MOTIVATION FOR ENGLISH LANGUAGE LEARNING AMONG THE STUDENTS OF THE DESIGN STUDY PROGRAMS AT THE ACADEMY OF APPLIED TECHNICAL STUDIES BELGRADE

Marija Mićanović [1], The Academy of Applied Technical Studies Belgrade
Tanja Radović[2], The Academy of Applied Technical Studies Belgrade

***Abstract**: The need for knowledge of languages in the modern world is very noticeable today. Linguists who have studied the process of foreign language learning have come to the conclusion that motivation is one of the key factors in the process of learning, especially in the acquisition of a foreign language. The topic of this paper is the research of factors that influence the motivation for English language learning among students of the Design study programs at the Academy of Applied Technical Studies Belgrade, Belgrade Polytechnics, with the aim of improving the process of English language teaching within the Academy. Special attention is paid to the analysis of students' opinions on the reasons that motivate them to learn a foreign language, as well as on the factors that can influence the improvement of their motivation.*
Keywords: Motivation for Learning, Students, Design Study Programs, English Language

1. INTRODUCTION

Motivation is defined as a desire or need that moves a person to a certain activity. Anyone involved in education must think about the motivation of their students as one of the key aspects of its successful implementation. What is very important is that motivation cannot in any case be viewed as a unitary phenomenon whose level is simply high or low. Motivation is a complex psychological phenomenon that consists of different levels. If we want to improve the level of student motivation, we have to observe it from several different angles and act accordingly. The research of motivation itself is very complicated, like all psychological processes in general, because we must first understand it and take into account all the factors that influence it. One of the important factors that we must take into account is the fact that motivation is an individual matter, which largely depends on the personal level of development of students, whether it is the sociological aspect, the existence of obstacles, the proximity of the goal, the needs of students, their work habits, their routine, organization of time and other factors that greatly influence the formation of motivation to learn foreign languages [1], as well as its persistence over time.

2. TYPES OF MOTIVATION

The study of motivation as a psychological phenomenon can be very interesting and undoubtedly very useful. It is very important to find out the origin of motivation, because that way we can influence it. Also, we must monitor how it develops, whether it grows or weakens over time, whether it changes or is constant. If we have an insight into these aspects of motivation, we can use this knowledge to motivate students to learn a foreign language better and more efficiently. If we study the level of students' motivation, we must take into account their activities and observe the psychological processes that activate them, and the motives that drive them to those activities. Are

[1] mmicanovic@atssb.edu.rs
[2] tradovic@atssb.edu.rs

these their inner desires, emotions, thoughts or needs to acquire new knowledge, or is their ambition driven by external factors? There is a constant tendency to view motivation as a concept that is unique and a constant effort of teachers and employers to simply raise the level, quantity and intensity of motivation among their employees or students. On the other hand, there are theorists who believe that there are different types of motivation, viewed from the aspect of its origin and outcomes. For example, there is a classification into intrinsic and extrinsic motivation [2], then the difference between motivation that is driven by the desire for knowledge and motivation that is aimed at the best possible academic result [3]. Also, there is motivation that is stimulated by achievement, as well as the one whose goal is to avoid failure [4]. For this reason, it is important to analyse the motives that drive students and approach the problem from the point of view that we see is most present among them and apply those methods that could give the best results.

In this paper, the authors will mostly deal with the difference between intrinsic and extrinsic motivation among the students of the design study programs at the Academy of Applied Technical Studies Belgrade and the strategies that can be used to improve the process of English language teaching within the Academy. The term intrinsic motivation refers to that aspect that includes psychological processes such as personal, internal needs, desires, attitudes, the need for advancement, curiosity, etc. Students who are motivated by this type of motivation learn a language because of their desire to improve and their need to learn is fueled by a sense of satisfaction from personal progress, regardless of the reactions of the environment. On the other hand, students who are motivated by extrinsic motivation are motivated by external factors. This type of motivation is separate from the actual activity that the student carries out and its goal in this case is to get a passing grade on the exam, a higher grade or avoid a certain type of punishment if the exam is not passed. Recent research has shown that extrinsic motivation that is stimulated by reward and not punishment to a certain extent enhances the level of intrinsic motivation [5]. However, if that reward is tangible, it can affect the reduction of the level of intrinsic motivation [6], so, in any case, intrinsic motivation, the kind of motivation that promotes the internal development and progress of students, should be nurtured.

3. RESEARCH

The research was conducted among the students of the design study programs at the Academy of Applied Technical Studies Belgrade. The survey was conducted in June 2021, online, anonymously, using the https://www.surveymonkey.com/ [7] tool. The survey consisted of ten questions and due to the restriction of the survey tool, forty students were able to participate in the research.

It was important for us to check whether the students are aware of the necessity of knowing the English language. All of the surveyed students answered positively to the question: *Do you think that knowledge of the English language is necessary for functioning in the modern world?* This implies that it is absolutely clear to them that functioning in contemporary world is virtually impossible without the English language. However, the response ratio was slightly different with question number two: *If you could choose, would English be your first choice as a foreign language that you would like to learn?* Even though majority of students chose English (72.50%), some for them opted for other languages (Table1). The reason for this might be the omnipresence of the English language or the growing market in non English speaking countries.

Table 1. Question Nº 2

Source: https://www.surveymonkey.com/

ANSWER CHOICES–	RESPONSES–	
Yes	72.50%	29
No	12.50%	5
Maybe	15.00%	6
TOTAL	40	

It was important for us to determine how many students had had the chance to learn the English language independently, in courses they took out of school context. Surprisingly, only 22.50% answered positively, while 77.50% said no. There are several possible reasons that could be the cause of this, apart from the lack of motivation. The lack of time needs to be taken into consideration, as well the financial aspect, since most of these courses aren't free.
The goal of question number 4 was to determine the level of motivation for independent language learning that includes various techniques and methods. *What is the most efficient method for effective English language learning?* Here we can see that the majority of students prefer learning the language independently but spontaneously, by watching movies or travelling, rather than taking classes (Table 2).

Table 2. Question Nº 4
Source: https://www.surveymonkey.com/

ANSWER CHOICES	RESPONSESSS	
Reading books in English language	7.50%	3
Taking English language classes	5.00%	2
Watching movies, TV shows, series etc. in English language	42.50%	17
Listening to music in English language	5.00%	2
Online communication in English language	12.50%	5
Travelling to English speaking countries	22.50%	9
Constant self improvement (writing down and learning new vocabulary, phrases etc.)	5.00%	2
TOTAL		**40**

When asked about the regularity of their attendance in courses English language 1 and English language 2, 37.50% students replied that they were regular in attending lectures, 37.50% attended the lectures, but not regularly, 15.00% attended lectures sometimes, and 10.00% didn't attend them at all. Question number 6 was: *Do you think that attending the lectures is beneficial for you*? It provided us with the following answers: 40.00% said yes, 10.00% said no, while 50.00% replied: up to a certain point. In the comment section they mostly appreciated the chance to communicate in English, but they also said that for those who are advanced learners it was beneficial up to a certain point. The next question was: *Do you think that the syllabus is compatible with the students' needs?* The students answered as follows: 32.50% said yes, 15.00% no, while 52.50% replied: up to a certain point. The reason for this can be found in the fact that students from several study programs attended the same course. When asked how they would describe their motivation in the period of learning the language in courses English language 1 and English language 2, the students provided us with the following answers (Table 3):

Table 3. Question Nº 8
Source: https://www.surveymonkey.com/

ANSWER CHOICES	RESPONSES	
I am motivated by the desire to learn as much as possible because that knowledge will be beneficial to me in the future	38.46%	15
I am motivated by the desire to learn as much as possible because I want to get the best possible grade on the exam	12.82%	5
I am motivated by the desire to pass the exam	48.72%	19
TOTAL		**39**

Unexpectedly, more than a half of students were driven by exam- related motivation, showing that a large proportion of students are extrinsically motivated.
The teacher, as a central figure in the process of English language teaching was also the subject of the survey. Questions 9 and 10 provided us with the following information (Tables 4 and 5):
Question 9: *Do you think that the teacher has motivated the students to attend lectures?*

Table 4. Question Nº 9
Source: https://www.surveymonkey.com/

ANSWER CHOICES	RESPONSES	
Yes	37.50%	15
No	17.50%	7
Up to a certain point	45.00%	18
TOTAL		**40**

And question 10: *Which of these strategies should the teacher employ in order to improve students' motivation?*

Table 5. Question Nº 10
Source: https://www.surveymonkey.com/

ANSWER CHOICES–	RESPONSES–	
The teacher should explain to the students the importance of knowing English language in the modern world	23.08%	9
The teacher should reward attendance by giving points	23.08%	9
The teacher should adapt the syllabus to the needs of the students	46.15%	18
The teacher should offer students the material for reading and additional practice	7.69%	3
TOTAL		**39**

4. CONCLUSION

Based on the information that the authors have gathered, it can be concluded that among the students of design study programs at the Academy of Applied Technical Studies Belgrade, a large proportion of students are aware of the necessity of knowing English language. However, the lack motivation for learning the language independently and the extrinsic motivation are present among more than a half of the total number of students. Their main goal is to pass the exam instead of gaining knowledge that they might find useful in future. Some of the strategies that could raise the level of motivation among the students might include some modifications in the teaching material and the introduction of certain teaching techniques that could develop a deep approach towards learning among students. All things considered, motivation is the key aspect of successful language learning and as such, it is necessary to implement all the available strategies to raise its level.

DOES FRANK LLOYD WRIGHT'S FALLINGWATER HOUSE REPRESENT A PRECURSOR TO SUSTAINABLE DESIGN?

Natalija Gaković[1], The Academy of Applied Technical Studies Belgrade

Abstract: *In this work, we analyze sustainable design on the example of Frank Lloyd Wright's Waterfall House project from the perspective of three critics. We use basic methods of structural-functional analysis and deduction, as well as the comparative method in the comparative research of the opinions of critics. The purpose of the research is to establish whether or not Frank Lloyd Wright's Fallingwater House is a forerunner of sustainable design and to explore to what extent critics' opinions on the subject overlap. In this work, the concepts of sustainable design and organic architecture are briefly presented, the character of Frank Lloyd Wright and his style of organic architecture are explored, the Fallingwater House project is analyzed, the opinions of three critics are analyzed and compared on the topic of sustainable design on the example of the Fallingwater House and it is established whether this project falls into the field of sustainable design.*
Keywords: Fallingwater, Frank Lloyd Wright, Organic architecture, Sustainable design, Green design

1. INTRODUCTION

Sustainable design and organic architecture represent similar, but not identical concepts in design that focus on the relationship between humans and nature. Frank Lloyd Wright is a pioneer of organic architecture, and his project Fallingwater is an example of this type of architecture in practice. The subject of the work is the analysis of sustainable design using the example of Frank Lloyd Wright's Fallingwater project from the perspective of three critics. The aim of the work is to establish whether Frank Lloyd Wright's Fallingwater represents a precursor to sustainable design or not, and to explore the extent to which the critics' opinions on this topic overlap. In the work, we employed basic methods of structural-functional analysis and deduction, as well as the comparative method.

2. SUSTAINABLE DESIGN AND ORGANIC ARCHITECTURE

Ecology from the second half of the 20th century experiences intense development, and in recent years, it constitutes one of the most expansive domains of contemporary theory. In order to prevent further degradation or provide space and time for the renewal of the natural environment, innovations are needed that contribute to reduction, elimination, conservation, and recycling of energy in all spheres, including design [1].
Sustainable design, or as it is otherwise called, eco-design or green design, represents an approach to design that takes into consideration the use of new materials and recycling of old ones, energy conservation in space, positioning of objects, as well as recycling of materials and spaces themselves [1]. All the aspects considered by sustainable design also relate to questions of sustainable architecture. Organic architecture, according to Slobodan Maldini, represents a "style of contemporary architecture that advocates for harmony between nature and humans through design integrated into the environment" [2]. The term "organic architecture" was first used by Frank Lloyd Wright as early as 1908 in the first of the articles "*In the Cause of Architecture*" that he wrote for the

[1]ngakovic@atssb.edu.rs

Architectural Record magazine. Wright offers an explanation of how a sense of the organic is essential for architects and how an understanding of the relationship between form and function, as well as the study of differentiation of forms, can best be derived directly from nature [3].

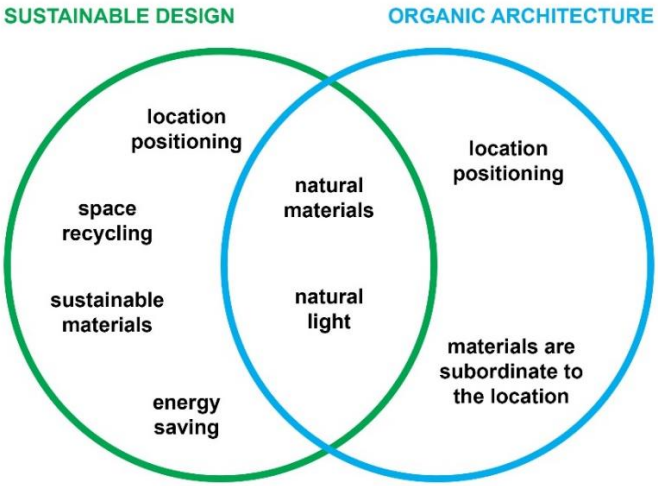

Figure 1. Chart of characteristics of sustainable design and organic architecture

From all the aforementioned, we can conclude that organic architecture shares much with sustainable design and that most of the principles belonging to organic architecture are sustainable. However, for some of them, being subordinate to the idea of unity with the environment, it's still a practical question whether they can be termed sustainable or not. We will explore this question through an example that represents the definition of organic design in practice – Frank Lloyd Wright's Fallingwater.

3. FRANK LLOYD WRIGHT AND FALLINGWATER PROJECT

Frank Lloyd Wright (1867-1959) represents one of the most prominent and influential architects of the 20th century. His works, according to the opinions of many art historians like Ljera, transcend the boundaries of a single architectural school or movement [4]. The style that Wright aimed for and is considered the inventor of is organic architecture. This architectural style presents a modern alternative to rationalism and is associated with establishing a direct connection with nature and the landscape in which the building is situated [4]. In addition to connecting humans with nature, Wright also followed the principle of his teacher Louis Sullivan that "form follows function," which was one of the slogans of the functionalist architecture of his time [5].

One of the best examples of Wright's architectural vision can be observed in his masterpiece, Fallingwater, designed and constructed between 1935 and 1939 during Wright's phase of full maturity. Fallingwater was built as a vacation home for the Kaufmann family above a valley surrounded by nature in a place called Bear Run in Pennsylvania, United States. The house was constructed on the cliffs above a waterfall and presents an entirely new vision of a home – integrated with its natural surroundings and displaying the house's openness to nature itself through terraces and cantilevered roofs [6].

Wright experimented with bold concrete platforms spanning three levels with cantilevered canopies, striving to achieve maximal physical and visual integration with the landscape. Among the materials utilized in the construction, stone and rocks found on the location were also incorporated. The chimney is positioned at the center of the grand hall, the main space of the house, from which the other rooms extend towards the exterior of the house [4]. The salon represents the largest room that occupies an entire floor of the house, except for a small kitchen for staff, and from it, the waterfall itself can be seen and heard. A concealed and narrow staircase connects it to the floor housing the bedrooms and small-sized bathrooms, unusually low-ceilinged, even as low as 195 cm in the lowest part, designed in such a way as to make the access to the terraces even more impressive. The entire house features extensive window surfaces to provide views of the surrounding nature [7].

Figure 2. Fallingwater exterior
Source: Fallingwater, https://fallingwater.org/what-is-fallingwater/

Even from the descriptions of the house's facade and its interior, we can observe how much attention Wright dedicated to the waterfall itself and its integration and permeation with each individual segment of the house. Every part of it was designed in a way that the observer could marvel at the waterfall and the surrounding nature.
Despite the harmony of the house with the surrounding nature, there are several conflicting opinions among critics regarding whether Fallingwater falls into the realm of sustainable design or not.

