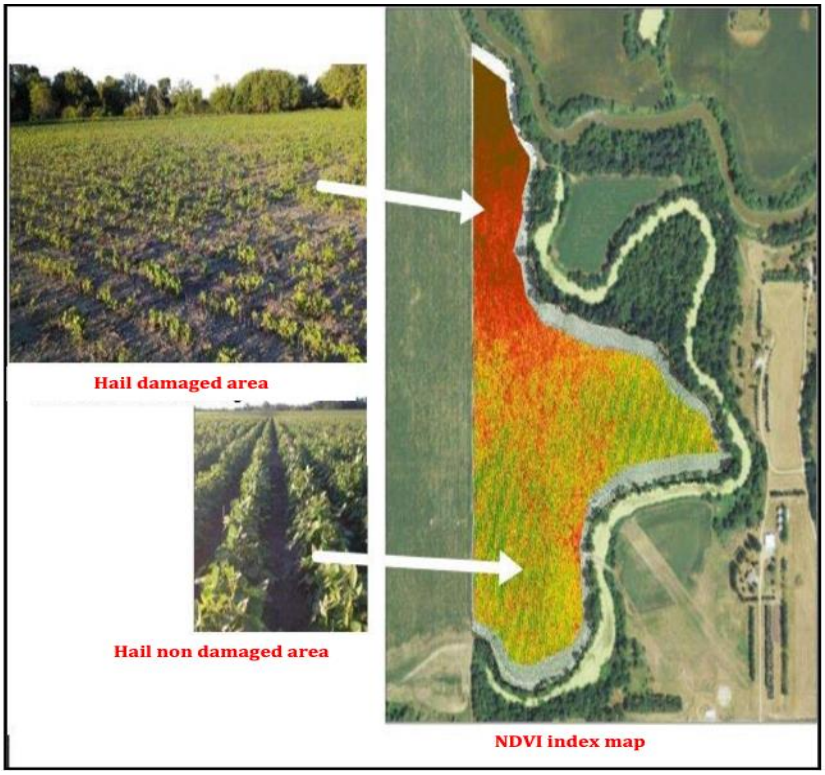

Figure 4. UAVs multispectral camera image with NDVI index map of plant condition [9]

3. CONCLUSION

Introducing students to drone technology, educators prepare them for real world application. Future careers in fields like, engineering, surveying, environmental monitoring, agriculture, and even disaster response may require drone piloting, operation and data analysis skills. By integrating drones into education, students gain practical skills that are in high demand in the job market, enhancing their career prospect. In first presented example on drone-based student assignment, student came to this conclusion: to overcome a higher weight, more thrust is required from the propellers, which requires higher RPM, which draws more power from the battery, thus decreasing the available battery life and flight time. Using the basic physics knowledge and existing flight time calculators, students learned how to optimize flight time for needed drone purpose by choosing adequate battery capacity and payload values. In the second drone application in education example student learn how to use drones in crop health monitoring and management.
These and many others diverse examples of drones as a useful tool in education demand that all future research and investment in drone-based education be focused on refining pedagogical approaches, determining the optimal student-drone ratio, expanding accessibility and exploring advanced application.

EXPERIENCES IN TEACHING AND MASTERING MATERIALS IN WEB APPLICATIONS COURSE IN VOCATIONAL EDUCATION

Đorđe Dihovični[1], The Academy of Applied Technical Studies Belgrade
Dragan Kreculj[2], The Academy of Applied Technical Studies Belgrade
Nada Ratković Kovačević[3], The Academy of Applied Technical Studies Belgrade

Abstract: *This paper presents the experiences in teaching and mastering the teaching contents and curricula of a representative group of students who enrolled in the first year of study in higher education in vocational engineering studies. Students originated from different high schools and have had different initial backgrounds in Informatics. After the entrance exam, a representative sample of 20 students and their success in subjects from Information Technologies and Computer Science was followed. Their work and success after the third year of bachelor studies is especially emphasized, with analysis of their results and presentation of the curriculum material they have mastered. The competencies gained and curriculum of the course in Web applications, which was taken during the third year are here presented. Parts of practical exercises performed by students are illustrated and supplied. The results of the exams taken in subject that was selected e.g. Web applications, are presented in a table, and the analysis of the data obtained is performed.*
Keywords: Teaching Experience, Computer Science, Information Technologies, Evaluation of Student's Competencies, Vocational Studies.

1. INTRODUCTION

Education at all levels should adapt to work and life during the Fourth Industrial Revolution. To prepare students adequately for the near and distant future job requirements, colleges, faculties and other higher education institutions should offer different education from the existing one [1, 2, 3, 4]. Due to increased automation and the application of new technologies, the way of working was changed, even before the Covid-19 pandemic. This made emphasis on an urgent need for mass training and reskilling of the workforce around the world [2, 3]. The Covid-19 pandemic has further strengthened and emphasized this need. The World Economic Forum announced in January 2023. [3] of more than 350 million people are being reached with better skills, jobs and education through commitments made as part of its Reskilling Revolution initiative, three years after launching at its Annual Meeting in Davos. According to *Future of Jobs Report 2023* [4] - Insight Report of the World Economic Forum published in May 2023, in the top ten of the most common labour shortages by occupations in 2022 in Europe, the second place takes "Metal, Machinery and Related Trades Workers" and the fourth "Information and Communications Technology Professionals" [4]. Labour shortage is a shortage or insufficiency of qualified candidates for employment.
Despite the fact that advanced and new technologies and methods are increasingly used in teaching, student progress does not have the expected growth trend [5]. Students were from different secondary education backgrounds. Some had graduated from high schools (gymnasiums), majority was from high schools specialized in some technical or technological field, and several students had graduated from secondary education in Economy or Social Sciences.

[1]djdihovicni@atssb.edu.rs
[2]dkreculj@atssb.edu.rs
[3]nratkovickovacevic@atssb.edu.rs

During last four years a reform was introduced in which the Technical College Belgrade became the Computer-mechanical Engineering Section of the Academy of Technical Applied Studies Belgrade. This happened during here described research. At the Technical College Belgrade (now Computer-Mechanical Engineering Section of the Academy of Technical Applied Studies Belgrade), there used to be a three bachelor study programs in vocational engineering: Computer Mechanical Systems, Industrial Engineering and Energy Efficiency with Clean Energy (or with Green Energy, depending on the year of approved accreditation). The entrance exam had three forms – one consisted of questions and tasks from the Technical-Technological field, another was in Informatics and the third was in Mathematics. Students could choose between these three entrance exams with respect to the preferences of study program they were keen to be enrolled in. The results of the entrance exam showed that the best success in Informatics was made by students who graduated from high schools (e.g. gymnasiums), while in the Technical-Technological part of the entrance exam, the highest number of points had achieved graduates of high technical schools specialized in engineering.
This trend in success continued during the first and second year of study, where students took a group of Mathematical, Informatics and Computer Science subjects, namely: Mathematics I, Mathematics II, Software and Computer Tools [6], Operating Systems with User Software, Object Oriented Programming [7], Information Systems; and a group of highly specialized subjects in Technical-Technological field of study that included: Mechanics I, Mechanics II, Machine Elements I, Machine Elements II, Materials in Mechanical Engineering, Strength of Materials, Machining Technologies and others. Selected representatives of the aforementioned groups of students were monitored during the mastering of the curricular material and taking the exams in the third final year of undergraduate studies, in the first year of specialist studies and in the second year of master's studies, all taken in vocational or professional studies. One course was chosen for each of the mentioned years of study. The course in Web Applications was selected from the third year of bachelor studies in professional education and presented here. The contents of this course and fragments of code are presented in this paper, and the progress of the represented groups of students is analysed regardless of their prior knowledge (acquired before the course mentioned), as well as the success of adapting and mastering skills during the final year of undergraduate studies.
The Academy of Technical Applied Studies Belgrade cares for students' success during studies and after graduation. The Career Centre for Students of the Academy of Technical Applied Studies Belgrade [8] is dedicated to the task of career development. The Alumni organization [9] keeps track of the graduates after graduation. In order to help navigate the information gathered regarding graduate students, a database was developed [10, 11, 12].

2. WEB APPLICATIONS COURSE

The curriculum for the subject Web Applications is given briefly, and the specific projects that students performed during the attendance of this course are described in here. The introductory part of this course presents the necessary steps that need to be applied to create a web application [13]. Examples such as data conversion, ASP.NET class, as well as session and application variables are presented [14]. The next lessons show the settings that are related to the Web server. The Web server delivers the requested Web pages to users who have entered a specific URL into a Web browser. The problem of complex controls is then addressed. The Calendar control is used to select the date, usually additional command buttons are entered on the web form. In order to create dynamic sites, it is necessary to introduce validation from the very beginning of development. Errors that can occur in the application by ignoring the validation include: by-passing important fields in which it is necessary to enter data; entering data in an inappropriate format that cannot be used (as is usually the case with e-mail address); entering the wrong data type; typing errors; etc. The next topic in Web Applications course deals with complex controls. The control panel serves as a container for other side controls. It determines the appearance and visibility of the controls it contains, and allows students to create and to program controls. The following knowledge units show XML - Extensible Markup Language. This

language is widely used as an alternative to the database, as well as to store configuration information about the application. XML has a similar syntax as HTML - Hypertext Markup Language [15].
Styles and master pages are the subject of the subsequent lectures. The reason for creating a master page as well as its difference in relation to the web form is shown. The navigation through the website is presented. To move from one side to the other, a navigation system is required, which consists of several components: the XML sitemap is in charge of defining the structure, the second component provides reading data from the site map file and converting it to an object model via controls XmlSiteMapProvider and XmlSiteMapDatasource.
The final lectures deal with the notion of relational database, and structured query language. Through examples, the students master the technique of storing knowledge in or retrieving it from the database. Then the ADO.NET technique is presented, as well as the process of establishing a connection, and an example of creating an e-business web application, and the application delivery process.

2.1 Connecting the Database through the Application

In order to create a new database, students run the following script:

```
CREATE DATABASE COLLEGE
GO
```

The following script creates a new table:

```
CREATE TABLE Students
(
 StudentID int identity primary key,
 Name varchar(50),
 LastName varchar(50),
 Sex varchar(10),
 Age int,
 Address varchar(50)
)
GO
```

The data is then entered using the following script:

```
INSERT INTO Students (Name, LastName, Sex, Age, Address)
VALUES
```

The code snippets for connecting the application to the database are shown with:

```
SqlConnection connection = new SqlConnection();
SqlCommand command = new SqlCommand();
SqlDataReader reader;
connection.ConnectionString = @"Data Source=academy server;InitialCatalog=College;"
+ "Integrated Security=SSPI";
command.Connection = connection;
command.CommandText = "SELECT Name, LastName, Age FROM Students";
connection.Open();
```

In another approach to solve the same task students also use the DataAdapter class and the DataSet class, and database query can be performed without keeping an open connection. The DataAdapter object executes commands to the database and loads the results obtained by executing the query, within the table of the DataSet object. Each data can then be accessed using the Rows property of the DataTable object by specifying the column name.

2.2 XML application

In the introductory exercises on this issue, students are using classes and methods of the XML Document Object Model, and easily create a XML file. Parts of the code are illustrated as follows:

```
//Create XML document
doc = new XmlDocument();
// If there is no current file, create a new one
if (!System.IO.File.Exists(PATH))
{
 //Create necessary nodes
 XmlDeclaration declaration = doc.CreateXmlDeclaration("1.0",   "UTF-8", "yes");
 XmlComment comment = doc.CreateComment("Ovo je XML          generisana datoteka");
```

In the first phase, students create a XML file from the application made in C#, and then perform the reverse procedure, namely read the XML file. Reading content from XML files is a necessary technique that is widely used in the case of saving configuration settings that are usually stored in an XML file and then used when loading an application. The students.xml file contains data on five students. By using the navigation buttons after loading the first record, the application allows students to view the next record, return to the beginning or view the last record. The parts of the navigation code are shown here:

```
private void ShowDetails(XmlElement currentStudent)
{
 txtName.Text = currentStudent.Attributes["name"].Value;
 txtNumberIndex.Text =
currentStudent.GetElementsByTagName("NumberIndex")[0].InnerText;
 txtDepartment.Text = currentStudent.GetElementsByTagName("Department")[0].InnerText;
}
```

3. RESULTS

The students arrived from different types of secondary education to take the entrance exam to enrol to bachelor studies in vocational engineering. Students were divided into three groups: graduates from high schools, from secondary technical schools and from high schools in social sciences. At the entrance exam, part of the exam in Informatics takes 60 points, and the maximum number of points was achieved by 93% of high school students, 78% of students from secondary technical schools and 43% of students from high schools in social sciences. The success of these groups of students in the subject *Web Applications* are given in table.

The percentage results regarding the success of this group of students in learning IT subjects, and numbers of students passing these exams during the first two years of study are shown in the Table 1. The percentage success of the same students in the subject of Web Applications and numbers of students passing this exam are shown in Table 2.

Table 1. Percentage results in IT subjects and numbers of students passing these exams during the first two years of undergraduate studies

Secondary education type	Grades					Passed in the first term	Passed in the second term
	6	7	8	9	10		
High school	12%	15%	33%	28%	12%	76	82
Secondary technical schools	64%	17%	10%	9%	0%	64	68
Secondary Social Sciences schools	92%	8%	0%	0%	0%	48	53

Table 2. The percentage success of students in the subject Web Applications and numbers of students passing this exam
Source: courtesy of PhD Djordje Dihovicni

Secondary education	Grades					Passed in the first term	Passed in the second term
	6	7	8	9	10		
High school	11%	18%	37%	18%	16%	83	87
Secondary technical schools	58%	16%	15%	7%	4%	65	67
Secondary Social Sciences schools	84%	9%	7%	0%	0%	47	52

4. CONCLUSION

The paper provides results of following a representative group of students who enrolled in the first year of study, with different prior knowledge in informatics. This group of students was monitored during the first two years of study, and the focus was on their success in subjects in Information Technologies (IT) and Computer Science. After the first two years, IT subjects were chosen in the third, fourth and fifth year of study. Based on the analysis and tabular data presented for subject Web Applications in the third year of study, it was determined as follows. The students who originated from professional high schools in technical and technological fields made a lot of progress during their studies, and in the final years their results were very similar to students who came from high schools (gymnasiums). The progress of students who previously attended secondary schools in social sciences was also noticed. The paper presents the curriculum of representative subject, *Web Applications*, and presents practical project tasks that students have mastered over the three years of bachelor studies in vocational engineering.

E-LEARNING: STUDY ON STUDENTS` OPINIONS

Marko Pavlović[1], The Academy of Applied Technical Studies Belgrade
Ana Petrović[2] , The Academy of Applied Technical Studies Belgrade
Đorđe Pavlović,[3] Western Serbia Academy

Abstract: *New technological achievements enabled changes in all aspects of scientific systems, especially in education during the coronavirus pandemic. ICT has become an integral part of the teaching process and it represents prestige in education. Electronic learning appeared as an idea that enabled the acquisition of knowledge and certain skills through information and communications technology. The aim of the paper is to compare the theoretical basis with the opinions of the students who experienced this way of learning during the coronavirus pandemic. The research was conducted on the territory of Belgrade in the winter semester of the 2022/2023 school year. The total number of students who participated in the survey is 112.*
Keywords: Internet, e-learning, research, students and results.

1. INTRODUCTION

Electronic learning is a term that was first used in the middle of the 20th century, when the first forms of computer-based learning were created [17]. In addition to this term, synonyms such as digital learning, online learning, virtual learning, learning on the internet are also used in educational institutions [18]. Electronic learning represents the process of acquiring knowledge, competences, intellectual abilities and development of critical and creative thinking through the implementation of teaching activities with the help of computer network, electronic and modern educational technology [19]. The closure of educational institutions during the COVID-19 pandemic encouraged them and the relevant Ministry to adopt the concept of alternative teaching under an urgent procedure in order to enable pupils and students not to be deprived of learning and thus to prevent the spread of further pandemics. E-learning system was adopted. The main component of internet learning is the use of computer technology [1]. Traditional teaching methods have been replaced by e-learning since the emergence of corona virus, because social gatherings in educational institutions were considered to spread the infection further. E-learning at the time was the best option since physical distance between employees and students was kept, although students did not really benefit from this way of learning [2]. Information technologies provide great opportunities for education and also training that will improve teaching, introduce innovations in the teaching process as well as stimulation of creativity of both teaching staff and students [3,4,5]. During the implementation of this type of teaching, educational institutions devoted a lot of effort and experience related to this type of education, which can also be present in the following years. In educational institutions around the world, processes are appearing that are exclusively related to learning, and information is continuously generated in order to use the knowledge that can be used for learning [6,7,8]. Electronic learning has a serious task in the educational system not only in Serbia, but also in the world. It changes the existing system and therefore represents one of the most important topics for research by the academic community [9].

Gaebel defines electronic learning as the use of different types of ICT and electronic devices in the teaching process [10]. Today`s students have a desire to study online and thus they are provided with the opportunity to improve their knowledge at colleges and universities around the world. A good ICT infrastructure is necessary for this type of learning. However, there are a large number of disadvantages regarding e-learning, the most important of which is acquiring theoretical knowledge, but when it comes to practical application, this kind of aspect is not feasible for certain professions. Another disadvantage is the lack of face-to-face learning which achieves a better interaction between teachers and students. Also, one of the disadvantages is that online learning is not very reliable, it can be difficult and even misused [11]. Many studies that investigated the possibilities and challenges associated with the transition from traditional to online learning came to the conclusion that the greatest lack is a good and adequate preparation for this new type of teaching. A study that examined the attitudes of students during the covid-19 pandemic, whether students are ready to learn online or not, came to the conclusion that a blended learning method must be available [12]. In addition to this study, Radha in her study investigates the process of e-learning among students who are familiar with web technology and the way to improve their knowledge, and this study indicates that e-learning has become popular among students in all educational institutions in the period of isolation caused by the virus [13]. Thus, teachers are the ones who have to design teaching activities in order for learning to be effective. In the new era of e-learning imposed on us by digitalization, e-learning will not be based on digital tools as much as on the improvement of laws for the management of content and activities related to distance learning. Any online learning functions according to the following model:

- Design, correction and distribution of teaching material,
- Evaluation of students` knowledge,
- Management of teaching and learning process.

The most famous distance learning system is Learning Management System (LMS). LMS provides program support that fully administers learning process, and the most famous are: Moodle, WebCT, Claroline, Sakai, Dokeos, Chamilo, ATutor, AHyCo and others [14].

Electronic learning today represents one of the main concepts in the development of modern education. Its special significance is reflected in its advantages and disadvantages. As it is well known, electronic learning enables teaching to take place anytime and anywhere, so there is no time, geographical or spatial limitations. With the use of the Internet, users receive constant technical support, teaching materials are always available and cost less, and everything is fast and transparent [15]. We should not ignore the fact of saving money, lower costs of organizing teaching, availability of many courses and other educational activities at any time [16].

So far, the results of the research on the attitudes of students and teachers of higher education towards e-learning show different attitudes. In his study, Dosari states that there is a positive attitude of students and teachers in higher education towards e-learning, and Bregar, Zagmajster and Radovan [20], [21] agree with him. However, Kundi and associates say that students who use e-learning are rarely satisfied with its functionality, so institutions of higher education encounter user dissatisfaction and dissatisfaction with this learning method [22]. Combined education gives excellent results in group work in which students cooperate and exchange their knowledge [23]. The research among professional nurses found that the main advantages of online learning are related to independent planning of study responsibilities (66.9%), user-friendly online environment (51.2%) and communication (20.9%) [24]. In the research by Lugonjić et al. (2021), which refers to the examination of the attitudes of nurses, the results show that 42.4% of students rated their computer literacy as high, 19.6% as very high, and 1.1% are beginners in using computers [25]. Most of the students who participated in the reseach (75%) had experience with only one subject in which they used e-learning at the time of filling out the survey [25].

2. RESEARCH METHODOLOGY

The aim of the research is to examine how electronic learning functions, what are its advantages and what are its disadvantages. The aim of the study is to examine the opinion of active students regarding

electronic learning and thus make a conclusion regarding it. The initial hypothesis is: H_0 Students are satisfied with e-learning. H_1 Students find it difficult to follow distance learning. H_2 Students find online learning content useful. The total sample consisted of 112 respondents. The research on students` opinions involved direct interviews with the students from the University of Belgrade. In order to reach the respondents more easily, the research was conducted in front of students dorms in Belgrade, and those were Košutnjak, Patris, Karaburma and Vera Blagojević. The research was conducted from the beginning of October to the end of November 2022. A research problem of this paper is what are the experiences of students using e-learning platforms.

3. RESEARCH RESULTS

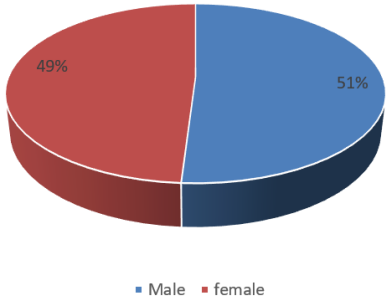

Figure 1 Sample structure with regard to the gender of the respondents
Source: Authors

Figure 1 shows the structure of the sample with regard to the gender of the respondents. In this research, only 1% more male respondents responded to the survey.

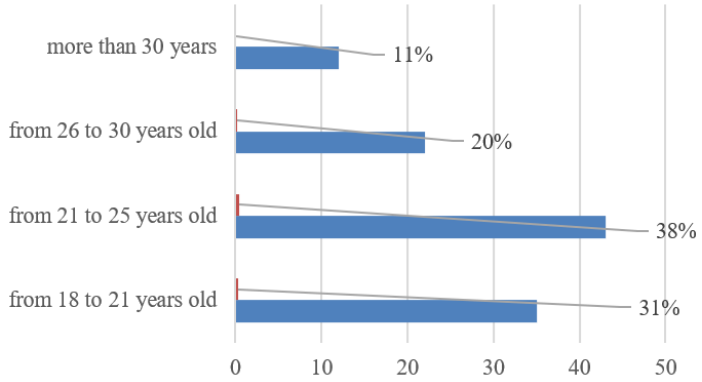

Figure 2 Sample structure with regard to the age of the respondents
Source: Authors

The highest response was among students in the age range of 21 to 25.

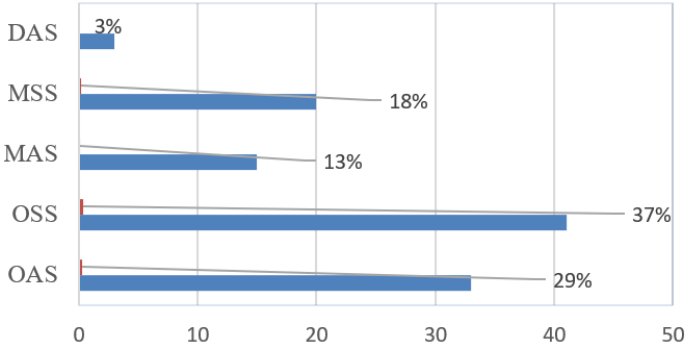

Figure 3 Sample structure with regard to the current status of studies
Source: Authors

The highest response in this research was among students at bachelor applied studies and undergraduate studies.

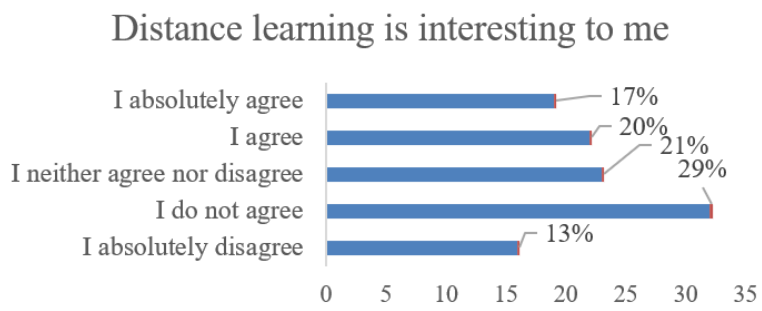

Figure 4 Distance learning is interesting for me
Source: Authors

From the above sample, we can conclude that distance learning is not interesting for students. A large number of respondents (29%) stated that distance learning is not interesting for them.

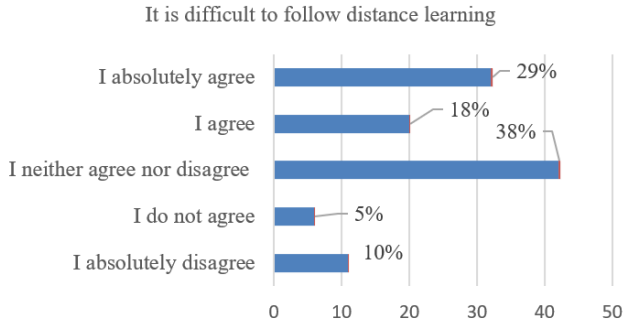

Figure 4 It is difficult to follow distance learning courses
Source: Authors

Based on the results, students expressed their opinions that they neither agree nor disagree, but a large percentage of them (29%) agree that it is difficult to follow lessons.

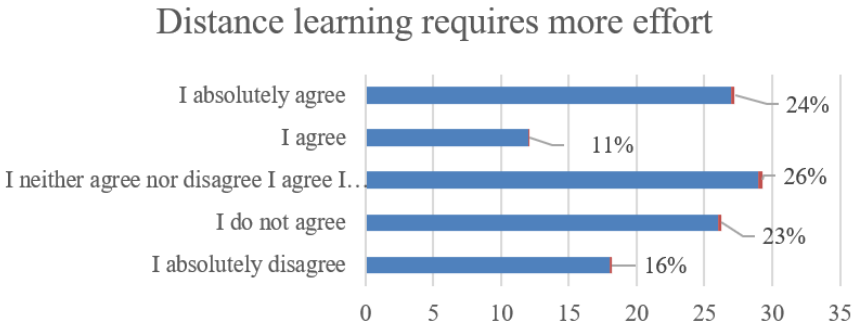

Figure 5 Distance learning requires more effort
Source: Authors

We can conclude that 24% of students think that distance learning requires greater commitment and more effort.

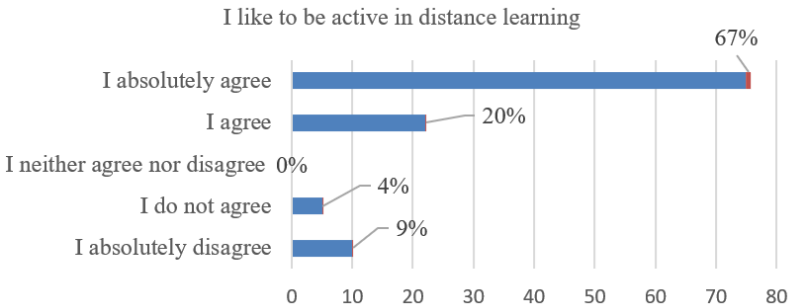

Figure 6 I like to be active in distance learning
Source: Authors

Regarding the online learning content, 87% of the respondents confirmed that they understand it. When asked whether independent work in distance learning suits them, 27% of students confirmed that this method suits them. When asked whether distance learning is stressful, the largest number of respondents answered that they neither agree nor disagree, while 20% of them answered that they absolutely disagree and that this way of learning is not stressful for them. In further research, 43% of respondents said that they use the Internet as an additonal source of teaching and learning material. While 55% of respondents would like to communicate with their teachers and colleagues via e-mail, 45% of them said that they sent their exam assignments (seminar papers, essays, etc.) via e-mail. 89% of students took their exams in the traditional way. 49% of students most often had consultations with their teachers and colleagues via Zoom and the Moodle application. During the pandemic, 90% of respondents used e-learning, but immediately after the pandemic students returned to their amphitheatres, workshops and laboratories. During the pandemic, students used the following platforms for online learning: Google Meet (38%), Zoom (32%) and Microsoft Teams (30%). When asked whether they are satisfied with e-learning, 58% of respondents answered with I neither agree nor disagree.

4. CONCLUSION

The obtained results indicate that students use the Internet as a source of learning and that it was their only way of learning during the pandemic. Moreover, they had communication with their teachers and colleagues and actively participated in the learning process. In most educational institutions, the following platforms were used: Google Meet, Zoom and Microsoft Teams. For some subjects, even after the pandemic, this type of learning is still used because there are only a small number of students who attend the same classes. Therefore, e-learning is successfully applied at all education levels, all ages and subjects. Students became aware of the importance of e-learning activities for their further development. Electronic learning is the future in educational institutions, so it is important to work on its further modernization and popularization. Based on the obtained results, it is recommended that institutions of higher education use a blended learning method. The hypotheses in this research: initial H_0 Students are satisfied with e-learning was partially confirmed. 58% of respondents confirmed it, although a large number of them did not express a positive attitude. H_1 Students find it difficult to follow distance learning was partially confirmed, as can be seen in Figure 4. H_2 Online learning content is useful for students was confirmed in the research, as seen in Figure 7.

Abstract: *The structural life of a functional component includes the period when the component has developed some sort of defect (e.g., crack). In such cases, damage-tolerant design utilizes fracture mechanics parameters for the assessment of the component's structural capability to withstand loads expected in the exploitation. One of the most fundamental parameters is the stress intensity factor, which characterizes the stress state near the crack tip. The critical value of this parameter is called fracture toughness, and it is the most suitable failure criterion for brittle materials. One of the most used materials in fused deposition modeling (FDM) technology is PLA polymer, known for its brittle behaviour. Due to good mechanical properties in comparison with other FDM polymers and excellent biocompatibility, the PLA material is not just a material for prototyping purposes but may also serve as a material for functional applications in medicine, food packaging, etc. The FDM printing parameters influence the final component's mechanical properties. The aim of this paper is to assess the impact of printing parameters, such as layer height, infill density, and raster orientation, on fracture toughness values.*
Keywords: PLA, Fracture toughness, Fused Deposition Modeling, Printing parameters.

1. INTRODUCTION

PLA (PolyLactic Acid) is a thermoplastic polymer derived from natural sources and is best known for its applications in Additive Manufacturing (AM) [1,2], namely, Fused Deposition Modeling (FDM), which is an extrusion-based AM technology. As a bio-based polymer, PLA represents a good substitute for other petroleum-based synthetic polymers, both for certain functional applications and for AM prototyping purposes. Due to the good mechanical properties investigated in [1,3] and proven biodegradability, PLA material is utilized in the food packaging industry and may serve in load-bearing biomedical applications, e.g., sutures, short-term screws, and resorbable fracture fixation plates [3-5].
Previously conducted tensile tests on FDM-prepared PLA specimens have shown a substantial influence of printing parameters on the mechanical responses of the material [1,2,6-9]. Lower layer heights improve the Ultimate Tensile Strength (UTS) but one has to keep in mind not to over-compress the layers [1,6]. Infill density influence was a subject in [7], showing the density influence from 10 up to 100 % infill with a 10 % increment. Raster orientation impact was a subject in [8], and the influence of nozzle temperature and printing speeds was examined in [9]. Thus, from papers [6-9] it is obvious that layer height, infill density, and raster orientation have the highest impact on the tensile properties of PLA material.

According to fracture mechanics fundamentals, there are three Modes of loading that can be applied to a developed crack. Mode I tends to open a crack, Mode II slides one crack face with respect to the other, and Mode III tears both crack faces (Fig. 1). In real-life conditions, these three Modes act together with Mode I being the most influential, [10]. Thus, the critical stress intensity factor in Mode I is usually referred to as fracture toughness (K_{IC}).

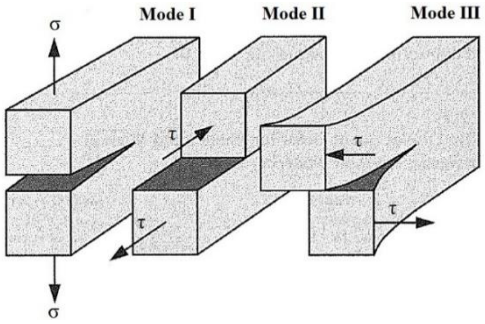

Figure 1. Three possible loading Modes on a crack.
Source: [10]

Fracture toughness assessment is a regular procedure for AMed materials, both for Mode I and II, [11-16]. The principal difference between Mode I and II fracture toughness is the testing setup, i.e., the number of supporting points on the specimen during the test: Mode I uses a three-point bending test procedure while Mode II uses a four-point bending setup. For example, there is thorough data on the fracture toughness values (both Mode I and II) of Selective Laser Sintered (SLS) materials, [11-14]. In FDM, except for securing the plane-strain state (described in detail in [10,17]), there are also a few more requirements, as explained in [15]. Except for regular fracture toughness tests, the addition of a set of cameras in order to capture crack opening displacement at the notch mouth and crack tip, and full-field strain states at the front side of the specimen ligament provides valuable information about the material, [16].