4. FALLINGWATER AS A PRECURSOR OF SUSTAINABLE DESIGN FROM THE CRITICS' PERSPECTIVE

4.1 Critics' perspective: Imnaculada Jiménez

Architect I. Jiménez considered Wright's works as a precursor to sustainable architecture [5]. In her essay "Frank Lloyd Wright: a Precursor of Sustainable Architecture," Jiménez wrote about Wright's pursuit of balance and harmony with nature, considering him one of the precursors of modern architecture. She noted that Wright applied principles of sustainable architecture even though he never explicitly mentioned them, attributing this to his upbringing in the natural environment on his uncle's farm. She referred to Wright's statement about how a person, the more connected to nature, increases their material and spiritual well-being, considering it an ideological principle that demonstrates Wright's inclination towards what we now call sustainable architecture. As evidence, she described his works as architecture rooted in the natural environment, in harmony with surroundings and people, a concept Wright himself defined as organic [5].
In Wright's interior design of the house, Jiménez draws our attention to the use of form, treatment of natural lighting, and the use of materials that were natural and never clashed with the environment of the house itself, as was the case with Fallingwater. She considers the design of this house as an enhancement of the environment it's situated in and describes it as an icon of the effort to connect humanity with nature [5]. From Jiménez's perspectives, we can arrive at an undeniable conclusion that Fallingwater truly serves as a splendid example of organic design. Wright's architecture and its principles were entirely aligned with nature and the environment in which he created his works. Additionally, the use of natural materials and the ample amount of daylight that Wright incorporated into his projects, including Fallingwater, are characteristics of today's sustainable design.

4.2 Critics' perspective: Order of engineers and architects (OEA)

The Lebanese magazine *Order of Engineers and Architects* drew our attention to Wright's view that architecture can transform the world and that architects should not be limited to designing "beautiful buildings." [8]. They convey their critical review of the exhibition "Frank Lloyd Wright – Organic Architecture of the 21st Century" organized by the Milwaukee Art Museum, in which speakers such as the director of the Frank Lloyd Wright Archives Bruce Brooks Pfieffer, the chief curator of the Milwaukee Art Museum Brady Roberts, and others aimed to present the argument that Wright's organic architecture foreshadowed today's enthusiasm for sustainability and green architecture. The critics of the "Order of Engineers and Architects" magazine agree that Wright respected nature throughout his life despite his modernist design, but they question whether and to what extent this

stance was related to his vision of organic design or merely his inclination towards natural materials rooted in his childhood in rural 19th-century Wisconsin. They also draw attention to the fact that Wright used reinforced concrete in his works, which certainly does not fall under natural and sustainable materials [8]. Based on the information provided by the critic of the "Order of Engineers and Architects" magazine, we can agree that Wright's concept of design and construction that takes into "consideration" the surrounding nature served as a good introduction to later sustainable design. However, due to details such as the use of concrete, it leaves us with an open question about whether his projects themselves, despite being organic, were truly sustainable.

4.3 Critics' perspective: Lloyd Alter

Lloyd Alter, an architect and a professor of Sustainable Design at Ryerson School of Interior Design in Canada, wrote an article for the magazine *Treehugger* discussing the contradictions in the sustainability of Frank Lloyd Wright's Fallingwater design [7]. Alter wrote how this house represents one of the most unsustainable ever built, a house that requires constant maintenance to combat moisture issues, which demands a significant investment of time and financial resources. Yet, paradoxically, it symbolizes the definition of green design due to its concept of the necessity of harmony between humans and nature [7].
The sheer size of the house, the fact that it was built as a vacation home rather than a permanent residence, and the information that it took four cars to transport the Kaufmann family and their staff to this wooded location all run counter to the principles of sustainable architecture. The extensive use of glass offered beautiful views of the surrounding landscape, but the heavy reliance on glass led to unusual junctions like the combination of glass and stone, which results in poor thermal insulation and contributes to higher energy consumption.

Figure 3. Representation of the Glass and Stone Junction on the Facade of Fallingwater House
Source: Fallingwater: A Contradiction in Sustainable Design, https://shorturl.at/nryLN

However, Wright integrated the house into nature by incorporating the surrounding rock formations into its interior and insisted on altering the shape of one of the main beams to accommodate a tree that was growing in that location, avoiding the need to cut it down. This decision reflects an environmentally conscious approach to construction. Another environmentally conscious choice was the use of cork tiles for the floors and walls of the bathrooms, a sustainable material.

Figure 4. Representation of the Beam 'Bypassing' the Tree at Fallingwater House
Source: Fallingwater: A Contradiction in Sustainable Design, https://shorturl.at/gpKOP

Alter doesn't come to a definitive conclusion about whether Fallingwater House is sustainable or not, but he highlights that it is undoubtedly an artistic masterpiece of exceptional importance due to the idea it conveys – the idea that humans should form a unity with nature [7]. From the perspectives presented by Alter, we can draw both "for" and "against" conclusions regarding the idea of Fallingwater House being sustainable. Undoubtedly, this house possesses numerous sustainable concepts within its design and execution, such as the use of local materials, ample daylight in the interior, and a construction approach that minimizes disruption to the surrounding nature.
However, the construction itself in a location like this—bringing machinery and workers to a waterfall in the forest—cannot be considered "beneficial" for the environment and thus contradicts sustainability principles. The emphasis on the view towards nature, extensive glass surfaces, and the house's position contribute to a high energy demand for heating and combating moisture. All of these factors are issues that could be addressed in today's context, but they still don't align with the idea of a sustainable design for this house.
All the contradictions highlighted by these three critics with varying perspectives leave us to draw our own conclusions about whether Fallingwater serves as a precursor to sustainable design or not.

5. CONCLUSION

Fallingwater by Frank Lloyd Wright undeniably stands as a masterpiece of organic architecture and embodies the essence of this style, emphasizing the harmony between humans and nature. Even Wright himself referred to this architectural approach as organic, a definition with which we wholeheartedly agree. By analyzing the opinions of critics about this project, we can come to the conclusion that this house, despite being categorized as organic architecture, still contains elements such as its location, dimensions, and maintenance methods that prevent it from aligning with the principles of contemporary sustainable design. Many of these elements could potentially be adapted to today's standards, but the house itself, as originally designed, cannot be deemed sustainable.
Furthermore, the Fallingwater house and the very idea of its construction in its intended location using materials found on-site undoubtedly represent one of the initial visions that prompted future designers and architects to think in the direction that led to the style of contemporary sustainable design. Although the house itself, by today's established criteria, may not be sustainable, it still serves as a precursor to the thinking that shaped the direction of sustainable design, and for that, we can be immensely grateful to Frank Lloyd Wright.

CHILDREN WITHOUT PARENTAL CARE IN SOCIAL PROTECTION INSTITUTIONS – PARK OF SUPPORT DESIGN

Natalija Gaković[1], The Academy of Applied Technical Studies Belgrade

Abstract: *In this work, we analyze the problems that are most often faced by the marginalized group of children without parental care in social protection institutions. We use basic methods of structural-functional analysis and deduction. The purpose of the research is to identify the problems that most affect this marginalized group and to devise ways to alleviate these problems. Through the work, we analyze the concepts of marginalization and social exclusion, the working methods of social protection institutions for housing children without parental care, children in these institutions, and the problems they face. Also, we propose ways to address these issues. This research aims to offer a design of an interactive installation that would draw the attention of society to the difficulties of children in social care institutions and provide us with the opportunity to help them.*
Keywords: Children without parental care, Social protection institutions, Interactive installation, Product design, Swing

1. INTRODUCTION

Marginalization represents a situation in which groups of people are excluded from the dominant culture and power distribution of society, and social exclusion is one of its key characteristics. Children without parental care in social protection institutions represent a specific marginalized group. Residential placements for children without parental care have existed in our country since the end of the 19th century and have evolved and been regulated over time, but any form of assistance is still welcome to their beneficiaries. Many experts have conducted research on the various problems faced by children in such living conditions, and we wanted to highlight among them those that we can alleviate in some way.

Through the following work, we will explore the concepts of marginalization and social exclusion of children without parental care, residential institutions for their placement, as well as the problems they most commonly encounter. In this work, we employed basic methods of structural-functional analysis and deduction. The subject of this work is the issues faced by children without parental care in social protection institutions. The goal of this work is to identify the problems that have the most impact on this marginalized group and to devise ways in which these issues can be alleviated through design. Since we have identified three types of problems, we have also devised a design for three functional spatial elements that together form an interactive installation. By drawing society's attention to the problems of children without parental care, this installation contributes to their mitigation.

2. MARGINALIZATION AND SOCIAL EXCLUSION

Marginalization is a sociological term that describes a situation in which groups of people are excluded from the dominant culture and power distribution of society. It pertains to the differentiation of certain social groups from the values and accepted behavioral norms that are commonly acknowledged. It also refers to the fact that certain social groups possess obstructed, disabled, or

[1]ngakovic@atssb.edu.rs

limited life, human, or societal opportunities, rendering them excluded from social processes and relationships. Some consequences of marginalization include negative social labeling, the emergence of prejudice and stereotypes, as well as discrimination. All of these often contribute to the inadequacy of social services to meet the needs of marginalized segments [1].
Social exclusion is one of the key features of marginalization and refers to the exclusion of certain members of society from the mainstream social currents. There are various ways and levels of social exclusion, with the most recognizable being the "vicious circle" often observed between unemployment, poverty, and social isolation. Social exclusion greatly depends on which marginalized group the individuals belong to, and children without parental care, especially those placed in social protection institutions, are in a particularly vulnerable position [1].

3. CHILDREN WITHOUT PARENTAL CARE IN SOCIAL PROTECTION INSTITUTIONS

The first recorded instances of organized social care for children without parental care in the world date back to the late 19th century when a large number of children were left without one or both parents due to frequent wars and poor economic conditions. Since then, children in the territory of Serbia have been placed in extended family, foster, or adoptive families, as well as in homes for children established by various associations. Conditions within these homes have been gradually improving, more accommodation places have been opened, and various assistance programs for children have been developed. However, the number of available accommodation places remains insufficient compared to the needs, as well as the resources for their improvement, and unfortunately, the number of foster parents has not significantly increased [2].
According to data from the Republic Institute for Social Protection and the latest three population censuses, it can be confidently stated that the number of children in Serbia has been continuously decreasing year by year. In the period from 2011 to 2020, the number of children in Serbia decreased by 6.7%, reaching a total of 1,198,957 in 2020. However, the number of children in the social protection system is increasing, and over the past 10 years, it has increased by more than 15%. Data from the Republic Institute for Social Protection indicates that at the end of 2020, there were 5,837 children in institutional care (both residential and foster care). The good news is that the number of children in residential care has been decreasing in recent years, but the overall number of children in foster care placements is still increasing [3].
Children without parental care are placed in various types of care arrangements, including informal care by relatives, foster care, placement in shelters or residential care facilities. Adoption is also one more option. The number of adopted children in Serbia has varied over the past 10 years, but in 2020, there was a 50% decrease in the number of adopted children compared to 2014 [3].

4. PROBLEMS FACED BY CHILDREN WITHOUT PARENTAL CARE IN SOCIAL PROTECTION INSTITUTIONS

Research in developmental psychology shows that the absence of parental care places children at a high risk on existential, psycho-physical, social, and educational levels, especially at a younger age and if it has persisted for an extended period [4]. Vidanović's research focuses on the psycho-social issues of children in social protection institutions. In the mentioned studies, we come across data about problems that experts frequently identify as the most common issues among children without parental care in social protection institutions. For children up to 14 years of age, common problems include disinterest in school, aggressiveness towards other children, disregard for rules, academic underachievement, lack of social skills, depression, aggression towards property, a tendency for theft, loneliness, communication difficulties with staff, psychosomatic issues, and running away from the institution. Concerning children above 14 years of age, who are approaching their departure from the institution, the most common issue observed is the presence of fear regarding the future and fear of the social environment, which arise as consequences of prolonged institutional stay. Although

residential facilities are not entirely closed environments, extended stays in them can induce a certain form of social isolation. Coupled with other negative experiences outside the institution such as stigmatization and encountering prejudices, this can lead to pronounced fears about entering the social environment and beginning independence, along with a lack of self-trust and low self-esteem [4].
The care of children in institutions is provided by caregivers, educators, and psychologists. However, we come to the conclusion that, in order to reduce social exclusion, education is needed not only for the children in residential care but also for the rest of society. This can be achieved through various programs that familiarize the broader society with the issues faced by this marginalized group and the potential ways to mitigate those issues. Through previous research, we have identified three distinct sets of problems that society could significantly influence.

5. PROPOSAL FOR ALLEVIATING SOME OF THE PROBLEMS FACED BY CHILDREN WITHOUT PARENTAL CARE IN SOCIAL PROTECTION INSTITUTIONS

5.1 Gathering Support through Donations

The first and simplest way to help would be to gather donations in the form of money, clothing, shoes, school supplies, children's furniture, toys, and all other material items that could be useful. Donations of this kind are common in practice, but as long as there is a need, they should be promoted and expedited in various ways. Besides items like clothing, shoes, toys, etc., for which the donation process is fairly well-known, the idea of people coming up with their own ways to help should also be promoted. For instance, if someone owns a paint shop, they could offer to repaint the rooms where the children sleep in the nearest home, or if someone has a child who has outgrown their stroller, they could donate it, and so on. There are many examples, but the main idea is for each individual to determine what they could personally do and to what extent.

5.2 Encouraging Foster Care and Adoption

Another way of assistance that we have identified as necessary is encouraging people to establish foster families and adopt children, in order to reduce the pressure on institutions and provide more children with families. It's often the case that people are not well-informed about the ways they can become foster parents, or they perceive adoption as a lengthy and nearly impossible process, so they don't consider it even if they cannot have children in other ways. Therefore, we have concluded that these methods of caring for children should be promoted by providing clear explanations about entering the foster care or adoption process.

5.3 Encouraging Social Integration

Encouraging the integration of children without parental care in social protection institutions into society represents a third crucial issue that we can address. Just as education is provided to these children within the institutions, our goal would be to educate society about children without parental care in a way that accelerates their inclusion. Some of the ways that could aid their integration include organizing workshops for life skills, finding employment opportunities for children aged 16 and above who are within the institutions, and securing accommodation options after they leave the system. For instance, someone who runs a private math or language school could reserve a few free spots for children from the institutions. Business owners of any kind could involve children aged 16 and above in their work, such as in artisan shops, hospitality establishments, agricultural enterprises, and more. They could set aside positions for them. Similarly, those who own hotels or other types of accommodations could allocate a few accessible rooms for temporary stay for these children after they leave the institutions, or even employ them, allowing them to pay for accommodation.

Additionally, addressing the language used to differentiate children without parental care from those with parental care is crucial. Using expressions that emphasize their positive aspects, such as "parent" instead of "adoptive parent" and "child placed for adoption" instead of "unwanted child," could help shift the societal perspective towards these children. By implementing these measures, we can contribute to a more inclusive and supportive environment for children without parental care, reducing the challenges they face in their journey to social integration [5].

6. DESIGN OF THE INTERACTIVE INSTALLATION "PARK OF SUPPORT"

We have presented all the problem groups mentioned in the previous chapter through an interactive installation called the "Park of Support." This installation would consist of three parts: a seesaw, a swing, and a tunnel. Together, these three elements would create a playground with the goal of drawing attention to children without parental care in social protection institutions, their issues, and what society could do to help them. Each of the three furniture pieces would have QR codes, which, in today's age where almost everyone carries a mobile phone, would direct us to ways in which we could assist this marginalized group. Within the playground area, there would be a specially designed board with descriptions of each individual element and explanations of how to scan the QR codes located on them.
This installation is designed to be easily set up at any location that receives a significant number of visitors throughout the day – such as parks, promenades, and more. The objective is to catch the attention of as many passersby as possible who could potentially offer their assistance to children without parental care in social protection institutions.

Figure 1. 3D representation of the "Park of Support"

Figure 2 and 3. Photomontages of the "Park of Support"

6.1 Seesaw - Gathering Support through Donations

The seesaw symbolically represents the idea that while someone is "up," someone else is "down," creating an association that those who have "more" can donate and thus help those in a more challenging position. Besides serving as a playful element for two children to rock back and forth,

additional rocking could occur in the central section, even with just one child, despite no one sitting on the seats. QR codes would also be placed in the central section, leading to links upon scanning, offering suggestions for necessary assistance in the form of donations to the facilities at that moment. The QR codes would also provide phone numbers of the facilities and addresses of homes and warehouses where intended donations could be delivered.
The construction of the seesaw is envisioned as a whole structure made of 5 steel tubes with a rustic finish, symbolizing the solidity and "weight" of the situation in which children without parental care in social protection institutions find themselves. The chosen material slightly resembles the bars that remind us of their confinement, but their form from the frontal side suggests their smiles, which we could evoke with our help. The seats are designed in a simple form, made of oak, coated with transparent varnish to showcase all the virtues and flaws of the material. This wood was selected as it's difficult to bend and "stubborn," yet firm and beautiful with all the natural patterns it possesses. Similarly, the lower part of the seesaw features slats made from the same material, serving as an additional play element and hosting QR codes leading to links with phone numbers of the facilities and addresses of homes and warehouses for donations upon scanning. The backrest is consciously not included to portray the "discomfort" of these children's lives. Instead, there's only a 6-millimeter diameter thin steel rod in the front part of the seat, forcing us to struggle to hold on.

6.2 Swing - Encouraging Foster Care and Adoption

Swinging is a state that recalls a mother's soothing and calming embrace, which is why we chose this piece of furniture. The shape of the swing and its widening from the ends to the center is designed to evoke a hug. The form in which the swing would be located represents a simplified house shape, a home that is denied to these children but could perhaps be offered by us. Another reason for choosing the "house" shape is that as a person swings with a certain momentum, they have a "house in sight," only to lose it from view, which can be likened to the search of these children for a home.
The house shape is envisioned from solid wood with a square cross-section of 100 x 100 millimeters, symbolizing both a home and stability. In contrast to the "warm home," the swing is designed with "cold" steel pipes with a rustic finish, bent into full circles that would connect to each other through welding. These connections wouldn't be concealed; instead, they would intentionally be left visible, depicting both "separation" and "connection." The swing's seat would consist of oak slats, separated from each other to prevent water retention, and coated with transparent lacquer. The swing's seat, shaped like a house structure, would be connected using only one rope with a diameter of 30 millimeters, seemingly thin and fragile, as if unable to bear the weight of the situation, yet managing to do so. On the side panels of the wooden house-shaped structure, QR codes would be placed, leading to links with stories of successful foster parents and adoptive families, answers to frequently asked questions, and contact numbers of relevant services for further inquiries.

6.3 Tunnel - Encouraging Social Integration

The designed tunnel would serve several purposes: as a play element, an understanding of the magnitude of difficulties and injustices these children face, suggestions on how we can help them, and an educational aspect aimed at reducing their discrimination.
The tunnel itself is envisioned as a set of 7 frames in a simplified house shape, the same ones that we imagined as the supports for the swings. This would visually connect these parts of the installation. Each of the 7 frames would have a steel bar hanging on ropes of different lengths, creating an element of "play" where one needs to reach from one end of the tunnel to the other without falling, with the added challenge that the bars are at different heights. The entire game is intentionally designed to be difficult to perform, symbolizing the challenging path these children in care facilities face - their journey is tough and full of setbacks, but we could make it easier for them. The choice of the "house" shape for the frames also reflects the frequent changes of foster families that many children without parental care experience. Just like in the previous examples, the frames are designed from solid wood

with a cross-section of 100 x 100 millimeters, and the ropes would support steel rings with a cross-section of 10 millimeters. The frames would be interconnected by steel pipes, similar to those used in creating the seesaw and swing.
In addition to the game, the tunnel would also serve an educational purpose. Each of the 7 frames on one outer side would have a QR code that, when scanned, would lead to links containing suggestions on how someone could help integrate children without parental care into society, questionnaires that passersby could fill out about the assistance they could offer, as well as phone numbers of individuals to whom they could ask questions, express their interests, and provide suggestions. On the other outer side of each frame, there would be an example of a crossed-out "negative" expression commonly used in society to refer to children without parental care, paired with a "positive" expression that should replace it. Some examples we used include: adopted child = child; rejected child = child given for adoption; adoptive parent = parent and biological parent = real parent. Adopting a "positive" language is just one way to decrease discrimination against this group of children.

Figure 4, 5 and 6. 3D representation of Seesaw, Swing and Tunnel

7. CONCLUSION

After analyzing the research of experts regarding the issues faced by children without parental care in social protection institutions, we have identified three groups of problems that we could help alleviate by drawing attention to them through design. For each group of problems, we have envisioned conceptual solutions in the form of distinct elements. Together, they constitute an interactive installation that would draw attention to the existence of this marginalized group, the common challenges they encounter, and possible ways to mitigate these problems.
The complete installation, along with the proposed ways to mitigate the problems it would offer, would leave room for each passerby to independently think and determine what they personally could do and to what extent to help alleviate the challenges faced by children without parental care in social protection institutions.

ANALYSIS OF THE SPATIAL ORGANIZATION OF A MODERN APARTMENT IN BELGRADE, CASE STUDY NEW DORCOL

Natalija Đukić[1], The Academy of Applied Technical Studies Belgrade

Abstract: *This paper deals with the analysis of residential construction in Belgrade today, with a special focus on the organization of the apartment and interior design. Today's moment is characterized by the "importation" of architecture, the interference of investors in the work of architects, and the fact that architecture is seen first and foremost through the prism of economic profitability and profitability. In Belgrade, in 2020, building permits were issued for over seven hundred thousand square meters of space, which, along with the fact that there are around two thousand active construction sites on the territory of the city, indicates the existence of extremely intensive construction activity. The subject of research in this paper are different types of organization of apartments in New Dorcol project, which speak about the daily life of the population of Belgrade.*
Keywords: Interior architecture, contemporary interior design, apartment typology, housing

1. INTRODUCTION

Architect Ivan Zdravković's words testify to the actions of architects, which must necessarily be in accordance with the moment in which they create, that when creating a house, a person strives to meet new standards and requirements, in terms of technical, aesthetic and health aspects, and that in this sense, the house should meets the requirements of durability, stability and comfort. Zdravković points out: "Architecture is the art that people come into contact with most often. Man lives in architecture, moves in it and thinks about it the most. The house is his main concern" [1].
When we talk about the overall architectural activity in Belgrade today - a true description would be extremely fruitful. Contemporary construction is characterized by the "consolidation" of projects, the construction of complexes and entire neighborhoods, such as K District, Central Garden, Belgrade Waterfront and many others. Large projects provide apartment buyers with additional facilities, and investors with more capital, and the opportunity to implement quality materials and achieve quality construction in relation to a large number of positions. Every society and epoch has an example of a typical apartment, and typical examples of spatial organization can be used to see the daily life of the middle and upper class of Belgraders today [2].
Regarding residential architecture as a reflection of the state of society, we can refer to Grlić's words: "That's why it (architecture) should not only be a picture or a reflection of the existing, but - and this already exceeds the limits of aesthetics - carried by a vision of the future and open to it. No one doubts that even then one day it will become obsolete and remain only a more or less successful document of the past. And yet, from that creativity, it will be seen how much that time, country, people, looked forward, how much it could bear to be now already in the future, and how much it was only tied to already defined tradition and built exclusively on the foundations of the known and of the existing, average and generally accepted aesthetic standard" [3].

[1]ndjukic@atssb.edu.rs

2. FLOORPLANS: CASE STUDY NEW DORĆOL

The Novi Dorćol complex, a residential and commercial area of approximately 100,000 m2, built on a plot of 2 ha in the Municipality of Stari Grad, in Venizelosova Street, was selected for analysis in this paper. The complex includes housing, business premises, as well as other facilities, such as a spa center, kindergarten, catering facilities, shopping facilities, green areas intended for rest and recreation. Residential units are structurally divided into square meters of different sizes, from one-room to five-room apartments [4]. The apartments are characterized by modern construction, a selection of quality materials, as well as a high level of finishing, with a special focus on energy efficiency. For the purposes of this work, one typical example of a one-room to five-room apartment was analyzed.

2.1 Studio Apartment: Spatial organization

The analyzed Studio apartment has an entrance area slightly larger than the average (6.12 m2), and includes a space for a shallow wardrobe on one side, as well as space for a washing machine on the other side, which significantly contributes to functionality in an apartment of modest size. From the corridor you enter the space, which doubles as a living room and bedroom (22.05m2), and includes an open kitchen (5.45m2). The bathroom is small, equipped with a shower cabin (4.62m2). The total area of the apartment is 39.01m2 [4].

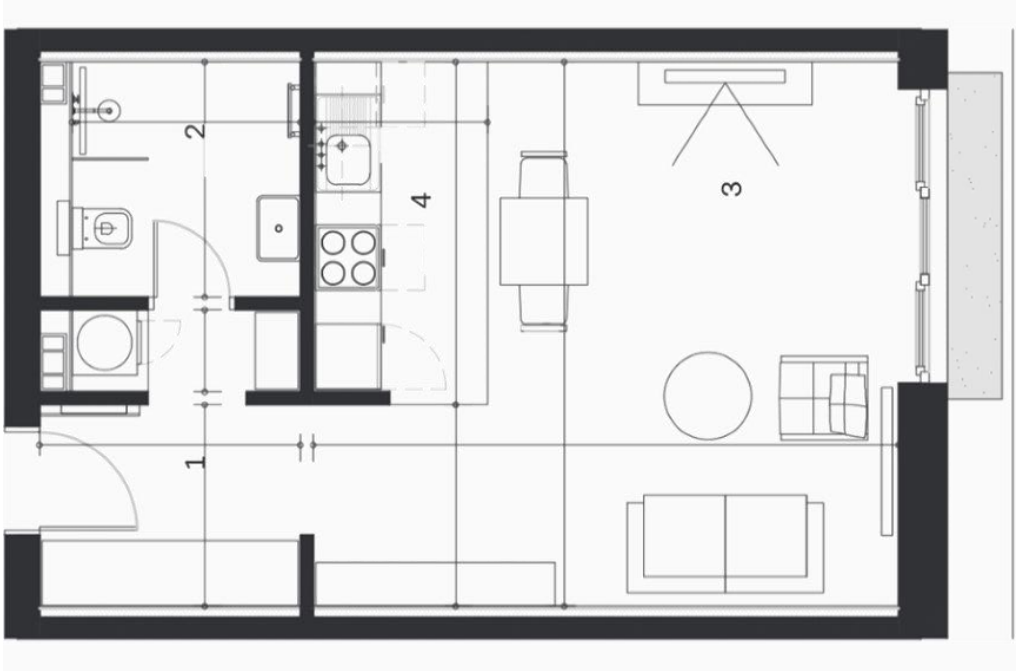

Figure 1. Floorplan: Studio apartment
Source: Novi Dorcol company site

2.2 One bedroom apartment: Spatial organization

The One bedroom apartment has an entrance area slightly larger than the average (7.9m2), which includes space for a shallow wardrobe as well as space for a washing machine and furniture storage. From the corridor you enter the living room, including open dining area (21.59m2), which represents the standard form of space organization. Also, the kitchen (5.76 m2) is part of the same space, and is not separated by a wall or any other type of visual partition. The bedroom has modest dimensions (12.43 m2), with one window, and a place for closets. The bathroom is very small, equipped with a shower cabin (4.02m2). The terrace is a significant addition to the living space, given the fact it is among frequent requests of buyers of apartments of modest size. (6.94m2). The total area of the apartment is 58.64m2 [4].

Figure 2. Floorplan: One bedroom apartment
Source: Novi Dorcol company site

2.3 Two bedroom apartment: Spatial organization

The Two bedroom apartment occupies a total area of 82.25 m2, which makes it average for the given typology. Although the entrance hall has an area of 10.68 m2, it is not a separate space, but is completely connected to the living room. Almost the same organization of the living room, integrated dining room and open kitchen that we had the opportunity to see in the example of the One bedroom apartment is also applied in the Two bedroom apartment, with very similar surfaces. (living room and dining room 22.94m2, kitchen 5.67m2). The living room opens onto a terrace of 8.28m2, and the apartment also has two balconies. From the entrance hall there is access to the shared bathroom, which also functions as a guest toilet (4.06m2). The sleeping area is separate and consists of a smaller room, usually a children's room (9.46m2), and a master bedroom (24m2), which has a wardrobe and an en suite bathroom (4.06m2) [4].

Figure 3. Floorplan: Two bedroom apartment
Source: Novi Dorcol company site

2.4 Three bedroom apartment: Spatial organization

The three bedroom apartment suitable for a family with two children has an entrance area of 9.41 m2 with built-in closets, which leads to the central area of the apartment. The kitchen is open, more comfortable than in apartments of smaller square footage, separated from the rest of the apartment by a light partition in the form of a counter (8.11m2). The living room (27.44 m2), with the adjoining dining room, has an exit to one terrace, while the other is accessed from the larger children's room,

and they occupy a total of 15.70 m2. The sleeping block is divided into two zones. The first consists of the parents' bedroom (15.06m2), with an attached bathroom (3.24m2), while the second includes two bedrooms of 12.57m2 and 15.52m2, next to which there is also a service (laundry room and storage area of 2.50m2), a guest toilet (2.04m2), as well as a children's bathroom (5.98m2). What distinguishes this apartment in terms of spatial comfort from others that we meet on the market today is the well-thought-out division of the bedrooms and the centrally placed living room with accompanying facilities. The total area of the apartment is 117.57m2 [4].

Image 3. Floorplan: Three bedroom apartment
Source: Novi Dorcol company site

2.5 Penthouse: Spatial organization

Penthouse as an apartment typology in Belgrade is somewhat newer, and represents a more formal than actual organization. It goes without saying that these are apartments of a larger area, on the last floors of buildings, however, they are not characterized by a significantly higher height, spatial comfort, or particularly luxurious equipment. The analyzed apartment occupies an area of 171.95 m2, of which the entrance and corridor are almost 21.82 m2, without any additional contents. The kitchen of 6.12 m2 is, unlike the other analyzed types of apartments in the complex, separate from the living room, which, on the other hand, just like in the other apartments, includes a space for leisure and a dining room (43.84 m2). In the bedrooms, an organization similar to that in the smaller apartments has been applied, the master's bedroom (19.92 m2) has an en suite bathroom, while the three children's bedrooms are of modest dimensions and are 14.55m2, 13.05m2 and 10.27m2. The apartment also includes a toilet for guests (3.12m2) and another bathroom intended for tenants (6.33m2) [4].