2. MATERIALS AND METHODS

Fracture toughness values can be calculated using different specimen geometries (see [13]), and the most utilized designs are SENB (Single Edge Notched Bend) and CT (Compact Tension). Standard [17] covers both these specimen geometries. The selected specimen design here is SENB, with 13 x 26 x 114 mm in bulk. Tests were conducted on a regular tensile testing machine, with a mounted three-point bending test rig. The test scheme with specimen geometry is shown in Fig. 2. Notch (see detail C, Fig. 2) was AMed, and pre-crack (3 mm long) was created via hammer tapping onto a razor placed in the notch- as suggested in the standard [17].
The fracture toughness value is calculated according to the formula in [17]:

$$K_Q = \left(\frac{P_Q}{BW^{1/2}}\right) f\left(\frac{a}{W}\right) \tag{1}$$

In (1), P_Q is the maximal detected load, B and W are specimen dimensions, and $f\left(\frac{a}{W}\right)$ is a formula which depends on the ratio between crack length and specimen width (see the full formula in [17]). Index ''Q'' in (1) signifies the conditional state of a calculated value, since load-displacement response must follow a linear trend and plane-strain condition at the crack front must be met. Namely, a specimen has to reach a certain thickness in order to obtain the plane-strain condition. In [17], the following size criterion must be satisfied:

$$B, a, (W - a) > 2.5\left(\frac{K_Q}{\sigma^y}\right)^2 \tag{2}$$

In (2), σ^y represents yield stress. For this particular case, the values are stored in [1].

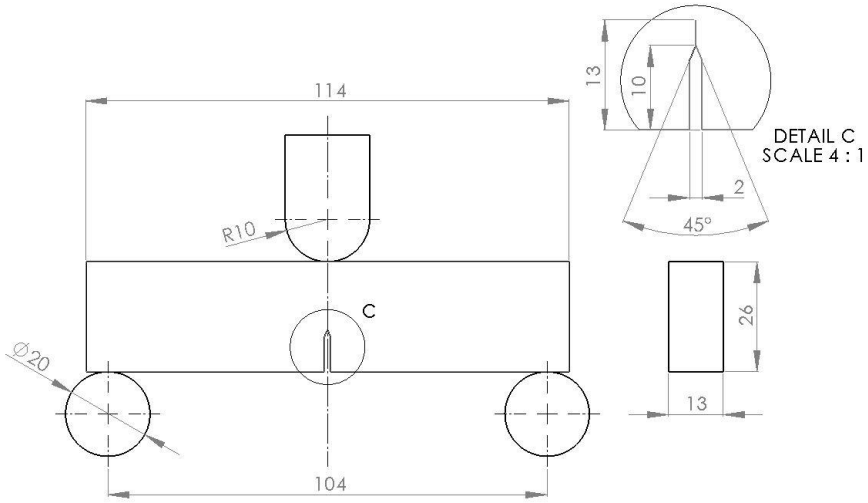

Figure 2. Three-point bending test scheme with loaded specimen geometry (units in [mm]).
Source: Personal image

To estimate the layer height, infill density, and raster orientation influence, the SENB specimens were sorted in four batches according to [1], with three specimens per batch:

- 1st batch: 0.1 mm layer height, 50% infill density, rectilinear raster orientation,
- 2nd batch: 0.1 mm, 100%, rectilinear,
- 3rd batch: 0.1 mm, 100%, circular,
- 4th batch: 0.2 mm, 50%, rectilinear.

The fifth batch from [1] was excluded since material drying is not a subject of this research. Fracture surfaces were observed using a scanning electron microscope LYRA 3 XMU FEG/SEM (SEM) operating at 2 kV. The images were taken in secondary electron contrast.

3. RESULTS AND DISCUSSION

In FDM, outer and inner layers are differently deposited as can be seen from the fracture surface SEM images in Figs. 3 and 4. Brittle fracture is more obvious in the outer layers (see Fig. 3). Inner layers exhibit a slight straining at ruptured ends (see Fig. 4), but this phenomenon probably appeared after the reached maximal load, since load-displacement linearity until reached maximal load was satisfied.

Before fracture toughness tests, the specimens were measured in width (W) and thickness (B) via a vernier caliper in three points, and the average values were used for K_{IC} calculation. Crack length (a) is set to 13 mm, and the ratio a/W is used for the calculation of f (a/W)- the exact formula is shown in the standard [17]. Maximal detected load (P_Q) is the highest in full-infill density batches, with rectilinear raster orientation specimens reaching values of almost 1 kN. Hence, all the data needed for fracture toughness calculation are stored in Table 1.

Table 1. Measured specimen dimensions and maximal detected load.

PLA data	B [cm]	W [cm]	a/W	f (a/W)	P_Q [kN]
1.1	1.315	2.649	0.491	10.32	0.267
1.2	1.308	2.663	0.488	10.32	0.264
1.3	1.312	2.649	0.491	10.32	0.268
Average	1.312	2.654	0.490	10.32	0.267
2.1	1.314	2.632	0.494	10.48	0.739
2.2	1.317	2.633	0.494	10.48	0.938
2.3	1.318	2.628	0.495	10.48	0.929
Average	1.316	2.631	0.494	10.48	0.869
3.1	1.320	2.594	0.501	10.65	0.507
3.2	1.318	2.592	0.502	10.65	0.527
3.3	1.322	2.590	0.502	10.65	0.545
Average	1.320	2.592	0.502	10.65	0.526
4.1	1.299	2.599	0.500	10.65	0.242
4.2	1.295	2.596	0.501	10.65	0.267
4.3	1.293	2.597	0.501	10.65	0.260
Average	1.296	2.597	0.501	10.65	0.256

The first calculated fracture toughness value is conditional (K_Q) and has to meet the size criterion, which evaluates whether the specimen has reached the required plane-strain condition. From Table 2, one can see that K_Q falls between 1.526-5.672 MPa*m^1/2. The size criterion shows that all the specimen batches meet the plane-strain condition, except for the 2nd batch (100 % infill, rectilinear raster orientation), where the thickness needed to reach the plane-strain condition is around 26 mm,

on average (as a reminder, SENB specimen thickness here is around 13 mm). Hence, the 1st, 3rd, and 4th batches meet the size criterion, and the conditional K_Q value there is actually the real fracture toughness value K_{IC}.
The K_{IC} value range in this research is between 1.526-3.388 MPa*m^1/2. The difference between the 1st and 4th batches suggests that layer height does not have a significant influence on K_{IC} value. An interesting conclusion can be drawn from full infill density batches, namely: in tensile tests, the highest UTS values were present in circular raster batch, where raster lines are parallel to the load direction (see [1]). But, in fracture toughness tests, using a three-point bending setup, the rectilinear orientation batch holds the highest load values even though the size criterion was not met. This is due to raster lines being at -45/+45° angle relative to the applied load. The conclusion from this research is in agreement with [18].

4. CONCLUSION

Fracture toughness tests were conducted on SENB specimens, made from FDM-prepared PLA material, according to the standard [17]. There are four specimen groups in total, with three specimens per batch. Batches differ in printing parameters, i.e., there are three variables: layer height, infill density, and raster orientation.
The infill density has proven to be the most influential parameter on K_{IC} values, then raster orientation, and lastly, the layer height was the least impactful.

This research was supported by the European Union's Horizon 2020 research and innovation program H2020-WIDESPREAD2018, SIRAMM [857124].

Abstract: *Games should enrich leisure time and provide a sense of advancement and fulfilment by following specific rules and overcoming obstacles to reach a particular goal. By analogy to games, our educational system is comprised of various sets of rules that participants are meant to obey. If it is looked through that prism, students can be perceived as players that acquire a different set of knowledge and skills that can be useful further in their careers. On the other hand, educators can be perceived as someone who design and imposes various challenges and obstacles for students to solve and overcome. Today, real-time rendering game engines provide accessible toolboxes for learning and implementing a different set of technical skills such as programming, solving logical problems, writing shader codes for different visual styles, and also set of artistic skills such as 3D modelling, painting, sculpting, and animating to name a few. Therefore, this paper aims to give insight into the theoretical background of what real-time rendering and game engines refer to and to describe some practices and initiatives promoting the implementation of real-time rendering game engines in the educational curriculum through different courses and workshops.*
Keywords: Real-time rendering, game engine, video games, education, gamification, edutainment

1. INTRODUCTION

The term ‘play’ refers to an activity usually not bound by externally imposed rules and is more casual, creative, and liberating. The term ‘game‘ refers to an activity that should enrich leisure time and provide a sense of advancement and fulfilment by following specific rules and overcoming obstacles to reach a particular goal. By analogy to games, our educational system is comprised of various sets of rules that participants are meant to obey. Both students and teachers. If it is looked through that prism, students are players who acquire a different set of knowledge and skills that can be useful further in developing their careers. On the other hand, educators can be perceived as someone who designs and imposes various challenges and obstacles for students to solve and overcome. Today, real-time rendering game engines provide accessible toolboxes for learning and implementing a different set of technical skills such as programming, solving logical and mathematical problems, writing shader codes for different visual styles, and also set of artistic skills such as 3D modelling, drawing, painting, texturing, sculpting, and animating to name a few.
Dempsey and his colleagues as well as Malone [1,2], define a game as ‘usually a contest of physical or mental skills and strengths, requiring the participant(s) to follow a specific set of rules to attain a goal‘. According to Suits ‘playing a game is a voluntary effort to overcome unnecessary obstacles’

[1] bojanb@uns.ac.rs
[2] milicn@uns.ac.rs
[3] jelena.kerac@uns.ac.rs
[4] rastko.m@uns.ac.rs
[5] adamovicsavka@uns.ac.rs

[3]. In his book ‘Level Up – The Guide to Great Video Game Design‘, Rogers [4] ultimately concluded that ‘a game is an activity that requires at least one player, has rules, and has a win and/or lose conditions‘. Chris Crawford [5], one of the game designer pioneers stated that - ‘The computer game is an art form because it presents its audience with fantasy experiences that stimulate emotion.‘ and that games are ‘intrinsically participatory in nature‘ which gives players ‘not the experience itself but the conditions and rules under which the audience will create its own individualized experience’. But, what is a video game? Maybe the simplest definition that gave Rogers is: ‘a video game is a game that is played on a video screen’ [4]. Academics and especially game designers also consider one of maybe most important factors of a video game – fun. The fun can not be looked upon solely as something amusing or as the result of a leisure time activity. Fun can be also achieved while working on something that may not be so interesting when one starts doing it. Csikszentmihalyi in his book ‘Flow: The Psychology of Optimal Experience‘ talks about the state – called flow state - in which we can merge ourselves when doing something interesting to us or when something becomes interesting to us by doing it [6]. This paper aims to give insight into the theoretical background of what real-time rendering and game engines refer to and to describe some practices and initiatives promoting the implementation of real-time rendering game engines in the educational curriculum through different courses and workshops.

2. REAL-TIME RENDERING AND GAME ENGINES

2.1 Real-time rendering

Akenine-Möller et al. describe real-time rendering as a process of rapidly making images on the computer and as the most highly interactive area of computer graphics [7]. Interactivity comes from the viewer‘s action and reaction through their feedback when the image appears on the screen which further affects generated real-time content. Besides interactivity, producing three-dimensional images is another condition to call the sequence of images rendered in real-time. These two conditions are sufficient conditions for real-time rendering but more than ever the third element became essential for real-time rendering, and that is graphics acceleration hardware [7]. The core component of real-time graphics is called the graphics rendering pipeline. An in-depth discussion on this topic is out of the scope of this paper, but the main function of this pipeline is to generate (or render) a two-dimensional image based on three-dimensional objects, virtual cameras, lights, etc. [7] Figure 1.

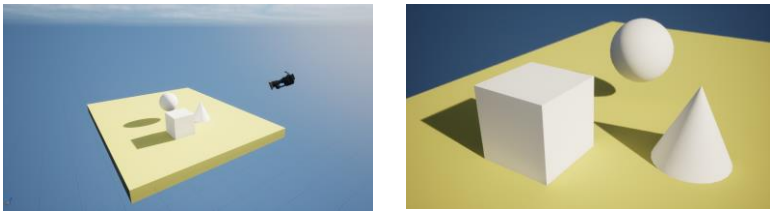

Figure 1. Locations of basic geometry shapes and camera in the environment (left), and 2D appearance of the shapes and environment through the camera lens (right)

2.2 Game engines

To discuss what a game engine is in its broadest meaning it must be separated from a specific game, genre, or hardware system. Sherod [8] describes a game engine as ‘a framework comprised of a collection of different tools, utilities, and interfaces that hide the low-level details of the various tasks that make up a video game‘. Lewis and Jacobson mention that the engine includes modules handling input, output (3D rendering, 2D drawing, sound), and generic physics/dynamics for game worlds [9]. According to Andrade, a game engine represents a reusable software layer allowing the separation of common game concepts from the game assets (levels, graphics, characters, etc.) [10]. The main goal of a game engine is to separate the game-making process into common video game features enabling

the use of code and game assets not just for one game but for reuse in different games. Today, there is a tendency to have a single game engine for different types of games, and not only games but also for animated movies, geographic and architectural visualizations, and ICVFX (In-Camera Visual Effects) used in the movie industry. Such an engine - ‚Überengine', according to Anderson et al., could potentially offer large benefits for the development of games, and apart from financial savings, such an engine would facilitate the transfer of programmers and artists across projects [11].

3. FINDINGS

3.1 Game engines in education curriculum

At the University of Novi Sad, Faculty of technical sciences, a couple of Departments started using game engines in their education programme. For example, at the *Department of Graphic Engineering and Design* [12], real-time graphics and game engines are used in two subjects: *Basics of Computer Games* [13] and *Computer Games* [14]. On those two subjects two game engines are being studied: Unity [15] and Unreal Engine [16]. The first one is introduced to students in first semester of the third year on the *Basics of Computer Games*, where the main goal of the subject is to give an introduction to and basics of game development and the game industry and basic terminology while simultaneously working on teaching students to develop their first 2D game. This subject also covers the basics of C# scripting language. Further on, in their second semester of the third year of studies on the subject named *Computer Games*, students continue to learn about game development by getting familiar with the concept of real-time rendering, introduction to game and level design, and concept of game engines, particularly Unreal Engine. In parallel students work in Unreal Engine on developing their first 3D environment by tackling basic concepts of level design, lighting, post-processing, animating cameras, modelling, and rendering.
Chair of Animation in Engineering, in the Department of Fundamental Sciences, at the Faculty of Technical Sciences in Novi Sad also implemented the Unreal game engine in their curriculum programme. In the subject named *Spatial Design and 3D Environments*, students learn to design immersive virtual spaces and environments in different disciplines [17]. Besides this subject Unreal Engine is implemented also in subjects such as *Simulations in Digital Animation*, *Advanced Simulation in Digital Animation*, and *Engineering Animation and Other Media* [18].
Faculty of Dramatic Arts in Belgrade also successfully implemented the utilization of real-time rendering techniques and technology through a four-year programme in the *Visual Effects, Animation and Game Art Department.* During their study, students are trained in the fields of animation, visual effects video games, and interactive media [19].

3.2 Educational and training courses, programmes and initiatives

Together with industry specialists, university educators have worked on various programmes where the implementation of real-time rendering graphics can help to tackle some of the modern technology challenges. One such project is conducted by educators and researchers from the *Mechatronics, Robotics and Automation Department* (Faculty of Technical Sciences in Novi Sad) [20] with the help and support of industry specialists from company *3Lateral* [21] through the EpicMega Grants programme [22] in 2021. The project is called *MetaCobots* which demonstrated the ability to design and deliver a framework for training and validation of human-to-robot interaction within the synthetic environments empowered by runtime simulations [23].
In February 2021, a team specialized in VFX and education courses – *Crater Training Center* [24] initialized together with *3Lateral*, the training programme called *Train The Trainers* [25] for university educators with the aim of implementing real-time rendering by using Unreal Engine, in curriculum programmes at their institutions. More than 40 university professors coming from Belgrade, Novi Sad, Kragujevac, Niš, and Zrenjanin successfully finished this educational course.

Further, the *Nordeus Foundation* situated in Belgrade, Serbia [26] started the *Gejmlab* platform [27] where the domestic public can learn all about gaming and game development from successful industry specialists. This platform aims to help people start their careers in the gaming industry by honing their love and interest in the world of games through a series of articles, courses, and tutorials.
One can not talk about the gaming industry in Serbia not to mention *The Serbian Games Association (SGA)* [28], a non-governmental, non-profit organization dedicated to the development of the Serbian gaming industry. Their main goal is 'to increase the competitiveness of their members on the global market, to create the best possible conditions for creating and publishing video games in Serbia, as well as to improve the talent and creativity of people involved in the sector.' One of their programmes includes ones such as *Playing Narratives* [29], a mentorship cohort with the aim of lifelong learning and exchange of knowledge between mentor and mentee creating an environment in which they can develop on a personal as well as professional level. Another of their initiatives is one called *Shift2Games* [30] which aims to popularize gaming professions and the creative industry as a whole, especially among the young population who are in the final stages of their education as well as professionals active in other relevant industries. *SGA* also provides a place where the public can search for job offers in the games industry.
The important role in implementing new technologies from the gaming and IT industries into education and vice versa plays *3Lateral* and *Materriya Talent Development* team through *Epic Games Community Lab* activities held in *Science & Technology Park in Novi Sad*, Serbia [31]. Through a series of lectures from industry specialists and university professors, they aim to bring together the gaming and education community, bring the audience novelties from creative industries and organize different education programmes such as *Fortnite Creative Fundamentals* [32], *Game Crafting: Unreal Editor for Fortnite* [33], and now renowned *Epic Games Fellowship programme* designed for the domestic public. Fellowship programmes (such as *Storytelling Fellowship* [34] and *World Building Fellowship* [35]) have a goal to gather specialists from gaming, VFX, animation industries, and education and through a series of lectures and practical workshops train them in using Unreal Engine for their further projects and researches.

4. DISCUSSION

With the advance of game engines and real-time rendering, it can be seen that these technologies are finding their way into the curriculum programme of different departments and different subjects. The tendency toward 'Überengine' is now evident more than ever. Game development is intrinsically interdisciplinary area gathering people from different professions to work collaboratively on the same project. From the game engine of today, it is required to be able to tackle various kinds of jobs, from modelling, texturing, shading, lighting, and post-processing to scripting, animating, and even movie and art direction and all of that in real-time.
There is a lot of research on the advantages and disadvantages of implementing games in education and teaching pupils and students about game development. There are usually two very different approaches in designing games in curriculum according to Klopfer et al. [36]. The first approach is to use commercial games (e.g. World of Warcraft and Civilization) to bring close the subject of research or develop certain skills. The second one generally avoids commercial games and focuses on educational games that help supplement traditional academic subjects. Klopfer and colleagues pointed out that 'while the first group embraces games and abandons school, the second group often embraces school to the detriment of anything that looks like real gaming.' The two approaches mentioned above tend to be more instructional in the way that teachers want to have a finished, downloadable teaching product as the party responsible for teaching the child [36].
Apart from this 'instructional approach', Kafai and Burke [37] adopted and wrote about the so-called 'constructivist approach' to using games in education. Kafai and Burke (2015) emphasize the idea that knowledge about rules, worlds, and interactions is, in this way, represented in a public entity (which is the game) and that playing and making games highlights the personal, social, and cultural dimensions of constructionist learning. They stated that making video games could help understand

the social, economic, and civil power of making and sharing. This is also supported by much earlier Piaget's work [38] who stated that games of construction are considered the highest form of gameplay, as games require children to build representations of the world according to their understanding.

5. CONCLUSION

From the findings represented in this paper one can not argue that implementation of real-time rendering through game engines is present to a large degree and probably will continue to be researched to a great extent in different departments as part of different subjects. These subjects and even departments intertwine each other in their findings to be part of a much larger whole wrapped in one common denominator called game development, animation, simulation, architecture, or even movie projects.

Application of game engines through different curriculum programmes can grow the community which is connected through different initiatives and joint projects directly with the professionals from the industries giving even more credibility to the educational institutions and their subjects as well as research projects. On the other hand, students can be prepared to work in team with people from different professions during their studies as well as on their tomorrow jobs.

And last but certainly not least, research done by academia when connected through community-driven and industry-supported events and programmes can give back to the industry by providing new research findings and vice versa. This started to show great possibilities for creatives not only who are part of a great team but also for individuals; not only for industry workers but also for researchers, students, and their professors.

EXAMINATION OF THE POSSIBILITY OF DYEING PRINTING PAPERS WITH PLANT EXTRACTS

Slađana Glišić[1], Faculty of Technology and Metallurgy, University of Belgrade
Aleksandra Janićijević[2], The Academy of Applied Sciences Belgrade
Predrag Živković[3], Faculty of Technology and Metallurgy, University of Belgrade

Abstract: *In this study, aqueous and alcoholic extracts of red cabbage were initially prepared, and offset paper sheets were dyed using the immersion technique. The sheets were dried under various conditions, both at ambient air temperature and elevated temperatures. The color change of the paper sheets was determined based on spectrophotometric measurements of the uncolored offset paper (reference value) and the dyed sheets were dried by two methods immediately after coloring, as well as at intervals of two and six days. The color fastness to distilled water and alcohol was also examined, and the impact of these agents on different samples was assessed over specific time intervals.*
Keywords: red cabbage, plant extracts, printing papers, paper dyeing, ink resistance to moisture

1. INTRODUCTION

The constant pursuit of ever-increasing profits, coupled with decades of neglect for environmental preservation, has resulted in pollution that is evident at every turn. Industries have surged in innovation and hyperproduction, prioritizing their capital without regard for the environment. Year after year, the environment has borne the increasing burden of various types of waste, which it can absorb less and less. Such behavior has led to a point where sustainable development must be the guiding principle in all aspects of prosperity. In nature, materials are found from which various products can be made, both synthetic ones that often have a detrimental impact on the environment, and recyclable and biodegradable ones with minimal adverse effects on the environment. Plant life is rich in substances that can be used to create various products, including dyes. Such plant-based dyes have been used since prehistoric times in various civilizations around the world [1].
Plant-derived dyes can be classified into groups of chemical compounds, or pigments, found in the plants from which they are extracted (Table 1).

Table 1. Classification according to colors and chemical compounds found in plants [2]

Color	PIGMENT	FRUIT AND VEGETABLES	FORMULA
Red	Anthocyanin	Strawberry, Blackberry, Cherry, Apple	
	Lycopene	Tomato, Watermelon	
	Betacyanin	Beet	

[1]glisicsladjana@gmail.com
[2]ajanicijevic@atssb.edu.rs
[3]peca@tmf.bg.ac.rs

Orange	Beta-carotene	Carrot, Mango, Apricot, Pumpkin		Beta-cryptoxanthin	Oranges, Tangerine	
Blue/Purple	Anthocyanin	Plums, Eggplant, Red Cabbage	Yellow	Lutein, Zeaxanthin	Corn , Avokado	
	Kurkumin	Tumeric	
Green	Chlorophyll	Broccoli, Spinach, Cabbage, Green tea	Black	Thearubigens	Black tea	
	Antocyanin	Blackberries	

In this study, the possibility of coloring printing paper with extracts of compounds from the anthocyanin group will be examined. The chemical formula of anthocyanin is provided in Figure 1.

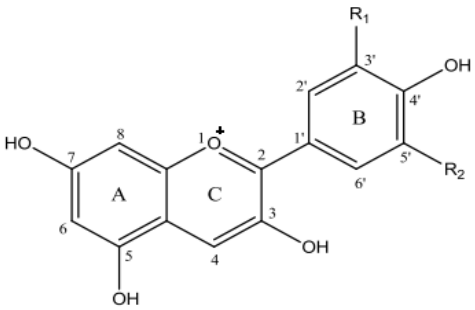

Figure 1. Structural formula of anthocyanin [3]

According to the groups R1 and R2, anthocyanins are divided into several subgroups, as shown in Table 2.

Table 2. Basic structure of the main anthocyanins commonly found in nature [3]

Anthocyanins	R1	**R2**	**Produced color**
Pelargonidin	-H	-H	Salmon orange
Cyanidin	-OH	-H	Crimson red and burgundy
Peonidin	-OCH_3	-H	Crimson red
Malvidin	-OCH_3	-OCH_3	Purple
Petunidin	-OCH_3	-OH	Purple
Delphinidin	-OH	-OH	Purple, lavender, and blue

Red cabbage contains cyanidin in its composition, which is reflected in its purple-blue color (Figure 2). Characteristic of red cabbage, specifically cyanidin in it, is its ability to change color with a change in the pH value of the environment. This property is interesting when coloring packaging paper, where a color change could indicate the condition of the packaged product.

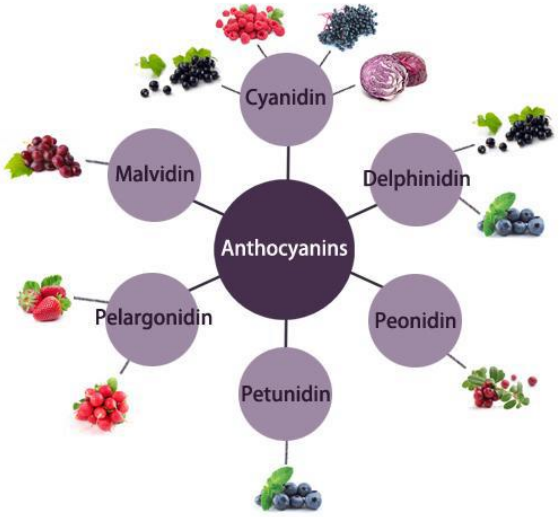

Figure 2. Graphic representation of anthocyanins, their classification, and the plants in which they are found [4]

In this study, printing paper will be colored using water and alcohol extracts of red cabbage. The coloring obtained with different extracts and under different operating conditions will be examined, as well as the stability of the coloring over time and under the influence of moisture and alcohol.

2. EXPERIMENT

The aqueous extract was prepared by blending 400 g of red cabbage for 3 minutes. The blended mass was immersed in 600 ml of distilled water and kept at a temperature of 150°C for 25 minutes with occasional stirring. After 24 hours, the mass was filtered through a triple-layered gauze. The alcoholic extract was prepared by blending 400 g of red cabbage for 3 minutes. The blended mass was immersed in 600 ml of 96% ethyl alcohol. After 24 hours, the mass was filtered through a triple-layered gauze. The leaves were dyed using the immersion method. A shallow container was filled with 100 ml of the aqueous extract. Prepared sheets of offset paper IQ MASTERPRINT, manufactured by MONDI, with a weight of 80 g/m2, were immersed in the extract for 15 minutes, with occasional stirring. The sheets were then removed and drained naturally (gravitationally). One group of sheets was air-dried at room temperature, and the other in the laboratory paper sheet former (blatbildner) between two sheets of dry paper at a temperature of 85°C for 5 minutes. Dyeing of sheets with alcoholic extract and drying was performed in the same manner as with the aqueous extract. The color of reference and dyed sheets was measured after 40 minutes, sufficient for sample drying, using the SpectoEye spectrophotometer from GretagMacbeth, under the following measurement conditions: D50, 2°, without optical filter, calibration on an absolute white standard, white background. On each sheet, color was measured at five points to examine uniformity and obtain the average value as a representative indicator. The measured color values are presented in the CIELab system (L*-lightness, a* green-red axis, and b* blue-yellow axis), and the color difference was calculated as.

$$\Delta E = [(L_2 - L_1)^2 + (a_2 - a_1)^2 + (b_2 - b_1)^2]^{1/2} \quad (1)$$

The colorfastness over time was determined based on color measurements of leaves left in the dark, exposed to air, after two and six days. The second group of leaves was subjected to the action of

distilled water and alcohol for 11 minutes and air-dried to investigate color resistance to these liquids. Measurements were taken after drying for 40 minutes, which was sufficient for the samples to completely dry naturally.

3. RESULTATS AND DISCUSSION

The extracts were monitored for 6 days, and in the aqueous extract, there was a change in color from purple to blue-green, while in the alcoholic extract, a slight change occurred from light purple to a darker shade. The results of color change measurements of dyed sheets compared to the clean sample of offset paper, measured on the same day as they were dyed, are presented in Table 3.

Table 3. Color change of offset paper dyed with aqueous and alcoholic extracts of red cabbage

Extract – drying conditions	L_{sr}	a_{sr}	b_{sr}	ΔE
Reference paper	93.90	1.09	-7.99	**0**
Distilled water – desiccant	81.93	3.22	-13.94	**13.6**
Distilled water – natural	83.40	1.00	-12.18	**11.3**
Alcohol – desiccant	84.45	7.05	-13.10	**12.3**
Alcohol – natural	84.86	3.39	-13.04	**10.6**

The most intense coloration is exhibited by the aqueous extract dried in the paper sheet former. The alcohol solution, air-dried naturally, has the least impact on coloring the offset paper. The difference between the best and the least intense coloring is 2.6. According to Table 4, this value is defined as the mean difference.

Table 4. Visual difference between two colors [5]

Value ΔE	Description of color difference
ΔE between 0 i 1	Generally, the difference cannot be applied.
ΔE between 1 i 2	Very slight difference, noticeable only to an experienced eye.
ΔE between 2 i 3.5	Moderate difference, noticeable to an untrained eye.
ΔE between 3.5 i 5	Substantial difference.
ΔE over 5	Massive difference.

The colorfastness over time was examined by monitoring the color of the sample after two days and after six days. The values of the color difference of the sample after two and after six days, compared to the color of the initial dyed sample, are presented in Table 5.

Table 5. Color change after the second and sixth day following dyeing

Extract – drying conditions	ΔE_{0-2}	ΔE_{0-6}
Distilled water – desiccant	0.8	1.4
Distilled water – natural	1.3	0.6
Alcohol – desiccant	0.7	1.8
Alcohol – natural	1.2	1.2

The color change after two days was smaller for samples dried on the paper sheet, regardless of the type of extract. After six days, the most significant color change was observed in the sample dyed with alcohol extract and dried on the paper sheet, while the smallest change was noted in the sample dyed with distilled water and air-dried. However, all identified differences are small and fall into the category of changes that are not noticeable to the naked eye or are very slight.

Testing color resistance to water and alcohol yielded the following results (Table 6):

Table 6. Color change due to the effects of water and alcohol on dyed samples

Extract – drying conditions	$\Delta E_{\text{destilled water}}$	$\Delta E_{\text{alcohol}}$
Distilled water – desiccant	9.6	2.2
Distilled water – natural	9.0	2,0
Alcohol – desiccant	10.7	1.6
Alcohol – natural	9.9	1.8

According to the results, it can be observed that the sample dyed with water extract and air-dried is the most resistant to the effects of distilled water. The sample dyed with alcohol extract and dried in the paper sheet former shows the least resistance to distilled water. Color differences between samples tested for water resistance are very small, below the threshold of human eye perception or barely noticeable. The sample dyed with an alcohol solution and dried in the paper sheet former is the most resistant to alcohol, while the sample dyed with water extract and dried in the paper sheet former is the least resistant. Again, the differences between them are below the threshold of human eye perception. Comparing the color change of samples, it is evident that all samples are significantly more resistant to the effects of alcohol than to the effects of distilled water. This significant difference in color change arises from the fact that the extracts are more soluble in water, as evidenced by the color change in distilled water after removing the sample. There was almost no change in color in alcohol.

4. CONCLUSION

The most intense coloring was achieved by dyeing with a water extract and air-drying in the paper sheet former ($\Delta E = 13.6$). Similarly, when dyeing with an alcohol extract, more intense coloring was achieved in the sample dried in the paper sheet ($\Delta E = 12.3$).
Comparing samples dyed with water and alcohol extracts and dried in the same way, it can be noted that slightly more intense coloring is achieved with dyeing from the water extract, although the differences between these samples fall into the category of those not noticeable to the naked eye.
The most colorfast dye after two days from the drying moment is the sample dyed with alcohol extract and dried in the paper sheet former ($\Delta E_{0\text{-}2} = 0.7$), while after six days, the most colorfast sample is dyed with a water extract and air-dried ($\Delta E_{0\text{-}6} = 0.6$). Given that these changes are imperceptible to the naked eye, it can be concluded that the color is stable within the observed time interval.
The most resistant to the effects of distilled water is the color of the sample dyed with a water extract and air-dried ($\Delta E_{\text{distilled water}} = 9.0$). However, this can still be considered a significant change, indicating that the color of the paper dyed with a water extract is not inherently resistant to moisture.
The most resistant to the effects of alcohol is the color of the sample dyed with an alcohol extract and dried in the paper sheet former ($\Delta E_{\text{alcohol}} = 1.6$), while the least resistant is the sample dyed with distilled water and air-dried ($\Delta E_{\text{distilled water}} = 2.2$). It can be concluded that the color resistance to alcohol is much greater than the resistance to water.

SOCIETY, ECOLOGY AND DESIGN EDUCATION: TRANSFORMATIVE LEARNING FOR FUTURE SUSTAINABLE AND HEALTHY ENVIRONMENTS

Jelena Ristić Trajković[1], Faculty of Architecture, University of Belgrade

Abstract: *To effectively tackle the complex socio-ecological challenges of our time, it is imperative to utilise design approaches that are both transformative and broadly applicable. Such design approaches must transcend traditional boundaries of fields, domains, and disciplines and foster cross-cutting collaboration and innovation. By adopting a holistic and inclusive perspective, we can work towards meaningful and sensitive solutions that address the multifaceted challenges facing our society and environment. Failure to do so could result in a lack of understanding of environmental values and problems, leading to a significant lack of progress and understanding in these critical areas of our lives. In line with that, design education can play a central role in creating more sustainable, equitable and healthy urban environments. Transformative learning can provide "a qualitative shift" in our living spaces at all spatial scales. It calls for dialogue, reflection, and action, whereas it addresses multiple ecological, societal, and health crises. This presentation aims to share lessons learned from international cooperations and projects, offering examples to enrich design education and practice development.*
Keywords: socio-ecological challenges, transdisciplinarity, holistic design, environment-behavior relations, living spaces

1. THE IMPERATIVE FOR CHANGE

As we progress through the 21st century, the relationship between human societies and natural environments becomes increasingly endangered. With the rapid advancement of science, technology, urbanization, and climate challenges, humanity's aspirations with regard to ecological imperatives are being fostered toward domination and disconnection. Addressing this re-examination demands an interdisciplinary approach recognising that our collective actions simultaneously affect both social structures and ecological systems [1]. Understanding the interconnections between these complex challenges is crucial to creating a regenerative, equitable, and harmonious future for all. The current epoch is recognised as the epoch of the Anthropocene, in which humans and our societies have become a global geophysical force [2]. Human influence has become the primary driver of change, surpassing natural processes [3]. Science and technology have transformed the human experience on Earth by compressing time and space, offering novel opportunities and perspectives of action, resulting in multiscale and rapid global transformation [4]. Biodiversity and cultural loss, resource depletion, social disparities, and degradation of health and well-being are just some of the crucial topics in this context. As Kolbert observes over the last half a billion years, there have been five mass extinctions, when the diversity of life on earth suddenly and dramatically contracted. The sixth extinction is likely to be mankind's most lasting legacy, and it compels us to rethink the fundamental question of what it means to be human [4]. As the global population grows and urban areas become more crowded, there is increasing pressure on resources, leading to complex issues that require new solutions. Addressing these challenges demands a collaborative effort, combining knowledge and expertise from various disciplines such as ecology, sociology, economics, and many others.

[1] jelena.ristic@arh.bg.ac.rs

In this context, design can serve as a bridging discipline, providing a framework to conceptualise and implement solutions considering both human and environmental well-being. The complexity of prevailing socio-ecological crises highlights the limitations of conventional design methods, emphasising the imperative for a shift in design practices [5]. The present situation underscores the imperative for design practices to shift towards more socially and ecologically responsible approaches [6]. To address the intricate socio-ecological issues of our time, we must employ design methodologies that should be adaptable across different contexts, promoting a holistic approach to regeneration and societal well-being. It implies creating a profound change in perspective, encouraging designers to integrate knowledge across various disciplines and topics, and critically assess their own beliefs and experiences. By embracing a holistic and transformative perspective, design education can pave the path for training professionals who are not only capable of creating visually appealing and functional spaces and objects but also profoundly considerate of the broader environmental, societal, and ethical implications of their projects. Such a systematic framework is often referred to as transformative learning. Emphasising systemic change and holistic understanding, transformative design is more than just an option. It's a critical necessity.

2. DESIGN EDUCATION AS A CATALYST FOR REGENERATIVE URBAN ENVIRONMENTS

2.1 Breaking Barriers: Transcending Traditional Disciplinary Boundaries

The traditional boundaries of individual subjects should not confine education. Schools and universities should encourage an interdisciplinary approach to help students understand the interconnectedness of human societies, natural environments, and built environments [7]. While providing in-depth knowledge and expertise in a particular field, discipline-specific approaches have limitations, especially when addressing complex, multi-faceted challenges. This narrow perspective can obstruct understanding and detecting expansive, interconnected systems and settings crucial for thorough problem resolution. Consequently, it might induce shortcomings like a limited scope of understanding, difficulty adapting to swift changes, susceptibility to repetitiveness, a restricted skill range, inherent biases, and disjointed communication. Merging varied expertise, viewpoints, and approaches through interdisciplinary collaboration often paves the way for groundbreaking solutions. In our rapidly changing world, an overly specialised focus can inhibit adaptability to fresh insights or novel technologies from different domains. A deep commitment to one discipline can introduce biases, causing professionals to overly favour their specific methods and perspectives, which might distort results and lead to miscommunication and lost opportunities. Depending solely on specialised training may not provide professionals with the broad skill set essential for diverse teams or ventures. In line with this, we must encourage ongoing dialogue, reflection, and action among all sectors and disciplines involved in environmental design and policy. Transformative learning has already marked notable successes, serving as a standpoint of optimism for educators and learners. Current achievements in this area not only validate the effectiveness of such an approach but also illuminate a promising path forward, especially in terms of its potential to reshape educational paradigms.

2.2 Transformative Learning: A Paradigm Shift

Transformative learning is a deep form of learning where individuals change their frames of reference, including belief systems and behaviour. Learning as transformation goes to the heart of human experience: our quest for meaning, our pursuit of growth, and our role as agents of change in an ever-evolving world. The interplay between individual development and societal change and how we change ourselves to adapt to or challenge the circumstances that surround us, is crucial, as it shapes not only our personal growth but also the evolution of our communities and societies [8]. In practice, transformative learning can happen in various settings – in formal education, professional development, or personal life experiences. It is crucial that it involves not just the individual learner but also the social and relational contexts in which they are embedded [9]. This concept has

exceptional potential for design education for a variety of reasons. It provides understanding and grappling with the complexity of contemporary multifaceted design challenges, cultivating critical and adaptive thinking, promoting empathy and ethical consideration, going beyond disciplinary boundaries, fostering lifelong learning, enhancing collaborative skills, and constantly questioning established norms.

Today's design problems, from urban planning to product innovation, are more complex than ever. The speed and nature of change in the contemporary world mean that designers must constantly adapt [10]. Transformative learning gives designers the skills to assess and understand their pre-existing beliefs and experiences critically, allowing them to address these multifaceted challenges holistically. Transformative learning fosters an adaptive and reflective mindset, enabling designers to evolve alongside the rapidly shifting landscapes of technology, society, and the environment. It highlights the importance of empathy and ethical reflection, ensuring designers consider their work's broader implications and responsibilities [11]. Design directly impacts users, communities, and environments. Traditional educational models can sometimes perpetuate linear, compartmentalised thinking. On the other hand, transformative learning challenges learners to break out of these barriers, promoting interdisciplinary thinking vital for innovative design solutions [12]. It continuously provokes a lifelong commitment to ensuring designers remain current, relevant, and effective. Design projects often involve teamwork and collaboration with professionals from diverse fields. Transformative learning equips individuals with the skills to understand and value diverse perspectives, fostering more effective and harmonious collaborative efforts. At its core, design is about envisioning and creating the future. Transformative learning encourages challenging the status quo and reimagining possibilities, which is fundamental for forward-thinking design.

Traditional design education often focuses on aesthetic and functional aspects, sometimes overlooking the broader environmental implications of design choices. Integrating social and ecological considerations from the outset helps designers to become advocates for environmental stewardship, ensuring that they consider the entire lifecycle impacts of their designs on ecosystems, societies and resources. Designers play a crucial role in shaping communities. By emphasising social aspects and human-centred design, future designers will learn to create spaces that support community, equality, and inclusivity. By fostering a deep, critical understanding of existing norms, this educational approach equips urban planners, architects, and designers with the tools to envision and create spaces and objects that are more sustainable, regenerative, equitable, and health-focused. Designing regenerative environments often demands challenging existing paradigms and rethinking established practices that might be detrimental to the environment and well-being, both in terms of personal well-being and the broader well-being of communities and the environment.

This educational approach emphasises the intricate connections between environmental sustainability, social systems, economic models, and cultural shades in urban design processes. Questioning existing power structures and societal norms leads to a design that prioritises social justice and equity, ensuring that urban spaces are accessible, inclusive, and beneficial to all, regardless of socioeconomic status. A heightened focus on health, encompassing both psychological and physical aspects, is also essential.

The concept of "transformative" in design and education denotes a profound shift in how we perceive, understand, and address challenges. It nurtures a culture of reflection. This reflective practice is crucial for continuous personal and professional development, fostering a mindset of lifelong learning and adaptation to new challenges and information. Rather than simply tinkering at the margins or making incremental improvements, transformative approaches seek profound, foundational changes in how we think and act [8].

3. INTERNATIONAL COOPERATION: LESSONS LEARNED

This section opens a discussion on various experiences, challenges, and gaps in the application of transformative learning realised within the framework of international scientific projects and expert networks:

1) SHiFT - *Social Sciences and Humanities for Transformation and Climate Resilience* – COST Action CA21166, European Cooperation in Science and Technology (2022-2026) [13].
2) HERSUS - *Enhancing of Heritage Awareness and Sustainability of Built Environment in Architectural and Urban Design Higher Education*, Erasmus + Programme of the European Union (2020-2023) [14].
3) sUser - *Introducing User-Driven Design and Agile Development Skills in the Case of Sustainable Service Housing for Elderly*, Erasmus + Programme of the European Union (2022-2025) [15].

3.1 Urban imaginary - Transdisciplinary time traveler's guide to our shared future(s)

This chapter shares experiences from an international summer school Urban Imaginary - Exploring our Urban Futures" which was hosted under COST action SHiFT - Social Sciences and Humanities for Transformation and Climate Resilience. The 5-day course took place in the National Museum of Science and Natural History and the Botanical Garden of Lisbon, Portugal, 3-7 July 2023.
The summer school was envisioned as a creative co-learning and transformative environment. It was conceptualised as an educational setting that intertwined both intellectual and experiential knowledge to enrich the body and mind simultaneously and synergistically. With 48 trainers and participants from varied disciplines across 20 countries, both from Europe and beyond, the program adopted a transdisciplinary and transformative methodology. This approach facilitated the exploration of various dichotomies, conflicts, and urban challenges and spurred discussions on innovative, regenerative visions for the future. Participants were immersed in a blend of theoretical lectures, interactive discussions, guided explorations, and integrated embodied and experiential learning sessions, consistently emphasising experiential and hands-on learning. The selected fusion of art and science in a transdisciplinary manner aimed to endow learners/travelers with both a tangible experience and a theoretical grasp of transdisciplinarity, demonstrating how to address real-world challenges holistically. Every morning of the course was initiated with an embodiment session in the Botanical Garden, tapping into the profound insights of embodied knowledge and the body's wisdom. As the sessions progressed, trainees grew more expressive, harmoniously aligning with fellow participants and nature, seemingly converging as a singular entity. The culmination of this learning journey was group presentations showcasing visionary urban design ideas for various Lisbon locations. These showcases amalgamated performance art, narratives, poetry, innovative design strategies, and visual illustrations, all underpinned by core values like kincentric futures, well-being, care, community bonds, utopian visions, transformative evolution, and heritage preservation. Participants' varied disciplinary and geographical origins brought a unique knowledge spectrum and experiential richness to their collaborative groups.
This summer school opened a spectrum of emotions and experiences for both trainers and trainees. The most crucial impression was the strength of creativity, embedded experience and wisdom in feeding scientific and technological innovations. Participants stated that the integrative approach creatively inspired even groups not primarily rooted in creative disciplines. They, in particular, acknowledged the transformative learning liberating potential to tackle serious matters with a light-hearted attitude, as it not only infuses hope but also makes it easier to deal with topics that might otherwise feel insurmountably difficult. It underscores the need for optimistic approaches when confronting with very daunting topics.

3.2 Reprogramming perspectives of architectural heritage

The built environment is more than just physical structures. It's a cultural narrative where interpretative and discursive methods frequently transcend traditional disciplinary ways of perceiving and comprehending space and culture. In recent years, there's been a clear imperative to incorporate heritage sustainability elements into design research, practice, and education. International Project *Enhancing of Heritage Awareness and Sustainability of Built Environment in Architectural and Urban Design Higher Education* (HERSUS) strives to contribute to this aim raising 1) a new profile of an architect/urban designer, a professional who is trained in the broad architectural domain, who

owns technical, technological, socio-humanistic and artistic skills and, therefore, equipped to contribute to the socio-environmental challenges, and (2) a new profile of architectural educator capable of assuming responsibility for the improvement of education and training of the future architects to enable them to meet the expectations of 21st-century societies worldwide for sustainable human settlements in every cultural heritage [14].
The objects and spatial wholes represent a legacy of a specific period or culture, characterised by the environmental, human, social, systemic, temporal, economic, and aesthetic values that form the basis for generating an architectural program. Contemporary design research, education and practice search for novel analytical tools and design strategies for understanding these values and addressing design issues. Architectural programming methodology assists in unravelling and steering through these complex design dilemmas. It advocates for an all-encompassing interdisciplinary method, striving to tackle the diverse aspects of our holistic environment, including the natural, built, social, cultural, and economic realms [16]. Such an approach also aims to foster a creative and cohesive link between the past, present, and future. The emphasis is placed on the design process, indicating that design isn't just the product and piece of art but a tool for challenging the current state and navigating the future.

3.3 Introducing System Thinking in the Case of Sustainable Service Housing for the Elderly

Europe's increasing elderly population urgently demands rethinking specific needs for housing and services. To provide a built environment that meets the demands of the residents, it is critical to introduce user-centred design and system thinking in the design process. In the design phase, many decisions are of great importance for ecological as well as social, and economic sustainability. Future professionals must have knowledge and competence on the adequate methods and tools that can be transferred to broader co-creation and user-centred design and enhance awareness of the importance of sustainability in environmental, economic, and social contexts. From this standpoint, this project develops a future-oriented teaching material and an integrated methodological framework developed by an interdisciplinary team of researchers. The project also considers behavioural changes for individual preferences, cultural values, and awareness to support active engagement for sustainable development. This is done by stimulating innovative learning and teaching practices to increase the quality and relevance of the curricula and by promoting inter-connected higher education systems to build the partner’s capacity to work transnationally and across sectors.
By breaking away from traditional silos of knowledge and embracing a more interdisciplinary and systematic educational approach, students can innovate more effectively. They learn to recognise systems at different spatial scales and complexities, understanding the interconnectedness of various elements of the system. This systemic view is a prerequisite for sustainable innovation, aiming to inspire students to find novel solutions that have multiple positive effects across the system.

4. CALL TO ACTION: ENRICHING DESIGN PRACTICES

Fostering a culture of perpetual learning and adaptability within the design profession is essential for design innovation and effectiveness. O'Sullivan highlighted the importance of embodied learning, a coming into ecological consciousness [17]. Transitioning to a transformative design approach should transcend traditional classroom confines. It is crucial to encourage students to challenge existing paradigms and introspect on their academic journeys. They should be prompted to consider the ethical, environmental, and social consequences of design and technology, cultivating a sense of responsibility and ethical citizenship. Engaging in community endeavours offers students a unique opportunity to witness collaborative problem-solving and grasp the tangible societal repercussions of ecological choices. Such hands-on experiences anchor their theoretical knowledge, illustrating the real-world consequences of both policy and design decisions. Developing emotional intelligence and fostering empathy is essential to comprehend and weigh environmental and design choices' emotional and societal consequences.

However, there are numerous obstacles in the transition to transformative design education. Starting from institutional inertia, where established systems and mindsets resist change, to the challenge of integrating positive experiences systematically. Furthermore, real-world application of design solutions often encounters technical, economic, and policy constraints. The balance between visionary design and practical implementation requires a deep understanding of these challenges. In line with that, interdisciplinary and multistakeholder educational partnerships could be vital in responding to the urgency of addressing socio-ecological challenges through transformative design. They can foster awareness of the broader impacts of design decisions and innovate responsibly, ensuring the health and sustainability of environments and communities for the future. Embracing a transformative learning model transcends mere academic knowledge—it's about driving impactful change and constructive action.

This research was supported by the Erasmus + Programme of the European Union through projects: 1) Enhancing Heritage Awareness and Sustainability of Built Environment in Architectural and Urban Design Higher Education (HERSUS), 2) Introducing User-Driven Design and Agile Development Skills in the Case of Sustainable Service Housing for Elderly (sUser) and by the European Cooperation in Science and Technology through COST Action - Social Sciences and Humanities for Transformation and Climate Resilience – CA21166 (ShiFT).

THE EFFECTS OF STYLE ON AN AESTHETIC ASSESSMENT OF DESIGN

Biljana Pejić[1], The College of Social Work
Bojana Škorc[2], Faculty of Fine Arts, University of Arts

Abstract: *This article describes the impact of artistic style on an aesthetic assessment - its effect on the complexity, noticeability and interestingness of an aesthetic object. In this research, the vases of different styles have been chosen as stimuli and the subjects estimated their aesthetic impressions. Research in experimental aesthetics showed that the perception and aesthetic value of a piece of art depends on many formal characteristics. The style was described as a set of important aesthetic characteristics, specific to a particular set of artworks. It has been approved that the impact of style increases with sensibility and education level of subjects. The research included 40 subjects, students of Art Academy. They were assessing 12 black-white photos of vases, using 7-degree scales for different criteria: beauty, complexity, interestingness and noticeability. Vases differed by style (Art Nouveau, abstraction, minimalism, postmodern art). The results indicate that all examined characteristics representing the style: complexity, prominence and interestingness, affect the aesthetic assessment of vases. Vases of Nouveau Art style were preferred, while the lowest scores were found for minimalistic-styled vases. Nouveau Art vases were seen as the most complex, most interesting and noticeable. For this group of subjects, interestingness appeared as the most important characteristic in aesthetic assessment. These findings are in concordance with Eysenck's finding of a linear connection between aesthetic noticeability and complexity and Berlyne`s idea of collative variables.*
Keywords: style, aesthetic assessment, complexity, interestingness, noticeability

1. INTRODUCTION

Effects of style on an aesthetic impression is one of the few focal issues in the field of psychology of art. Many pieces of research demonstrated the fact that the style of artwork plays an important role in the process of forming the aesthetic impression and aesthetic assessment. Style strongly influences the assessment in visual arts [1,2]. According to some authors, style as a factor is a stronger predictor of aesthetic value than excitement [3].

The effect of style becomes visible and measurable observed in the process of assessment of visual art objects which differ in the levels of realism or abstraction [1,2]. Realistic art objects are more frequently observed as beautiful and pleasant compared with abstract visual art objects [2,4,5,6,7]. The effect of style becomes stronger in observers with higher levels of art education and experience in art [1,8]. Many studies show that in general, artists tend to highly evaluate abstract art, while other groups prefer representational art [6,7,9,10,11,12]. Fine analysis of the responses shows that the differences between the responses were based on different constellations of various aspects of the work of art participants paid their attention to [13,14,15,16,17,18]. The group of non-artists was more attracted by bright colours, content and realism, while artists based their assessments on elements of composition (lines, forms and colours) and their relations [17,19,20]. The non-artists were attracted by the meaning and semantics, while artists estimated formal characteristics of paintings, style and relations of elements [13,21,22].

[1] b.pejic@yahoo.com
[2] bskorc@yahoo.com

At the same time, there are some gender differences registered, female observers preferred impressionism and rococo styles, while male observers preferred expressionism, cubism, pop art and abstractions [6,23,24,25]. Polzella [24] found that female observers described the painting of impressionism as more pleasant and relaxing than other works of art. Furham and Voker [7] found lower estimations in female subjects for traditional, pop-art or Japanese paintings in their life space than male subjects. Pop art has been seen as less valuable, and pop artists as less talented by subjects. Style, as a constellation of characteristics, appeared as an important aspect in the classification of works of art. Aesthetic assessment of everyday objects, such as buildings [26], furniture [27], the phones [28], showed that the style of the object appeared as the most important factor of aesthetic decision. Whitfield and Slatter [27] asked their subjects to create a living room and found that subjects chose elements according to style, not according to their personal preferences. The style has been seen as the most important criterion.
Considering such findings, the aim of this research is to observe the effect of style on an aesthetic assessment of everyday objects. The focus of this research is on the effects of style – its complexity, salience and interestingness.

2. METHOD

2.1. Subjects

A total of 40 subjects were included, they were the students of visual arts from Academy of Arts Novi Sad. There were 75% female and 25% male included. They were students from the groups: painting, sculpturing, graphic arts, new media and design. This group was expected to be sensitive to formal aspects of an aesthetic experience and familiar with art history.

2.2. Stimuli

There were 12 black-white photos of vases presented, representing 4 art styles: Art Nouveau, abstract art, minimalism and postmodernism (Figure 1). Each style has been represented by 3 examples. In order to simplify the procedure and avoid the effects of colours, black-and-white photos have been used. Vases as objects have been chosen because they are at the same time works of art and everyday objects.

Figure 1. Vases of different styles
Source (from left to the right)**:** https://www.pinterest.com; https://www.etsy.com; https://www.pinterest.com; https://www.dezeen.com

Art Nouveau style is ornamental, representing natural forms such as a leaf, a flower, human or animal body shapes, unusual colours, curved lines, and strict lows of harmony and contrast. The abstract style uses forms in a non-traditional way, symbols, simplicity, asymmetry, and geometry. Minimalistic vases are simplified, with reduced lines, high symmetry and reduced expressiveness, they are focused on geometric forms. Post-modernistic vases are disproportional, and asymmetric, with oblique forms, focused on details and decoration, they represent the combination of typical styles.

2.3. Instrument

The list of four seven-grade scales has been used. The scales were: beautiful - ugly, simple – complex, uninteresting – interesting and non-noticeable – noticeable.

2.4. Procedure

The subjects assessed their impressions using the list of scales. Their task was to note one of the numbers representing their impression. Grades on the scales varied from –3 (least present characteristic) to +3 (most present) with 0 in the middle. Stimuli have been presented in random order. There was no time limit. The research was organized in groups.

3. RESULTS

The analysis of variance showed a statistically significant effect of the style on all the scales included: scale ugly-beautiful, $F(3)=8,76$, $p<.001$; scale simple – complex, $F(3)=105,39$, $p<.001$; scale uninteresting – interesting $F(3)=48,97$, $p<.001$ and scale non-noticeable – noticeable $F(3)=37,26$, $p<.001$.
Regarding the impression of beauty, the highest scores have been registered for the vases of Art Nouveau style, next were abstract vases, while post-modernistic and minimalistic styles were assessed as less beautiful (Figure 2). Regarding complexity, the higher scores have been related to Art Nouveau and post-modernistic styles, lower scores have been related to abstract and minimalistic styles. Scales of interestingness (Figure 3) and scale of noticeability (Figure 4) showed similar results, the higher scores were given to Art Nouveau and post-modernistic styles, and the lower scores were given to abstract and minimalistic styles.

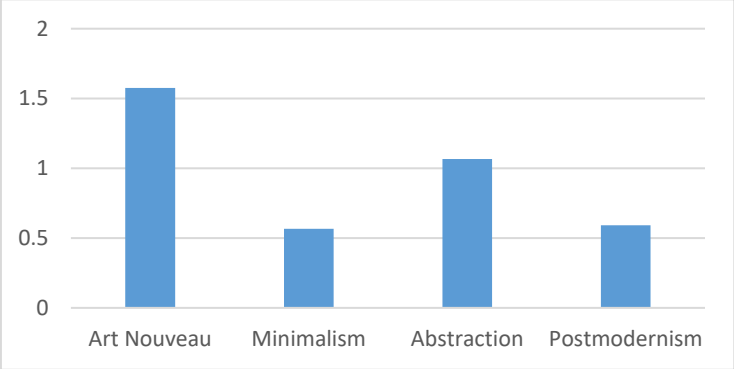

Figure 2. Scores on the scale of Beauty

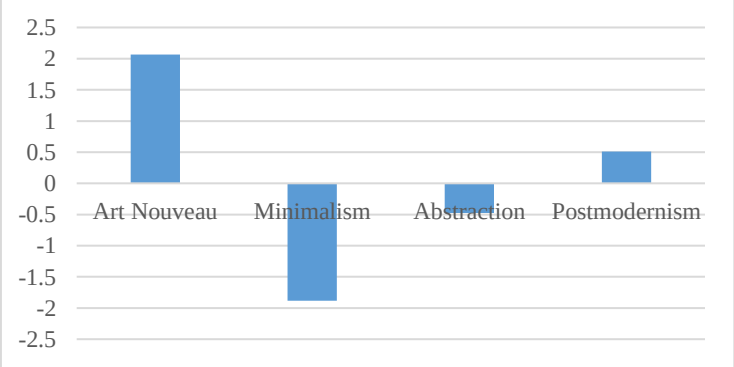

Figure 3. Scores on the scale of Complexity

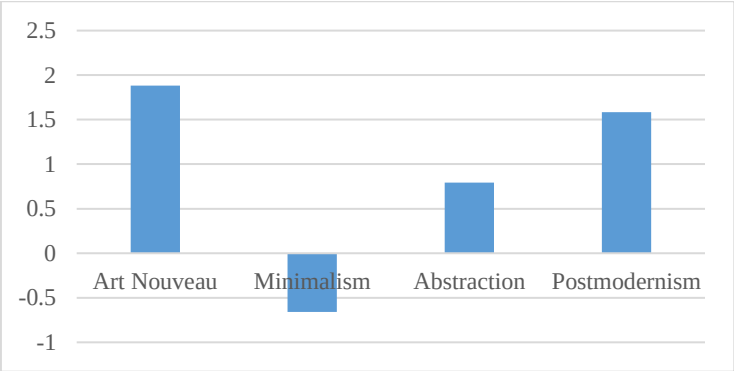

Figure 4. Scores on the scale of Interestingness

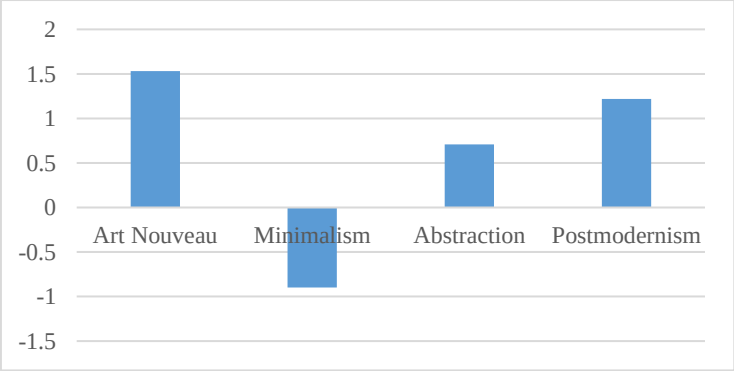

Figure 5. Scores on the scale of Noticeability

The analysis of correlations showed a positive relation between the scale of Beauty and all other scales. The correlation between Beauty and Interestingness was significant and high ($r=.507$, $p<.001$), the correlation between Beauty and Noticeability was significant and moderate ($r=.391$, $p<.001$), while the correlation between Beauty and Complexity was significant and low ($r=.240$, $p<.001$).

4. DISCUSSION AND CONCLUSIONS

The results confirmed the effects of the style on an aesthetic impression of objects. It is congruent with many previous findings and research done [1,2]. Also, it is noticeable that characteristics such as complexity, noticeability and interestingness are important aspects influencing the process of aesthetic evaluation.

In this research, the Art Nouveau style has been estimated as the most beautiful. The reason for that could be found in style characteristics, rich decoration, curved lines, and exaggerated lows of harmony and contrast, which are typical for this style. These vases were also estimated as complex, interesting and noticeable. At the same time, the minimalistic style has been recognized as less beautiful, very simple, boring and not noticeable. The characteristics of this style (simplification of forms, symmetry, subtle forms, clear lines) were seen as less beautiful by subjects. It is in accordance with many previous researches which have found a close relation between an aesthetic impression and the complexity of visual objects in the fields of art and design. As it has been shown by Berlyne [29], the correlation between the complexity and aesthetic value is strongly positive but not linear, it appeared always in interrelations with other aspects of aesthetic objects.

Post-modernistic style showed low scores on the scale of Beauty and high scores on scales of Noticeability and Interestingness. At the same time, the abstract style showed high scores on the scale of Beauty and lower scores on all other scales. This finding deserves more interest and requests further clarification. That shows that aesthetic impression is a complex phenomenon based on interrelations between formal aspects of the object. In this research, asymmetry, simplification and reduced forms of objects have been highly valued when applied in an abstract style but less valued when applied in a post-modernistic style. Having in mind that the subjects were students of visual arts who were

educated in art history and highly sensitive to the aesthetic values of objects, it could be expected that abstract and minimal art would be even less accepted by standard audiences. As has been shown by many pieces of research, abstract art is a powerful cultural tool but is accepted only by selected groups of audiences and is generally rejected by standard, less educated and less sensitive audiences who prefer decorated and realistic objects [6,7,9,10,11,12]. Regarding ornaments and decoration, they appeared as the main criteria in non-artistic audiences. In this study, it was noticed that complexity and decorations were not the main criteria as would be expected for the standard audience. For this group of subjects interestingness and noticeability (salience) were more powerful factors in forming aesthetic evaluation. The analysis of responses of the audience to abstract art and potential differences between artistic and standard audiences deserve the future interest of psychologists.

The main restriction of this research is the small sample of visual stimuli, conclusions regarding style should have been based on a much bigger sample of style representatives. However, the findings lead us toward new insights into the complex and subtle process of aesthetic reception.

Abstract: *This article is focused on the impact of familiarity on the aesthetic assessment of vases. Vases are chosen as research objects because of their artistic and functional value and are rarely used in experiments. Familiarity is seen as a subjective category closely related to closeness. It was of interest to test the relation between familiarity as a category and the aesthetic value of objects. The subjects were 40 students of Art Academy, a visual art course. They were assessing 15 black and white vase pictures, using 7-degree scales by criteria: beauty, familiarity and closeness. The vases shown were balanced by style (neoclassicism, Art Nouveau, abstraction, minimalism and postmodern art). The results indicate that the highly ranked vases by familiarity and closeness were not experienced as the most beautiful. Subjects experienced as most beautiful vases that were ranked as less familiar and distant. Those findings confirm the thesis that high aesthetic rank is based on a certain level of novelty. They are also in concordance with research that found novelty as an important aspect of aesthetic value and interestingness.*
Keywords: style, aesthetic assessment, familiarity, visual objects

1. INTRODUCTION

Familiarity is an important dimension of aesthetic assessment. Although many findings confirm the strong influence of familiarity with aesthetic assessment, there is no clear agreement between the researchers. A few different hypotheses try to explain this relation.
Usually, the relation between the familiarity and aesthetic value of works of art is described by a reversed U-curve [1,2,3,4,5]. According to those authors, the highest aesthetic values are given to objects that belong to the middle level of novelty, objects that are not completely new or completely familiar.
Another group of authors found a positive linear relation between familiarity and aesthetic value [6,7,8,9,10]. According to them, the beauty of artworks increases with familiarity. The art objects that are seen as the most beautiful are at the same time most familiar to the audience. This relation has been found in the assessment of paintings. It has been noticed that subjects preferred the representational paintings describing them as most familiar to them, while the abstract paintings have been described as less familiar [8]. It has been approved that the aesthetic value of paintings increased by familiarity and at the same time the pleasantness and will to see this painting again, increased too [9].
The third group of authors has found a negative linear correlation between the familiarity and the aesthetic value of art objects. According to them, less familiar works of art have been experienced as more beautiful and reversed, and the more familiar art objects have been experienced as less beautiful. This relation has been confirmed by experiments using simple

[1] b.pejic@yahoo.com
[2] bskorc@yahoo.com

visual stimuli [1], and lately, it has been confirmed by experiments using novel, provocative and ambiguous stimuli [11,12,13,14,15,16].
The diversity between many different findings shows that the influence of familiarity with aesthetic assessment is still an open issue for researchers. There is no simple answer to the question of how familiarity as a dimension influences the response of the audience - does the object that is familiar and is frequently exposed to the audience become more beautiful or not? This problem becomes even more complex when the familiarity is observed in interaction with other factors, such as complexity or symmetry, in the process of forming the aesthetic assessment.
The diversity of research results could be understood by keeping in mind the different research methods used, various samples of stimuli and different levels of experimental control. It has been noticed that, together with factors related to formal aspects of art objects, personal factors such as the level of education in art and art history, experience in art and many others, participate in the process, influence the aesthetic decisions and change the levels of familiarity [17,18,19,20,21,22,23].

2. RESEARCH

In this research, the intention is to test the impact of familiarity on the aesthetic assessment of the design of objects, keeping in mind the diversity of results obtained by different authors. The majority of research has been using fine art paintings as objects, and in this research, well-designed everyday objects have been used as stimuli. They have two-fold functions being at the same time art objects and objects for everyday use. Design is related to the usefulness of objects and it could be assumed that the level of familiarity is higher experiencing such objects compared with experiencing paintings and other fine art objects. Since the design is determined by the function of the object, a certain level of novelty is requested in order to keep the interest of the audience. The design of useful objects is a process which includes constant exploration, innovation and variations of forms, which are visible through different styles and variations within the style. In this research the relationship between the aesthetic assessment and factor of familiarity has been observed, using objects of different styles. The vases have been chosen as objects because they were not commonly used as stimuli in research.
In order to test the relation between familiarity and the aesthetic assessment, two scales have been used – familiarity and closeness, combined with the factor of style.