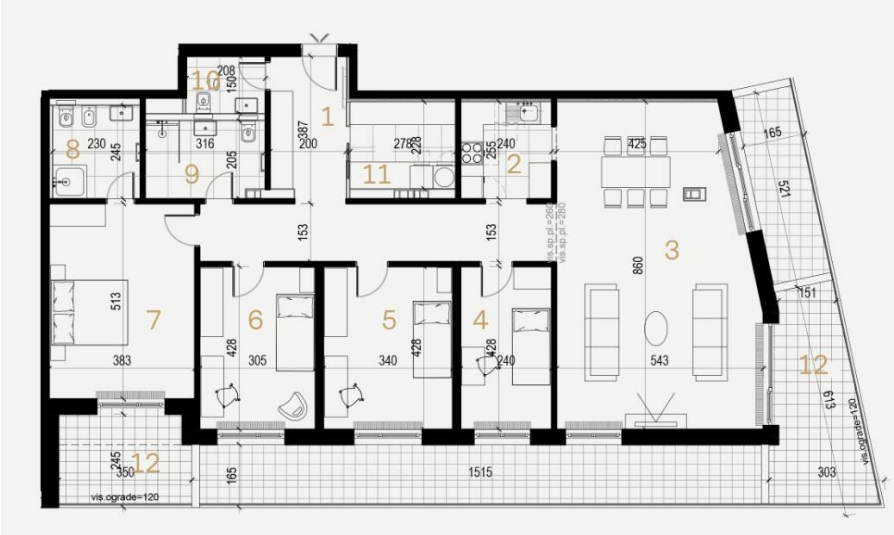

Figure 3. Floorplan: Penthouse
Source: Novi Dorcol company site

We can conclude that designers apply the following rules when designing apartments: the entrance hallway usually includes built-in closets for storage, the kitchen is open to the living room (except in the five-room apartment), which also includes the dining room. If there are several bedrooms, the largest room in the apartment has its own bathroom, while the other tenants use their own bathroom, which sometimes has a guest toilet. Apartment buyers value terraces, and almost every apartment includes them in some form and area. The apartments are simple, understandable to customers, but without any specifics, both in terms of design and organization. Grlić, although he supports the position that we should turn to modern architecture and meaningful interventions, asks the following question:
"as much as modern forms often have extraordinary, and if you want new poetic qualities, you should still not completely ignore the danger that contemporary simple lines and menacing gigantic masses can sometimes lock us in solid concrete boxes so that we will no longer be able to rest our eyes anywhere on one unforeseen detail and tear apart the iron logical and rational edifices that do not own property, capture the free flight of independent search and the possibility of individual, and that means human, human life. Will we not become constantly and against our will surrounded by those uniform silhouettes and become more and more one-dimensional people ourselves, reduced to one mold of feeling, thinking, breathing, will we not harmonize our hopes, desires and imaginations with that modern simplicity of lines and dismiss them contemptuously, as banal and pseudo-humanistic, and the questions themselves, where is the human being lost in this technical perfection?" [3].

3. CONCLUSION

Analyzing the examples, we came to the conclusion that modernization is visible in many fields, but particularly in residential architecture. This work showed that the basic principles in the construction of residential units today are constructivity, functionality and economy, which is in full accordance with the time in which the development of economy and technology is accelerated. Architecture is marked by a paradox - although an architectural work can be modern and advanced at a certain moment, in accordance with the aspirations and needs of man, it inevitably becomes obsolete, because it remains fixed at the moment of its creation, while man is constantly changing, and with him, his needs. It remains with us, and that architecture is a testimony of a certan time, of habits and wishes of the people who lived at the time of its creation.

DESIGN TO THE MEASURE OF MARKETING

Predrag Maksić[1], The Academy of Applied Technical Studies Belgrade

Abstract: *In the 1970s, corporations began to understand the importance of market research and marketing. Changing policies of companies that turned to marketing allowed consumerist design to evolve. The design has been assimilated into a consumerist society dominated by a market economy based on marketing. In this paper, it will be shown how marketing played a key role in developing the ideology of consumerist design, and how marketing design was created. "Marketing design" certainly could not function without an author/designer. The author is an ideological product, an ideological figure who is actually a symbol and apparatus of marketing design. Also, one example of author will be analysed, the one who creates by marketing design rules and who is available to corporations in order to turn the dream of marketing into reality will be presented.*
Keywords: design, author, marketing, ideology, consumerism.

1. INTRODUCTION

During the seventies of the 20th century, like never before, there was a huge effort by the capitalist world to achieve complete control over the market by imposing specific policies and standards of behaviour. It was about achieving control and exerting great influence in the production and development of public opinion, by creating a new taste and unilaterally monopolizing the evolution of culture. In this sense, the role of design was by no means negligible. In the 1970s, corporations began to understand the importance of market research and the scope of the marketing approach. Changing policies of companies that turned to marketing allowed consumerist design to evolve. In further development, design has become a kind of hyperspace that acts transgressively and spectacularly on consumers. In the eighties, nineties and 2000s, design moved toward the field of branding.

Along with informatics, tourism and the entertainment industry, design has filled the world of global consumption to the limit. Its character began to correspond to the global distribution and regulation of capital. Consumerist design evolved into the so-called "brand style". Brand style is a design procedure in which a certain design with all its characteristics refers to itself. New products that are created as a result of this procedure are recognized on the search engine as families or families of designer products. Such products have a clearly defined target group and are linked to a specific brand whose name is followed by a typical appearance.

As far as postmodernism is concerned, in the 1970s it spawned new revolutionary ideologies in design, primarily due to the practical and theoretical breakdown of the modern movement. However, due to the character of the postmodern style, the design has been assimilated into a consumerist society dominated by a market economy based on marketing. In other words, design has proven to be a good ally of the spectacle society.

2. DESIGN ACCORDING TO MARKETING

According to Almeric De Angelis, the 1970s in the world of design dictated the production of a soothing climate [1]. This is conditioned by the aspiration towards a society in which less and less

[1]pmaksic@atssb.edu.rs

space is provided for individual initiative, and in which many responsibilities and concerns of the individual are taken away and redirected to certain centers of power. In such a system, with the help of communication techniques, advertising and self-promotion, a market dynamic is created that sustains itself with products that are not a reflection of individual needs but rather an expression of imposed desires. Dorfles wrote about the potential of advertising and self-advertising value of design, who concluded that a typical design tends to simultaneously advertise itself through the product and the product through itself [2]. This meant that the design possesses the aspect of *representational symbolism*, i.e. a symbolic element that has the ability to emphasize the characteristics that determine makes the item interesting and attractive to the consumer. It is precisely for this reason necessary that a certain design object is often subjected to a renewal process.

The way marketing played a key role in developing the ideology of consumerist design was explained by Nigel Whiteley [3]. Whiteley offered a framework for understanding the relationship between marketing and design, as well as the influence of marketing on the evolution of consumerist design by clarifying the phenomenon of creating desires, lifestyles, internationalization of design through mass media, then even greater acceleration of product development, two-dimensionality, obedience and loyalty of consumerist design to companies. Consumer design from then until its next evolutionary phase correspond to the measure of marketing.

This *tectonic change* is basically a version of the culture industry [4] that was critically analysed by Adorno and Horkheimer. The term *culture industry* refers to the similarity between popular entertainment and mass production. Adorno and Horkheimer warned that the production of cultural objects could be distributed like any other object in a capitalist society. Those objects were consumed on the mass market, which is passive because of its uncritical taste and way of accepting cultural goods. In this way, the audience is led to believe that the quality of consumed items is a reflection of the successful functioning of the state and its political economy.

Having recognized the importance of marketing in business, companies during the seventies and eighties, in the context of political events, accepted the ideas of marketing. Over the years, companies have not only changed their appearance and outlook, but also their overall business policy and organizational culture. For examples of such companies, Whiteley points out and follows the development of Sony, Philips, Ford, John Deere and Baker Perkins, which enthusiastically accepted new trends.

By studying trends in the context of lifestyle, the company was able to predict consumer desires even before consumers had any idea that they would want a new product. This influenced the development of commercial skills of companies, but also the importance of the role and evolution of *consumerist design* in that new system of gaining power and control in the market. These tendencies were also encouraged by political factors, as stated by Whiteley [3]. Thus, the creation of new desires, as opposed to satisfying the real needs of consumers, became the predominant development direction of consumerist design during the eighties.

In the 1980s, consumerist design ensured that lifestyle was a greater determinant of taste than any national or regional characteristic. The internationalization of culture through the mass media and the increase in the growth of trade in old and new markets on a global scale led to the development of companies. Technological development has made communication, transportation and travel accessible to the impoverished masses. This kind of connection has made the seductive appeal of designer products accessible to almost everyone. In this sense, the aesthetics of the product is now the predominant tool in attracting consumers.

The idea that design is a means of stimulating consumption was also put forward by Guy Julier, but supplementing it with the view that the idea of consumption is in fact a means of pacification, coercion and manipulation of the masses. Of course, these statements have their roots in the positions taken by members of the Frankfurt School, more precisely Adorno and Horkheimer. Julier saw the concept of modern consumer within neoliberal conservative ideologies [5].

Whiteley showed how consumerist design did not arise spontaneously from entrepreneurial culture, but developed as an inevitable consequence of capitalist society and market economy. Consumer design has evolved, i.e. made a shift and developed its skills in the direction of satisfying desires.

This type of design has become the prevailing cultural and social norm with values that are largely more implicit than explicit. It is a design in which the consumer is not the driving force but marketing is. Whiteley states that the *consumerist design* that has now evolved into *design by marketing*, or marketing design, offered no socio-political vision. The problems that were evident at the time, poverty in the midst of wealth, problems of minority groups, class divisions, low incomes, were not the subject of marketing design. This design does not need to deal with these kinds of problems because there is no profit in it.

Relying on research from corporations, Whiteley states that marketable designers are completely freed from their relationship with society:

To a large extent, designers are not shy about choosing sides. Conversations with designers from consulting firms and reader letters sections in design magazines are full of unrestrained and thoughtless ideological statements about design and its role in society. The common argument of designers is that the interests of their clients and the interests of the client's clients are identical: a successful product or service satisfies the customer who buys it, which in turn satisfies the company because thanks to it remains profitable [3].

Whiteley explains such attitudes by saying that asking designers in accordance with marketing, asking coherent questions can harm in a financial sense, and that they consider such issues extremely political and ideological. The opposite argument would be that the design of modernism is a failed project and that a system in which design is the handmaiden of capitalism defeats all other alternatives. Every object designed for marketing is part of a system, which has a certain appeal, but is also destructive for the environment and leads to social divisions.

3. KARIM RASHID AND THE IDEOLOGIES OF MODERN DESIGN

Marketing design certainly could not function without an author, that is a designer. The author is an ideological product, that is, an ideological figure who is actually a symbol of a certain discourse. The author does not represent only one element in the system, he plays a certain role in determining current topics and classifying quality. The author, therefore, enables the design to be defined, unified, to separate the elements from each other, that is, to establish a certain design [6].

Here we are not talking about human as such, but about a kind of symbol and apparatus whose purpose is to create. In contemporary society, the society of postmodernism, the function of the author is clearer insofar as through design he sets the ideological direction in which certain currents of discourse are revealed. In the following lines, an example of an author who creates his opus in the context of marketing design and is available to corporations in order to turn the dream of marketing into reality will be presented. Moreover, his work goes beyond marketing itself and becomes a creation in itself. An example of an author-icon, designer-star and celebrity is one of the most talented contemporary world designers - Karim Rashid.

Acquaintance with the icons of the Italian postmodernist design scene will turn out to be crucial for the development of Rashid's colourful style, which is a key element of the likeability and acceptance of his style among the widest masses. Until now, Karim Rashid has designed over 3000 products, including interiors, clothing, footwear, furniture, lighting, art, music installations, and recently entire buildings. For his design, Rashid received a large number of international awards. These included Garbo's trash can, OH Chair, Issey Miyake's bag, Umbra's plastic bowl, Nambé's kitchen utensils, and so on. He also designed interiors for Morimoto restaurant in Philadelphia, Semiramis hotel in Athens, showroom for Deutsche Bank and Audi. However, industrial products for the world's largest manufacturers are his specialty, so he worked for utility items for Method and Dirt Devil, bicycles for Biomega, furniture for Artemide and Magis, brand identities for Citibank and Hyundai, high-tech products for La Cie and Samsung, luxury accessories for Veuve Clicquot, Swarovski and Kenzo, and so on. Today, Rashid's works are part of the permanent exhibition of the world's most famous museums, such as the Museum of Modern Art in New York and the San Francisco Museum of Modern Art, Center Pompidou in Paris. Rashid has been working as a professor of industrial design for more 10 years and is a frequent lecturer at the world's largest universities and conferences.

His work is characterized by sensual curves and bright colours. Often described as *sensual minimalism* (in the words of Rashid himself) but also as a *blobject*. Blobject is an English term that refers to a designed object of industrial design characterized by gentle curves, bright colours and abstraction. This word is a coin of the words blob and object. The word was coined by journalist Phil Patton in 1993 in Esquire magazine. Paton defined the blobject as a colourful, mass-produced, plastic, postmodernist, consumerist product that in most cases invites users to an emotional connection, based on the principle of low desires and visual attributes. Blobject is a curvilinear utility object with floating shapes, and the forerunner of this style and approach to design is styling. Blobject is fluid, curvy, attractive and above all spectacular.

In the book Evolution, Peter Stathis states that Rashid's style stands out for its futuristic, contemporary, closeness to the fashion industry system, according to the principles of haute couture [7]. However, it is about ephemeral qualities. Rashid's works are not solid forms, they represent a new system of communication and connect the homogeneity and technologies of the modern world. This designer moves the design project to the level of glittering formal language, eliminating any part of a specific culture or social element. It is therefore a global language of symbols, forms that can be accepted anywhere in the world, that attract the masses and attract users based on the principle of creating desires. In other words, Rashid's design is a typical example of an *object of desire* - *blobject* is an object of desire. In the book I want to change the world [8], his works are described as colourful, sensual objects, but at the same time fresh, bright and new in concept and form, especially in the field of furniture design and industrial design. The materials and techniques that Rashid uses reflect contemporary trends in technology – plastics, surface printing and certainly computer-aided design. These objects have the characteristic of gathering symbols of the cosmopolitanism of culture, and give an indication of the future of the digital era. For this reason, Karim Rashid's work can be described with the word organicism (organically designed form). Whether it's chairs, vases, lamps or bags, curves and sensual lines dominate.

Rashid does not hide his fascination with the tendencies of globalism either in his statements or in his books. Moreover, he sees in them an opportunity for his own progress and promotion. In the large number of interviews, he gave to the world's largest media, Karim Rashid did not hide his design strategies and ideologies. What's more, he speaks freely about them and exposes his globalist design, in which a lack of awareness of the real social needs of the population can be observed, and a design approach from a purely formal-abstract point of view, which encourages the wishes of consumers. With this kind of media coverage and accessibility to other designers, Rashid promotes exactly the marketing design.

Rashid's design, based first on styling and then on postmodern Italian design, is the embodiment of contemporary global trends in contemporary design and its policies. His design and his media and professional activism are actually aimed at building and maintaining the design discourse as a dispositive dimension. In this sense, Rashid only in principle or did not include the real social aspect at all, and shyly and unconvincingly flirted with elements of ecological design. In interviews, Rashid often insists on democracy, which is actually a bizarre cannibalistic concept of contemporary global neoliberalism. As a result of his action comes a mosaic of designer products that have not only penetrated into the fabric of consumers, actually those who can pay for it, but also into the fabric of the design discourse itself, determining the ideology and values of designers around the world.

The United States and Europe, like the rest of the world, have ceded political power to the control of the biopolitical system and overall economic power. It is a time when social life is ruled by multinational corporations and their marketing policies. They require symbolic and visual representation, and Rashid's spectacular design perfectly matches the corporate logic. Rashid, as well as designers similar to him, are still growing on the wave of this dialectic, far more successfully than alternative design approaches. Ambition and self-centeredness lead Rashid to quasi-theory and criticism of the world. He foresees a colourful future painted by his projects. For him, there is neither past nor present, only a colourful future filled with blobjects.

He does not oppose the design of spectacles encouraged by corporations. In fact, we can't just talk about simple co-opting where design simply works for corporations, or swimming on the wave of investment, because such a discussion frees design from responsibility. If a fundamental turn towards an alternative design discourse is not possible, then society is in trouble. If it is not possible for the design discourse to be critical of the existing functioning systems of the world and to recognize the ideologies of alienated design.