2.1. Subjects

A total of 40 subjects were included, they were the students of visual arts from the Academy of Arts in Novi Sad. Gender structure: there were 75% of females and 25% of males included. They were students from the groups: painting, sculpturing, graphic arts, new media and design. It was expected that this group was sensitive to formal aspects of an aesthetic experience and was familiar with art history.

2.2. Stimuli

There were 15 black-white photos of vases presented, representing 5 art styles: neoclassicism, Art Nouveau, abstract art, minimalism and postmodernism (Figure 1). Each style has been represented by 3 examples. In order to simplify the procedure and avoid the effect of colours, black-and-white photos have been used. Vases as objects have been chosen because they are at the same time works of art and everyday objects which represent the characteristics of style.

Figure 1. Sample of stimuli of different styles
Sources from left to the right: https://www.karlkemp.com; https://www.pinterest.com; https://www.etsy.com; https://www.pinterest.com; https://www.dezeen.com

Neoclassicism as a style is represented by characteristics such as stable proportion, symmetry, order and clear form, harmony and balance. Art Nouveau style is ornamental, representing natural forms such as a leaf, a flower, human or animal body shapes, unusual colours, curved lines, and strict lows of harmony and contrast. The abstract style uses forms in a non-traditional way, symbols, simplicity, asymmetry, and geometry. Minimalistic vases are simplified, with reduced lines, high symmetry and reduced expressiveness, they are focused on geometric forms. Post-modernistic vases are disproportional, and asymmetric, with oblique forms, focused on details and decoration, they represent the combination of typical styles.

2.3. Instrument

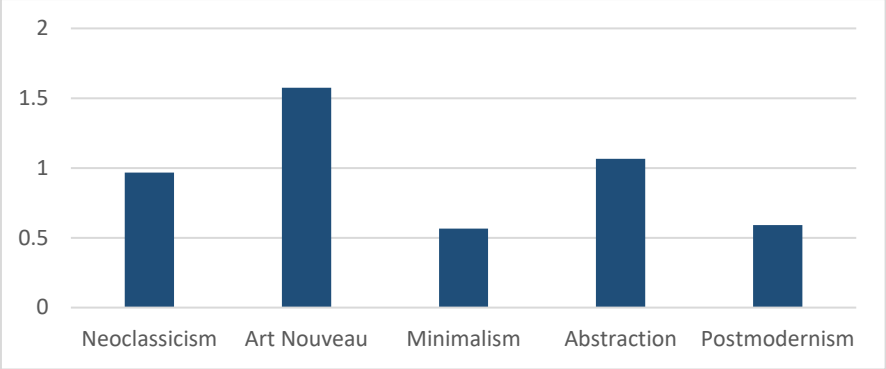
Aesthetic assessment of objects has been measured by the scale of Beauty (beautiful – ugly) and familiarity has been measured by two scales: Familiarity (familiar – unfamiliar) and Closeness (close - distant). Seven-grade, bipolar scales have been used.

2.4. Procedure

The subjects assessed their impressions using the list of scales. Their task was to note one of the numbers representing their impression. Grades on the scales varied from –3 (least present characteristic) to +3 (most present) with 0 in the middle. Stimuli have been presented in a random order using PPT presentation. There was no time limit. The research was organized in groups.

3. RESULTS

The analysis of variance showed statistically significant effects of style on all the scales used. Effects of the style on the factor Beauty show the following results: $F(1)=6{,}53$, $p<.001$; effects of the style on the factor Familiarity show the following results: $F(1)=9{,}87$, $p<.001$; effects of the style on the factor Closeness show the following results: $F(1)=3{,}50$, $p<.01$. The results confirm the effect of style to all the dimensions observed, there are differences between the styles according to impressions of beauty, familiarity and closeness.
Measures of the beauty of objects showed the following rank order: Art Nouveau style has been experienced as the most beautiful, it has been followed by the abstract style and neoclassicism, while the vases of post-modernistic and minimalistic styles have been experienced as less beautiful (Figure 2.)



Picture 2. The Beauty of different styles

The results for the scale Familiarity show high estimations for neoclassicism and minimalistic styles and lower estimations for Art Nouveau, abstract and post-modernistic styles (**Figure 3**).

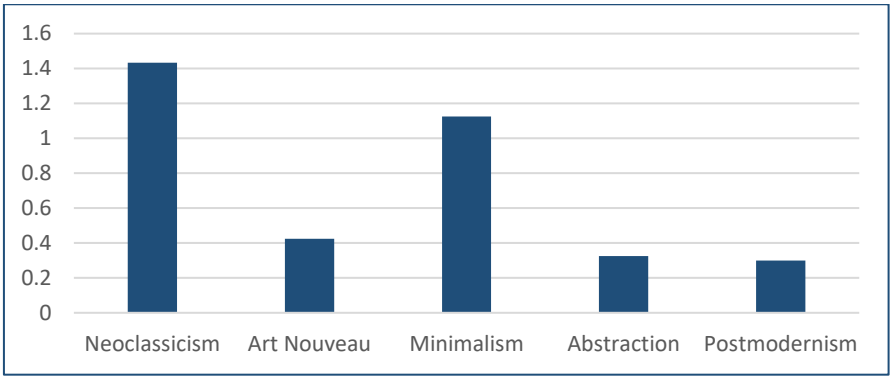


Figure 3. Familiarity with different styles

The results for the scale Closeness are similar to those obtained for the scale Familiarity – the highest measures have been ascribed to neoclassic and minimalistic styles, while the lowest measures have been ascribed to vases belonging to abstract, Art Nouveau and post-modernistic styles (**Figure 4**).

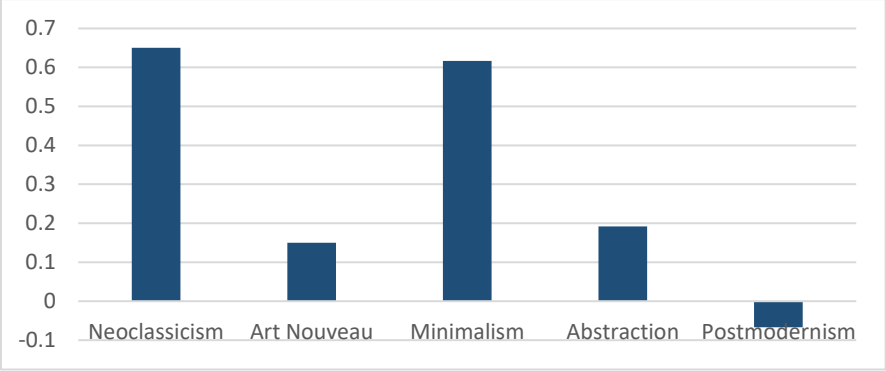

Figure 4. Closeness of different styles

The analysis of the correlation between the scales showed statistically significant correlations between all the scales used. There are certain differences between the levels of correlation. The highest correlation has been found between Closeness and Familiarity ($r=.52$, $p<.01$) which was expected. The correlation between Beauty and Closeness was also high and positive ($r=.39$, $p<.001$). The correlation between Beauty and Familiarity was low and significant ($r=.18$, $p<.01$).

3. DISCUSION AND CONCLUSIONS

The results show that dimensions of familiarity and closeness were not directly related to beauty. The vases that were experienced as the most beautiful were not most familiar at the same time. The highest estimations have been ascribed to Art Nouveau vases which were estimated as modestly familiar and close by the observers. The results are in the concordance with the hypothesis of a reversed U-curve. According to this idea, the most beautiful objects belong to the middle measure between the opposites [1,2,3,4,5].
The vases that are experienced as modestly beautiful belong to abstract and neoclassic styles. The vases that are experienced as less familiar and close by the observers belong to the abstract style. At the same time, neoclassic vases are experienced as familiar and close by the observers. The results show that the intensity of aesthetic assessments and level of familiarity depended on the definition of familiarity as a dimension. It is obvious that considering the design of objects, subjective experience of closeness is a stronger predictor of aesthetic value than familiarity.
It is also obvious that high estimations of beauty are related to a modest level of novelty, the extreme dimensions, such as being too familiar or completely unfamiliar to an observer will decrease the aesthetic value [2]. The novelty of art objects attracts the observers, evoking interest and attention. In order to evoke aesthetic interest, the design of the object should find a fine balance between familiarity and novelty.
The limitation of this research is the small sample of stimuli, future research based on a systematic and fine-balanced set of stimuli is expected to give new insight into this phenomenon.

ANALOGOUS PRINCIPLE AS AN ADDED VALUE IN GRAPHIC DESIGN IN THE POST-INDUSTRIAL ERA

Dragica Nikodinović[1], The Academy of Applied Technical Studies Belgrade

Abstract: *This paper delves into the realm of graphic design in the post-industrial era, conducting an analysis of both analog and digital working principles. We aim to uncover their unique characteristics, prevalence, significance, and the implications they hold for graphic design solutions amidst a rapidly evolving technological landscape. Notably, we emphasize the near-total reliance of commercial graphic design on software and vast databases of graphic elements and photographs.Our exploration extends to the promises presented by the continuous advancement of technology and the rise of new media. Additionally, we address the issue of generalizing visual elements that make up the visual content of graphic communication. Within this context, we examine the creation of new digital originals and the replication of analog visual elements following digitization. Moreover, we pose critical questions about overproduction, quality, and the ramifications of societal globalization. The paper also seeks to define the term "post-industrial era" while identifying its defining characteristics. We dedicate attention to visual identity, scrutinizing the processes involved in its creation, alteration, and acceptance, and the critical role it plays in branding, as well as its impact on individual identity stability. Ultimately, our objective is to underscore the significance of implementing the analogous principle in graphic design within the digital age, elucidating why the analogous approach serves as an added value in the realm of digital graphic communication*
Keywords: Analog, Digital, Visual Identity, Added Value, Software

1. INTRODUCTION:

Starting from the twentieth century, one of the primary roles of aesthetics is to serve the society of spectacle[1]. To exist, art should resist this. Perhaps this is one of the main reasons why many theorists today do not see the work of graphic designers as a part of applied arts. Among all artistic disciplines, design is most often abused in the service of mass media, with the aim of acquiring profit and hegemony. For this reason, aesthetics has long ceased to be a question of beauty and now deals with all aspects of life. Although it may seem that such a world is innocent and does not exist in reality, it is actually mirrored in the public and semi-public space through graphic communication solutions.

2. PROPAGANDA AGAINST PROPAGANDA:

Designers who have a desire to oppose this working model and who aim to bring their creativity closer to art can use the same means they use for communication in their work in a subversive way, i.e., propaganda against propaganda. Throughout history, artists such as Jenny Holzer (Figure 1) with her slogans at airports and in public spaces, and Barbara Kruger (Figure 2) through billboards and posters, have shown us the best ways to do this by questioning the commodification of the female body in consumerism. According to the art critics of the Frankfurt School, art must not be in harmony with society in any way. They believed that mass media was destroying it. According to them, art must constantly change, shifting its position. Besides these radical ways of acting, we have the opportunity to bring the aesthetics of graphic visuals closer to art, elevating their artistic quality. In

1 dnikodinovic@atssb.edu.rs

spectacle, nothing new is created, but it is only explained differently. Following that logic, and as an additional value, the analog approach can be applied to graphic communication as a consequence of the accelerated work pace and the creation of databases, which will be discussed in more detail later, today's designers mostly use the same elements, symbols, and photographs that are readily available to them. This is the primary reason why visual solutions in the field of digital graphic design lack the artist's unique touch and suffer a loss in quality.

2.1 ANALOGOUS AND DIGITAL WORKING PRINCIPLES:

Software is becoming an increasingly essential, and often the sole, tool for implementing graphic design solutions. On a global scale, only a small number of individuals have control over these software applications. Human potential is often underestimated, with the justification that humans are slow and inefficient. What primarily hampers efficiency in work is the need for expressing desire. In the book Digital Partisans, two principles are mentioned, the analog and digital. The process where order emerges from order, and where a human services while a machine creates, is called digital. When chaos arises from order, and order from chaos, we have an expression of the analog model, characterized by mastery, uniqueness, and originality. From an economic perspective, in the past, the value of unique products crafted by craftsmen or under their supervision represented an analog model. With the replication of labor through various pedagogical models, the digital model emerged. Today, the most significant difference between these two principles is aesthetics. Analog is rapidly disappearing in the field of communication and information technology. In the digital age, every copy becomes an original because it must meet production standards. This is the best example of order from order.

Figure 2. B. Kruger, Untitled (We Don't Need Another Hero), 1987
Source: www.whitney.org

2.2 THE ECONOMY OF LUXURY:

The fact that analog has become a luxury economy was first recognized by Marcel Duchamp (Figure 3), who placed everyday objects in a new space and context, thereby changing their function and value. Andy Warhol (Figure 4) followed him, addressing issues of consumerism, reproduction, originality, and machine production. For Warhol, no counterfeit is counterfeit as long as it satisfies the expected similarity. The development of new technologies initiates the development of mass communications. Brands are obliged to follow trends and technical evolution to offer their consumers a range of new possibilities. Today's consumers expect a product to possess both the reliability provided by a digital copy and the uniqueness of the product in an aesthetic sense to nourish their individuality. This distinctiveness is achieved through an analog approach, leaving digital aesthetics on the margins. According to Manovich, as a society, we have not yet fully abandoned analog thinking and creativity. According to him, the new era still encompasses both the analog and digital worlds, marked by the accelerated development of technology and new media, as well as the adaptation of analog media to digital cultural understanding. Communication is both passive and active, and

experiences are both tactile and digital. The computer has become a universal workspace, and the historical significance of the digitization of culture lies in the fact that creatives use the same technology, processes, and software, regardless of whether the final product will be delivered through old or new media.

3. DEPENDENCE ON TECHNOLOGY:

Every day, we are becoming more and more tethered to technology, so it can be concluded that we have entered a state of dependency. Upon examination, we see that humans have embraced cyborgization through medicine and various aids such as prosthetics long before the industrial era. Art has often legitimized different ideologies, serving as a means of verification and giving them an elitist character. Many artists who address the issue of cyborgization, such as Stelios Arcadiou (Figure 5 and 6), connect themselves with computers, embed prosthetics and implants, considering the human body to be outdated. However, from a sociological perspective, this opens up a wide range of questions.

The best example of cyborgization, or the merging of humans and technology in everyday life, is smartphones and smartwatches. This way, we become highly dependent on the rapid availability of information and the transmission of our experiences through social networks, expecting quick responses from our virtual friends.

Figure 5. and 6. Stelios Arcadiou,
Source: theproudmag.com

3.1 PASSIVE DESTRUCTION OF MEDIA AESTHETICS:

From a young age, we have been taught that our work should constantly be evaluated and assessed, which can significantly impact an individual's self-esteem. For this reason, we create the best version

or versions of ourselves virtually to be more accepted, followed, liked, and shared. In this way, one's identity can be greatly compromised. Through social media, we follow people who create aesthetics in their posts on the internet and select information to be appealing to a specific target group. We often adopt their good practices, attempting to buy or imitate their lifestyle, depending on whether we can afford it. This creates digital idols and identities that we aspire to become. The reason for this can be defined through the passive destruction of media aesthetics, which Professor Vladislav Šćepanović discusses in detail in his book "Media Spectacle and Destruction." According to him, by destabilizing and undermining personal identity through constant conformity to fleeting fashion and technological trends, by dismantling the cult of the family through separation, decentralization, and shifting the attention of its members to personalized content from various media, and by diminishing the importance of traditional communities, a terrain is created for the easy manipulation of the individual. People increasingly prefer the sensation of information because the need for belonging and community is precisely what brands promise, and in return, we give them our trust, money, and time. The lonelier people are, the more they turn to work, consumption, and ways to find satisfaction. Strength, authenticity, tradition, image, status, and the size of a brand are perceived based on its visual identity and communication. Visual identity can be defined as the external manifestation of the ideas, company, brand, organization, or location, created based on its internal values. Since information is best conveyed through images, this speaks to the power of the influence of graphic communications. It is presented through symbols, colors, typography, and the way they are composed. These elements should be created and communicated in an original way, with connotations to what is being presented. Significant resources are invested in creating the visual identity of brands. It provides people with security in decision-making, as it creates a representation of something that, in most cases, they do not know.

3.2 TO BE OR TO HAVE:

According to Fromm, we can either "be" or "have." Human consciousness is formed based on what it possesses. Material goods have gained symbolic value. Television has promoted the accumulation of material possessions as the primary imperative for many years. This, in turn, has imposed desires and needs upon us. Today, media still presents aestheticized information. There is a depletion of originality, uniqueness, and irreplaceability, and the aura is lost, replaced by an industrial mode of production. Television belongs to linear media because it follows a narrative. Unlike movies that require our complete presence and attention, with television, we absorb information but can choose the atmosphere in which we watch it. The internet today seems much more democratic as a medium compared to what television was over the last fifty years. However, it hasn't destroyed television, just as television didn't destroy movies, radio, and newspapers. It belongs to metamedia or digital media. These metamedia use old media as their primary material and try to perceive the world in a new way. In the information society we live in, memory is the most important characteristic, and the computer is crucial, unlike in the media society where it was film, with perception taking center stage. Metamedia use data from databases indexed by algorithms. Every process or task is reduced to an algorithm, a series of simple operations that a computer can perform. Software represents the engine of modern society. Databases allow us to create a narrative in a way that suits us, giving us greater possibilities for interaction and easier promotion of our values and connections. In this way, we reveal everything about ourselves without even being aware of it. Technology is presented as neutral. It can pose the greatest danger, given the high potential for abuse. The promises of the digital utopia, as we have the opportunity to read about in the book "Digital Partisans," involve an easier way of working. In return, individuals are expected to be much more productive, as they have help. Technology offers mobility, but it requires the maximum mobilization of the subject. This way, designers are expected to be productive and creative for the brand at all times. Portable technology, software, and communication allow work in any position and place.

4. STOCK PHOTOGRAPHY AND GRAPHIC ELEMENTS:

Aesthetics have become the dominant characteristic of media because images sell products. For this reason, designers use databases of photographs and graphic elements as the simplest solution for gathering materials to create visuals for broadcasting. Advertising photography is the most common type of photography in the society of the spectacle. From the beginning, its function has been to stimulate the desire for consumer purchases. In the diffuse spectacle, it has largely pushed illustration off posters. Products are presented in the best possible light, with models who promote them having a flawless appearance in perfect scenography that suits the product. Given that the spectacle erases the boundary between the true and the false, it creates an impression that we should aspire to such scenes because they seem attainable. Stock photo banks are places where digital collections of images, logos, and vectors are stored for purchase, often for the purpose of creating graphic communications for specific brands and magazines. They only have connotations and perfectly represent a society of the spectacle in its full glory. The backgrounds are extremely simple, models are attractive, and searching such image banks is usually done based on keywords. It can be observed that this is another way in which we disrupt originality and authorship, which should distinguish graphic design solutions.

4.1 ROOTS OF SELLING GRAPHIC ELEMENTS:

By examining the history of posters, we learn that artists from the 19th century, having exhausted social and cultural themes, were not reluctant to create commercial posters. The question arose as to whether painting was interfering with contemporary posters. Many artists, seeing the market potential, produced images and drawings on their own initiative, which they would sell and put in the context of products. This can be considered the beginning of selling graphic elements. With these facts, we can conclude that the existence of such visual banks is not a product of modern times but has been emerging and adapting to the needs of the society of the spectacle.

5. POST-INDUSTRIAL PERIOD:

Although the term post-industrialism is first found in literature in the 1920s, most authors agree that the post-industrial period should be associated with the second half of the 20th century and a time of rapid technological and scientific development. It is a period characterized by an increased importance of knowledge and mass communication, where education and mass media take precedence over the production of goods. Due to the significance of information itself and its dissemination, this period is also called the information era. According to Bell, some of the main characteristics of the post-industrial era or the social world are scientific knowledge and higher education. He believes that cooperation and reciprocity are above coordination and hierarchy. New technologies initiate changes in all aspects of contemporary life and ensure further progress of society. For the analysis of this period, Toffler's theory is interesting. He identifies social acceleration as the basic characteristic of the super-industrial civilization, as he calls the post-industrial period, and points out that science is at the center of technology.

5.1 LIGHT PEN:

Computer technology developed intensively after World War II. There was a tendency to equate computers with humans. In the book "Virtual Art" by Oliver Grau, we learn that Ivan Sutherland made the most significant contribution to the interface, calling it a mediator between humans and machines. He presented all this in his doctoral thesis called "Sketchpad," published in 1963. This created the possibility of drawing on the screen using a light pen. Sketchpad is a precursor to modern illustration programs like Adobe Illustrator. During the 1960s, the first exhibitions on Computer Art

were organized in Europe and America. From 1970, computer art became an integral part of the Venice Biennale.

5.2 ORIGINAL AND REPRODUCTION:

In digital art, the concept of an "original" becomes less significant because there is often no clear distinction between a copy and an original. According to Benjamin, the era of technical reproduction marked the beginning of the mass esthetization, where the aura, uniqueness, and originality were lost. Software and computer hardware are responsible for this transformation. Therefore, the notion of the cult of the original, as proposed by Benjamin, does not apply to visuals that are created digitally. The aura might only be recognizable in cases where the inaccessibility of the work is intentionally provoked. For example, in the case of an expensive installation that is rarely exhibited in a remote part of the world, making it challenging for most people to attend the projection. In digital work, we are always limited by the technical capabilities of the software. The creation process is more like a dialogue, and the final image is the result of computer operations. Numerous tools available in software programs encourage designers to create new visual and graphic solutions directly without the need for analog processes. This approach generates solutions that do not have a material original, and as such, they are ready for further reproduction in both virtual and physical realms. Much of what analog work offers is impossible to fully replicate with digital methods, including the freedom of drawing expressed through the spontaneity of lines resulting from our emotional impulses, the transparency of watercolor hues, the irregular blotches and brush strokes, the imperfections of printed graphic surfaces, the natural variation and diversity of typographic characters in handmade typography, and more.

6. CONCLUSION:

Based on the points mentioned above, it is evident that analog methods are often by passed in contemporary graphic design solutions. The need for speed and the availability of technology have led to a reduction in the quality, originality, and creativity of design solutions created through digital means. Therefore, analog methods, as part of the process, offer an additional value in building identity today.Technological advancements have enabled us to digitize a significant amount of graphic elements from analog works, which are far richer than what we could create digitally from scratch. We can utilize this material for creating graphic communications in countless original ways, either independently or in combination with digital elements and effects offered by software.

DESIGN AS A FORM OF COMMUNICATION DECONSTRUCTIVE APPROACH TO DESIGN

Dusanka Komnenic[1], The Academy of Applied Technical Studies Belgrade

Abstract: *In the broader sense, visual communication is the essence of this presentation. Although design is a narrower field of the paper, graphic design is its focal point. Most of the statements are based on research in the arena of graphic design. This paper will explore how to identify good design and what is a concept that defines it. It is also important to underline that this paper is based on notes on graphic design in the Western world, allowing that assumptions and definitions may vary across geographies. Visual information is initially perceived intuitively. It is based on liking, loving and attractiveness. Those descriptions alone, mean nothing. A question here is why do we like or love the design? Design is also often recognized as good or bad; beautiful or ugly, right or wrong, etc. What do these concepts really stand for? What are the true meanings of those classifications and based on what are we making such statements?*
Keywords: Design, Visual communication, Communication, Elements of design, Principles of design

1. INTRODUCTION: What is Visual Communication?

Communication is a word of significance, here. Communicative design is what makes a good design. Still, it is not enough that message is being delivered. How it is being delivered becomes crucial. An analogy with words could be made now; there is a difference if a message is just plainly said or whether it is delivered through poetry. A line between *a message is sent* and *a message is communicated* here is drawn. A message communicated stands for good design!
One can define visual communication as the practice of visually representing information in a way that can be effectively understood. It is everything that is crafted and perceived visually, such as: painting, drawing, sculpture, industrial design objects or graphic design objects.
It will be exhibited how visual impulses (liking and loving) are deconstructed into basic principles and elements of design and thus transformed into reason. It will also be argued how the reason converts into knowledge before it becomes innate. From this point on, visual information is perceived intuitively again. In the end, it becomes clear when the design is communicative and when it is plainly bad.

2. GRAPHIC DESIGN What is it?

Graphic design may be defined as “the art and practice of planning and projecting ideas and experiences with visual and textual content”. [1] In other terms, graphic design communicates certain ideas or messages in a visual way. Technically, graphic design is the communication of an idea using visual means. It is art or skill of combining text and pictures in print or digital media.
Yet, what is graphic art? What Graphic means? Is drawing graphic art? Is calligraphy graphic art? Is photography graphic art? Some people might identify black and white two-dimensional works by name of graphic. This would be wrong as graphic does not have to be black and white. It, however, may be presented in a plethora of colors. How do we know if something is graphic art vs. simply a drawing, for example? Where is the catch?

[1] dkomnenic@atssb.edu.rs

Everything we call by name of Graphic has a matrix. It can be digital or physical matrix, but it has to have one. Graphic is never an original piece; it always has 2 or 200002 copies of the same matrix. It involves reproductive methods such as: engraving, etching, lithography, photography, serigraphy, and woodcut. In contemporary world, graphics assume digital files (that can be multiplied numerous times). Graphic also means that one visual solution has 2 or 20002 exactly the same prints (from the same matrix printed with the same parameters). What we identify as graphic today is everything from photography (negative film or digital file as matrix), packaging design (layout as a file), billboards (digital files), posters, etc. Calligraphy and typography were mentioned before. In this context calligraphy is not graphic art, while typography is. Calligraphy is hand written; so even though one may utilize a certain letter style while writing, the letter would turn out having multiple differences to one another (no matrix; hand is not a machine).Typography, assumed by its name, is graphic art; every time one presses a letter in a certain font, the letter turns out exactly the same.

3. ELEMENTS OF GRAPHIC DESIGN

Elements of graphic design are the basic units of which visual composition is constructed. They are the features that help the designer convey messages and help the viewer read the design adequately. Elements of design are fundamental pieces of any visual composition. As number and preference of the elements may vary among the designers, the most ubiquitous are as follows: line, shape, color, value, typography, texture, size, space [2].

Line
Often the starting point for all artistic expression, the line is one of the most essential elements of design. It can be unbroken, broken, or implied. A line can be vertical, diagonal, horizontal or curved. Implied line moves our eyes through the composition and gives a sense of dynamics.

Shapes and Form
Objects are two-dimensional. All objects are composed of shapes, and all elements of design are shapes in some way. Forms are three - dimensional, and there are two types: geometric (man-made) and natural (organic).

Color
Hue typically references to a wavelength of light in the color spectrum, which is blended from the primary colors of red, green, and blue (commonly referred to as RGB).

Value
Value refers to the lightness or darkness of a color. It defines a color in terms of how close it is to white or black.

Typography
Typography is the art of arranging type. This one is critically important as it can greatly affect the design’s messaging. Different weights (bold, regular, or light), combined with varied sizing, colors, and spacing, add power to the concept a designer is trying to communicate. Typography ultimately defines good or bad design.

Texture
Texture in design refers to how things look like they would feel if they were to be touched. For example, texture can be rough, smooth, glossy, soft, hard, etc. It gives warmth to the design.

Size
Size is simply how small or large something is. In design, size is used as an indication of importance and it can also create visual interest in a design by using contrasting sizes.

Space
Space refers to the areas of design that are left blank. These areas include any distance or areas between, around the other design elements. Designers intentionally place spaces in the design to add emphasis to areas they want to be in focus.

4. PRINCIPLES OF GRAPHIC DESIGN

There is no real consensus in the design community about what the main principles of design actually are. That said, the following six principles are those mentioned most often in articles and books on the subject: balance, emphasis, alignment, variety, unity and contrast [3].

Balance
Balance is the concept of visual equilibrium of similar, opposing, or contrasting elements that together create a unified whole. It refers to the appropriate arrangement of the objects in a design to create the impression of equality in weight or importance. It comes in 2 forms: Symmetrical (when the weight of a composition is evenly distributed around a central vertical or horizontal axis) and Asymmetrical (when the weight of a composition is not evenly distributed around a central axis).

Emphasis
It marks the location in a composition which draws the viewer's attention. It is also referred to as the focal point. It is the most important area or object when compared to the other objects or areas in a composition.

Alignment
Alignment is about keeping the design organized. All aspects of the design should be aligned with the top, bottom, center, or sides to create a visual connection between the elements.

Variety
It refers to the combination of different elements. Those elements are put together based on intricate similarities, such as values, lines, textures, shapes, hues, etc. As the opposite of unity, variety should provoke changes and awareness in the art piece.

Unity
In art, unity conveys a sense of completeness, pleasure when viewing the art, and cohesiveness to the art. Unity is used to describe the relationship between the individual elements and the whole of a composition. Colors can provide unity when they are in the same color groups, and a splash of red can provide variety.

Contrast
Most compositions include a variety of different and opposing elements. This can include a range of lighting, an assortment of colors, or even an array of textures. A designer can increase the contrast between two objects to highlight, for example, one being in the foreground and the other in the background.

White Space
White space, also referred to as negative space, is the area of a design that do not include any design elements. The space is, effectively, empty. Many beginning designers feel the need to pack every pixel with some design elements and overlook the value of white space. But that white space serves many important purposes in a design, especially as it gives the elements of the design room to *breathe*. Negative space can also help highlight specific content or specific parts of a design. If you are a design maker (as opposed to only a viewer) you might think: "What could I add to the composition; it lacks something." Usually, the answer is that something needs to be removed from the composition

and not add to it, as white space is usually overlooked, yet one of the most important principles of design. What space is to interior design, white space is to graphic design.

5. CONCLUSION: A voyage from intuitive understanding to a design connoisseur

In contemporary world, when there is a need for visual communication, it will be, most likely, communicated via graphic design. This decision would be made on a mere fact that through graphic design the same message could be delivered to as many people as needed. We may now imagine that instead of graphic design a message is presented through painting (which is also a legitimate way to communicate visually). There is only one painting of the kind and there are only a few people to see it. Graphic design, thus, in all its scope, is the way to go today. Graphic design is a democratic medium.

Clearly presented above is how the complexity of visual communication can be deconstructed onto basic principles and elements of design and how this deconstructive approach serves us to better use and read visual vocabulary. It is the same principles and elements of design that we all use; creativity here is the major factor that combines all these together, yet different from other visual solutions. For example: If the same message is delivered through not wisely chosen principles and elements of design, the message would, most likely, be misunderstood. Principles and elements of design could be associated to words. Creativity of a designer is a potential that may transform words into poetry.

This presentation illustrate how we are to distinguish good from bad design; it is never a question whether the design is pretty or not. It has always to do with whether it communicates the message effectively or not. We need to understand that displaying a message blatantly, is not a design; it is message only. What architecture is to building, design is to communication.

Design is never pretty. It can be ugly because it does not communicate. If we perceive it positively, it is then beautiful, as it communicates to a spectator effectively. It is beautiful because it transforms messages to visual poetry with wits, craftsmanship and ease. A viewer must feel a sense of joy or content [4], when looking at good design. Good design adds value to the meaning. Good design goes beyond communication. It speaks to the higher senses and it is thus, being ingrained in our mind. A sole message is rarely remembered; feelings are remembered. Good design is lovable design and that is the one that is truthful, direct, concise and the one that sparks joy [4,5].