4. CONCLUSION

Marketing design is a logical continuation of consumerism. Therefore, the purpose of design from this point on was to instill a desire for possession into the consumer. In other words, design has become a tool within the company, carefully processed. What is important for the topic of this work is that the tectonic shift in design actually marked the triumph of the ideology of American styling. The styling evolved into a consumerist design, and then by the end of the 1980s, it developed as a marketing design. Design is presented as a universal remedy for the social and economic problems of society. In the same period of the seventies and eighties, cracks appeared in the field of design, and criticism developed that exposed the values and ideology of the consumer society. A new ideology developed on the foundations of the postmodern spirit, but also in the field of social movements that began to appear at the beginning of the seventies of the twentieth century.
It is possible to distance yourself from such phenomena and focus on a more alternative approach to design, than to marketing design, that really takes into account the real interests of society. The contemporary design discourse, set up as an aid to marketing, alarmingly calls for internal transformation. The designer, if he is not captivated by egocentrism and the spectacle, truly strives both for his own freedom and for the freedom of society, which means that he wants to exclude himself from the existing discourse and avoid subjectivation that leads to the non-recognition of human and animal, to the non-recognition of tolerance, human existence, and leads to falling into antagonisms and conflicts with which modern society is filled with too much. Behind the self-centred and spectacular show-off within the design discourse are actually star authors whose ambiguity surpasses even the largest mechanisms of consumerism and marketing. In the existing system, they represent at the same time the victims of the system, but also the executioners.

THE EXPERIENCE AND PERCEPTION OF THE LIGHT COLOUR IN THE SPATIAL CONEXT

Sandra DePalo[1], The Academy of Applied Technical Studies Belgrade

Abstract: Within the realm of architecture and design, the light colour is one of the essential factors that shape and define the perception of the space. Light profoundly influences our emotional and visual perception, giving space life, depth, and meaning. This paper delves into a deep understanding of the significance of light, from the fundamental scientific principles to the sophisticated colour theories. Through the exploration of various theories from esteemed thinkers and basic scientific concepts, this study examines how the colour of light shapes our experience of space, both quantitatively and on a profound subjective level. The study addresses the technical aspects of light, its impact on our emotions, behavior, and visual experience, as well as its importance in shaping the identity of a space. While the technical attributes of light can be precisely measured and planned, its true potential lies in its ability to evoke individual and collective responses, thereby shaping the identity and ambiance of a space.
Keywords: light, light colour, spatial identity, experience, perception.

1. INTRODUCTION

In the world of architecture and design, light is one of the essential elements that breathes life into space, shapes it, and transforms our perception of it. Light plays a pivotal role in our visual perception of our surroundings and also represents an indispensable element in architecture and design thus understanding its influence becomes of utmost importance. While light, at its essence, is electromagnetic radiation visible to the human eye, its true magic lies in how it affects our perception, emotions, and memories. It molds our emotional experience of space, giving it life, depth, and meaning. From fundamental scientific principles, through colour theories established by thinkers like Newton and Goethe, to the sophisticated application of light in shaping the identity of spaces, this paper guides through a comprehensive analysis of light and its significance. In this intriguing journey through light, we explore how it, particularly its colour, shapes and influences our perception of the world around us, both on a quantitative and deeply subjective, emotional level.

2. LIGHT COLOUR AND TEMPERATURE

The nature of light has remained mysterious and challenging to comprehend for many years. Today, we know that light behaves both as a wave and a particle, a phenomenon referred to as wave-particle duality. Light, by definition, is a type of electromagnetic radiation emitted when photons are in motion. This energy characterized by its frequency of electromagnetic wavelengths is part of the broader spectrum of radiation known as the electromagnetic spectrum. Visible light is a part of that spectrum, with wavelengths recognized and processed by our eye receptors, falling between ultraviolet and infrared radiation, within the range of 380 to 780 nanometers. The primary parameters for lighting design are six visual principles of light, factors considered in illuminating architectural spaces: illumination and luminance, colour and temperature, height, intensity, direction, and

[1]sdepalo@atssb.edu.rs

distribution. In this study, the focus is on light temperature and colour as direct influences on the perception of space and time.

2.1 Light Temperature

Our biological rhythm is determined by the daily cycle of light and darkness. Throughout the day, the sun travels a 180-degree arc across the sky, illuminating the landscape and enabling us to see colours (red, orange, white, blue, pink, purple, and everything in between). Within interior spaces artificial light sources replace daytime light. By selecting lighting fixtures, their frequencies, colours, and temperatures, design takes on a specific atmosphere and ambiance. The Kelvin scale has been adopted as the international standard for scientifically measuring light temperature. The Kelvin is the basic unit of the Kelvin scale, an absolute temperature scale named after the British physicist William Thomson, known as Lord Kelvin. At around 800 kelvin, light appears as a dull red glow. Around 3000K, light becomes orange; at 6000K, light is bright white, and between 9000 – 10000K, we see light as blue. Light temperature significantly affects the ambiance of space. LED lights allow the choice of colour temperature to adjust lighting as needed. The images depict a significant difference in the interior ambiance when two different light temperatures are used.

Figure 1. Different light temperatures, left- 6000k cold light, right- 2700k warm light
Source: Lighting by design

2.2 Light Colour

Colors are a product of the different wavelengths of light in the visible spectrum. Different colors correspond to different wavelengths, and our perception of color is a result of how our eyes and brain process these different wavelengths of light. Small differences in the frequency or wavelength of light can indeed lead to different colors. The shortest wavelengths are purple and blue light, while red light has the longest wavelength. Our visuall experience through the colours we see is light that is a combination of different light waves and white light. White light is reflected through many different waves, creating the perceived colour. White light is composed of a continuous series of all colours in the visible spectrum. In practice, we can consider a colour of an object to be the colour the object reflects when illuminated by white light, i.e., an object will be coloured in a certain colour if its surface absorbs white light only in a specific wavelength range. Light colour adds identity and orientation to the space. It is used as a visual compass, emphasizing important places and as a guide to those places. Coloured light leaves a strong impression on a place. The primary colours we see are shown in the table. If the wavelength is of medium length from two adjacent ranges, transitional colours are created.

Colour	Wavelenght [nm]
Red	~ 635-770
Orange	~ 590-635
Yellow	~ 565-590
Green	~ 520-565
Cyan	~ 500-520
Blue	~ 450-500
Purple	~ 380-450

3. THEORIES BEHIND THE COLOUR OF LIGHT

3.1 Newton

In the 17th century, Isaac Newton discovered that prisms could separate and combine white light, a phenomenon he described in his book "Opticks." Newton noticed that when a narrow beam of sunlight hits a glass prism at an angle, part of the beam was reflected, and the other part passed through the glass, emerging as strips of different colours. Newton's hypothesis was that light consists of particles of different colours, with different light colours moving at different speeds in transparent materials, and red light moves faster than violet light. As a result, red light bends less sharply than violet light when passing through a prism, creating a spectrum of colours. Colour is not inherent to an object; rather, the object's surface reflects some colours and absorbs others. The human eye only sees the reflected colours. Newton, through his "Prism Experiment," discovered that white light produced by the sun separates into a rainbow of colours when passing through a prism. When white light hits a white object, it appears white to us because it absorbs no colour and equally reflects all colours. When light touches a coloured object, the light of that colour is reflected back. A black object absorbs all colours equally and reflects none, so it appears black. It is estimated that the human eye can see about a million shades of colours.

3.2 Goethe

Goethe's “Theory of Colours” ("Zur Farbenlehre") explores the phenomenon of colour and how people perceive it. Although his theory was considered less scientific than contemporary colour theories, his understanding of colour as a subjective experience that changes depending on the context, had a significant influence on artists and philosophers. In contrast to Newton's scientific approach, which studied the refraction of light through a prism, Goethe approached colours from a phenomenological perspective, studying how observers perceive them. He concluded that perception determines colour. Goethe believed that colours arise through the interaction of light (which he described as a positive force) and darkness (which he described as a negative force). For example, blue arises when darkness predominates over light, while yellow results from the dominance of light. Goethe recognized relationships between complementary colours and developed the concept of complementary colours. In this section, particular emphasis is placed on the emotional and aesthetic aspects of people's reactions to colours. Goethe detailed many emotions and atmospheres that different colours can evoke. He criticized Isaac Newton for his approach to colours, claiming that Newton's theory does not take into account the complexity of human colour perception. "People experience the effect of colours before they become aware of them. Colour possesses a powerful constitutional energy. It can lead to radical change in us." [1] Although Goethe's colour theory was not fully embraced by the scientific community, it had a significant impact on many artists, designers, and philosophers. It particularly caught the attention of Reinesance artists and philosophers of the 19th century, as well as modern artists of the 20th century who were interested in the emotional and subjective nature of colour.

4. VISUAL EXPERIENCE THROUGH COLOURED LIGHT

Our visual experiences are not solely determined by the physical characteristics of the light; they are also influenced by our bodily and physiological reactions to the light that our retinas receive as information. Coloured light can generate powerful visual perceptions that impact our emotions, behavior, and subjective experience of space. The deliberate use of colours affects our perception of the environment and evokes various emotions. Different colours tend to provoke a wide range of psychological reactions. Red, for instance, evokes strong emotions such as passion, high energy, and excitement. Within specific contexts, red light creates a sense of warmth and comfort, while in others, it suggests danger or urgency. Blue is associated with a feeling of calm, coolness, and serenity. In lighting design, blue light can create a sense of spaciousness and tranquility. However, excessive use of blue can also convey a sense of coldness or alienation. Green is commonly linked to the nature, growth, and renewal. It often evokes a sense of peace and harmony. In the space, green light elicits a feeling of freshness and relaxation. Yellow is bright and cheerful, promoting optimism and positive energy. Yellow light creates a sense of warmth and brightness. Purple is associated with luxury, mystery, or spirituality and is often connected to creativity and imagination. Orange is a warm colour that evokes enthusiasm, energy, and warmth . When orange colour dominates the spatial ambiance it can be utterly stimulating.
The visual impression created by coloured light also depends on the intensity and strength of the light, as well as the context in which it is used. For instance, diffused blue light creates a relaxing ambiance, while sharp, directional blue light evokes a dramatic and intense effect. Regardless of the physical properties and accepted psychological and social norms related to the colour, our experience of colour also depends on the individual perception, cultural factors, and one's previous individual experiences. What may be calming to one individual may feel cold or alienating to another. The influences of the visual impression in the spatial context are explored through psychology and philosophy, broad areas of study that intersect and deal with understanding and our perception of the world around us, light, colour, and space, as well as their impact on our emotions, thoughts, and behavior.

5. IDENTITY THROUGH COLOUR

The colour of light plays a crucial role in shaping the identity of the space. Lighting dramatically alters our perception of space, its function, atmosphere, and affects an individual's sense of it. Through light, the space communicates specific emotions, values, and intentions, its colour creating the ambience of that space. Lighting emphasizes the purpose of the space; light in a workspace enhances productivity and reduces eye fatigue, whereas in a restaurant, diffused and warm lighting is used to create an intimate atmosphere. Architectural details, artwork, or other aesthetic aspects of the space

gain the importance through different lighting techniques. Through the colour of light, designers emphasize or conceal specific details within the space to achieve the desired visual effect.
In commercial spaces, the colour of light is vital for branding. Colours used in logos and marketing materials can be integrated into the lighting of the space, creating a consistent and recognizable brand identity. The colour of light also highlights the cultural or social values of the community.
In some cultures, certain colours may have symbolic meanings or are used in specific ceremonies or rituals, influencing our emotional reaction to the space. For example, spaces illuminated by soft, warmly coloured light easily evoke feelings of security and comfort, while the opposite is true for spaces illuminated by cold, harsh light. Appropriately designed lighting improves the functionality, aesthetics, and overall experience of the space, while inadequate or discordant lighting can lead to confusion or discomfort. Different light colours can provoke different emotional responses.
Warm tones like red or orange create a sense of comfort and warmth, while cool tones like blue can evoke a sense of calmness but also distance. The colour of light can influence social interactions within the space. Restaurants often use warm, diffused light to create a more intimate atmosphere that encourages conversation, while office spaces may use brighter, neutral lighting to stimulate productivity. The orientation and function of the space can be clearly defined through the colour of light. For instance, blue lighting in a specific section of a store indicates a technological department, while green lighting emphasizes natural products. The colour of light can evoke specific memories or associations.
A space illuminated with light reminiscent of a sunset can remind visitors of a beach vacation, while a space with cold, sterile lighting can resemble a hospital environment. The perception of the space's aesthetics is directly related to the colour of light. Light that highlights architectural details or artworks influences the aesthetic value of the space. Controlled use of colour within a space can induce various psychological reactions, such as euphoria with magenta or tranquility with deep ultramarine blue.
While there is a connection between colour and emotion, individual colour perception remains profoundly subjective. When coloured light defines the interior space, it also affects our perception of the space outside the illuminated area. This occurs due to our eyes' adaptation to a specific shade and the visual effect of complementary colour when viewed in different lighting. This effect results from the function of photoreceptor cells in the retina. For a full experience of colour, a visual change is required to allow the brain to adjust to the colour difference.

Source Architectural Lighting Designing with Light and Space

6. CONCLUSION

The colour of light represents a fundamental component in our perception and interpretation of the space. Its role extends from technical aspects, such as light intensity, to the subjective experiences it evokes in observers. Lighting, particularly its colour, not only shapes the visual and emotional experience of the space but also influences its identity and function. Certain theories, such as those

presented by Newton and Goethe, provide a deeper understanding of the role of the colour and light, both physically and in the context of human perception. The colour of light is a powerful tool for shaping the identity of space. Whether the goal is to create a specific ambiance, emphasize functionality, aesthetics, or brand identity, carefully chosen light colour transforms the space and influences all of its users. The perception of spatial identity through the colour of light is a complex interplay between the objective design of the space and the subjective experience of the individual using it. While the technological aspects of light can be objectively measured, planned and designed its true value and impact manifest through the individual and collective human reactions to the different illuminated spaces.

TECHNO-PRAXEOLOGICAL OPINIONS ABOUT DESIGN: VIEWS FROM PERSPECTIVE OF PROTECTION OF CULTURAL HERITAGE

Suzana Polić[1], *Society for Ethics and Valuation in Culture and Science, Belgrade*

Abstract: *The focus of this research is a techno-philosophical and praxeologycal analysis of issues into field of design in relationship to connection of ideas, discourses and values of classical and contemporary approaches to intellectual heritage of design. Leitmotif of this research provided two Italian exhibitions, entitled "Design Before Design" and "Design after Design". Multidisciplinary examination especially focused to action and meta-action in thinking about design, with view to heritage conservation (materials and technologies), and protection of intangible cultural heritage. The analysis in the paper will be shown on Le Corbusier's work "The die is cast".*
Keywords: design, techno-philosophy, praxeology, cultural heritage, Le Corbusier

1. INTRODUCTION

The very wide and multi-layered field of praxeology can be explored in almost all areas of life, and in the field of design it is especially dynamic due to the penetration of new technologies that expand the concept of visuality in different directions of visual culture. That is why it is important to add a praxeological view to the observations of design from standard viewpoints, which includes the triad of criteria related to ethics, effectiveness in fulfilling the purpose, as well as the efficiency that measures the relationship of use in relation to the purpose in relation to the input used, [1]. Also, in the multidisciplinary view of design, very important the philosophical observation once made by Sellars, which drew attention to the process of multiplying sciences and disciplines on the intellectual scene, where the unification of this multiplicity takes place by building scientific bridges between them and where each separate discipline is important, and he must have a sense of how he fits into the intellectual environment as a whole, [2]. Observing from the sphere of techno-philosophy, the famous Danish architect Fisker writes that "...the ethics of functionalism says that no form is something in itself. Form only acquires the meaning it must fulfill through function...", representing the point of view that our environment should be characterized by a whole - as opposed to simply consisting of a series of individual, sensational works, [3]. However, the practical use of knowledge, as stated by Ristić in his interpretation of Habermas, "... whether it is about translating it into technologies and strategies or communicative practice, should be the subject of research into a praxeology, which includes research into the possible interaction of science and politics", [4]. Bearing in mind that it is 100 years since a significant event in the sphere that unites design, economy and politics, when Guido Marangoni (1872-1941), journalist, founder and director of "La Casa Bella", as creator, advocate and chief animator, started the project of international exhibitions of decorative arts in the Villa Reale di Monza (bienle), and then in the Palazzo dell'Arte in Milan (trienale), the research presented in this paper had as its light motive two international exhibitions from 2016: "Il design prima part design. Guido Marangoni e le Biennali di Monza 1923-1927" [5] as part of the XXI Esposizione Internazionale della Triennale di Milano, when presented the exhibition "21st Century. Design After Design". This evocative-heritological view of interwar Italian design, which developed in a critical period of Italian history dominated by the fascist regime [6], in this paper give as time

[1] suzanapolic64@gmail.com

frame of wider research, from which the initial results are presented here, related to the work "The die is cast", by the Swiss-French architect Le Corbusier.

2. VISUALITY, PRAXEOLOGY AND DISCOURSE AS PART OF METHODOLOGY

2.1 Visuality

As Davis points out [7], methodologically, visuality is the subject of research in traditional artistic, as well as scientific and philosophical disciplines, such as aesthetics, art history, psychology and visual-cultural studies in history, sociology and anthropology. In the middle of the last century, heritology was added to these sciences, as a science whose subject of research is the protection of tangible and intangible cultural, scientific and technological heritage [8]. At the beginning of the 21st century, the thought appeared that every space for writing is a "material and visual field, the properties of which are determined by the technology of writing and the ways in which that technology is used by the culture of readers and writers", [9]. Mirzoeff emphasizes that the word visuality was first formulated by Thomas Carlyle in 1841 in his lectures On Heroes [10], where he points out that„Reading Carlyle in the imperial context leads to a distinction between Visuality 1, which is proper to modernity, and a Visuality 2 that exceeds or precedes the commodification of vision". Research also shows that the phenomenon of different modalities of visuality can be observed in all historical epochs: in prehistory, in non-verbal languages, long before a verbal language emerged, [11], in ancient Plato's Κρατύλος [12, 13], then in the Renaissance double activities of viewing and representation [14], as well as in Baroque visions as palimpsests [15] and Cartesian perspectivalism, the reigning visual model of modernity [16], where "...the intellect inspects entities modeled on retinal images" [17], and so all the way to the postmodern heterochronic space heterochronic other space [18], with numerous invisible cultural layers and intermediate layers. At the same time, as stated by Kirby according to Dewey, "...the more honestly we refer to facts, the greater the importance of distinguishing between facts that condition human activity and facts that are conditioned by human activity." To the extent that we ignore this difference, social science becomes a pseudo-science", [19]. In this sense, as one of the representative tasks in the research of the mentioned complex issues, Le Corbusier's tapestry entitled "The Dice is Thrown" from 1960 [20], was chosen for the case study.

2.2 Discourse and factography

Richard Stockton Dunlap's doctoral dissertation defended at the London School of Economics in 2014, entitled *Reassessing Ronchamp: the historical context, architectural discourse and design development of Le Corbusier's Chapel Notre-Dame-du-Haut*, [21], can be considered a turning point in the understanding of the ethical relationship to factography in the research of discourse phenomena. Dunlap analyzes the primary and secondary discourse and shows the modes and strategies of Le Corbusier in his effort not to publicly reveal the facts about his creative process, about symbolic devices that carried hidden meanings within his tmysterious iconographical program, which is why he used the so-called elliptical language with the use of quasi-references. Because of this, many meanings and sources of Le Corbusier's inspiration are still insufficiently known, or are insufficiently presented to the general public, although significant monographs dedicated to the artistic, architectural and intellectual heritage of Le Corbusier, whose authors specialize in the research and interpretation of his work, are dedicated. Referring to precise factography, Richard Stockton Dunlap particularly points to the uncritical attitude of various authors towards Le Corbusier's autobiographical explanations (which he calls *parallel construction*), then to the spread of these canonical explanations in a series of texts that are not subject to criticism (which he calls *discourse enclosure*), as well as excluding those explanations from epistemological review procedures (*explanatory privilege*).

2.3 A techno-praxeological view

Another significant source for research in this work is the analysis of Le Corbusier's explanations, thinking and techno-praxeological observations (though not explicitly under that terminology), which was published in 2022 under the title *Le Corbusier Ineffable Space and Synchronism: From Architecture as Clear Syntax to Architecture as Succession of Events*, authored by Marianna Charitonidou, [22]. From the cited quotations, the sources of which are precisely listed bibliographically, it can be seen that there are several significant points on which Le Corbusier based his creativity. From the more extensive observation given by Charitonidou, quotes from Le Corbusier's thoughts that have universality, in the sense that they can be related to different aspects of his creativity beyond architecture, were selected and analyzed for this research. On the basis of the techno-philosophical analysis performed, the parameters listed here in italics can be formulated with the appropriate quote from Le Corbusier's thoughts in parentheses: ***processuality*** ("first look, then observe and finally maybe discover... and then inspiration can come"), ***the primacy of immediate experience*** ("don't photograph, draw; photography interferes with seeing, carving into the mind"), ***memory as a source*** (ideas are placed "into the interior of memory", waiting for their form to be concretized / "it is drawn in order to be pushed inside, in one's own history, seen things"), ***testimony*** (the drawing as an "impartial witness and engine of the works of the creator"), ***ineffability***, as what cannot be described in words (the work is able to cause the effect of "ineffable space" when it acquires "its maximum intensity, proportion, quality of execution, perfection"), as well as ***concordance*** "A phenomenon of concordance occurs, exactly as in mathematics") and ***illumination*** (a message to architects:"You are 'social beings' rather than artists—you are leaders, followed by millions of individuals who are ready to follow you if you seize the exact moment when 'illumination' exists between you and them", which would could be placed within the framework of the metaphysical components of Le Corbusier's thinking.

3. „LES DÉS SON JETÉS" ["THE DIE IS CAST"]

Le Corbusier's work "Les dés sont jetés" (Fig. 1) has a well-known and complex pre-history of commission by the Danish architect Jørn Utzon, who designed the Sydney Opera House, a great architectural work of the 20th century [23]. Luke Slattery, in a text entitled *Le Corbusier tapestry The Dice Are Cast comes home to Sydney Opera House*, calls Le Corbusier an architectural genius and speaks of the "vibrant proto-Cubist glory" of this tapestry, [24] concluding with the words: " Ultimately *The Die is Cast* connects with something bigger than Sydney and its Opera House: the DNA of modernism itself". This is the conclusion of the text, in which the author shows that in conversations with several credible interlocutors and experts on the work "Les dés sont jetés", he failed to get an answer about the meaning of the symbols shown in this work, where everyone indisputably recognizes only the miniature sailboat, while our the impression that everything else belongs to the domain of guesswork. The numerous questions that this work raises, both in terms of an independent artifact, and in the context of the development of the Sydney Opera House project and the final arrival of "Les dés sont jetés" in its building, due to space limitations and the unavailability of the necessary documentation, cannot be the subject of this work. Therefore, only the elements that are on the level of the relationship between actions and meta-actions (details A and B, Fig. 1) are considered here, could be a framework for analysis based on the above-mentioned sources that are internationally confirmed in the factual and bibliographic aspect. Due to the limitation of space, it is also not possible to present an integral analysis of the work here, but it is possible to present a methodological approach in connection with the selected elements of the work "Les dés sont jetés" as representative symbols important for the thematization of this work.

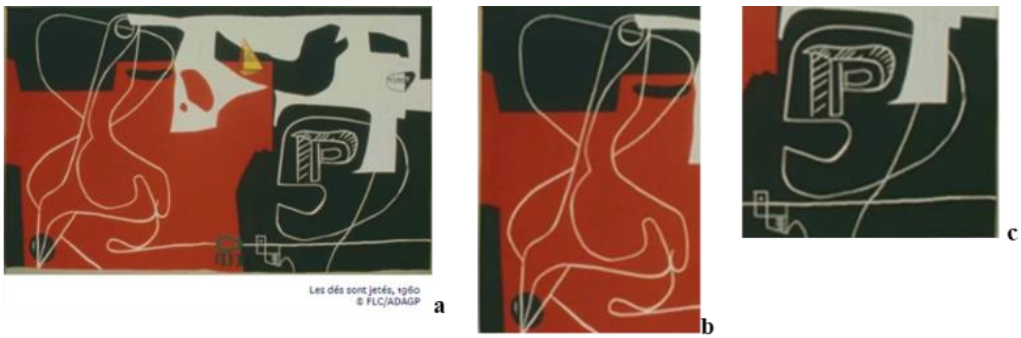

Figure 1. „Les dés sont jetés“, 1960. : Wool tapestry, H: 2,18 m x L: 3,55 m, signed and dated at top right Le Corbusier 60 Paris, Fondation Le Corbusier, [20]; b - detail A; c - detail B

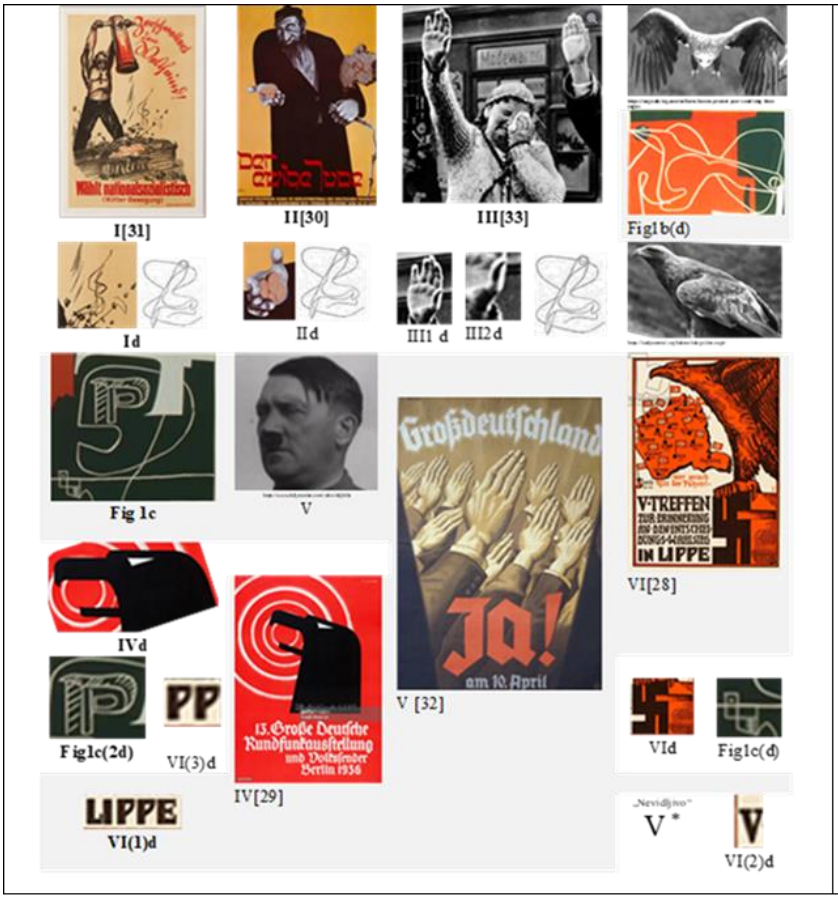
3.1 Factographic analysis

"Quoiqu'il en soit, les dés sont jetés" / “Either way, the die is cast” is a phrase that Le Corbusier mentions in a letter dated 31.10.1940. wrote to his mother (1940-10-31: LC LETTER TO MARIE JEANNERET FROM OZON) [25]. As can be seen in Dunlap's research, it is a letter that documents the sensitive issue of Le Corbusier's "extensive involvement in the Vichy government during the war" as well as "the danger he faced after the fall of Péten." Among other things, Le Corbusier writes about Hitler: „We are in the hands of a winner and his attitude could be overwhelming. If the deal is sincere, Hitler can crown his life with a grandiose work: the development of Europe.” Dunlop also writes in his thesis that Le Corbusier, „to conceal his past, he created a consistent story about the period of German Occupation that obscured his involvement in Vichy”. Historiography records that in the summer of 1933, Hitler said: "The die was cast in Germany on January 30th. And I don't think the opponents who were laughing back then are still laughing today." He said it "in front of an enthusiastic crowd of ten thousand Germans" [26]. As Gregor Taxacher states, "On January 30, 1933, two weeks after the national elections, Reich President Paul von Hindenburg appointed Hitler Chancellor, a formal legal act celebrated by the Nazis as the 'seizure of power.' The fate of the Weimar democracy was sealed." [27] The fortuitous circumstance that local elections in the small province of Lippe marked that turning point immortalized the Lippe region on a Nazi poster (Fig 2-VI), called „V meeting to commemorate the decisive election victory in Lippe”, [28].

3.2 Visuality in context

The visuality of the mentioned poster calling for the celebration of the Nazi victory in the Lippe area, as well as other propaganda Nazi posters (German Poster announcing a radio broadcasting in Berlin (August-September 1936), (Fig2-IV), [29]; Poster The Eternal Jew (1938 poster advertises a popular antisemitic traveling exhibit called Der Ewige Jude, (Fig 2-II), [30]; Nazi Party election poster with a man smashing a financial building with a battering ram, (Fig 2-I), [31]; poster encouraging Germans to vote in favor of annexing Austria (The caption reads "Greater Germany: Yes on April 10th."), (Fig 2-V), [32]) represents a visual that was imprinted in the consciousness of contemporaries of the Nazi rise Germany. In addition, there were photographs that also left an indelible visual mark on memory, such as the photograph Weeping woman in the Sudetenland saluting the triumphant Hitler in 1938 (Fig 2-III),[33]. A visual analysis indicating how such visual impressions could generate the symbols A and B in "Les dés sont jetés" is shown in Figure 2. Visual analysis shows that elements - details from several posters and one photograph from the time of Nazi propaganda, which are still present in the public electronic space today, as parts of different collections, undoubtedly exist in the work "Les dés sont jetés". There are also the basic colors that are dominant in Nazi poster design: red and black.



Morphologically, detail A clearly reflects the interweaving of the projections of the eagle in flight and the eagle at rest. The eagle's head as a Nazi symbol is also common to detail B, which represents the synthesis of two forms: the eagle's head from the poster promoting radio in Berlin and the head - the portrait of Hitler. Within detail B, there is also a discrete, marked interpretation of the swastika, and the double letter P, which dominates the name of the Lippe area, is particularly dominant. A sharply defined letter V on the tapestry that is not visible in the electronic reproduction, and about which the conservator from International Conservation Services, Julian Bickersteth, speaks: "...a sharp V-shape, invisible in reproduction, has been woven into the field of white" [24] also exists on the same poster in the word "V-Treffen". The Nazi salute shown on numerous posters, photographs and films is reduced to one finger connected in the same representation of the eagle in detail A, i.e. it is a sublimation of the motif.

Figure 2. Visuality in context - analysis, [28-33]

4. CONCLUSION

The paper presents shortly observations of theoretical research in the field of techno-praxeology in the context of cultural heritage protection. Recent scientific studies show that there is a need to reexamine known results and new document research to confirm or disprove opinions and existing knowledge about design and works of art that belong to world heritage. Among such works is Le Corbusier's tapestry "Les dés sont jetés", which in a long series of years poses very serious questions to the professional and scientific public about deciphering the displayed symbols and the author's message. Due to the exceptional sensitivity of the subject and the great reputation of Le Corbusier and Jørn Utzon, as well as the reputation of the institution associated with this topic - the Sydney Opera House, which was included in the UNESCO World Heritage Site list in 2007, and in which in the Western Foyer since 2016 the work " Les dés sont jetés", the scientific community is obliged to provide a broader, multidisciplinary scientifically based interpretation, which should allow the work to be contextualized in accordance with the message provided by the author.