GRAPHIC DESIGN BY MIODRAG VARTABEDIJAN VARTA VARTA'S GRAPHIC MARK IN YUGOSLAVIAN AND WORLD DESIGN

Duško Trifunović[1], The Academy of Applied Technical Studies Belgrade
Anamarija Vartabedijan[2], The Academy of Applied Technical Studies Belgrade

Abstract: *In the era of cultural renewal after the Second World War, the first generation of graduates of the Academy of Applied Arts, Belgrade, pioneers of graphic design in Yugoslavia, created contemporary works that defined the field of modern graphic design related to everyday life and social needs in the region. The artistry and aesthetics of applied graphics and graphic design, as a new concept in the phase of affirmation, were implemented wherever there was a need for public and mass communications in the spheres of culture, politics and economy – propaganda or agitation, and thus influenced the formation of citizens' tastes. Graphic design appears as a product of the ideological and existing economic context, and in accordance with the development of graphic technology and the great changes that took place in the printing process in the sixties.*
One of those pioneers, who from the end of the 1950s until the end of the first decade of the 21st century actively participated in the development and changes of both graphic design and the improvement of printing, was Miodrag Vartabedijan Varta, a Serbian artist of Armenian origin, painter, graphic artist and designer, who received the greatest international recognition in the field of artistic book design.
Keywords: Book, design, vartagraphy, illustration, calligraphy

1. INTRODUCTION

At the graphic workshop of the *Open Graphic Studio* at the National Museum of Serbia in 1990, he formalised his technique of *vartagraphy*. This technique created images on paper or canvas using the frottage method which involved taking rubbings of stone reliefs with hard metallic chalks and oil pastels. This process created an authentic pictorial representation of a texture, inscription or picture, which he then transposed into modern art and graphic design.
The creativity of Miodrag Vartabedijan Varta sublimates his origin, climate and social conditions in which he lived. In Varta's creative works, you can feel the fusion of the influences of all the cultures that left their mark on the soil of the former Yugoslavia, as well as the grounding in Armenian roots and culture. He proudly emphasised his individuality, right to personal attitude and freedom of artistic expression. In his work, he achieved aesthetic harmony according to intrinsic artistic laws. The link that binds his creative endeavours in the field of graphic design and artistic creativity into one whole is the rich cultural history of both nations to which he belonged, as well as the human and artistic need to honour that heritage through contemporary art (fig. 1). Transition from civilisation to civilisation, fusion of traditional and modern, quoting mythology is a typical tendency at the end of the 20th century, positioned as the art of postmodernism.
Miodrag Vartabedijan Varta was born on 23/05/1933 in Mladenovac. He graduated in 1958 from the Academy of Applied Arts, Belgrade (graphics department), and in 1961 he completed postgraduate studies. After graduating in 1958, he worked as an art editor in many newspapers and publishing houses: Jugoslovenska Revija, Pregled, Potrošački Informator, Građevinarstvo, Žurnal, Zvezdina

[1]dtrifunovic@atssb.edu.rs
[2]avartabedijan@atssb.edu.rs

Revija, Nota, JAT-ova Revija, Ateks catalogue, Sokoj newsletter, etc. In 1963, he left Potrošački Informator to become the art director of the magazine Jugoslovenska Revija. In 1983, he became the art director of the *Motovun* Publishing House in Istria, Croatia. On June 15, 1992, his employment status ceased to be valid due to the political s ituation between Croatia and Serbia.
He illustrated approximately 20 books for children and adults. He designed over 60 posters in the fields of tourism, medicine and the food industry, as well as dozens of newsletters, prospectuses, catalogues, diplomas, memorandums, and logos.
He was the art director and designer of over 300 photo-monographs of countries and cities, as well as books in the field of art and cultural heritage which were printed in five or more world languages, including titles such as: *Chilandar*, 1977; *China*, 1980; *Studenica monastery*, 1981; *Arts and Crafts of Yugoslavia*, 1984; *World Encyclopedia of Naive Art*, 1984; *Gypsies of the World*, 1988; *America*, 1988; *Russia*, 1989; *Patriarchate of Peć*, 1990; while *Tibet*, 1981, by Jugoslovenska Revija, was printed in 14 languages with a circulation of 240,000 copies.

Figure 1. Illustration and design, Belgrade Audio Anthology, LP, 1981

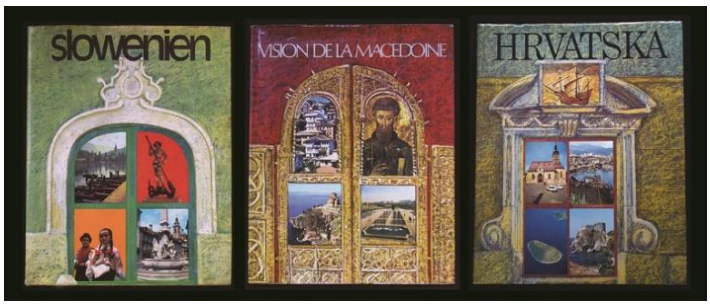

Figure 2. Book design of photo-monographs, Slovenia, Macedonia, Croatia, seventies

He cooperated with publishing houses from 70 countries around the world, worked on book projects in China, England, Switzerland, France, Slovenia, Croatia, Bosnia and Herzegovina, and Italy – where he also supervised the printing of books. He was a long-term collaborator and designer for cultural institutions: Serbian Academy of Sciences and Arts, National Tourism Organisation of Serbia, Belgrade Philharmonic Orchestra, Open Air Museum *Old village* Sirogojno, Belgrade City Institute for the Protection of Cultural Monuments.
In 1992, he became the art director of the *Interprint* graphic publishing company and a full professor at the Belgrade Polytechnic College for the courses Graphic Design and Calligraphy. He retired in 2000. He was a member of ULUPUDS (The Applied Artists and Designers Association of Serbia), ULUS (Association of Fine Artists of Serbia) and the Journalists' Association of Serbia.
He had more than thirty-five solo exhibitions in the country and abroad, and participated in group exhibitions more than 250 times. He was the recipient of 85 awards and recognitions in the field of graphic design and fine arts, among the most significant of which are: The Acquire Award of the Ministry of Culture of the Republic of Serbia at the October Salon, Belgrade in 1980; Award of the English Booksellers in London for the photo-monograph *Russia* which was among 5000 books printed in English in 1990; Grand Prix in Leipzig in 1993 for the photo-monograph *Bohinj*; ULUPUDS Lifetime Achievement Award in 2000; Coat of arms of the municipality of Mladenovac for his life's work in 2003. He died on September 8th, 2009 in Belgrade. He was buried in the Alley of Distinguished Citizens at the New Cemetery in Belgrade.

2. THE FIRST ILLUSTRATED MAGAZINES AND PRINTING DEVELOPMENT

As the art director of *Review – Yugoslav Monthly Magazine* (Jugoslovenska revija), a newly opened illustrated and exclusive magazine, printed in five foreign languages and distributed all over the world, he gave his artistic mark to the pages from the very first issue in 1963. He created a magazine, advertisements and designed the first greeting cards in Yugoslavia. Formed with a dynamic change of large images and text, always recognisable cover pages with superb photos and a modernly designed header, the *Review* was an important propaganda tool of Yugoslavia abroad. Presenting

important names in culture and art, cultural heritage and the beauty of the country, the content in the editions of the *Review* influenced the construction of the multinational identity of Yugoslavia, showing the strength and importance of the country on an international level. In 1965, he received the Annual Award of ULUPUDS for the artistic design of the *Review* magazine, and in 1966 and 1968, he received the first prize in Milan for advertisements created for Yugoslav Air Transport – JAT (Premio Europeo Rizzoli Torchio d'Argento). The magazine was printed in Italy from 1967, where Varta supervised the printing and the complete realisation of the magazine. Apart from improving the quality of printing in the Serbian and Slovenian printing houses with which he cooperated, these experiences brought him new knowledge and opened up the possibilities that he was looking for in his graphic solutions. It was a pioneering time for the introduction of colour into printing and experiments with three, and later with four colour printing processes [1].

3. TRADITIONAL SYMBOLS IN VARTA'S ARTWORK AND GRAPHIC DESIGN

Traditional symbolism appears to be the essential source and subject matter of a considerable part of Miodrag Vartabedijan Varta's artwork. By combining the technique of frottage – rubbing, painting and collage he transposes the inscriptions and figures from stone monuments into modern authentic works of art, which thus becomes the guardian of art heritage.

His artistic exploration is based on stone inscriptions, the oldest and most enduring documents of writing, ornamentation, and symbols, which are the most significant achievements of civilisation. Symbols, as a visual interpretation of human understanding of the world, are collective means of communication and comprehension, and became integral elements of Varta's artistic work. Working as an art director on numerous photo-monographs that presented the culture and heritage of Yugoslavia and the world, he had the opportunity to engage in artistic work on-site. Accumulating records, visual materials, impressions, and artifacts, the influence of the collective unconscious sedimented and emerged as a palimpsest through the chosen artistic expression, whether it be graphics, paintings or books. [2] As a painter and graphic artist, he reached the pinnacle of creative possibilities in book design as well as illustration and graphics. The book, as a portable guardian of heritage, knowledge, and ideas, communicating through space and time, occupied a central place in Varta's creative interests.

In his design of photo-monograph covers in the mid-1970s, pastel and collage were often used. Book covers such as *Croatia*, 1972, *Macedonian Vision*, 1972, and *Slovenia*, 1974 (fig. 2) are collages featuring a pastel technique, a stone texture and a characteristic arched window with ornaments, combined with attractive photographs visible through window frames. All the monographs and photo-monographs designed by Varta are originally and richly formed, presenting a stylistically unified whole, which is the fundamental and most significant component of the book's visual design. From the unique and attractive book cover, thoughtfully designed endpapers, to creatively typographically designed chapter headings, vignettes and decorations, with pages dynamically presenting accompanying photographs alongside the main text, such designs bring forth a diverse interplay of colour, shape, and typography. Examples of Varta's graphic design thinking can be seen in *Chilandar*, 1977 (fig. 3) or *Arts and Crafts of Yugoslavia*, 1984 (fig. 4). Varta directly interprets and conveys the theme through book pages that are clear, well-structured, legible, and accessible, yet visually lavish. Text and image harmoniously alternate on these pages. On one hand, Varta always prioritises the function of the book in the treatment of text and theme, while on the other hand, allows the image and visual design to claim space, creating aesthetically harmonious relationships. [3, 4] By combining these two logical tendencies, the application of typographic purity and clear design, and the insistence on visually rich and elegant book design, Varta creates their own artistic expression in graphic book design, which remains exemplary even today.

Figure 3. Book design of photo-monograph Chilandar, 1977

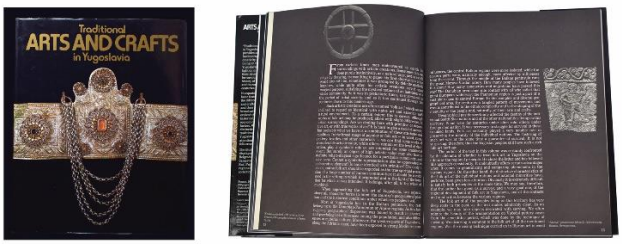

Figure 4. Photo-monograph - Arts and Crafts in Yugoslavia, 1984

The education textbook for the 7th grade of primary school, *Zelengora Lake* (Jezero na Zelengori), 1968, by Petar Gudelj, with an illumination fragment from the Miroslav Gospel on the hardcover, does not resemble a textbook and was then, as a complete creative endeavour, something entirely new (fig. 5). It changed the previous understanding of school books and became a model for future textbooks, considering the design and illustrations created with the utmost taste and balance, to the last text and verse. [5]

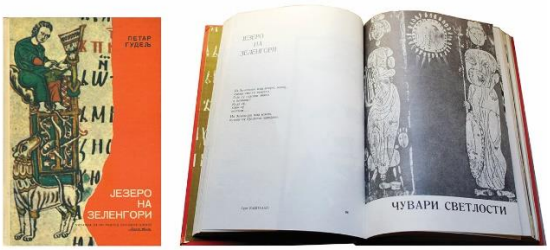

Figure 5. Illustration and design for the textbook Zelengora Lake, 1968

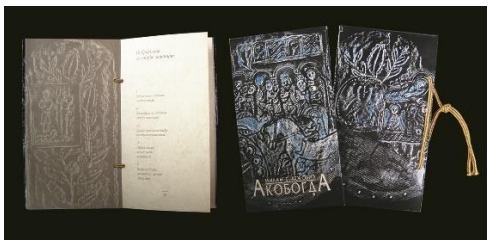

Figure 6. Illustration and design, Poems - Akobogda, 1995

From the early 1990s, Varta shaped the covers of many books with fragments of Armenian or Serbian stone monuments. The book *God Willing* (Akobogda) by Milan S. Kosović is richly and thoughtfully illustrated with composed motifs from temporally and geographically different sources (fig. 6). Impressions from reliefs intertwine: the Assumption of the Virgin Mary, architectural arches, ornaments and symbols – birds, horses, and warriors, as well as floral motifs with distaff. The inner pages, printed on imitation parchment paper, are enriched with initial letters and vignettes, as well as illustrations that occupy whole pages [2].

Among the multitude of posters, newsletters, prospectuses, catalogues, charters, memorandums and logos that he designed, there is also a logo, as well as the annual programme of the Belgrade Philharmonic Orchestra (fig. 7), with a stylised depiction of a lahuta player from a stone relief from the 15th century (bifora of the Kalenić Monastery); a poster for the 40th Yugoslav Documentary and Short Film Festival (Festival jugoslovenskog dokumentarnog i kratkometražnog filma) from 1993 (fig. 8), dedicated to ethnological film (multiple imprints of Serbian anthropoid crosses, arranged in a diagonal sequence as if dancing a reel, and the figure of a young man rubbed from a tombstone holding the festival's logo in his hand).

Figure 7. Logo and annual programme of the Belgrade Philharmonic Orchestra, 1992

Figure 8. Vartagraphy and poster design for the Yugoslav Film Festival, 1993

4. TEXT LAYOUT

When it comes to the layout of text, Varta carefully selects fonts and their variations in the chosen size for each project. The primary focus is always on ensuring that the text is clear, structured and readable, designed in a modern way with thoughtfulness and creativity. In accordance with the formats of designed graphic products, the width of text columns is determined. Initial letters are used in positive space and in outline versions, often in large dimensions with significant indentation. Various width and appearance typographic lines (dotted, dashed) are applied in its design. In the case of photo-monographs, the entire page is placed within a rectangular frame with margins, designed with text and photographs. Headings are underlined to highlight them and make them visually rich. They are also expressed in pagination, often placed in the margin. In Varta's books, from the cover and its jacket, through to the endpapers, introduction page, half and full title page, book block, preface, table of contents, bibliography, bookmark, it is all designed as a unified entity with text, photographs and visual illustrations. The same applies to catalogues, brochures, magazines, posters, business papers, greeting cards and even to small business cards. The unity of ideas, function, aesthetics, and production itself is at the highest level and in line with the printing standards of that time and beyond. Sometimes, impressive results in text layout are achieved even with seemingly limited resources.

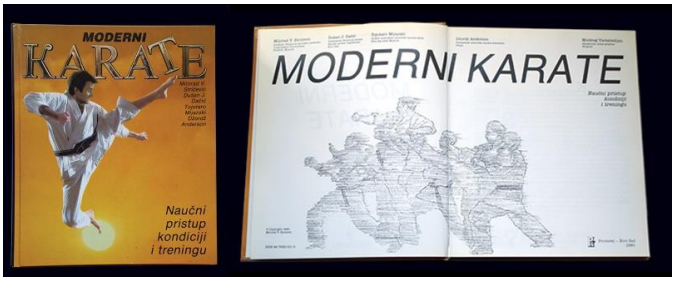

Figure 9. Illustration and book design – Modern Karate, 1990

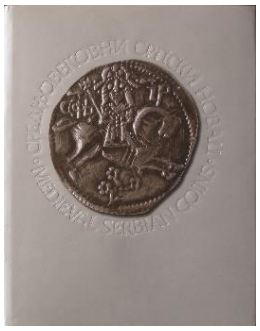

Figure 10. Monograph design with blind embossing technique, 1997

In photo-monographs, the use of a large title is composed across facing pages of the book, featuring large photographs or details related to the theme. These titles are carefully selected and skilfully used to create a harmonious aesthetic balance between large and small, calm and restless elements. In the book *Modern Karate* (fig. 9), the full title page is in cursive combined with a linear illustration and text, forming an aesthetic whole. On the cover there is a photograph of a karateka with one leg positioned on a heated point (sun), symbolising Japan and the Land of the Rising Sun, while the other leg performs a kick that lifts the letter "T" in the title. The cover of the book *Medieval Serbian Coins* (fig. 10) features a title in both Serbian Cyrillic and English language, arranged in a circular shape around a coin and designed using a blind embossing technique on a silver background, creating a three-dimensional appearance resembling a medieval coin impression. For the cover of the book *Szentendre* (Sentandreja) (fig. 11), a photograph featuring a cross is chosen and used as the letter "T" in the title, creating a unique composition with the typography of the title.

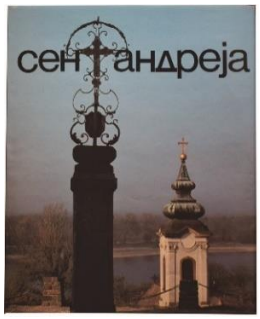

Figure 11. Book design of photo-monograph Szentendre, 1982

Figure 12. Catalogue design with die-cut form, 2004

The unconventional appearance of the catalogue for the exhibition *Animalistic Sculptures (Animalistička Plastika*) by Mira and Sava Sandić (fig. 12) is achieved by using a die-cut form that shapes the catalogue into the contour of an owl sculpture.

5. CALLIGRAPHY

As a tireless explorer of new forms of artistic expression, Varta also tried his hand at calligraphy. For his design works such as book covers, exhibition catalogues, certificates, diplomas and invitations, he creates calligraphic inscriptions for titles as well as entire alphabets including Cyrillic and Latin scripts that he used in his work.
He utilised wooden sticks for writing, which he cut and shaped in various ways. Sometimes a straight-edged tip, which leave a uniform trace when writing, while at other times he would cut the wooden stick tips with two or three incisions, allowing the trace to be composed of two or three lines when writing.
Varta's typographic script *Varta Script* (fig. 13), a cursive character of uppercase letters, is derived with emphasised serifs that give liveliness to the handwriting, along with jagged edges that give it a pictorial quality.

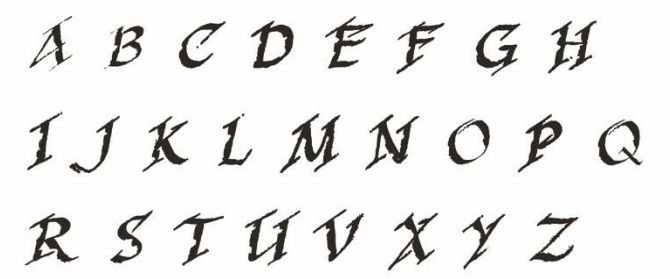

Figure 13. Varta-script, 1999

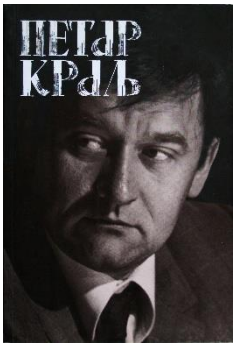

Figure 14. Calligraphy in cover design, monograph - Petar Kralj 1999

6. CONCLUSION

Varta's rich opus of interests and in-depth explorations in artistic design, which can be seen in his creations, provides a picture of an authorial signature that remains recognisable, unique, and enduring in these regions, like an inscription in stone. Varta's retrospective at the Museum of Applied Arts in 1983 was called *Book and Painting* and the exhibition *From Stone to Book* at the Art Gallery *Stara Kapetanija* in 1990, indicating that stone, picture, and book are inseparable parts of the structure of his creativity. Following his own path, leaving traces of cultural heritage, he developed his distinctive modern artistic expression which he transposed into assigned graphic forms. Layers of influences from various cultures expressed through modern means have made his work accepted and published worldwide. In this way, symbols from forgotten cultural records have become contemporary codes of Varta's unique language of graphic communication. Varta's work will remain a source of inspiration for young emerging artists for years to come.

Abstract: *This study presents a novel approach to redesigning two famous Anglo-Saxon medieval Lyres, namely Trossingen and Sutton Hoo, using parametric Computer-Aided Design (CAD). The redesign process was based on early chronological publications, with the initial objective of creating lightly modified replicas of the two medieval instruments while minimizing assumptions and enhancing their sound. The redesigned instruments consisted of various components, such as soundboards, bodies, and yokes. To analyze the impact of different configurations of the soundboards on the structure and sound quality of the instruments, two configurations were designed and compared using spruce and maple materials. Concerning the soundboard's thickness and materials, modal analysis was employed to identify the resonant frequencies of the instruments. The insights obtained from this analysis were utilized to optimize the design of the lyres, aiming to enhance their sound quality and overall performance. Using modal analysis, this research contributes to the preservation and documentation of the musical heritage linked to the lyres and offers in-depth insights into their construction and acoustics.*
Keywords: CAD, FEA, Modal Analysis, Parametric Design, Medieval Lyres

1. INTRODUCTION

The Anglo-Saxon lyre (also known as the Germanic and Viking lyre) is a historically rich and culturally significant musical instrument that appeared in the 1st millennium CE warrior graves. It is part of a strand of lyre development distinctly separated by the Greek-Roman lyres (such as the Lyre of Classical Greece), with findings dated as early as the Iron Age discovered in numerous places in Austria, England, Brittany (France), Poland, and Scotland (where the bridge of a lyre dating to 2300 BCE was discovered in the Isle of Skye) [1,2].
Even if this stringed musical instrument, inspired by lyres played by Germanic tribes, has left a mark on various historical records and artifacts, our understanding of its original design and construction is somewhat restricted due to limited well-preserved remains.
Today, the Anglo-Saxon medieval lyre carries profound significance in its historical context, representing cultural identity and artistic expression. Its relevance extends to historical revival, academic research, cultural heritage, artistic inspiration, and experimental music, making it a valuable instrument that continues to bridge the gap between the past and the present.

Following this direction, the Sutton Hoo lyre is of immense significance due to its representation of Anglo-Saxon artistry and its role as a musical instrument from the early medieval period. Accordingly, the Trossingen lyre represents medieval Germanic artistry and its role as a musical instrument from the Iron Age. Together, they contribute to understanding cultural and social aspects of those times [3]. Figure (1) illustrates the two well-known replicas of the lyres from Michael J. King since 2012.

Figure 1. Sutton Hoo and Trossingen Lyres replicas by Michael J. King in 2012 [4][5]

Numerous studies have already been carried out on lyre reconstruction; however, the available documentation remains inadequate, often lacking minor specifics [6]. This research aims to restore the Anglo-Saxon lyre using parametric design approaches. Our variations will undergo modal analysis by employing various design methods, resulting in different lyre configurations. Modal analysis helps to preserve and document the musical heritage associated with the lyre by providing detailed information about its construction and acoustics. The models developed in this study serve as invaluable tools for instrument makers, allowing them to experiment with different geometric characteristics and material properties to estimate and enhance the acoustical characteristics of the instrument before its physical construction.

2. Methodology.

The present study introduces the redesign concept using parametric three-dimensional Computer Aided Design (CAD). The process involves Solidworks (Dassault Systemes, Yvelines, France) as the 3D CAD software to create parametric designs for the individual components and generate the final assemblies of the lyres. As a widely used CAD and CAE program, SolidWorks is recognized for its exceptional flexibility for a wide range of applications in many sectors and for its automation, user-friendly interface, logic, and simple learning process. It makes use of a parametric approach and contains a process tree to track the history of the components' alterations.

As Figure (2) illustrates, the Anglo-Saxon lyre comprised a total of 9 components: the main body or soundbox, the soundboard, arms, yoke, bridge, tail, tailpiece, tuning pegs, and strings. Typically, wood was employed for crafting all parts except the strings, which could be made of gut. The main body was predominantly shaped by carving a solid wood piece, aiming for its distinctive teardrop or pear-like contour. The interior was hollowed to enhance resonance and sound projection. The soundboard, fixed at the top of the main body, was securely attached to prevent vibration damping, featuring small soundholes, drilled or carved, to enhance acoustic qualities. The arms were symmetrically attached to the body. Tuning pegs were positioned on a separate component known as the yoke. An essential element, the bridge, was situated perpendicular to the strings near the soundbox's vertical centre, facilitating the strings' proper positioning and effective transmission of vibrations. Lastly, historical accuracy was maintained through adornments such as engravings, paintings, or patterns that embellished the lyre's appearance [7].

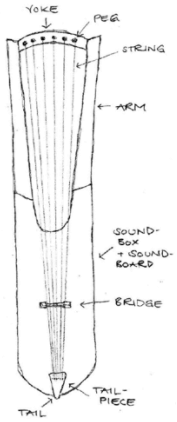

Figure 2. A lyre with all its components [8].

3. Design and Configurations

3.1 Sutton Hoo Lyre

The initial lyre under examination, the Sutton Hoo, was designed according to the data provided by Myrtle and Rupert Bruce-Mitford in chapter IX of their 1983 book "The Sutton Hoo Ship Burial – Vol. 3". [9] The design of all major components, encompassing the body, soundboard, and yoke, was carefully guided by the insights provided in this book. However, minor assumptions in specific areas were introduced to complete the design due to certain gaps in the available information. The complete assembly includes a total of seventy-one components, which are derived from eight individual parts. The structure's core comprises three primary components: the body, soundboard, and yoke. The body is thoroughly hollowed to create a vibrating chamber, enhancing the amplification of sound. Towards the upper section, two arms extend from the main body, connecting to the yoke through tapered joints referred to as escutcheons. Positioned atop the body, the soundboard also vibrates to produce sound waves. It was designed in two variations: the first exhibits variable thickness, ranging from 3 to 7 mm at its centre, while the second maintains a fixed thickness of 3 mm, as illustrated in Figure (3). The bridge, located in the middle, serves as the medium that transfers the vibration from the six strings to the soundboard. These strings are fastened at the bottom with an endpin, referred to as "tailpiece", and secured at the yoke through six pegs. Finally, there are 53 nails positioned around the periphery of the soundboard to firmly attach it to the body. Figure (3) also reveals the final assembly, as well as its exploded view.

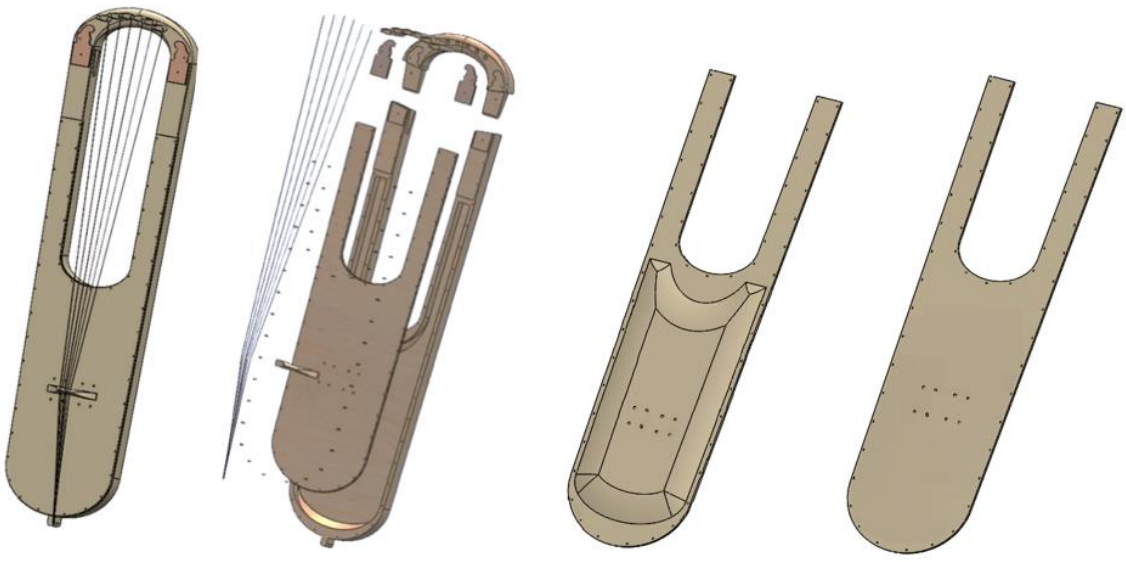

Figure 3. The Sutton Hoo Lyre assembly (left) with two soundboard configurations (right)

3.2 Trossingen Lyre

The Trossingen lyre followed the same design principles. Reference materials, including publications and images by Barbara Theune-Großkopf, served as the foundational basis for the design process. Many design challenges mirrored those encountered with the previous lyre and were resolved efficiently. In this instance, the escutcheons were omitted due to the integrated yoke into the solid lyre's body, resulting in a total assembly consisting of 20 components derived from seven individual parts, as clearly depicted in the exploded view in Figure (4). The main body was hollowed to facilitate vibrations, and four small pegs were strategically added to connect the soundboard to the body. The tuning pegs and strings design were influenced by the information provided in Großkopf's publications, while, as mentioned earlier, the tailpiece and bridge were shared components between both lyres. In terms of soundboard thickness, two configurations were developed. The initial approach, based on previous research, featured an adaptive thickness, from 3 mm at the edges to 7 mm at the center of the model. The second configuration maintained a consistent 3 mm thickness throughout its entire extent, as indicated in Figure (4).

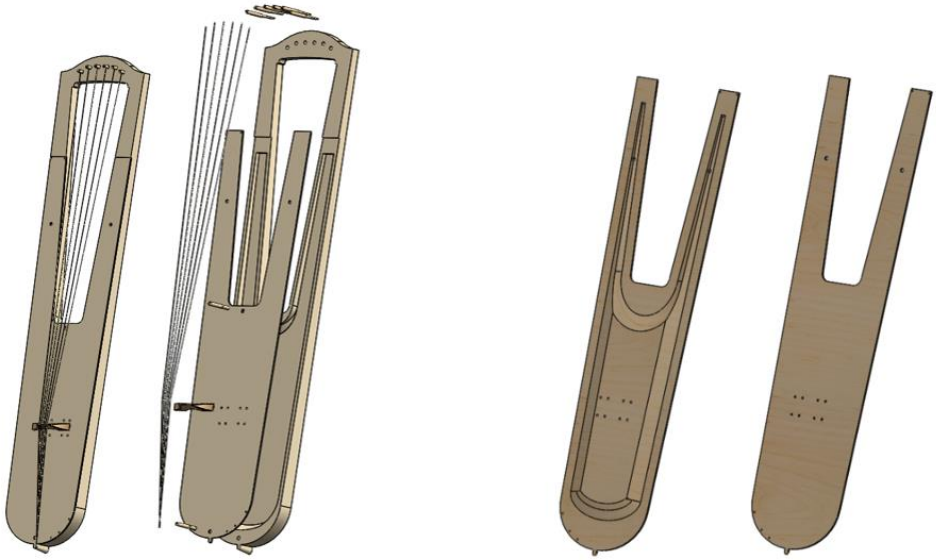

Figure 4. The Trossingen Lyre assembly (left) with two soundboard's configurations (right)

4. Modal Analysis

Modal analysis was also accomplished, which is a specific type of vibration analysis that focuses on identifying a system's natural frequencies and modes of vibration in the current work to determine the resonant frequencies of the instrument and vibrational patterns of its various components. This information was used to optimize the design and construction of the lyre, as well as to improve its sound quality and performance. Modal analysis helps to preserve and document the musical heritage associated with the lyre by providing detailed information about its construction and acoustics. The two configurations of each lyre, Sutton Hoo and Trossingen, were analysed using ANSYS (Canonsburg, USA, PA) software. The first three resonant frequencies of the four configurations are illustrated in Figures (5-6), while Table (1) indicates the first ten resonant frequencies of each analysis. The modal analysis of the ancient lyres, Sutton Hoo and Trossingen Lyre, showed significant shifts in resonant frequencies between their initial and improved designs. For the Sutton Hoo Lyre, there was an average reduction of approximately 9.9% (ranging from 7.6% to 17.1%) in resonant frequencies, with the most substantial decrease occurring in the first mode, which decreased by 6.019 Hz. Similarly, the Trossingen Lyre exhibited an average decrease of about 8.1% (ranging from 4.7% to 12.5%) in resonant frequencies, with the most notable change observed in the sixth mode, which decreased by 27.96 Hz. These changes suggest substantial improvements in the acoustic characteristics of both lyres with their improved designs.

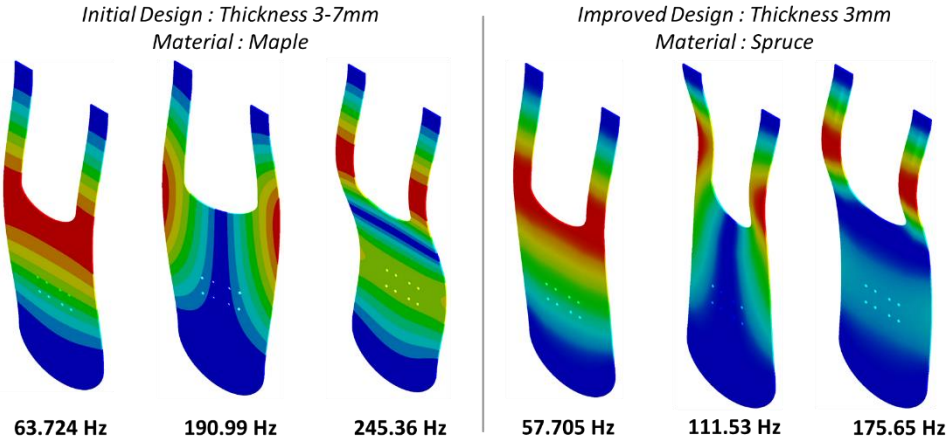

Figure 5. The first three resonant frequencies of the Sutton Hoo soundboard's configuration.