VISUALITY, METHOD, AND LABAN'S ORTOGRAPHY: ONE PARALLEL

Suzana Polić[1], *National Museum in Belgrade*

Abstract: *Sources of inspiration for the formation of authentic orthographic and methodological systems are a challenge for researching the emergence and logic of constituting visual opinion. In this paper, one of the possible formative influences on the work of Rudolf von Laban, the most famous movement theorists in the 20th century, which is also the author of an authentic orthographic system, is being investigated. A research on the work of this artist was conducted on the basis of electronically available documentation from several European collections. One possible parallel was presented, which is based on thesis about processes of subtraction from the archetypal content of visual impressions.*
Keywords: visuality, method, orthography, multidisciplinary, old rare manuscripts

1. INTRODUCTION

The research of cultural heritage in the field of visuality offers a view from the perspective of heritology, as a science dedicated to the future of human experience, which examines phenomena that, in their passage through time, encompass the values and qualities of visuality in different areas, harmonizing and multidisciplinary enriching scientific knowledge, [1]. In this work, in the focus of the thematization is such a phenomenon, which connects visuality with movement analysis, through orthography (dance notation), which is known today as *Labannotation* or *Kinetography Laban*, after its author and founder, movement theorist Rudolf von Laban (1879-1958), the founder of choreology, the discipline of dance analysis, [2]. The work is inspired by two studies on the work of Rudolf von Laban. The first of these, Laura F. Brandl's study explores the joint effects of the modern system of dance notation and the rise of geometric abstraction in the applied arts during the first decades of the 20th century, and supports the hypothesis of a co-constitutive relationship between visual abstraction and the dance body in the European avant-garde [3], by exploring possible similarities between the early geometric compositions of Rudolf von Laban and the visual artist Sophie Taeuber-Arp, who moved between the Laban dance school and the Dada art circle between 1916 and 1919 in Zurich. Another study by author Miklós Vojtek, a playwright, deals in detail with the biographical research of Rudolf von Laban's life in Bratislava, where this artist was born, educated and spent part of his life, [4]. In relation to the focus of the first study (geometric compositions), as well as the focus of the second study (formative influences in the artist's creativity), in this paper, the research is aimed at unifying these two focuses. Therefore, the subject of research is the formative influences from which the geometric compositions in the creation of Laban's orthography could arise. This time, the fact that Laban often stayed in the cities of Austria-Hungary at the time, Sarajevo and Mostar, is taken in to account, which is why his biographers point out that he was educated in both Western and Eastern cultures [2]. Accordingly, the hypothesis is presented and advocated that the visual abstraction of Labannotation could have been inspired by archetypal signs, characteristic of ethnological motifs that Laban could see in the mentioned cities. In this way, knowledge from the field of ethnology and ethnomusicology is introduced into the multidisciplinary framework, in addition to the history of art,

[1] suzanapolic64@gmail.com

geometry and movement, as a possible new contribution to elucidating the origin of abstract geometric figures in the orthography of Rudolf von Laban.

2. TRANSPOSITION OF MOVEMENT INTO A SEMIOTIC SIGN

Semiotics, as the study of signs and marking practice [5] provides the possibility to translate non-verbal language into a meaning adequate to the field of expression. Gillian Rose points out that semiology is thus embedded in a rich and complex set of ideas whose implications are still actively debated, and that "... a semiological analysis entails the deployment of a highly ordered set of concepts which produce detailed accounts of the exact ways the meanings of an image are produced through that image", [6]. Therefore, the transposition of movement into a semiotic sign was an important step in the scientific research of play by Rudolf von Laban, who was equally creative in both the practical and the theoretical domain, where his writings on choreutics, choreology - the analysis of dance and movement, eukinetics and observation, through thousands of drawings, they record every spatial nuance, dynamic variation and temporal relationship between individual movements. Therefore, his intellectual heritage (German Expressionist Dance or Ausdruckstanz, Labanotation or Kinetography Laban) unites contributions sublimated in theoretical methods guided by the practice of movement, as " a complex system of analysing the characteristics of movement, particularly its pathways through space, and its 'effort' and 'shape' Theoretical methods driven by movement practice", [7]. The *Encyclopaedia Britannica* notes that Laban, "After publishing a shorthand system for his theories (Choreographie, 1926), he developed a more detailed and more widely applicable notation—one that spelled out the elements that produce the movement pattern—and published it in the book Schrifttanz ("Written Dance") in 1928. This work provided the basis of the system that bears his name — Labanotations",[8]. Valerie Preston-Dunlop, author of the monograph *Rudolf Laban An Extraordinary Life*, believes that his search for the basic vocabulary of expressive movement identified the basic factors of movement flow, with weight, embodying time and space. His works were the result of researching society in the way Brecht did in their fields at that time in dramatic art, Malevitch in constructivist visual art, as well as other artists in the visual language of Dadaism, [9,3,].Bearing in mind that every individual lives and creates under the influence of his contemporaries, Jean-Gabriel De Tarde points out that: "... let us not forget that every invention and every discovery consists in the interference in somebody's mind of certain old pieces of information that have generally been handed down by others " [10], and that each discovery or craft comes from analogy with a previous discovery that copies a common principle, [11]. On the other hand, John Yolton, speaking about perception, argues that there is a constitutive moment that has to do with a natural geometry of the mind and that there is at least one element that is not simply mimetic, [12]. In addition to the influence of contemporaries and the natural constitution of the mind of a creator, as Vojtek points out, there should be an awareness that the influences of childhood, adolescence and youth, in addition to inherited tendencies, are decisive in the development of each personality and that getting to know them contributes to a better understanding of the artist's entire oeuvre, [4].
For research in this paper, from Vojtek's extensive study, we analyze here only two significant facts: i. In his early youth, in the tavern of his grandfather Antal Laban, Laban came into contact with numerous domestic and foreign newspapers and magazines, [4].Without pretensions to make any direct conclusions other than showing a possible atmosphere, here is given the example that Laban as a nine-year-old boy, in 1888, could thus see a photograph (Fig 1a) from the magazine La Nature, for which R. Krauss in his study The Im/pulse to See, states: "The zootrope illustration appears in an article on Jean - Etienne Mareys chronophotographic recording of a bird in flight, from which three-dimensional models were eventually constructed ", [13]. Such or a similar photograph could have left a trace whose reflection would have been recognized in the drawing (Fig 1b), which shows Laban's thinking about movement. As Dick McCaw points out, „The different meanings of the German word "freie" characterise Laban's philosophy of movement. He believed that everyone should practise this free, freed, and freeing dance for their mental and physical health; an idea encapsulated in the first three words of the text:'Tanz is Bewegungsfreude' – 'Dance is the pleasure of movement'", [14].

a b

Figure 1. a- Detail, from *La Nature*, 1888, [13]; b- Detail from Laban drawing, Rudolf Laban Collection compiled by Dick McCaw from archives is in Leeds Special Collections, [15]

ii. As a city child, Laban came into contact with folk art at an early age: fairs were held near his grandparents' house, he was fascinated by women dressed in colorful folk costumes, and for his puppet theater he acquired two villager dolls, which are in his presented became angels, [4]. It is reasonable that he would show such an interest for folk art in visiting other cities where he often stayed, such as Sarajevo and Mostar, from where he could take away many visual and musical impressions. Therefore, we "peek" into the treasury of the *Zemaljski muzej u Sarajevu* (National Museum in Sarajevo), through the important publication *Ornamentation des oeufs de pâques coloriés en Bosnie-Herzégovine*, by Cvetko Đ. Popović (*Ornamentation of colored Easter eggs in Bosnia and Herzegovina, in Serbian: Ornamentika šarenih jaja u Bosni i Herzegovini*) from 1966, (Fig. 2) which shows geometric and other motifs that we compare to fragments from the work of Rudolf Laban, searching for possible inspiration that this artist could get by getting to know the ethnological motifs of these regions, [16]. The Serbian expert in folklore ornamentation, Jelica Belović-Bernadžikovska (1870-1946), who was an associate of the Austrian folklorist and owner of Vienna's *Anthropophyteia museum* Dr. Friedrich Salomon Krauss (1859 – 1938), wrote in 1918 that the most beautiful collection of colorful eggs from Bosnia was held by the National museum in Prague, and museum of Dr. Kraus, [17]. How emphasizes Cvetko Đ. Popović (1896-1980) painting eggs and believing in their miraculous power is part of folk customs that are deeply rooted in the Christian tradition, which is associated with Easter. Popović cites an article by the ethnologist Tatomir Vukanović (1907-1997) from the magazine of the *Umetnički pregled* (*Art review)* from National Museum in Belgrade, published in 1940: "…just as the egg is a symbol of fertility and life force, in the same way many patterns and ornaments painted on eggs have a significant meaning in folk religion and magic role, they serve as symbols of beauty, happiness, fertility, life force..."[18,19]. The layout of the ornamental surfaces, the regularity of the production, the beauty of the motifs, as well as the motifs made with parallel lines, in the form of smaller or larger rhombuses, comparative decoration with lines and dots, which can be seen on the colorful eggs (Fig. 2), contain elements that are known from archaeology since the Stone Age: triangles, spirals, slashes, simple and double stars, crosses, swastikas, sun chariots, S-motifs, the moon, dots in different arrangements, chess motifs, etc. Most of these motifs are symbolic. Reflections of such symbols can also be recognized in the patterns of Rudolf von Laban, as shown in the comparative analysis (Figs. 3, 4).

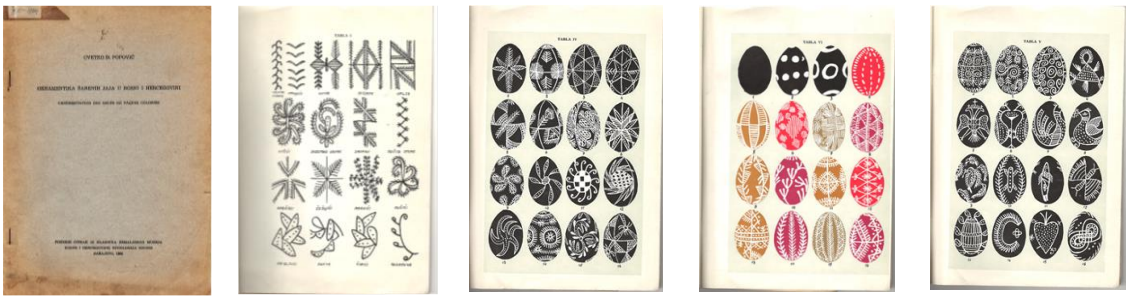

Figure 2: Title page of the publication *Ornamentika šarenih jaja u Bosni i Herzegovini* and representations from the collection of colored Easter eggs of the National Museum in Sarajevo, [16].

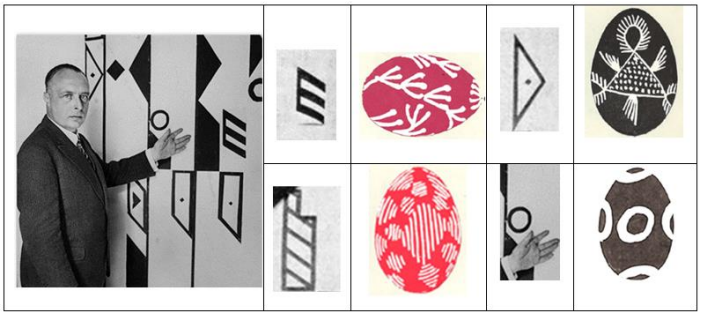

Figure 3: Rudolf Laban presenting his notation system, circa 1929, [20] and comparative view to patterns of egg from National museum in Sarajevo, [16].

When it comes to notation, returning to Jean-Gabriel De Tarde's universal opinion that every discovery comes from analogy with a previous discovery that copies a common principle, from the history of the development of notation [21], we can recognize a parameter that Tard calls a common principle. In this paper, in key study, we see common principle in medieval manuscripts based on neumes, which are interpreted in music the way word morphology is interpreted in linguistics. Just as visuality allows us to perceive deep connections between graphic and musical expression, this is also evident in the case of the connection between graphic expression and dance movement in Labannotation (Fig. 5). In the search for an archetype containing a common principle, as an example, we took one orthography from Laban's journal Schrifttanz (Fig. 5a) and compared it with a manuscript of a musical composition from the golden period of Serbian medieval culture [22], Acolouthia from the 15th century, in Serbian-Byzantine style, authored by the Serbian Orthodox hieromonk and composer Isaiah the Serb (*Fig. 5b*), whose chants were included in the well-known Anthologion 928 from the National Library of Greece. Comparing the details from Laban's orthography and Isaiah's manuscript visually confirms that this common principle exists (Fig. 5c), where we are talking about the physiognomy of the neuma and its expressive configuration, not about contextualization. It is reasonable to assume that, through a comparative analysis, similar details could be found in a large number of Neuma manuscripts, both of orthodox provenance and Gregorian, which according to the French expert in the philosophy of music and modal analysis, professor Jacques Viret, has its origins in Byzantine: "The origin of Latin neumatic notation could be located in Byzantium". As Viret concludes, "...a more specific comparatism takes into account the analogies, pointed out by C. Floros [*Die byzantinischen, slavischen und gregorianischen Tonfiguren und Formeln, Dokumentation*], between the records of Gregorian and Greek-Byzantine liturgical chants, which also includes the problem of the origin of Latin notation, and indirectly of its nature." Viret points out the graphic duality: “This graphic duality overlaps with the fundamental distinction, common to Christian liturgies, between cantilla readings – adapted to all-purpose formulas – and songs of a melodic character, composed for and on a text with which the melody is one (without excluding the occasional use common formulas)”, [23,24].

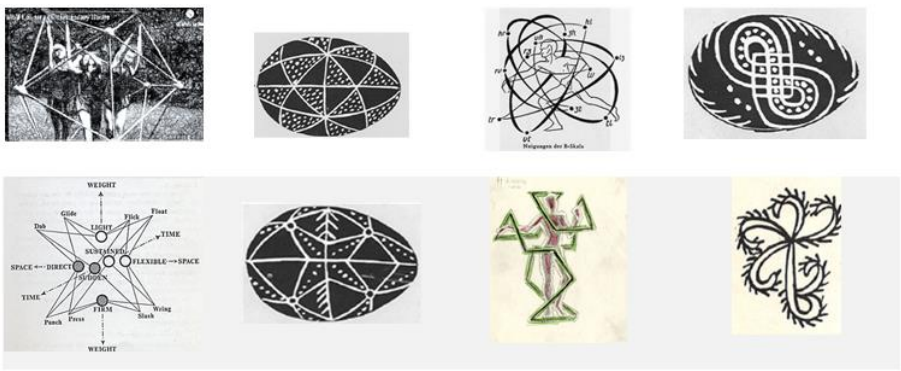

Figure 4: Comparative view to Laban’s philosophy of movement (insert from “Documentary Raitre” and drawings) and geometrical counterparts as possible sources of inspiration - patterns colored Easter eggs of the National Museum in Sarajevo, [25,26,27]

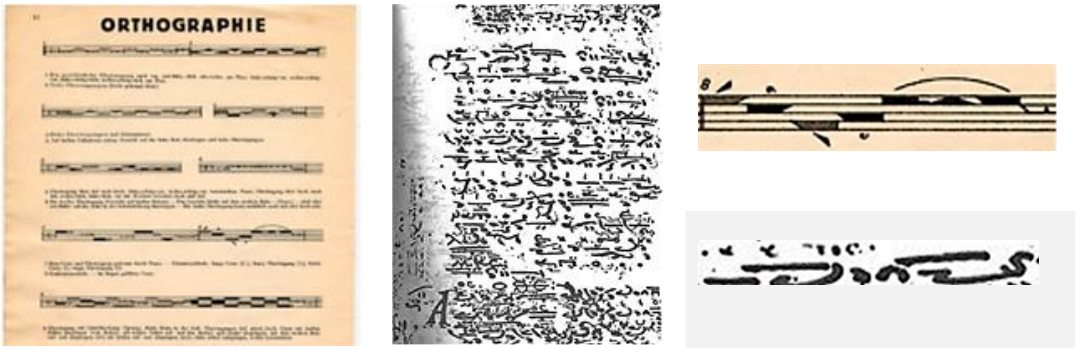

Figure 5: Detail - Excerpt from Rudolf von Laban's journal Schrifttanz, 1928, [3]; Detail from neume manuscript of music composition *Acolouthia* by Isaiah the Serb (XV sentury); comparative view to orthography and neume details, [28].