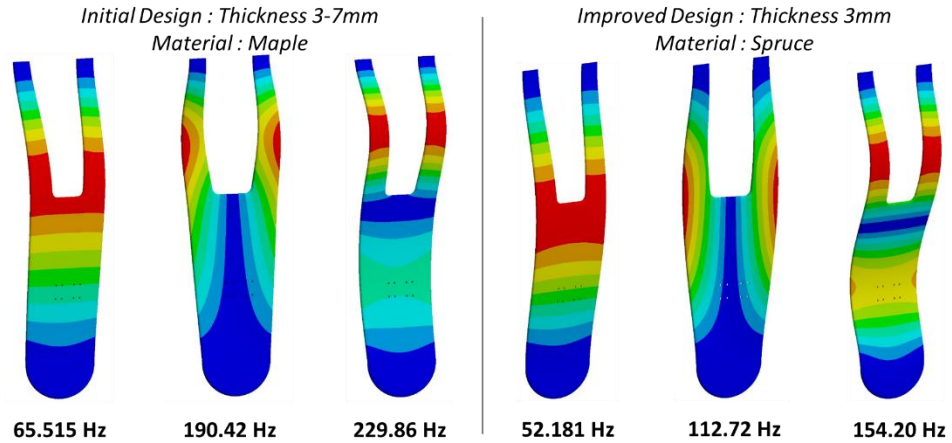

Figure (6) The first three resonant frequencies of the Trossingen soundboard's configuration.

Table 1. The ten resonant frequencies of each soundboard

Lyre	**Sutton Hoo Lyre**		**Trossingen Lyre**

7th	704.35	482.09	710.57	503.72
8th	882.27	545.77	801.29	580.47
8th	993.96	683.70	902.84	640.09
10th	1037.6	763.76	988.82	752.28

5. CONCLUSION

The created models serve as valuable resources for instrument craftsmen, having the convenience of easily tweaking geometric attributes and material properties. These models also serve as instruments for fine-tuning the acoustic properties of an instrument on an individual basis before embarking on the construction process. Moreover, modal analysis serves an additional purpose by contributing to the preservation and documentation of the lyre's musical heritage. This is achieved by furnishing

comprehensive details regarding the instrument's construction and acoustic properties. Acoustic analysis, in general, entails the utilization of signal processing techniques, encompassing factors like wave propagation, amplitude, wavelength, and spectral content. A profound understanding of wave interactions and the influence of environmental and boundary conditions, which culminate in normal mode oscillations, is vital.

Abstract: *The Fused Filament Fabrication (FFF) technology involves various printing parameters that can be investigated and analysed to understand their impact on the final printed model. The infill of the model, consisting of both the pattern and density, holds a crucial role in the slicing software of the 3D printing process. The selection of infill pattern, such as grid, lines, or gyroid, can greatly affect the strength, weight, and stability of the printed model. Moreover, the infill density, which determines the amount of material inside the model, directly affects its overall mass and volume. Hence, these parameters also have an influence on the mechanical behaviour of the printed object. This research aims to examine the different infill patterns available in commonly used slicing software. All patterns were tested at a specific density using cylindrical block pieces. The research methodology involved employing two distinct image processing techniques. The 2D image processing of the slicing phase was carried out using programming language, while the 3D image processing was conducted using micro-computed tomography (μCT) on the printed models. The analysis and comparison between the pixel data obtained from the 2D image processing and the voxel data derived from the 3D computed tomography, provide valuable insights into the relationship between imaging data and the final mass of each printed model. These insights contribute to a deeper understanding of the impact of infill patterns and densities in 3D-printed objects.*
Keywords: Additive Manufacturing, Multimedia Data, Computed Tomography, 3D Printing, Image Processing

1. INTRODUCTION

Fused Filament Fabrication (FFF) additive manufacturing technology has revolutionized both the manufacturing industry and the researchers by enabling the creation of complex and intricate models, layer by layer. There are more than 500 different settings [1] to examine in the FFF technology. Infill, one of the most crucial parameters in FFF 3D Printing technology, plays a significant role in determining structural integrity, mechanical properties, and overall performance of printed parts. It refers to the internal structure or lattice pattern printed inside the solid shell of an object.
The infill pattern is critical because it affects the strength-to-weight ratio, stiffness, and durability of the printed object [2]. By strategically altering the infill pattern, designers and engineers can optimize the mechanical properties of 3D-printed parts to meet specific requirements. Research studies [3,4] have extensively explored the influence of infill parameters, such as pattern type, infill density, and infill percentage, on the performance of printed parts. The choice of infill pattern, including

[1] m.tzimtzimis@ihu.edu.gr
[2] dsagris@ihu.gr
[3] david@ihu.edu.gr
[4] d.tzetzis@ihu.edu.gr

honeycomb, rectilinear, gyroid, and others, directly impacts the mechanical behavior and functionality of the printed object. Furthermore, infill density, or the amount of material used for filling the internal structure, can be adjusted to balance strength and material consumption. A higher infill density enhances the structural integrity and strength of the object but consumes more material and prolongs printing time. Conversely, a lower infill density reduces material usage and printing time but may compromise the strength and stiffness of the printed part. The influence of infill in FFF 3D printing technology is not limited to mechanical properties alone. It also affects other factors such as weight, cost, heat transfer, and aesthetic appeal [5,6]. The ability to optimize these factors by adjusting infill parameters makes FFF 3D printing a versatile and adaptable manufacturing method.
On the other hand, multimedia data analysis has emerged as a vital research area due to the explosive growth of multimedia content in various domains, including education, healthcare, and production lines. With the increasing availability and diversity of multimedia data, there is a growing need to develop robust techniques and algorithms to extract valuable information and gain insights from these complex and heterogeneous datasets [10]. Multimedia data refers to data that encompasses different forms of media, such as images, videos, audio, text, and sensor data, often combined [11]. These diverse types of data present unique challenges in terms of their volume, variety, velocity, and veracity, commonly known as the four V's of big data. Analyzing such data requires advanced computational techniques to handle the complexity, heterogeneity, and large-scale nature of multimedia datasets [12].
The aim of this study is to analyse the impact of the infill pattern in the 3D printing process, by analysing multimedia data from various sources. The thirteen different infill patterns available in the slicing software, were investigated through 2D image processing, and 3D μCT. The analysis and comparison between the pixel data obtained from the 2D image processing and the voxel data derived from the 3D computed tomography, provide valuable insights into the relationship between imaging data and the final mass of each printed model. The image processing phase is conducted before the 3D printing process, while the computed tomography and the mass measurement are conducted subsequently after the 3D printing process.

2. METHODOLOGY

The approach encompassed a series of three consecutive stages. The initial step involved replicating the printing process, specifically the slicing method. A cylindrical sample, appropriate for compression testing [7], was created and imported into the slicing software (Cura™ Ultimaker software). The software has thirteen distinct options for configuring the infill pattern, including variations like Grid, Lines, and three-dimensional designs such as Gyroid or Cubic. These patterns are depicted in Figure (1). Polylactic Acid (PLA) was the chosen material for this investigation. The remaining printing variables were kept consistent to ensure a uniform G-code file across all printing instances. The unchanging parameters of the G-code are outlined in Table (1).

Table 1. The constant printing parameters

Printing Parameters	**Value**
3D Printer	*Creality Ender 3-S1*
Layer Thickness	0.2mm
Infill Density	*25%*
Walls	0
Speed	60mm/sec
Print & Bed Temp.	210°C / 60°C
Support & Brim	No / No
Cooling System	100%
Flow	100%

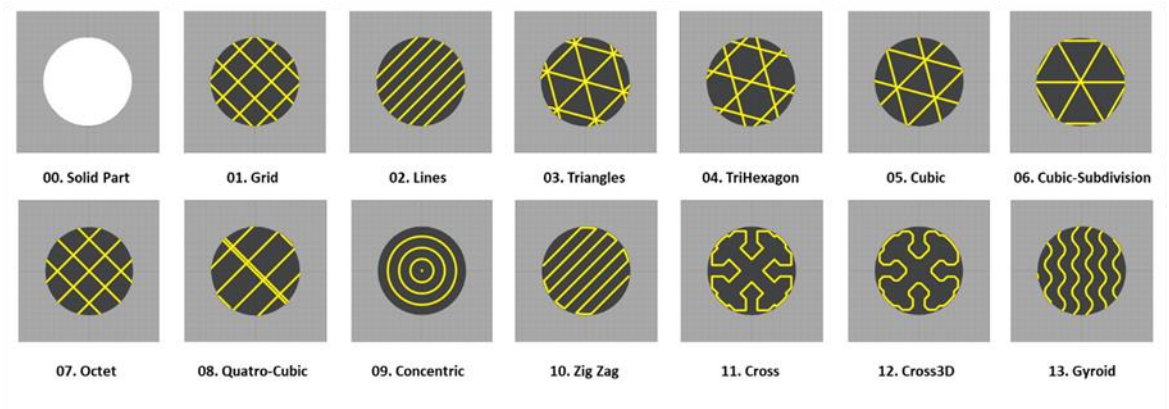

Figure 1. The thirteen available patterns investigated.

The initial approach involved determining the mass. Given the dimensions of the cylindrical section in the experiment (D 12.5mm x H 25mm), the computed surface area, equated to 1.226 cm^2. The complete volume of the object was calculated to be 3.066 cm^3. Concludingly, the density of the PLA material (Spectrum, Parkowa, PL) is manufacturer-stated as 1.24 g/cm^3 and the solid cylindrical segment had a mass of 3.80 grams. Following the 3D printing procedure, each pattern was subject to measurement using a digital balancing scale.

3. ANALYSIS AND RESULTS

3.1 Computed Tomography

Following the mass measurement, internal images of the samples were examined through the application of μCT. A micro-CT apparatus (Tomoscope HV Compact 225kV, Werth Messtechnik GmbH, Germany) was employed to acquire the CT-data and VGStudio MAX 2.2 software (Volume Graphics GmbH, Germany) to compute the total count of voxels present within each printed cylindrical specimen. Since all cylindrical specimens displayed symmetry across all axes, the analysis was restricted to the intermediate layers spanning from layer 25 to layer 100, which corresponds to a height of 15mm out of the total height. A solid segment measuring 15mm in height contains an estimated 440.224 million voxels, encompassing a circumscribed volume of 1780.23mm^3. Table (3) outlines the measurements obtained from μCT for the 13 distinct patterns, while Figure (2) illustrates an example of the 3D reconstruction derived from the μCT in various infill patterns.

Table 3. Voxel Measurement from Computed Tomography

No.	Infill Pattern	Voxels Amount (gr)	Voxels Ratio (%)
00	Solid Part	440.224	100
01	Grid	67.794	15.40
02	Lines	67.926	15.43
03	Triangles	88.705	20.15
04	Tri-Hexagon	86.107	19.56
05	Cubic	76.334	17.34
06	Cubic-Subdivision	65.241	14.82
07	Octet	84.214	19.13
08	Quatro-Cubic	88.088	20.01
09	Concentric	61.851	14.05
10	Zig Zag	63.436	14.41
11	Cross	70.788	16.08
12	Cross3D	59.738	13.57
13	Gyroid	73.121	16.61

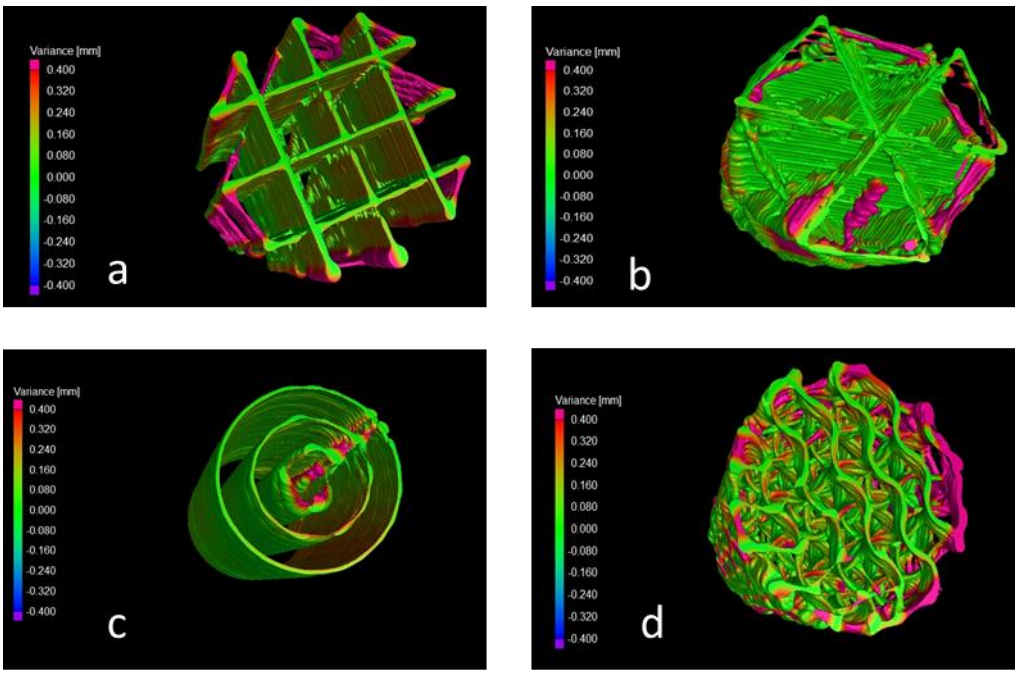

Figure 2. 3D reconstruction of the Computed Tomography in Grid (a), Cubic (b) Concentric (c) and Gyroid (d) infill Patterns

3.2 Image Processing

The outcomes from the two subsequent evaluations – measuring the mass of the printed samples and determining the voxel count through computed tomography – generated information for each distinct infill pattern. The image processing analysis is a pre-processing technique that furnished valuable insights into the 3D printing outcome. Employing the Cura slicing software numerous screenshots for each infill pattern were extracted in JPEG format. During the image processing stage, a highly significant factor is maintaining consistent image dimensions, and consequently, an identical pixel count throughout the entire experimental process. If there's a variance in the image aspect ratio compared to the other images, it would lead to inaccurate area calculations [9]

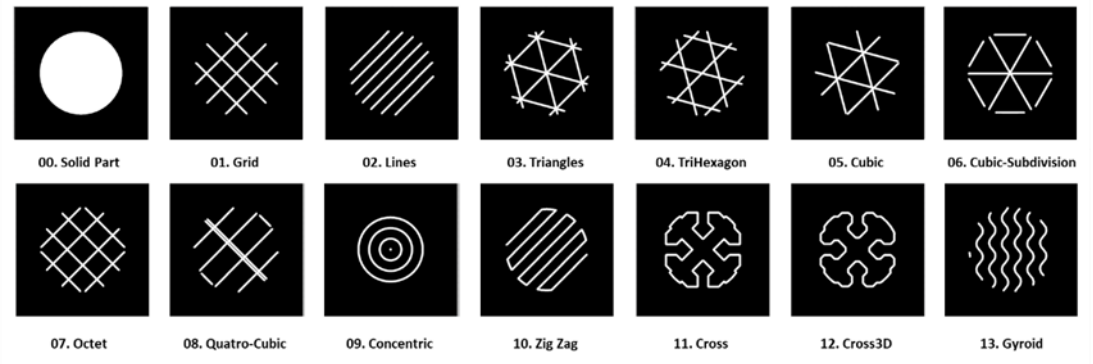

Figure 3. The binary format conversion of the solid model and the infill patterns

The image processing algorithms were executed using the MATLAB computing platform. The images were first transformed into grayscale and subsequently into binary format, where the white pixels indicated the printed volume, as depicted in Figure (3). The identified white pixels within the solid component were 129,825. The overall average count of white pixels across all instances was 21,631 with a corresponding average ratio of 16.66%, as detailed in the results in Table 4.

Table (4) White Pixels detection and the corresponding ratio

No.	Infill Pattern	Pixel Amount (gr)	Pixel Ratio (%)
00	Solid Part	129,825	100
01	Grid	19,728	15.24
02	Lines	22,747	17.52
03	Triangles	24,729	19.05
04	Tri-Hexagon	22,856	17.61
05	Cubic	20,208	15.57
06	Cubic-Subdivision	19,477	15.00
07	Octet	23,618	18.19
08	Quatro-Cubic	20,892	16.09
09	Concentric	18,342	14.13
10	Zig Zag	24,731	19.05
11	Cross	21,561	16.61
12	Cross3D	19,886	15.32
13	Gyroid	22,374	17.23

The results of the three evaluation techniques were equivalent. The pre-process approach of the image analysis verified the subsequent post-process techniques of mass measurement and computed tomography. Measured ratios for all infill patterns, encompassing the comprehensive average from each approach, are outlined in Table (5). Notably, the Triangles, Tri-Hexagon, and Octet infill patterns demonstrated the most favorable average outcome, hovering around 19%, whereas the Cubic-Subdivision, Concentric, and Cross3D patterns yielded the lowest ratios, averaging less than 15%

Table 5. The ratios from every infill pattern in the three methodologies

No.	Infill Pattern	Ratios (%)			
		Mass	Voxels	Pixels	Average
01	Grid	16.05	15.40	15.24	**15.56**
02	Lines	16.84	15.43	17.52	**16.60**
03	Triangles	18.42	20.15	19.05	**19.21**
04	Tri-Hexagon	17.89	19.56	17.61	**18.35**
05	Cubic	16.05	17.34	15.57	**16.32**
06	Cubic-Subdivision	14.21	14.82	15.00	**14.68**
07	Octet	17.89	19.13	18.19	**18.41**
08	Quatro-Cubic	18.68	20.01	16.09	**18.26**
09	Concentric	13.42	14.05	14.13	**13.87**
10	Zig Zag	16.05	14.41	19.05	**16.50**
11	Cross	14.74	16.08	16.61	**15.81**
12	Cross3D	13.42	13.57	15.32	**14.10**
13	Gyroid	18.42	16.61	17.23	**17.42**
Average		**16.32**	**16.65**	**16.66**	**16.55**

The techniques introduced for visualizing and analysing multimedia data from μCT and image processing assist in comprehending the amount of the extruded material, hence the total mass of the printed model. Nonetheless, there are certain factors to consider when assessing the information required through this approach. For the μCT analysis, the precise alignment of the printing trajectory is crucial for obtaining quantitative results [8]. For instance, in the case of a 100μm layer height and a voxel resolution of 10μm, each layer is captured with exactly ten voxels. To ensure the accurate assignment of each print path layer to the corresponding voxel size, the registration error in this dimension should be less than five voxels.

4. CONCLUSION

This research investigates the various infill patterns offered by commonly used slicing software. All patterns were subjected to testing at a specific density using cylindrical block pieces. The research methodology involved the utilization of two distinct image-processing techniques. The slicing phase's 2D image processing was accomplished through programming, while the 3D image processing was conducted via micro-computed tomography (μCT) on the printed models. The utilization of image processing to evaluate infill patterns has yielded a preliminary analysis method for FFF 3D printing technology. This image-based process method could be used for further analysis of various 3D printing parameters, enabling the anticipation of printing outcomes without the necessity of executing the actual process. Across all 13 infill patterns, the image processing method yielded relatively consistent results, all of which fell notably below the desired percentage (ranging from 6% to 10%). The capacity to assess and forecast the behaviour of a 3D printed object before its physical construction serves to significantly diminish the experimental time required for subsequent analyses involving varied printing parameters and distinct CAD designs. Moreover, a machine learning approach can be implemented to analyse even further the G-code file and replicate a more accurate extruder path.

LEATHER RECYCLING IN THE CONTEXT OF HAUTE COUTURE

Ivana Desnica[1], The Academy of Applied Technical Studies Belgrade

Abstract: *In this paper we will show both theoretical written work and original artwork created as a result of research in a number of different areas. As well as exploring traditional craft jewelry-making techniques as an important part of intangible cultural heritage and their importance in preserving and maintaining the continuity of the country's cultural tradition, the theoretical research focuses on ecological and environmental issues and the possibilities for sustainable design and art. The aesthetic expression of jewelry, which through its richness and diversity suggests a visual link with a traditionally recognizable appearance of jewelry, is the main idea of this thesis. However, through the use of completely different materials and jewelry making techniques, jewelry is placed in the context of contemporary design. The focus is therefore on the process of the creation of the object itself, in a modern way, through the use of traditional forms. It is precisely this approach of creating and confronting diversity: traditional - modern, old - contemporary, handmade - machine-made, etc., that makes it possible to fully explore the possibilities of old craftsmanship, harmoniously combined with the new values of the modern age, pointing to the paramount importance of the presence of artistic engagement.*
Key words: Recycling, Ornament, Leather, Couture, Jewelry.

1. INTRODUCTION

The environmental impact of technological progress, the amount of waste produced, climate change, etc., are everyday issues in today's social systems. Production processes generate substantial amounts of waste, and achieving efficient waste usage calls for significant changes in the way of production and consumption. This leads us to consider the role recycling plays in the 21st century. Currently, industrial production is shifting toward industrial ecology, which relies on the level of corporate awareness and logistics in the business system - and is based on the connection between industry and natural systems. The fundamental principle of industrial ecology is the eco-efficiency of a complicated industrial system with the goal of lowering resource and energy usage, consequently minimizing the overall waste of the industrial sector. This project is the result of the author's involvement in the design and creation of fashion accessories for more than two decades. The idea of reusing waste materials to create high quality garments, ornaments, jewelry and other fashion accessories was inspired by professional experience and knowledge of the significant amount of waste and the problems of its processing and disposal. The focus was on how to use waste to create innovative new products through art and design.

2. INDUSTRIAL ECOLOGY AND SUSTAINABLE DESIGN

The concept of *sustainable development* seeks to assure that society advances by utilizing available resources to fulfill its needs without harming natural resources and the environment. Consequently, environmental protection necessitates an array of diverse system solutions. The term *eco-efficiency of industrial systems*, known as *industrial ecology* [1], refers to the objective analysis of the

[1] desnica.ivana@gmail.com

industrial production process. This includes the generation, treatment, and disposal of waste within the system. Industrial ecology explores the relationship between industrial systems and natural systems. One fundamental concept of industrial ecology is that of the eco-industrial network, which involves the eco-efficiency of a complex industrial system with multiple factors that result in the exchange of materials and energy between different organizational units. The primary goal is to minimize the consumption of resources and energy, thereby reducing the amount of waste generated by the industrial sector. This industrial symbiosis results in enhanced resource productivity during the production process, waste reduction and generation, and utilization of waste materials as valuable raw materials in other production sectors. The industry generates 360 million tons of waste annually. A significant amount of waste in the leather goods industry is post-industrial rather than post-consumer. Recycling is a feasible solution for approximately half of the leather materials that become waste. Both the economy and the environment reap the benefits of proper disposal methods. Recycling, as a global imperative that modern society deals with in different areas and through many forms of action, has also intrigued numerous artists to join the fight for better utilization of natural resources. This type of artistic activity is increasingly present in many spheres of artistic creativity. Many established world designers accept the concept of sustainable design - 3R concept: *reduce, reuse and recycle* [2].

3. COMBINING TRADITION AND NEW TECHNIQUES

From a historical perspective, jewelry is a distinct aspect of a nation's spiritual and material culture as it has utilitarian, religious, and aesthetic properties. Over time, jewelry has undergone significant changes in function, characteristics and aesthetics. Essentially, it functions as a type of clothing, with a practical purpose, manifesting the owner's status in their class, family or religious group. The symbolic and aesthetic value of jewelry and its ubiquitous use make it a compelling subject. Traditional jewelry making is an important part of a nation's intangible cultural heritage. To preserve this heritage, it is essential to maintain the historical techniques through ongoing research in current jewelry-making procedures. In the creation of jewelry, various techniques are used, such as forging [3], pressing, engraving [4], filigree [5], granulating [6], enamelling [7], etching etc, each with its own unique characteristics. In this project, each of these techniques was chosen for its crucial role in the practical application or experimental development of a new process. Recent technological advancements have enabled the enhancement of old techniques and the introduction of new processes for producing jewelry. The use of sophisticated materials, combined with improved technical processes and emerging technology, has resulted in a rise in both the quantity and diversity of forms, designs and embellishments. The concepts of intangible heritage and traditional craft are in a constant state of flux, which reminds us of the ageless nature of art. Thus, it is possible to establish a correlation between art, culture, intangible heritage and the nature of their existence, as their survival depends on constant and repeated revival.

4. THE PROCESS OF CREATING LEATHER JEWELLERY BY HAND

The research process was aimed at exploring the possibilities of working with leather under modern technical and technological conditions. The results obtained brought together different practices that could be used to create a new and innovative leather treatment process. The aim of this part of the research was to create new tools and technological processes for the assembly of leather elements that would imitate the appearance of metal jewelry.

4.1 Leather selection and preparation

The practical part of the project was preceded by a long study of the technology of leather processing and preparation in industrial conditions. This was essential to ensure that the material reached the required thickness (0.10-0.40 mm) and fine quality equivalent to that of the historical

jewelry pieces that served as the inspiration for this project. Since this material has not previously been used in the production of this kind of decoration, selecting a type of leather that complements its aesthetic and technical properties requires knowledge of all types of leather and their characteristics in order to make a good choice. When selecting the material, the initial step was based on the purely visual appearance of the leather itself, the richness of its colors and the variety of its textures, which in their visual characteristics resemble certain types of precious metals, precious and semi-precious stones or other materials used in the manufacture of jewelry. The final selection included a range of leathers, from calfskin and lacquered leather to *spazzolato*[2], as well as textured leather. Prior to this, each type underwent a technical analysis to assess its hardness, elasticity, and requisite strength for further processing. Only the leather that met the above technical requirements was used in the final selection. Over 40 distinct types of leather were used in the production of ornaments and completed pieces of jewelry. The initial phase of preparing the leather for processing involved *thinning* the leather through *splitting*. Based on extensive research and thorough analysis of the techniques and tools traditionally used in jewelry making, through a series of conducted experiments was discovered that the use of only two basic and simple tools - the hammer and the *holepunch tool*[3]- could produce excellent results and facilitate further steps in the process. It started with the base of the circle, specifically circles of different sizes, i.e. diameters (from 1 mm, 2.5 mm, 3 mm, up to 30 mm). Then, hole punching tools were made of different diameters (f).

4.2 Variability of circular patterns as a fundamental artistic motif

The following section focuses on the creation of circular designs using a range of experimental techniques. The ultimate goal is to produce a unique ornament by combining multiple circles of varying sizes within a single larger circle. All this supports the claim made by Slavik Jablan that *the potential of the modular design principle is limitless. The variety and richness of motifs are produced by variations of geometric sets of fundamental elements* [8]. Another important principle that I adhered to in this project is the concept of *modular design*. This involves utilizing variations of geometric sets of fundamental elements to produce limitless and intricate patterns. By applying this technique, an extensive array of modular designs can be obtained, each one featuring a unique, aesthetically pleasing appearance. A structure is generated using a modular approach based on symmetry theory to calculate the number of distinct structures obtained by certain *algorithms* [9] that ensure completeness, according to Slavik Jablan's combinatorial formulas. In doing so, this methodology has the potential to generate novel and contemporary ornamental forms, thereby redefining the aesthetic relationship of ornament and symbolism through the circular prism. The development process of the circle as a fundamental component, leading to the ultimately accepted visual solution, was challenging. It involved numerous alterations, adaptations to the given production conditions, and unsuccessful attempts. However, exploring potential solutions resulted in successful outcomes via mutual union, multiplication, and combinatorics with varying forms and numbers. This study, conducted during the early stages of research, analyzes the technical process that determines the feasibility of the project, and defines the direction for the aesthetic development of ornaments. It is the point when the circle, as a fundamental element and one of the earliest and most straightforward graphic symbols, exhibited its universal nature, owing to its distinct visual appeal and the possibility of creating many derived forms and ornamental compositions.

[2] The term *spazzolato*, derived from the Italian word for *polished*, refers to a type of full-grain leather used in the leather goods industry. This leather has a higher shine than average but is typically less lustrous than traditional lacquered leather.

[3] *Hole punch tools* are made from specifically designed materials to withstand hammer impacts. They are produced by specialized companies that manufacture both manual and machine tools and equipment for the production of leather and footwear.

4.3 Achieving Visual Dynamics

In Figure 1, the process begins with a circular element containing smaller circle copies arranged at equal intervals, forming the foundation for the following phase. Once the initial phase has been completed, the elements within the same circle of the ornamental motif are multiplied by repeating the whole process, with the difference that the separated circles return to the same position and change direction, i.e. rotate 90 degrees. To create intricate designs, strings of ornamental structures are used within the same grid, grouped in a circle to create a final ornament.
Visual dynamism is introduced by the ornaments created as a result of the symmetrical reflection of the isolated element in the first phase and the new division of the color fields within a circle - the change in their position creates a new visual interaction within the same ornament. Therefore, the structural alterations and discrepancies that emerge at each production stage can be traced throughout the ornament's development, and each instance of the same element's variation yields a distinctive ornament while maintaining the circular motif's use. Next is the classification of colored ornaments, which broadens the range of motifs. I followed the path of the development of the circle motif through the variability of the changes in the shape of the ornaments, while preserving symmetry as the basic visual language of their building and structural elements. At the same time the regularity and decorativeness of the rosette elements was preserved through the complexity and integrity of the individual form of the ornament and as a part of the building element in the structural composition being created. The decorative archetypes designed in this project are presented through the richness of color combinations (Fig. 2).

5. CONCLUSION

This project demonstrates that the modern resource management model can establish a connection between eco-industrial networks and the cleaner production system. The focus has been on traditional jewelry-making techniques, some of which have been used in their original form, while others have led to the creation of new innovative processes and workflows, always with a view to preserving the processes. Traditional jewelry-making techniques, which have been included in the UNESCO list of intangible heritage protection since 2003 as part of the techniques of old crafts, concentrate on the process of making and transferring knowledge about skills and crafts, rather than on the product as the end result of the making process [11]. We see modernity as an interpretation of new ideas, which helps to clarify today's perception and understanding of ornament. It is interesting to consider the interplay between heritage and modernity, as well as the contrast between artisanal and industrial approaches. This dialogue can both inspire and challenge our understanding as it shapes the aesthetic consciousness of contemporary society. The process also has wider implications. These include recognizing the continuity of jewelry making and expanding the meaning of ornament. The selection of fundamental decorative shapes and their subsequent amalgamation were influenced by manufacturing techniques and technical procedures when forming compositional pieces.

DESIGN AND EDUCATION: TRADITIONAL AND ONLINE ENVIROMENT

Jelena Jocić[1], The Academy of Applied Technical Studies Belgrade
Maida Gruden[2], The Student's City Cultural Center

Abstract: The theme of this paper represents a cross-section of Annual School Exhibitions of works by Academy of Technical Vocational Studies – Belgrade design students, from 2004 to 2023 in cooperation with Dom Kulture Studentski grad, and explanations the educational process and cooperation with our school. In addition to the presentation and written work, posters and catalogs from 2004 to 2023 will be displayed in a special showcase. The connection between traditional and digital approaches in the educational process become even more prominent during the Covid pandemic. Online exhibitions have become a new reality. Development of digital media and their implementation in the educational system led to a different expression and communication in art and design.
Keywords: *design, education, online environment, digital art, communication*

1. INTRODUCTON: Relationship Between Traditional and Digital Approach

Relationship between traditional and digital approach in the field of education and design is an intertwined process and permeates each other. The idea is the basic starting point in art and design. The title theme of the exhibition „Distance that unites us" held in 2021. was inspired by the situation caused by the COVID-19 virus pandemic in which we lived and how it affects creative processes in the sphere of design and art. The situation led to a change in the presentation of artistic content and design and their communication with the public in the form of online exhibitions, but it denied the possibility for a more direct, physical and spiritual experience of artistic and design work and interaction in real, tactile, spiritual and physical communication.

Figure 1. *Poster for student's exhibitions in DKSG, 2021.*

Figure 2. *Poster for student exhibition in DKSG, 2022.*

[1] jjocic@atssb.edu.rs
[2] maida.gruden@dksg.rs

Contemporary aspirations in the field of design, emergence and use of new technologies and materials, increasingly massive use of digital technologies in design and market demands, encourage us to modernize and raise the quality of teaching. It also obliges us to prepare students for today's market in accordance with their creativity. The exhibition is also an opportunity to evaluate our pedagogical abilities in nurturing young talents, through their work in classical art techniques and digital technologies. The exhibitions included all segments of sociological aspects - topics such as education, ecology, health, culture, anti-war movements and other current topics of modern society.

The development of digital art and the use of digital technologies in design flow together with the development of computers. The set of digital technologies has transformed traditional techniques such as drawing, painting, sculpture, graphics into new forms such as internet art (network art), pixel art, data art, computer games, digital installations and they are becoming generally accepted artistic practices. One example of the acceptance of digital art is the artist Andy Warhol[3], who created digital art using the software „amiga paint", which he publicly introduced at Lincoln Center, and whose art has influenced all areas of contemporary design from graphic to fashion. I would also like to mention the artists Barbara Kruger[4], known for conceptual art and graphic design, and the artist Josh Begley[5], digital artist known for data visualizations, and his work *Every NYT Front Page since 1852*.

2. NEW TECHNOLOGIES AND DIGITALIZATION IN ART

Famous for her incisive photomontages, Barbara Kruger has focused increasingly over the past two decades on creating environments that immerse the viewer in language. At the Hirshhorn, Kruger recently completed *Belief+Doubt*, a site-specific installation that fills the museum's lower-level lobby and bookstore. Using a bold color scheme and towering text, *Belief+Doubt* explores themes of money, power, and belief. The phrases in her works often include pronouns such as "you", "your", "I", "we", and "they", addressing cultural constructions of power, identity, consumerism, and sexuality. Kruger's artistic mediums include photography, sculpture, graphic design, architecture, as well as video and audio installations.

Figure 3. *Barbara Kruger Installation, Hirshhor Museum and Sculpture Garden, 2012.*

[3] Andy Warhol, (1928-1987), American artist, painter, film director, writer and star. He is the founder of „Interview"magazine.

[4] Barbara Kruger, (born January 26, 1945), American conceptual artist and collagist associated with Pictures Generations, Professor at the UCLA School of the Arts and Architectures.

[5] Josh Begley, (born 1984), American digital artist, creator of Metadata+, an iPhone application

Known as *word art*, her method includes developing her ideas on a computer, later transferring the results (often billboard-sized) into printed images. Most of her work deals with provocative topics like feminism, consumerism, and individual autonomy and desire, frequently appropriating images from mainstream magazines and using her bold phrases to frame them in a new context.
At the beginning of the eighties of the twentieth century, Andy Warhol used *Amiga* computers to generate digital art, including *You Are the One*, which he helped design and build with Amiga, Inc. Andy Warhol was a pioneer in digital art. The world of digital art has exploded with online galleries and auctions, cryptocurrency trading, and a plethora of artists, both old and new, creating and selling digital artworks as NFTs (non-fungible tokens). This new era of art has quickly become a global sensation; it has proved itself to be unimaginably lucrative, and a powerful cultural force in the democratization (and general transformation) of art itself.

Figure 2. *Warhol and the Amiga – The Andy Warhol Museum*

The world of digital art has exploded with online galleries and auctions, cryptocurrency trading, and a plethora of artists, both old and new, creating and selling digital artworks as NFTs (non- fungible tokens). This new era of art has quickly become a global sensation; it has proved itself to be unimaginably lucrative, and a powerful cultural force in the democratization (and general transformation) of art itself.
The young American digital artist Joch Begley known for his data visualizations. He is the creator of Metadata+, an iPhone app that tracked every reported United States drone strike. In July 2012, Begley developed an iPhone application that would send a push notification every time there was a US drone strike in Pakistan, Yemen, or Somalia. In 2014, after five rejections, Apple accepted Begley's iPhone app. It was then approved as Metadata+. Josh Begley has compiled every front page of The New York Times since 1852 and created a fascinating visual timeline that documents the history of the image. taking the form of a video, the piece feeds through thousands of pages collected from the late 19th century up to the present day, capturing the chronology of text and picture-based layouts. while early examples are clearly devoid of any imagery, later covers begin to feature some hand-drawn illustrations, before the introduction of the camera completely changes the face of the publishing industry. The 55-second-long video rapidly streams through the most major international events in history, yet its mesmerizing quality is truly triggered by the introduction of photography. Begley’s film demonstrates the paper’s increasing use of black and white images, before color photography changes the game; today, a multitude of pictures feature liberally across front pages. more than 60,000 covers are included in the short film, packing history into a single, hypnotizing minute.

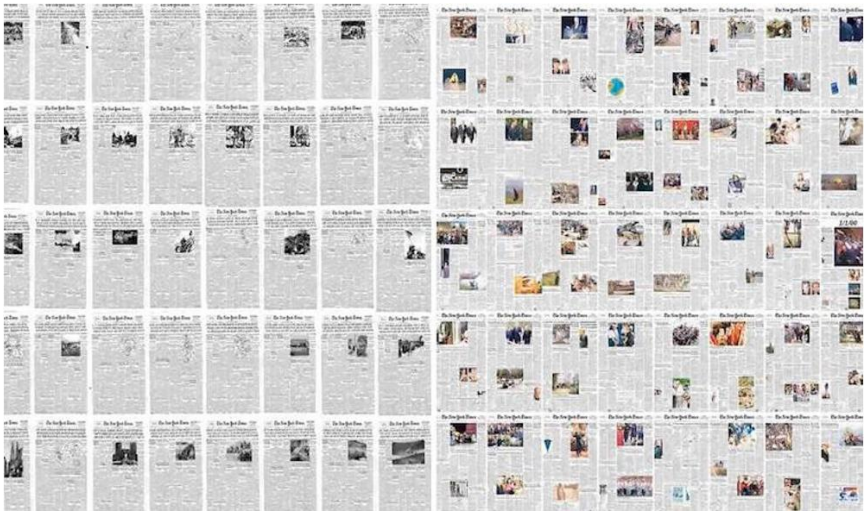

Figure 3. Joch Begley, Every NYT Font Page since 1852 in 60 Seconds, video, 2017.

3. SIGNIFICANCE AND COOPERATION BETWEEN ATSSB AND DKSG

Dom kulture Studentski grad[64] is one of the places in Belgrade with the longest tradition that provides space and support for students and young artists to present their creativity to colleagues, peers, and the more professional, as well as the general public. Through its activities, DKSG enables students to actively participate in the process of conceptual preparation and technical realization of the exhibition that is accompanied by the catalog. For decades, since the opening of this institution in 1974, the art program of DKSG has profiled itself as successful in the act of early recognition and discovery of young talents, which is of exceptional importance as an incentive to young authors in their further creative path and career.

Figure 4. *Dom kulture Studentski grad, Belgrade*

The implementation of all segments of the Art Program of the Student City Cultural Center is aimed at encouraging the development of creativity and critical thinking in the visual arts, bringing contemporary art closer to students, developing awareness of art as an important educational tool that can be used to reflect on modern life and encourage one's own creativity. From year to year, exhibitions are held where students, young artists, art historians and curators have the opportunity to present to the public the latest artistic production realized in the most diverse media from drawings, through graphics, photography, design, new media art (digital art, art installations, video arts, artistic research) to a unique art form that develops at the intersection of different disciplines, which is an art book. By affirming innovative ways of art presentation, media representation and communication, the aim is to promote the reception and popularization

[6] Dom kulture Studentski grad, (The Student City cultural center), (was faunded in 1971.), The House of Culture is an educational institution within the Ministry of Education, Science and Technological Development of the Republic of Serbia

of fine art in the wider public. Permanent education in the field of artistic practices and theories takes place through workshops, lectures, conversations with artists and other relevant actors of the Serbian art scene.

A significant part of the art program's work is cooperation with art academies from the country and abroad. It is also an opportunity for art faculty students from other cities to be directly present in Belgrade and to meet their colleagues and the audience in direct communication.

In this sense, DKSG nurtures two biennial events that network students of Art and applied academies from the country and abroad and multi-year cooperation with the Design Department of the Belgrade Polytechnic, Academy of Technical Vocational Studies Belgrade:

1. DKSG has been organizing biennial exhibitions of student drawings and graphics continuously and alternately since 1981. The basic idea of these exhibitions of student works is to gather and display the works of future academic fine and applied artists in one place, and thus provide an insight into the unique manuscripts of different fine arts schools. Every year, more than 100 authors have the opportunity to exhibit at the Biennale of Student Drawings and Student Graphics. The prize of the Biennale consists in organizing a solo exhibition for the awarded author in the Gallery of the "Student City" Cultural Center. The fact that many, especially the awarded participants of the Biennial of Student Drawing and Student Graphics, have prominent positions on the contemporary art scene, both here and abroad, confirms the quality and representativeness of this manifestation.

2. The 2nd International Student Biennial of Book Art, a form that develops at the intersection of various disciplines (graphic design, illustration, literature, photography...) is a unique student event in Serbia that was initiated by the editor of the DKSG art program Maida Gruden and Prof. Olivera Batajić (FPU) in in the House of Culture, Student City, in cooperation with the Faculty of Applied Arts from Belgrade. The Biennale has developed further and the Cultural Center from Belgrade has joined us as a partner.

3. Cooperation with the Department of Design of the Belgrade Polytechnic, the Academy of Technical Vocational Studies Belgrade through the annual exhibition of undergraduate students' works, five accredited study programs: Graphic Design, Interior Design, Industrial Product Design, Fashion Design and Concept and Character Design opens opportunities for the students of the Belgrade Polytechnic to professionally present their work related to the culture of everyday life and to introduce themselves to the wider market and enable them to establish contact with future employers. In the last few years, the works of Master's students in graphic design, as well as special thematic projects dealing with current topics of contemporary society, have been presented as a separate unit. Exhibitions are often accompanied by a fashion show and lecture programs. DKSG is aware of the great importance of this exhibition as an opportunity to include the experience of exhibition activity for students in the teaching process. Students have the opportunity to familiarize themselves with the organization of exhibition settings and public presentations of their work. For many, it is the first professional presentation and viewing of work in a new dimension before the public and the media. Cooperation with the Belgrade Polytechnic department was not interrupted even during the Corona virus pandemic, since the practice of online presentation of student works through virtual exhibitions on the website of the Belgrade Academy of Technical Vocational Studies was established.

During the covid pandemic, DKSG also strove to develop new activities that did not necessarily require a physical presence. The online series "Where are they and what are they doing today" was launched with the idea of presenting, in the form of short video clips, artists who had their first independent exhibitions at DKSG, as well as the winners of the Biennale of Student Graphics and Student Drawing awards, and who are still active participants on the contemporary art scene, and some of them are very notable authors on the international scene as well, such as Professor Jelena Jocić from the Department of Belgrade Polytechnic. In each episode of the series, many artists talk about their artistic journey, role models, creative inspiration, as well as their current work, future plans and other interesting topics. Video contributions are broadcast on the DKSG YouTube channel and shown on DKSG social networks.

In addition to working with students of art academies, DKSG is also dedicated to working with students as an audience, given that this cultural center is located in the surroundings of one of the largest student dormitories in the Balkans - Student City. Namely, since 2020, DKSG has been implementing the international project "They: Live - student lives revealed through context- based art practices", which deals with student life from the end of the Second World War to today in four countries: Serbia, Croatia, Montenegro and Spain in the context of daily life in student dormitories, cultural habits and free time of students, interpersonal and gender relations, as well as social and political involvement of students. The goal of the project is to encourage the student population to participate in the understanding and joint creation of contemporary art, using archival materials and participating in practical artistic activities during artist residencies in student dormitories.

Figure 5. Annual exhibition of works by ATSSB design students, Belgrade, 2023.

The project is implemented within the European Union's "Creative Europe" program for culture and media. During the year 2022, 5 art residencies were realized in student dormitories lasting one month in Belgrade, Novi Sad, Rijeka, Madrid and Podgorica, in which pairs of artists and curators developed participatory artworks with students who today live in student campuses using the collected archive about student life published on the international digital platform Topoteka.

4. CONCLUSION

The New technologies and their implementation in the educational process are an integral part of the future and modernization of teaching processes, as well as the digitization process. Cooperation between DKSG and ATSSB is of great importance for our students, through this exhibition activity students get to know the organization of the exhibition itself and the public presentation of their work. For many, it is the first professional presentation and review of their work in front of the public and the media. With this cooperation, we encourage students to engage even more in their creative work, pointing out to the public young talents and introducing future students to the design study programs of the Academy of Technical Vocational Studies Belgrade and the Department of Belgrade Polytechnic.

DESIGN, FASHION AND THE INDUSTRY: THE CONTEXT OF THE EMERGENCE OF FASHION DESIGN AND READY-TO-WEAR CLOTHING PRODUCTION

Jelena Zdravković[1], The Academy of Applied Technical Studies Belgrade

Abstract: *This paper aims at providing some insight into the context in which the fashion system was first established through haute couture and the accompanying ready-to-wear clothing production during the second half of the 19th and the start of the 20th centuries. The main focus is on the technological aspects and the research into the prerequisites which facilitated the industrial production of garments. Since the moment when the first garment was made with the use of machines represents a moment in history when the requirements for the laying of foundations for the fashion design were met, this paper also gives an account of the inventions (first and foremost machines used for pattern-making and sewing) which had contributed to the emergence of textile and fashion industry.*

Keywords: fashion design, fashion industry, ready-to-wear clothing, *haute couture*, *prêt-à-porter*

1. INTRODUCTION

The new social and cultural circumstances during the 19th and at the beginning of the 20th centuries, technological development and the industrialization brought about the establishment of the new paradigms in art as well as in the field of clothing. During the 18th century a distinction was made between the fine art and crafts whereas the garment production remained affiliated with the crafts during this "aristocratic moment" for clothing as Gilles Lipovetsky put it [1, pp. 22-30]. In the 19th century and during the first decades of the 20th century, through numerous movements, associations and schools (from Arts and Crafts movement to Bauhaus), an approach to the design of utilitarian objects emerged which took into consideration esthetics and functionality, ergonomic and economic components, included the use of crafts, knowledge about fabrics and application of the new technologies. Fashion made a grand entrance onto the scene of visual arts with the opening of the first *haute couture* fashion house (*maison de couture*) in Paris in 1857 when Charles Frederick Worth (1825-1895), a dressmaker, became a fashion designer, i.e. became an undisputable author who can impose dictates of fashion [1, p.67]. The first term for fashion was *couture* which is French for sewing or needlework, [2] which encapsulated the very essence of the trade, only to be substituted by the term *haute couture* which suggested originality and high level of execution of tailor-made garments [1, 3]. With a view to supervising the organization, management, improvement and protection of haute couture creations [4, p. 298 – footnote 29] a Chamber of Paris Designers *(Chambre Syndicale de la Confection et de la Couture pour Dames et Fillettes)* was formed in 1868 and in 1910 *La Chambre Syndicale de la Couture Parisienne* was constituted [2]. Worth marks the start of the reign of "a hundred years' fashion" as Gilles Lipovetsky [1, p. 65] refers to the period which started at the end of the 1850s and lasted till the 1960s dominated by the *Paris haute couture* and when dictates of fashion spread to other European cities and the rest of the world from France. *Haute couture* was accompanied by the development of serial, industrial

[1] jzdravkovic@atssb.edu.rs

production of standardized clothing reaching a larger number of customers – ready-to-wear garments (in French – *confection*). According to Gillo Dorfles, an aesthetician and art critic, one of the first conditions a utilitarian object should meet in order to be considered in the field of design is the manner of its production which includes mechanical production [5]. The possibility of recreating the produced object, i.e. the serial production, as well as designing objects with an aesthetic component built in, are the prerequisites mentioned by Dorfles, [5] which can be applied to fashion design as well. *Haute couture* and ready-to-wear clothes are the two intertwined sides of fashion, which have continued to develop alongside the visual arts on the one hand and in accordance with the technological development on the other.

2. FASHION AND THE INDUSTRY

Since the story of fashion does not rely solely on exceptional talented individuals who worked in this area of applied arts, but also on, among other things, technological development which facilitated the growth of fashion design and mass production of garments, innovations which made a significant impact on the textile and fashion industries should be mentioned here. The changes in textile industry started in the 18th century with the implementation of innovations such as the flying shuttle (1733), the spinning jenny (1764), power loom (1786), Jaquard loom which enabled the production of fabrics with complex patterns (1801) [4, p. 305]. However, the industrial production of garments started somewhat later in the 19th century with the use of the sewing machine. It took a long time to perfect the sewing machine from 1829 [4: p. 430 – footnote 11; 6: p. 56] so that it could be used in industrial production. The production of clothes also evolved over time finally being organized in factories according to the division of labour as opposed to having one worker in charge of an entire garment (the complete garment method) [7, p. 74]. In the early days of mass production of clothes cut denim workman's trousers for Levy Strauss in 1850 had been sent out to machinists' homes in individual bundles to be sewn [6, p. 56]. Factory-made clothes in England, France and the US in the beginning ranges from clothing for armed forces, rough sailors' clothing, i.e. work clothes during the American "gold rush" in the mid-19th century to ordinary urban daywear for men which appeared as early as in the 1830s and 1840s in London [7, p. 73]. English tailors situated on the celebrated Savile Row brought to perfection the construction of men's suit by using a tape measure, which had been in use since the end of the 18th century, thus enabling the taken measurements to be exact [8, p. 155]. In addition, tailors of men's suits further developed the system of pattern cutting by relying on mathematical calculations and by taking into consideration the proportion between the height of the body, width of the back and other parts of the body while their pattern-cutting systems were published so that others could use them [4, p. 376]. Significant contribution to setting up a system of the pattern cutting was made by a German mathematician Henry Wampen in his publications: *The Mathematical Art of Cutting Garments According to Different Formation of Men's Bodies* (1834) and *Mathematical Instructions in Constructing Models of Draping the Human Figure* (1863) [4, p. 376 – footnote 2]. In the segment of tailored suit made for women, by borrowing strict male shapes menswear tailors replaced dressmakers who created dresses by draping fabrics directly onto the body or, more often, based the pattern on unstitched old dresses [4, p.386, 388]. Men's suit at the start of the 19th century through its shape and appearance had already been designed in modernist style whereas following the "Empire" style women's fashion became more complex, intricate and the shape gained more in volume, which was why it had been difficult to adapt the shape and the production of dresses to the requirements for factory-made clothing.

An American inventor, Isaac Singer, filed a patent for an improved sewing machine in 1851 and continued afterwards to develop variations of a foot-treadle machine until 1859 and by the 1860s started their mass production in his company [6, 9]. Since then, sewing machines have played an important role both in making clothes at home and in industrial production [6, p. 56]. An increasing number of women's magazines published patterns, many in life sizes, which could be used for making clothes at home [4, p. 386-387]. However, in order to make complex shapes in mechanical

serial production precision is required, both in pattern cutting and in the sewing process, in addition to having to standardize sizes. As a consequence, the first dresses made according to standardized measurements appeared in 1870 [1, p. 98]. Less demanding items were made in factories on a larger scale, clothes with simple outlines, as well as fashion accessories – underwear, scarves, lace shawls, coats and small capes [1, p. 98]. Nevertheless, in time the use of the sewing machine in serial production included all of the articles of clothing (coats, rain coats and everyday clothes for a "new woman" to go out in or to wear to work, dresses, skirts and blouses tailored after men's shirts) [7, pp. 77-78] reducing the time needed to make a dress to 1/7 of the time necessary for making it by hand [4, p. 305 – footnote 33].

On the other hand, the use of synthetic fibres allowed cheap imitations of more expensive fabrics to be made such as artificial silk, available since 1892 in France [4, p. 306; 7, p. 71]. This fabric has been known as viscose rayon since 1924 [2, pp. 213, 270]. During the 19th century the centre of silk production was in Lion, France, which was connected with the fashion houses in Paris, the centre of fashion [7, p. 70]. In order to allow the ladies to follow the *Art Nouveau* style in fashion at affordable prices, in addition to the artificial silk, hand-made embroidery and lace were replaced by mechanical versions [4, p. 306]. Textile innovations and the search for new materials continued into the first half of the 20th century when synthetic fibres were produced, [2, 7] namely, *nylon* in 1940 and *polyester* in 1941, *acrylic* substitutes for wool in 1947 and finally *lastex* in 1930 [10, p. 80] and *lycra* in 1958.

As Suzanna Shonfield states, Worth ran his fashion house up to the late 1870s practically according to the rules of industrial production considering the number of copies he had been turning out [11, p. 29]. The House of Worth had 1200 employees at the start of 1870s, which included tailors, seamstresses, embroidery workers and models [8, p. 173]. Owing to the use of sewing machines and the division of labour which allowed only pattern cutting, embroidered interventions and hemming to be done by hand, *haute couture* designs could be reproduced faster while cheaper versions were made from other, less exclusive fabrics [11]. During the period between 1890 and 1910 mass production of clothing exploded in the UK and the USA [7, 12]. In France *haute couture* designers fought to control the production and distribution of products and conquer new markets through licensing, thus preventing unauthorized copying and ensuring the protection of their rights as authors of the designs. This is why the philosopher Gilles Lipovetsky saw *haute couture* as a commercial enterprise and a part of the luxury industry, which borrowed the idea from ready-to-wear clothing to group together once separated actions of buying directly from the factory, selling fabrics and making finished garments, for the purpose of making a profit [1, p. 97].

The beginnings of the textile industry and industrial clothing manufacture in Serbia were recorded in the text "Herald of Culture" (*Vesnik kulture*) published in the magazine *Tekstilna industrija*, no. 12 in 1927 [13]. According to this source, a company founded in 1907, *Kosta Ilic and Sons*, functioned as a "concern of textile products" which included, *inter alia*, "a baize factory (since 1907), a department for cotton and canvas industry (since 1910), a spinning mill for worsted wool, department for haberdashery (since 1923)" and these factories supplied with fabrics the First Serbian Clothing Factory (*Prva srpska fabrika konfekcije a.d.*) in Kanak, which was founded after the World War I as a part of this concern [13, pp. 232-233]. This factory produced ready-to-wear garments for children and men, undergarments and military uniforms [13, Ibid.]. Between the two world wars Belgrade had a number of fashion houses which followed Paris fashion and on occasion offered quite original designs, as was the case with Katarina Mladenovic who patented "The Procedure and Mixture for Plastic Coating of Fabrics" in 1923 [13, p. 133].

3. HAUTE COUTURE VS. MASS-PRODUCED FASHION

Lipovetsky mentions that, following the example of Worth, twenty *haute couture* fashion houses appeared at the exhibition in 1900 and this number increased to 72 in 1925 when the exhibition of decorative arts was held. However, after the World War II the number started to fall and in 1959 about 50 fashion houses were registered [1, p. 68]. *La Chambre Syndicale de la Couture Parisienne*

prescribed rules that fashion houses were to observe in order to secure their status as a couture house and these included the number of employees in workshops, which was not to be under 20, and a presentation of at least 50 original designs as a part of collections in each season shown to the Press in Paris [2, p. 130]. Organized fashion shows (Fr. *la revue*) offered an overview of new designs through a variation of stage shows. They appeared between 1908 and 1910 when fashion became "hypercentralized" and a highly regulated system had been established [1, p. 68]. After the World War I summer and winter collections were shown in Paris at a pre-defined time and, primarily for the sake of foreign buyers, mid-season collections were introduced for spring and autumn [1, p. 69]. Couture houses showed collections to respectable foreign clients or authorized buyers, predominantly from America and Europe, who could purchase creations made-to-measure or obtain licensing rights for serial production of the selected designs which provided them with the paper or linen patterns [2, p. 130]. Since ready-to-wear clothing developed side by side with *haute couture*, soon after the spectacular fashion shows of Paris couture houses, simplified versions of the shown designs were available at affordable prices [1, p. 69]. Fashion thus acquired a democratic and international air.

Technological advancement and production growth continued after the World War I and as Lipovetsky asserts "industrial clothing manufacture was profoundly transformed" mainly due to the division of labour in industrial production, innovations in the chemical paint industry and textile industry, as well as newly improved machines [1, p. 67]. Electrical sewing machine appeared on the market in 1921 [6, p. 56] and in the 1930s circular blade rotary cutter was introduced, [7, p. 80] allowing the expansion of production capacity and the rise of mass-produced fashion. By quickly adopting new technological inventions and offering ready-to-wear lines of clothing to clients the US was at the forefront of this trend. The concept of ready-to-wear clothing (also known as ready-made and off-the-rack) included mass-produced garments for women, men and children, of different styles and made from various fabrics, available in all sizes, sold in shops and department stores [14]. Mass-produced fashion as a "ready-made garment" also keeps the designer's name – the brand name that brings a certain cultural capital to the product. In response to the American version of mass-produced fashion, France introduced *prêt-à-porter* lines in 1949 in an attempt to "merge the industry and fashion", to industrially manufacture clothes according to fashion trends [1, p. 106]. Most designers of haute couture, including Pacquin, Worth and Poiret, were aware of the importance of the American market [11, p. 29]. However, in addition to those who obtained licenses to reproduce French designs, there were too many unauthorized copies flooding the market. This issue was addressed by the designers' associations, nevertheless, the licensing practices and the possibility of buying the rights for mass production brought into question the "exclusivity of haute couture designs" [11, p. 35].

Gabrielle Coco Chanel (1883-1971) was not concerned about this as she had always wanted to participate in the creation of accessible, functional and even mass-produced fashion. In an interview for *Vogue* in February of 1953, in the second half of her career, she sums up her goals in fashion: "I am no longer interested in dressing a few hundred women, private clients; I shall dress thousands of women" [11, p. 37]. Chanel announced something similar with her first collection for women in 1917 when she used jersey, a fabric that had not been used for women's costumes before except for sportswear and outer garments. Staying true to her fashion philosophy, Chanel sectioned off a small part of her couture house (registered with the Paris Haute Couture Chamber in 1919, right after the First World War) for making "ready-made clothes" [11, p. 37]. Patou and Lelong presented the same year as Chanel their first collections inspired by "ready-made clothes" [11, p. 35]. This moment heralded the rise of *prêt-à-porter* and the gradual decline of *haute couture* in the following years. Lucien Lelong (1889-1958), famous for his *haute couture* collections in Paris, was the first designer of *haute couture* who added a ready-to-wear department within his couture house, opened in 1918, in 1934 [15, p. 22]. Pierre Cardin (1922-2020) and Yves Saint Laurent (1936-2008) [16] continued to develop accessible fashion through *prêt-à-porter* collections following in the footsteps of Chanel. Pierre Cardin was the first *haute couture* designer to allocate a store for the *prêt-à-porter* collection in 1959 (a *prêt-à-porter boutique)* which caused him to be expelled from the Paris

Designers' Chamber [17, p. 101]. Yves Saint Laurent, on the other hand, in 1960s successfully expanded the offer with *prêt-à-porter* collections, which he designed with the same care as *haute couture* collections under the brand name *Rive Gauche* (in 1966 he launched a *prêt-à-porter* collection for women and for the first time in 1969 for men) [16, 17]. The number of buyers of haute couture and clothes made-to-measure was much lower in 1960s [1, p.104], which caused Cristobal Balenciaga (1895-1972) to close his Paris fashion house in 1968 as he refused to comply with the market demand to start a mass-produced line of clothes and signalled that haute couture had reached its end [10, p.194]. On the other hand, YSL fashion house remained in the field of *haute couture* until 2002 when it turned completely to *prêt-à-porter* collections [11, p. 143]. At that time only 11 registered couture houses remained [11]. In the meantime, Paris introduced a practice of showing *prêt-à-porter* collections the way *haute couture* collections had been shown once and the event was trade marked as *Prêt-à-porter Paris* [6, p. 39].

4. CONCLUSION

Fashion was considered in this paper from the perspective of technological and industrial revolution which facilitated the "merger of fashion and industry". In other words, the artistic elements in fashion had to be adapted to technical requirements for mass-production of clothing. It has been established that ready-to-wear clothing even precedes *haute couture* and that *haute couture* was set up according to the rules of ready-to-wear clothes production – designing, producing, presenting and selling were conducted in the same space and there was a licensing option for luxury products. Bearing in mind the position of the fashion industry today and contemporary mass-produced clothing, the paper sheds some light on the context which surrounded the emerging fashion industry and the birth of ready-to-wear clothing for mass markets. Haute couture started losing its relevance in the 1960s and when there is talk today of the end of fashion, it is actually "the death of haute couture" that is being referred to. The retreat of couture houses before the ready-to-wear designer lines and closure of many of them marked the new era in fashion which has introduced new rules. Once hypercentralized fashion has become plural and global. This inaugurated *prêt-à-porter* collections whereas the surviving couture houses have joined the market for mass-produced clothing. Fashion for the masses and the global market in the 1990s, according to numerous fashion theorists, heralded the definite end of fashion. If we look solely at the market share of *haute couture*, it is pointless to comment it as a significant part of contemporary fashion, however, it is still relevant in the context of fashion advertizing of the now dominant *prêt-à-porter* fashion collections.

Abstract: *In this paper, we investigate how the design of everyday objects and ideology are connected. In different cultures ideology is present as a design component, both in a spatial, geographical, and in a temporal, historical sense. In this way, culture and ideology become part of the story or biography of a certain object or visual solution. Numerous examples show that there is no object that, through either form, use, production or market, does not reflect the ideology with which it is inevitably connected. Even an ornament that we believe has a purely decorative function reveals the ideological background from which it arose. In cases where the ideological plan is emphasized to the point of explicit expression, the design becomes an instrument of propaganda. Every day, utilitarian objects become a platform for ideological messages with clear content. In this paper, we will present some examples of clear and unambiguous propaganda messages as a means of introduction into a certain ideology.*
Keywords: Ideology, Propaganda, Design, Visual Culture, Material Culture

1. INTRODUCTION – IDEOLOGICAL COMPONENT OF DESIGN

Van Dijk defines ideology as a basis for the social representation of members of a certain group, and Fairclough defines it as a construction of reality that contributes to the production, reproduction or transformation of relations [1]. Berger and Lukman talk about this mutual relationship in "The Social Construction of Reality": "Society is the product of man. Society is objective reality. Man is the product of society" [2]. In this dialectic, the only thing left out is the variability that is immanent in the reconstruction and development of ideologies, and therefore in everyday life and the experiences that man acquires and creates at the same time.
Every functional society has a "main" reality that is sometimes ideologically imposed and represents a dominant structuring force in the formation of people's perception and judgment [2]. Observing everyday life as an experience that is intertwined with the use of various tools, objects, constructed and designed spaces, it is clear that they also represent a reflection and part of the ideological structure. Companies and designers involved in the production and design of new products today focus on the communication, semantic and ideological components of everyday objects. The awareness that objects represent an integral part of culture and that as such they can shape new experiences, initiate new concepts and significantly influence the economy and politics, has been present from the very beginning of thinking about products as an outcome of the industrial revolution. In 1978, Horst Oehke especially emphasized that design is not limited only to the sensory perceptual plan of the object. The designer should deal with the needs of social and individual life. In 1979, the D**esi**gn Zentrum Berlin set a complex definition of design in the context of the exhibition, in which

[1] knikolic@gmail.com
[2] danica.glodjovic@gmail.com
[3] ninkovicaljosa@gmail.com

the obviousness of the object's function, the visibility of modern technological achievements, the prominent uniqueness of the object, the ecological, energy and ergonomic component, and especially the relationship between people and objects [3] were repeatedly emphasized. In his definition from 1987, Michael Erlhoff particularly emphasized the social component in design: "Design, which, unlike art, requires practical reasoning, finds application in four spheres – social, functional, meaningful and concrete" [4].

On the example of the construction and manufacture of canoes in the Solomon Islands, it is possible to see how culture and ideology are incorporated into the design process itself and how a realized canoe becomes a specific utility object that will never be marred by something as mundane as market value. The people of the Solomon Islands build a special type of canoe for tuna hunting, which is a sacred task, dedicated to the deities. As this type of canoe is considered an expression of superior skill and artistry, supervisors are brought in to oversee their construction. Each boat produced in this way is dedicated to a deceased person and once dedicated and launched it cannot be sold or exchanged [5]. Therefore, the ideological basis of the subject is not a peculiarity related only to industrial design or to Western culture. Each newly created object is incorporated into the culture in which it will be used and gets its place in the connotative network of meanings. These meanings are not fixed to the object itself, but exist only in the context of its use. The same canoe, rug or vessel has one meaning and significance in the culture in which they were created and a completely different meaning when they are used or traded in a different cultural and ideological framework.

The ideological basis of industrially produced objects was instrumentalized at the beginning of the 20th century and culminated in a sharp division during the Cold War, although at that time function and aesthetics were still in focus as the two main components along with rationality, i.e. economic profitability when it comes to socialist social systems.

2. ORNAMENT AND IDEOLOGY

During the period of modernism, ornament was stigmatized as a superficial and unnecessary component. Decorativeness, which has no other function, was undesirable, it was considered kitsch and an instrument for seducing uneducated buyers. It acquired this status through its separation from function and its physical connection with the exterior of the object. In the 1950s in East Germany, at a congress of the Association of Architects, Kurt Liebknecht, the president of the association, attacked the principles of "formalism" – a style in art and design reminiscent of the Bauhaus and modernism. He claimed that formalism is "foreign to people" and even hostile, and that the Bauhaus is an international weapon of imperialism. It was emphasized that "formalism" is actually "form without ornament" and that design in East Germany should turn to the old German styles known to workers and farmers. Their slogan illustrates the ideological basis of the design they proclaim: "socialist content, national form". Even the very term "industrial design" was undesirable, prompting a discussion on whether to change the name of the school from "Institute of Industrial Design" to "Institute of Applied Arts". Ornament is recognized as a part of tradition and an expression of traditional style [6]. Soon, the lack of resources – natural raw materials as well as money – led to a different approach in architecture. East Germany accepted the necessity of building typical houses with a reduced appearance, and baroque and rococo furniture did not fit into such an architectural form, so soon the production of furniture without complex details, sporting a geometric shape increasingly reminiscent of the modernist style, begins. This style will be called economic rationalism. In his dissertation, "The Significance of Industrial Product Design in a Developed Socialist Social System", Martin Kelm, president of the East German Industrial Design Association (Amt für industrielle Formgestaltung, AIF) points out that "consumption in socialism is not only a matter of satisfying needs through the purchase of things, but a process through which a socialist personality is created". Successor to the Bauhaus, the Ulm School of Design further deepens the separation from ornament through a sharp break with the historical ballast of class and culture, rejecting the aura of expensive artefacts (tables and bulky furniture).

3. DESIGN AND PROPAGANDA

Propaganda is a powerful tool often used by political ideologies to increase the number of supporters and impose value systems and opinions. Technological progress, natural raw materials and superior design of industrial products are also related to political and social progress, i.e. they represent its manifestation and thus hold a significant potential for use in propaganda purposes.
The politicization of modern art and design was also one of the "weapons" of the Cold War. Superiority, a better standard of living, as well as economic and scientific progress [7] were shown through the design and shaping of everyday life. Product design during the 20th century was marked by the ideological struggle between East and West, between two ideologies – socialist and capitalist. The State Department funded exhibitions that traveled around Europe in the 1950s promoting American design as proof of American dominance and the superiority of capitalism over communism.

3.1 Psychological and emotional component of design as a platform for propaganda

Boudrillard gives a kind of semiotic interpretation of the "Traditional environment" or the interior of a house by interpreting the shapes of the furniture, the organization of the space and the positioning of the objects: "The arrangement of furniture offers a faithful image of the familial and social structures of a period. The typical bourgeois interior is patriarchal; its foundation is in dining-room/bedroom combination. Although it is diversified with respect to function, the furniture is highly integrated, centering around sideboard or the bed in the middle of the room. There is tendency to accumulate, to fill and close off the space. The emphasis is on unifuctionality, immovability, imposing presence and hierarchical labelling" [8].
The basic function of objects in such an interior is the personification of interpersonal relationships. In this relationship, Boudrillard sees that objects transcend their physical space and utility function and achieve a psychological and emotional connection with people during their interaction. A certain combination of furniture and interior decoration becomes a representation, a picture, of what we call home. Furniture becomes the "spatial incarnation" of emotional ties and family permanence, but also a mirror or extension of wider social structures. Like clothes, furniture and interior decoration are a reflection of the ideology that shaped them. He sees the ideological function of the system of objects in the need for personal achievements, which is satisfied through the acquisition (purchase) of objects. As David Raisman says: "The product now in demand is neither a staple nor a machine, it is a personality" [9]. The customer, through the acquisition of objects and the desire to be a subject, becomes an object themselves by fulfilling the sociologically imposed need for achievement through possession. Since the differences in the items are determined at the industrial, production level and the consumer's choice is only seemingly free, it renders authenticity through acquisition – an illusion. The system that Baudrillard describes is based on democratic ideology and is affirmed as one of the aspects of social progress by giving everyone the opportunity to climb the social ladder characterized by greater material luxury and special personalization of objects [8].

3.2 Propaganda in textile design

War rugs are traditionally associated with the area of Iran and Afghanistan. The practice of crossing the feminine craft of carpet weaving and war scenes is linked to the period of the first attack of the Soviet Union on Afghanistan in 1979. Carpets are usually associated with private life, domesticity, apoliticality, decorativeness, comfort and warmth of the home, so the juxtaposition with acts of war, politics, aggression and destruction seems surprising and shocking, assigning a completely new function to an everyday, traditional object – subversive communication. While the war carpets from the period of the Soviet attack retain the artistic elements of traditional carpets, shaping the motifs in a manner characteristic of the traditional transposition of forms, the war carpets from the period of the beginning of the 21st century are more reminiscent of posters. The forms are stylized as in the

graphic design of politically engaged posters, and only the border has been retained from the traditional elements.

From 1894 to 1942, a large part of Japanese traditional kimonos and textiles in general were decorated with explicit images of modern wars, violent attacks on enemies, tanks, fighter planes and warships. Such Japanese "war patterns" are often called "propaganda kimono", but this term does not quite reflect the complex interweaving of meanings that the creators, producers and users associate with this textile.

The propaganda kimono predates the contemporary use of textiles and clothing for propaganda purposes. Even at the beginning of the 20th century, the Japanese kimono was a tool for explicit propaganda, and for centuries it has been a powerful communication tool at the heart of numerous rituals and ceremonies. They were created as a response by kimono manufacturers to society's desire for modernity. Brightly colored designs are associated with social realism, Art Deco, Dadaist and Cubist collages, cartoons. Propaganda kimonos were mostly worn at home and at private gatherings. Since these designs were mostly on the inner layers of clothing, only a small number of family members and friends would see them.

A typical kimono from the 1920s depicts the Western idea of a consumerist future – cities, steam locomotives, cars and airplanes. Historians note the year 1931 and Japan's advance towards Manchuria with the establishment of a puppet regime as Japan's turn to militaristic nationalism and increased isolation from the West. This is why propaganda kimonos combined nationalist themes with iconography from popular culture. For example, a child's kimono from 1933 shows a boy in a sailor suit, surrounded by a battleship, a biplane, a modern American car and small soldiers in uniform.

As Japan's isolation intensified, motifs associated with Japan's rare friendships, such as Italy and Germany, appeared more and more on kimonos. Images from Italian colonies – Somalia and Ethiopia – appear on kimonos. One kimono shows a strange contrast between Mussolini's haughty pose and an innocent Ethiopian boy in a military convoy pushing a wagonload of weapons. There are also pictures supporting Nazi Germany, but they are not even close to the German propaganda of the time. Stylistically and conceptually, they are completely different. Japanese designs include locomotives that merge with fighter planes, but also a mixture of gentle and brutal. One kimono features a small boy with a puppy, shown packing aid for soldiers at the front. There are no racist symbols or any implication of racial superiority in these depictions unlike German Nazi propaganda.

A kimono from the 1940s celebrates the signing of the Tripartite Pact between Italy, Germany and Japan and features three flags in a foam of smoke and fighter jets, reminiscent of the chrysanthemum – a traditional Japanese symbol.

After the war, these patterns became a source of shame and were suppressed and forgotten [10]. The secrecy of the collectors of propaganda war kimonos is understandable from the contemporary context. Although the Japanese war kimono is not the only example of a war textile, it is conceptually and aesthetically different in approach compared to the others. The combination of tenderness and brutality, absence of hatred and focus only on images of victory and success, an unusual combination of traditional and modern, Western perception in relation to self-perception, makes them authentic. From the aspect of communication through design, this is an interesting expression within a common function.

4. CONCLUSION

These examples of propaganda through textile materials and implying ideological motives represent one form of specific communication through design. It appears on the very surface of an object that has primarily a decorative and protective function and that is not explicitly perceived like a poster or an illustration or a print on a t-shirt. However, no design product is ever truly ideologically neutral, whether the message is explicit or not. The ideological plan appears from the very beginning of the development of industrial design and mass production of objects. The continuation of the Bauhaus school in East Germany had a strong Stalinist ideological component, just as the original Bauhaus

rested on leftist ideals of prosperity, social justice and the availability of quality products to the masses [6]. Design in East Germany was oriented towards a departure from Western or American aesthetics in order to create a utilitarian and authentic look associated with mechanization and industrial progress. Designing objects in the spirit of modernism and the illusion of freedom of choice and socio-economic progress, abundance and achievement was part of the American dream and an instrument of seduction and promotion of liberal capitalism. By studying the semantic and communication component in design and semiotic analysis, it is possible to analyze the ideological component in the industrial design of everyday objects as well as the everyday life of people in a certain period. Given that design deals with the future, the shaping of the ideological component of new objects shapes the future relations of users and the world of objects, as well as material and immaterial culture.

THE SOCIAL SIGNIFICANCE OF VIDEO GAMES

Ljubomir Maširević[1]*, The Academy of Applied Technical Studies Belgrade*

Abstract: *The aim of the paper is to point out the social significance of video games. Video games are used today in the development of artificial intelligence, as an educational tool for students, soldiers and pilots. They are also used to maintain the mental condition of young and old. Video games apply technologies of virtual and augmented reality; they became a place of protest against entertainment industry and started the fight for their own artistic status, e-sport was created, they are the scene of conflicts of gender and racial politics, they became a new virtual space for socialization of young people, around them specific cultures of fans are formed creating a gaming subculture. Secondly, it will be explained how, via mobile gaming industry, video games reached the widest social strata and generations and thus became a mainstream industry from a subcultural one, and video games became mass media in the full sense of that term. Today gaming industry earns more than film and music industry combined and every year its social significance becomes greater.*
Keywords: *Video games, society, gaming industry, gamer*.

1. ECONOMIC PROSPERITY OF THE INDUSTRY AND INCREASE IN THE NUMBER OF VIDEO GAME PLAYERS

A paper on the importance of video games could start in different ways, but we will start by citing data on the explosion of earnings within this industry and the huge growth in the number of (consumers) players. The video game industry is a very lucrative and rapidly growing sphere of popular culture and entertainment. According to the results of the website STATISTA, the video game industry is a billion-dollar business and has been for many years. During the year 2022, the revenue from the global gaming market is estimated to be almost US$347 billion, with the mobile gaming market generating an estimated US$248 billion of the total [1]. Furthermore, the video game market revenue is projected to reach US$385 billion in 2023 and US$522 billion by 2027 [1]. The largest market is mobile games with a market volume of 286 billion US dollars in 2023 [1]. In a global comparison, the largest revenue will be generated in China (US$109.2 billion in 2023) [1]. The average revenue per user (ARPU) in the video game market is projected to reach US$142.50 in 2023 [1]. The importance of this industry from the perspective of economic potential and profit earning is therefore enormous because it is more than the music and film industries, combined together, have earned in years. Many national economies of the world, among them the Serbian one, are starting to see the export and sale of video games as an important part of their economy. Also, there is data on the constant growth of employees within the industry, which brings with it above-average incomes [2].

However, the growth of earnings in the industry would not be possible if there was not a constant increase in the number of players, while the entire industry depends on the number

[1] ljmasirevic@atssb.edu.rs

of players and on their willingness to spend money while playing the game. The explosion in the number of players and the transition of video games from the world of subcultures to the mainstream is primarily due to mobile gaming. Ever since, in the 2010s, the transition to smart mobile phones with high processing capacities in everyday life, an increasing number of people have started to consume video games. Smartphones today, like computers, are open systems with strong processing capabilities for which a wide variety of video games are developed, and some of them are extremely audiovisually complex. According to a report by DFC Intelligence, there are nearly 3.1 billion video gamers in the world as of mid-2020. This means that about 40% of the world's population plays video games in some form. The report also shows that the largest market for video games is Asia, with 1.42 billion pay-to-play game users, followed by Europe with 668 million [3]. The fastest growing segment of video gamers are those who play games only on their smartphones, accounting for nearly half of all video game users. Mobile gaming makes up the majority of this market and is responsible for the high prevalence of video games. For example, data from DFC Intelligence shows that out of nearly 3.1 billion gamers, only about 8% of them consume video games using consoles, although this small group is significant to the industry, as it has the highest consumption per user [3]. In the past, only IT enthusiasts, mostly men, sat for hours in front of the screen passionately playing video games. Today, the demographics have changed with the advent of mobile devices and now both men and women alike, as well as young and old, play video games. The advent of smartphones with their touch screen interfaces has made games easier to play, which has led to the fact that today children as young as three, with underdeveloped motor skills, start consuming video games. During the 20th century, young children could not play video games because there were no devices that they could use without mastering the motor skills of controlling a joystick or a computer mouse and keyboard.

In the paper "Why and how video games are important", the author Alidini states that according to the research available to him, children aged 2 to 5 years represent the fastest growing group of players [4]. Alidini states that, according to projections, children will play games every day until they turn 18, and the time they will spend consuming video games will equal or exceed the time they spent in classes in elementary and high school [4]. Furthermore, data from 2014 show that 91 percent of Americans under the age of 17 have played or are playing computer games [4]. Many of them will continue to practice video game consumption in some form even in the later stages of life. Since the video game industry is worth about 347 billion US dollars in 2022, it aims to attract loyal players from an early age, which in practice means adapting them to the consumer discourse or indoctrinating it with it so that they continue playing as long as possible in life [4]. Due to the frequent availability of mobile devices, today's children are falling prey to this industry, which is why in many countries of the world, in the past decade, the public has come forward and intensified debates about perspectives, possible regulation and the place of video games in society.

2. SOCIAL IMPACT OF VIDEO GAMES

During the 1970s, video games were a negligible part of the world of the games played by humans. The world of games for children and adults in a short period of time was filled with video games and, as stated, today they are a mass type of entertainment [5]. In human civilization, play was an element which every human being grows up with and it represents an essential feature of life [5]. However, unlike the games that children have been playing for decades on the streets, in the yards of their houses or in front of their buildings, video games are created by the video game industry, and the question immediately arises whether video games are a matter of spontaneous and disinterested playing or promotes an ideological view

of the world and, as mentioned, encourages consumerism (many video games cost from scratch, while in the later gameplay something can always be bought with money from virtual tools or weapons and the like or for some add-on the user is offered to watch commercials in order to pay). In his book *The PlayStation Dreamworld*, Alfie Bown writes that smartphones and video games, from fulfilling our desires to play, gradually begin to influence what we want and control us [6]. Although video game users think they are doing what they want, there still seems to be nothing spontaneous and natural about someone's desire to buy something (a weapon, a new life, shorten the waiting time for a reward) from a video game in order to improve the situation of their virtual character during the gameplay. The video game industry has the power to create desires for players (especially children) and organize their fulfillment. Of course, users, especially young people, tend to view externally imposed desires as their own. Summarizing his arguments, Bown says that video games do not fulfill the user's wishes, but transform the way we want them [6]. Second, video games demonstrate the existence of corporate hegemonic control of cyberspace [6]. Third, the desire for a certain physical object does not exist before the electronic media and technology through the process of mediation created the desire for it.

Contrary to this, it could be said that there are independent video games that are not the fruit of corporate capital and do not represent an attempt to manipulate and indoctrinate their users. However, as Maravić writes in his book *The Total History of Video Games*, the idea of most independent video game developers was not to distance themselves from the industry, but quite the opposite, for their game to find its way to large corporations and become a commercial hit that will bring them wealth. [7]. Therefore, a great number of video games was created as a capitalist product intended for certain target groups of users. The last decade has seen the creation of extremely complex games in terms of gameplay and high-quality audiovisual experience. The production costs of such video games are so high today that they often exceed the budgets for making Hollywood films, and any error in judgment and failure in the market can be fatal for the studio that markets the video game and lead to its shutdown. Therefore, creating video games is a very risky business. Potter states that only 3% of all games make a profit [8]. Experimentation with gameplay, aesthetics, and game mechanics is left to independent developers, while the industry follows established practices using tried and tested formulas, genres, and clichés. Therefore, profit and directing the user's desires to spend more, within the game itself, is a key factor for the video game industry. Industrially produced video games follow established rules in order to achieve commercial success with a large audience. Some of those rules are that the game must reward good players, be relatively easy to learn (even if they are complex it is not evident at the very beginning), be available on all platforms (from consoles and computers to smartphones), furthermore, the game must be predictable for the consumer and it must present a challenge (that after the start of the game, new levels of the game with an increasing challenge follow). If these rules are not respected in the production of a video game, it can easily become simple and players will quickly lose interest in it. However, it should be noted that the movement of indie developers represents an important experimental field of the industry because when a novelty in the world of independent games becomes popular, the industry appropriates it without exposing itself to risk [7].

Although it has been established that video games are created as a product of industry and have a manipulative side, they still satisfy man's need for play. The vast usage of video games among the human population has led to the fact that they are nowadays used for a wide variety of purposes, including as a means of training pupils or students. The frequent use of video games created a virtual space for the socialization of youth, formed groups of fans and specific subcultures. According to Maravić, video games today are much more than just a game [7]. They are real media and have the property of a technological device that

serves as a means of communication, they can convey meanings and be the environment within which communication takes place [7]. One specific area of human behavior has been heavily influenced by video games, and that is traditional sports to which esports has joined. Esports is the competitive playing of video games at a professional level. In other words, it is an organized type of sport where video games are played, in which players compete against each other, often for significant amounts of money and prizes [9]. Video games, as part of esports, are mostly played on computers, but also on consoles and mobile devices, and can be individual or team-based and usually involve professional players or teams, organized tournaments and large audiences. "Esports competitions are often held in large arenas and stadiums, with fans filling the seats to root for their favorite players and teams. Esports events have become increasingly popular in recent years, with many of the biggest tournaments and competitions taking place in large arenas and stadiums" [9]. These events can attract thousands of fans from all over the world, who gather to watch their favorite players and teams compete. Esports is a growing industry today that has attracted many players, fans and sponsors. Some of the most popular esports games are *League of Legends, Dota 2, Counter-Strike: Global Offensive, Fortnite and Overwatch*. Esports first became popular in East Asia, especially in China and South Korea, where professional games were licensed as early as the 2000s. However, esports has spread to other regions, such as Europe and America, where many gaming events are held and leagues have been established.

It should be said that there has been professionalization in this field of video games (as in traditional sports during the 20th century) and that esports is not only a form of entertainment, but also a potential career path for many players who aspire to become professionals. Esports players can earn funds from various sources, such as rewards, salaries, sponsorships, referrals and YouTube streaming. In addition to players, coaches, analysts, commentators, YouTubers and other professionals working in the industry can also make money from esports. Today, cable operators, in addition to traditional sports channels, also have specialized channels for the transmission of esports with an accompanying team of expert commentators. Esports can be a lifestyle choice and a professional orientation, including players, coaches, analysts, commentators and others working in the industry [9]. Today, there are dedicated esports leagues and organizations around the world, and many universities even offer esports scholarships to talented players [9].

The growing social importance of video games was recorded by the academic community, so in addition to media studies or film studies, special video game studies were formed. According to theoretician Mitrović, within the academic community "... video games are studied as a media phenomenon, a technical-technological phenomenon, a (pop) cultural artifact, and a narrative and dramaturgical practice that includes interactivity in the canonical models of creation, presentation and reception of story worlds. At the same time, other artistic practices involved in games (music, graphic design, performance) are studied, as well as anthropological, linguistic, psychological and sociological (from identity and gender studies to the recognition of addiction) and economic research and approaches" [10]. According to Mitrović, in the academic circles themselves, 2001 is considered the starting year of video game studies, because the first scientific international scientific conference on video games was held in Copenhagen in that year. Many believe that the development of criticism and theoretical reflection is the reason for the inclusion of film in universities and its classification as art, so that the same is necessary for video games. More and more higher education institutions are opening majors needed by the video game industry such as: concept character design, visual effects, programming, animation, video game design and game art. Additionally, outside of college, private schools are booming with courses that offer quick and cheap training for jobs in the growing gaming industry. Staff from these courses are

usually able to perform a fraction of the work in the industry or to work in one program standardized and templated work.

3. CONCLUSION – TENDENCIES IN THE GAMING INDUSTRY

Some of the latest trends in the industry include new cloud gaming technologies, the inclusion of augmented reality (AR) and virtual reality (VR) technologies, and the use of artificial intelligence (AI). Experts from the video game industry hope that in 2023 it will be possible to play video games in the cloud, because the technologies and services have reached the necessary level. Cloud gaming refers to video game streaming that allows players to play games on their devices over an online connection without the need to purchase new gaming hardware or install games locally, and can provide access to video games to players who are unwilling or unable to afford appropriate devices for the latest industry products. With this progress, the video game industry expects a significant increase in the number of players, as expensive hardware will no longer be an obstacle to entry into the world of video games. Also, VR and AR technologies have shown great potential because consumers are highly interested in them and the gaming industry will move in the direction of implementing these technologies in their products. The key difference between VR and AR games is the level of virtual world immersion and social interaction. VR gaming offers a more visually immersive experience that can transport us to different worlds, but at the same time isolates us from our surroundings. AR video gaming offers a broader social gaming experience that can enhance or alter reality, but also leads to limitations in the perception of reality. AI is widely used in the video game industry, however, over time, as it develops, more and more opportunities for its implementation arise. The application of AI in games is not only reflected in the creation of very realistic supporting characters in video games, but also in improving the user experience during gameplay. Finally, AI already participates significantly in the design and programming of entire video games, and over time its use and importance will increase.

Concluding the paper on the social impact of video games, we can state that all the mentioned trends suggest that video games have become one of the dominant forms of entertainment and earnings. The data indicate that both the number of players and the number of employees in the video game industry is growing, and that the forecast is that this growth will increase from year to year. At the beginning of the 21st century, the academic community began to give credibility to video games as a medium, a cultural phenomenon and an art form. Today, video games still do not have the same status as film or music, but things are changing in that field as well, so more and more art faculties are opening majors related to character design or some other aspect of video games. All of this development of video game influence takes place under the veil of capitalist production, and critical studies of video games never lose sight of the fact that gaming often functions as a supplement to capital. Critical academic studies must also deal with the negative aspects of video games such as the process of gamification in which game design principles are used to stimulate workers who in fact become the objects of the game. Although the gaming industry is a type of creative industry, it is nevertheless characterized by the characteristics of neoliberal capitalism, such as user control and direction, consumer values, cheap labor (outsourcing) and profit.

INTERDISCIPLINARYNESS OF SUSTAINABLE DESIGN

Maja Milinić Bogdanović[1], The Academy of Applied Technical Studies Belgrade
Nebojša Bogojević[2], The Faculty of Mechanical Engineering and Civil Engineering, Kraljevo

Abstract: *Sustainable design in the fashion industry, with a focus on the footwear industry, implies new approaches in planning, design, engineering and production of the final product. It is no logner enough today, that a designer is exclusively occupied with the creative process. The designer is now expected to know special software packages that speed up the process of working out his conceptual solutions, construction models, networking into a complete production system. The designer must know new technologies of the production process itself, and all so that the design he creates is of a sustainable type. Those new technologies include additive manufacturing, which is already applied by well-known global fashion companies. By implementation of the disciplines of science and design, with specialized software to ensure the saving of time and materials, with the application of additive manufacturing technology, there are chances that the design we create today will protect our living environment, but also ensure its profitability.*
Keywords: Interdisciplinarity, CAD/CAM, Additive manufacturing, Sustainable design, Eco materials

1. INTRODUCTION

Interdisciplinarity in design should connect different aspects of the product, so that all its parameters are functional, profitable and harmless to our environment. In order to achieve such design solutions, it is necessary to move our thinking from just "beautiful creation" and to include in product design research based on consumer experiences (UX-user experience). Also, scientific experiences and new technologies, taking into account ergonomics, if necessary for that area of design, experiences from an economic point of view, in order to check the profitability of the production concept, but also experiences of environmental protection, based on analyzes of the biggest polluters. Introduction of the additive manufacturing process (known as 3D printing) in the footwear production, may be one of the solutions to improve the sustainability in this industry. This paper aims to indicate possible procedures that can be used to improve the approach to footwear design, in order to highlight aspects of sustainability and present examples of how additive manufacturing is used to footwear manufacturing, with a special emphasis on FDM (Fused Deposition Modeling) technology. The additive manufacturing, which is being developed every day, show great potential for future progress in the various branches of industry. The Aeronautics and Space industry, as well as the automotive and medical industries are the application of 3D printers for manufacturing products [1]. The concept of applying additive manufacturing also implies the use of materials that can be processed, recycled, reused with redesign or in a completely new design solution and used in subsequent production the so-called 6R concept - which implies (Reuse, Recycle, Redesign, Remanufacture, Reduce, Recover). Based on this approach for the product development, we are talking about the "circular production" model (CM-Circular Model), which has proven to be one of the good engineering solutions that should be considered for sustainable production. In such circular model, the design of the product, the used materials and production process, plays an essential role [2].

2. DESIGNING THE PROTOTYPE

The development of footwear products begins with the creation of conceptual solutions, which can be prepared in one of the software programs specialized for designing and modeling footwear, but also in some other software with the possibility of exporting an STL file, which is further used to prepare the digital model for additive manufacturing [3]. The Shoemaster project is proved to be the most complete software package, in the footware production. The main advantages of using this program are increasing the efficiency of the designer's work, because softvare provides a possibility for easy change of conceptual solutions, providing the best solution, changing the design lines with the simulation of the materials that would be used. Through Shoemaster Patterns, the basic pattern is quickly and accurately created, which is necessary in classic production, while the production of the footwear with additive production, is guided only by a 3D model. Software programs ensure efficiency and infallibility in certain tasks related to engineering design, such as reducing the complexity of the design process in production, reducing the time spent on project preparation, reducing project work costs, as well as reducing costs related to all production operations.
When creating conceptual solutions for classical footwear production, it is impossible to perform complicated design solutions, while the creation of conceptual solutions with software is limited only by the designer's imagination [4]. German designer and architect Stefan Henrich designed and produced the "Cryptide" footwear model inspired by the feet of mythical creatures. The model was produced using selective laser sintering-SLS technology on a Sintratec S2 printer. (fig. 1)

Existing shoe styles are completely different and the question is when the market will be ready for some radically different solutions. [5]. With the help of such software, it is possible to scan the foot, and record 3D data about the feet, from technologically advanced 3D foot scanners and achieved data can be imported into Shoemaster CAD systems, in order to make orthopedic footwear. Advanced CAD/CAM system for shoe development engineers, enables integrated control and optimization of all stages of the development process. Networking is also reflected in the fact that new design solutions can be easily obtained. Clearly, Shoemaster is a flexible 3D CAD system that allows creative designers to quickly develop new ideas and concepts.
It provides such design tools for building different solutions, experimenting with multiple ideas. What is also important is that this reduces the number of physical samples. Creating virtual prototypes, data for rapid prototyping and accurate transfer of design ideas to production, are essential for more efficient production. (fig. 2)

Ensuring the improvement of the quality of the project infrastructure through the reduction of modeling costs, as well as faster production testing, is the goal of every small and large manufacturer. Acceleration of the production of duplicate models, designed in a fast and efficient way can be achieved today only by using software that is adapted to a specific production. In the footwear industry, it is necessary to classify every piece of leather into I, II, III class, and what is shocking in today's possibilities of technological progress, is that in many factories this is still entrusted to the experience of a worker. Certain companies have improved their production by using the Shoemaster software in this segment to avoid the error of the human factor, so that the scanner classifies the leather and the classification is entered into the database from which the information is further retrieved, so that a certain part of the upper assembly can be cut with a Cater machine from the required skin class. This reduces costs related to the production of knives used to cut parts. It is also possible to calculate the consumption of leather and synthetic materials, with different methodologies, to make the estimation of material procurement and production costs fast and efficient. It manages databases of materials and suppliers, and that database is simple and can be connected to the company's warehouse system. With this program, we can develop our own technical specifications, integrated with template engineering modules, to share technical information that is always updated. Shoemaster makes it possible to significantly reduce the time required for pattern output and input, as well as grading, which results in faster flow and increased production capacity. A flexible and fast 3D CAD data customization system allows shoes designed for the mass market to be quickly adapted to individual requirements. This system of production process has already been improved compared to classic production, because the software speeds up and specifies all the mentioned work operations, but thinking about the progress of this branch of industry, additive production would bring an even simpler and more precise way of production. Camper is a Spanish company that successfully makes footwear using additive manufacturing, especially Fused deposition modeling-FDM technology. The company uses printers with two extruders, in the production. (fig.3)

Design for easy assembly and disassembly; Design for efficient joining and fastening; reduction of the number of shoe parts, increased flexibility of the model and connection between the parts of the model. Within footwear, parts and materials are standardized. Design solutions are mainly guided by modularity [6].

3. ADVANTAGES OF ADDITIVE PRODUCTION-CIRCULAR PRODUCTION

If we consider the concept of production from the point of view of circular production, additive technologies are the future. As already existing studies have shown, the circular design approach involves rethinking the design of the product, not only for its use, but also for the user environment [7]. All segments of the product manufacturing process are considered, where at the end of that journey there is the end of its life, and in this sense the reuse of the product is highlighted, facilitating its new insertion into a closed production loop and finally disassembly for improved recycling possibilities. An interdisciplinary approach to this problem can bring better and safer

solutions. According to data from 2019, a record year for the volume of footwear produced, 24.3 billion pairs or more than 65 million pairs of footwear were produced and sold per day [8]. The footwear industry is an important branch of industry, and the production of footwear itself is a demanding and complex process. As already mentioned in certain types of footwear, such as sports footwear, protective footwear or those produced for the needs of the military, they can consist of up to 60 or more individual parts including very demanding manual work that can have around 360 production steps. The traditional production approach is still very complex, machine-intensive for the production of footwear parts and assembly of the final product. In addition to certain software packages that can improve and speed up production, it is still a very financially demanding process overall. Consequently, footwear manufacturers are looking for new ways to optimize their production process [9]. Additive production is an alternative to classic production, which allows shoe manufacturers to simplify the production process of individual shoe components or the entire shoe assembly, all depending on the designer's idea [10]. Unfortunately, these approaches are still in their infancy and it is difficult to say whether the footwear industry is aware that additive manufacturing is a sure advance in this branch of the industry.

The advantages of additive manufacturing compared to the classic process can be seen in the following benefits:

- Less time and costs for developing a conceptual design solution
- Lower cost of setting up and improving prototypes and lower costs of tools used in industry
- Environmentally acceptable method of production because it emits less CO2 emissions
- Economically more affordable production of small batches
- Feasibility of complex design forms, without limitations of the designer's imagination
- Shorter product delivery time
- Complex products relatively easy to manufacture
- Flexibility of the production process - production at the request of special customer requirements
- Quick and efficient design change and production launch of a new model
- Less waste generated after production
- Rapid prototyping

The main steps to produce custom 3D printed footwear include: data collection, which can be done with the help of 3D foot scanning, anthropometric measurement based on anthropological data, creating a 3D model of the foot using 3D software such as a CAD program, further in the process involves 3D data analysis to ensure accuracy and precision of data, shoe design, calculation of projected material consumption, prototyping, simulation and testing and production. In this way, it is possible to produce shoes that are designed and optimized for orthopedic problems, but also high comfort shoes that provide absolute support properties for the individual consumer [11].

4. ADDITIVE PRODUCTION AS A SYSTEM FOR PRODUCTION OF SUSTAINABLE DESIGN

If the production system is considered as a circular process, and if we consider the possibility that material should be recycled in the footwear industry, it is sure that the additive production has numerous advantages compared to classic production. Within 3D printing, two production segments are separated. These are the assembly segment and the disassembly segment. These segments aim to reduce costs and improve reliability without changing product function, and are based on specific design principles. The system viewed in this way has significant potential for circular production, which reduces waste, energy consumption and production costs in small production scales [3]. It also facilitates reuse by creating parts in a modular design that facilitates their reuse and repair [12]. In addition, additive manufacturing enables the development of sustainable products, taking into account the principles of sustainable and circular development from the beginning of the design process. This can result in products that are more sustainable and can be easily recycled or reused at the end of their life [13]. Referring to research from 2020, it is estimated that 3D technologies can use up to 97% of the used material [14].

Additive production compared to traditional production has the following advantages:

- Efficiency of the material used: unlike traditional manufacturing, in additive manufacturing it is created only what is needed for the product with a minimal support structure. In the Aeronautics and Automotive industries, for example, additive manufacturing enables the production of lightweight products that provide weight savings and thus lower fuel consumption. Repairs to certain parts can be completed using 3D technology, which essentially extends the life cycle of the original part. Waste is reduced because fewer product replacements are required. Biodegradable materials are another way that additive manufacturing contributes to reducing environmental pollution.

Effectiveness of existing resources: refers to how streamlined 3D machines are in general. Because these machines have less need for auxiliary equipment than traditional machines, additive manufacturing requires fewer resources and has less energy needs. Also, because these auxiliary tools and equipment are not required for production, smaller manufacturers can make parts closer to customers, reducing transportation costs.

- Manufacturing flexibility: the ability to quickly switch between different products without expensive or time-consuming setup enables a more streamlined supply chain and cost-effective production runs that meet customer needs. [11].
- Inventory reduction: The ability to make products on demand reduces inventory. With additive manufacturing, it is possible to respond quickly to customer orders, it is not necessary to have large stocks of manufactured goods, and in this way, production has an effective effect.
- Waste reduction: Additive manufacturing contributes to material utilization almost entirely. In addition to the fact that materials can be recycled, no waste remains after additive manufacturing, which is not a situation in traditional manufacturing.

To date, 3D printing has primarily been used only for the production of specific parts of footwear, such as the sole, which is the layer of the underlying sole. The mechanical performance of the materials used varies from one to another and has very different applications. The area that can be further improved, is the area of the material wich can be used for the production of the shoes in additive manufacturing. Also, a good understanding of key process parameters is very important in the complete process, such as manufacturing orientation, printing speed and layer thickness, all of which affect the mechanical properties of the finished product [15], so research in this area is just emerging.

5. CONCLUSION

Today, interdisciplinarity is a prerequisite for economical, sustainable and environmentally friendly production in all branches of industry. Footwear production is also an area that has room for improvement, and the approach to include research and conclusions from different disciplines in the complete design of production leads to the complete progress of this area of the industry. Additive manufacturing can still be seen as a way of making products that is not used enough, justified or unjustified, but it is certain that 3D technologies allow designers to reach different solutions than traditional ones. Not only that, but that by using these technologies, both, designers and everyone else, in the chain of the production process has an awareness and responsibility towards the ecology, but also the sustainability of production in the footwear industry.