3. CONCLUSION

The research of visuality shown in this work was focused on the geometric aspects in the work of Rudolf von Laban, more precisely on the research of possible sources of influence from the formative period of this artist, based on known biographical data. The results show that Laban's universal philosophy of movement could have been inspired by the ethno-geometric motifs that, as a great fan of folk creativity, he could see in his childhood. The look at the geometric motifs on the objects in the collection of the National Museum in Sarajevo was not intended to result in any proof, but can be considered as an description of initial idea for a possible claim that folk art was the primary inspiration for the geometric expression of Laban, given that it lacks a more precise analysis of folk creativity from Bratislava, where Laban was born, educated and worked for some time and certainly acquired the most significant visual impressions. Also, an example of a comparative analysis of details from the Neum medieval manuscript and Laban's orthography, points to basically archetypal influences on the artist, where the manuscript shown is just one light-motive and example for thinking in that direction. With respect to all expert opinions that Laban's work was greatly influenced by contemporary art (constructivism / Dadaism), it can be concluded that what determined his philosophy of movement geometry in the formative period should still have been primary: in addition to the natural geometry of the mind and contemporary art, there were also most significant influences of the visuality of folk creativity.

BIOART AND OUR CREATIVE BIOTECHNOLOGICAL FUTURE

Željko Zdravković[1], The Academy of Applied Technical Studies Belgrade,

Abstract: *Bioart, a growing interdisciplinary field at the intersection of biology, art, design and technology, is rapidly shaping our creative biotechnological future. This abstract explores the transformative potential of bioart as a medium for artistic expression, scientific exploration, and ethical inquiry. Bioartists employ living organisms, genetic materials, and biotechnological processes to challenge our preconceptions of life, identity, and the boundaries between art and science. This work examines the diverse manifestations of bioart, from genetically engineered sculptures to living installations, and the ethical implications that arise from manipulating life itself. Through an analysis of prominent bioart projects and the philosophical underpinnings of this genre, we illuminate the profound impact of bioart on our understanding of biotechnology, bioethics, and the creative potential of emerging scientific disciplines. As the boundaries of art and science continue to blur, bioart promises to inspire a new era of creativity, innovation, and reflection on the intricate relationship between humans and the living world. This abstract offers a glimpse into the dynamic field of bioart and its potential to shape our exciting and creative biotechnological future.*
Keywords: Bioart, Biotechnology, Plants, Art, Design, Future, Artificial intelligence

1. INTRODUCTION

Plant biotechnology is actually a very complex science that includes a large number of areas, and as a term it has been used with a much wider meaning since the beginning of the 1970s of the 20th century. It includes the entire spectrum of methods used for the manipulation of organic materials with the aim of meeting the requirements of many industries, especially food industry [1]. According to biologist Ana Simonović, "biotechnology combines disciplines such as genetics, molecular biology, biochemistry, embryology, cytology, systems biology and bioinformatics, as well as practical disciplines such as chemical engineering, information technology and robotics" [1]. It is applied in several industrial areas, but also in basic research and environmental protection. It is basically divided into traditional and contemporary. Modern biotechnology today attracts the most attention first of all because of the areas that belong to it, such as: genetic engineering, cloning and tissue engineering.

2. PLANT BIOTECHNOLOGY AND GENETIC MODIFICATION

To increase yields in agronomy, two approaches are used today:
1) crossing and selection of plants
2) spraying with pesticides and herbicides

In order to improve the quality of seeds, traditional genetic manipulations introduce desired traits into seed stocks [1]. However, in addition to certainly good results, there was a problem in the time duration of crossing the varieties. What was changed during the 20th century in relation to the

[1]zzdravkovic@atssb.edu.rs

traditional way of genetic modification and what resulted in the main achievement in this field of science is, as Simonović defines it: "the possibility of lateral transfer of genes from other organisms to cultivated plants, which then begin to produce new proteins, which was impossible to perform with traditional crossing methods" [1]. At the very beginning of the new millennium, more than half of America's total cotton and soybean crops were already genetically modified. Today, the United States is by almost any measure the globally dominant player in plant biotechnology. Almost half of global GMO production takes place in the US.

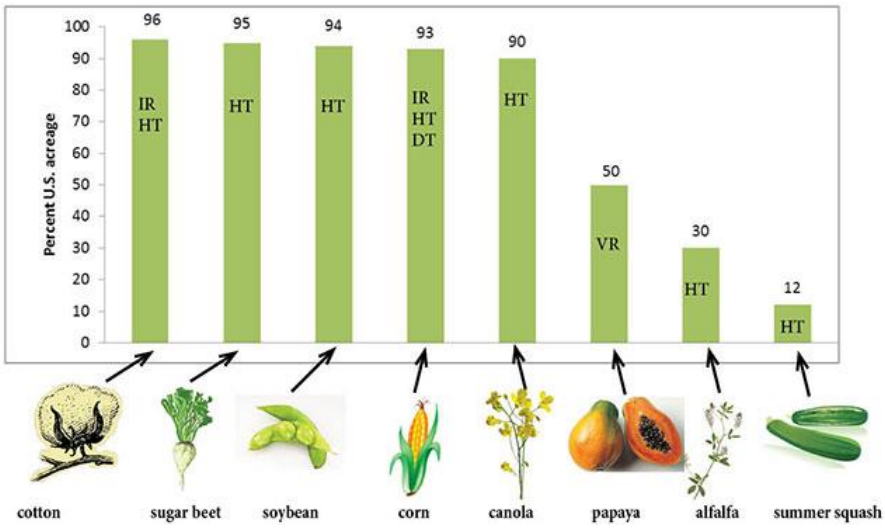

Figure 1. Figure 1. Currently grown GM crops in the U.S., traits for which they are modified, and percent of total acreage of the crop that is planted to GM varieties. IR=insect resistant, HT=herbicide tolerant, DT=drought tolerant, VR=virus resistant.

From the other side, many countries in Europe still do not approve the cultivation, sale and marketing of GM products on their markets, including Serbia, which may currently have the strictest laws on this issue. In the National Sustainable Development Strategy for the period (2009-2017), GM is mentioned in the part of the document that refers to "Biodiversity and nature protection" within the sectoral objectives, where it is stated that in this area: "the implementation of effective measures to control genetically modified organisms (GMO) in accordance with EU practice" [2].

On the other hand, within the framework of Agenda 2030, to which Serbia committed itself as a signatory in 2015, within "Goal 17", which also includes the target value for the "exchange area", it is mentioned that Serbia within the framework of the multilateral trade system, under the future auspices The World Trade Organization: "there is only one open issue of the ban on genetically modified products" [3].

It would be said that it has not been fully clarified what is specifically meant here, and whether it is an open question whether it is a positive or negative tendency for the Republic of Serbia. Or even more simply, what is actually expected of us by 2030?

3. SMART PLANTS AND BIODESIGN

Artificial intelligence, as a very advanced technology in the future, will not only affect the development of humans and animals, but also the plants themselves. Today, moreover, we have the opportunity to see the first experiments with the creation of artificial plant parts, in this case an artificial leaf that can create oxygen in space with water and light. Here we are not referring to imitation of the plants that we can buy in most stores today, but to a real invention in which the chloroplast, which is an integral part of every plant, is actually excluded. The cloned silk leaf is the invention of the British-Italian inventor and engineer Julian Melchiorri, whose profession is closely related to biotechnology and bio mimetic engineering [4].

Figure 2. Artificial leaf of Julian Melchiori (2014)

The application of biotechnology went one step further, so in 2016, a group of students from the Art Institute of Chicago, inspired by a cactus, created a concept for a roof plate structure that has a mechanism for "collecting water from fog".
Like a cactus, a "Fog catcher device" is able to collect and store water for later use [5]. Little is currently known about the specific technology or materials used to make this product, but its applications could be numerous. Biotechnological design (Biodesign) is already dealing with the issue of water management, which unequivocally indicates a very sustainable relationship between man and the ecosystem, where this is another example of technological innovation in a product inspired by Biomimicry.

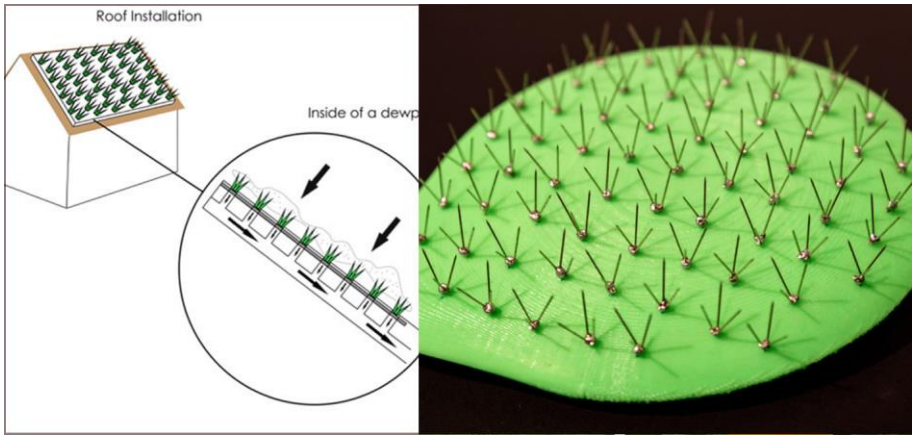

Figure 3. Fog catcher, Dew Point (2016)

It is certain that biotechnology and its processes, as well as potentials, strongly inspire art and significantly contribute to constant innovation, both in the world of applied arts and design, and in many other fields.

4. BIOART: FROM THE POINT OF VIEW OF ART AND DESIGN

In addition to many technological-industrial innovations derived from biotechnology as a base, there are also many artistic works that are very inspired by the same theme and that come to us from the artistic practice called BioArt [6]. This art actually uses the scientific processes of biotechnology, ie. creates experiments through artistic narrative that people make with bacteria, living tissues or any other life processes in the laboratory or outside. Within the group of BioArt there are, for example, Microbial art, Evolutionary art, Hybrid art and others.
One of the artworks that has recently attracted a lot of attention from the audience is Baroque Biology - Paper Theater by the Canadian bioartist Dr. Jennifer Willet. This artwork is actually a

series of Petri Dishes containing imagined biological vignettes in which non-human organisms teach humans complex biotechnological processes. These settings are very reminiscent of the serial engravings of the English painter and printmaker William Hogarth.

Figure 4. Baroque Biology with Petri Dishes, GMO Bacteria, Collage Materials (2019)

Like fairy tales from a biotechnological future, each allegory focuses on a fox or microbe, plant or fungus, trying to usefully communicate with humans about the biological processes which they use for survival, reproduction, and/or aesthetic pleasure [7].
Also, an extremely interesting and instructive artwork called From Teosinte [8] to Tomorrow, which enters to the land art zone, comes from the artists Molly Renda and William H. Dodge. They created a large one-acre corn labyrinth in the park of the North Carolina Museum of Art. The labyrinth itself is a symbolic entrance to multiple locations of this site specific land/art composition.

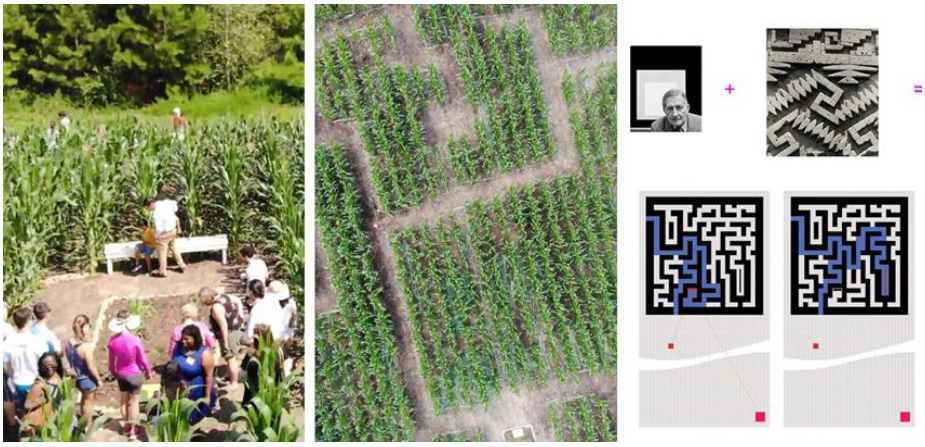

Figure 5. From Teosinte to Tomorrow, Molly Randa and William Dodge (2019)

This work of art is "rooted" in the earliest form of biotechnology, specifically in selective breeding and offers multiple ways to solve the "puzzle", and the terrain covered with teosinte plants represents thousands of years of agricultural history. As one of the earliest cultivated cultivars in the Western Hemisphere, the cultural significance of corn has invited conversations about issues such as population growth and climate change, but also about class, identity, community and genetics in society. Exploring the labyrinth was a very experiential way for a wide audience to engage with art in nature, to consider the issues that are the focus of this exhibition as well as to place themselves in a timeline that is measured in millennia [9].
What is also very common with the artistic practice of Bioart are various controversies surrounding many artworks where even in some cases the artistic narrative is being questioned. One of the those kind of works belonging to this group of art, which really does not leave anyone indifferent, is the

experiment of two British designers and artists Michiko Nitta and Michael Burton from the year 2010 under the name Algaculture [10].

Figure 6. Symbiosis of man and algae - Algaculture (2010)

In this work, they study and shape alternative ways how to power up and nourish our bodies, where they create a symbiosis of humans and algae, and where they propose that humans could actualy function according to the principles of photosynthesis, which would allow us to obtain food through light, in the same way plants obtain it. This is a very obvious example of the search not only for our self-sustainability, but also of redesigning the future human evolution which towards perhaps to some new "species" that would have the capabilities of both currently completely separate entities - man and plant.

5. CONCLUSION

In conclusion, bioart stands at the crossroads of creativity, science, and ethics, offering a fascinating glimpse into our creative biotechnological future. This interdisciplinary field has the power to transform our perception of life, art, and technology, challenging conventional boundaries and fostering a deeper understanding of the complex relationship between humans and the living world.
Throughout this exploration of bioart, we have witnessed the incredible diversity of projects and ideas that bioartists bring to life, from genetically modified organisms that serve as living canvases to thought-provoking installations that prompt us to reflect on our place in the natural world. By harnessing biotechnology and genetic manipulation as mediums for artistic expression, bioartists have demonstrated the limitless potential of human creativity and innovation. Furthermore, bioart serves as a catalyst for ethical discussions surrounding biotechnology. As we manipulate the building blocks of life in the pursuit of artistic expression, we must grapple with profound questions about the implications of our actions on ecosystems, living organisms, and the broader ethical landscape. Bioart compels us to consider the moral dimensions of biotechnological advancements, reinforcing the need for responsible and sustainable practices. In the grand scheme of our biotechnological future, bioart offers a powerful vision of creativity and introspection. It encourages us to question the nature of existence and our role in shaping it. As the boundaries between art and science continue to blur, bioart provides a compelling testament to the ingenuity and imagination of the human spirit. It invites us to envision a future where artistic expression and scientific innovation coexist, fostering a deeper appreciation for the wonders and complexities of life itself.
Ultimately, bioart transcends traditional artistic paradigms, pushing the boundaries of our creative biotechnological future, and inspiring us to explore the uncharted territory where art and science converge. As this captivating field continues to evolve, it has the potential to shape our understanding of life, technology, and the ethical considerations that will guide us in an ever-advancing biotechnological era.

USE OF GOLD COLOR IN INTERIOR DESIGN

Jelica Živković[1], The Academy of Applied Technical Studies Belgrade

Abstract: *This paper researches the use of gold color in interior design, the types of materials used, their production, as well as their use. We will focus particularly on investigating the application of the gold color in wall decoration methods and techniques, as well as its use in glass, metal, stone, and wooden materials.*
Keywords: design, interior, gold, color, technique.

1. INTRODUCTION

The use of gold in interior design has a long history, dating back to ancient civilizations such as Egypt, where it was associated with wealth, power and divine beauty. Today, gold remains a timeless and versatile choice for adding the opulence and warmth to interior spaces. Golden color in interior design can bring a touch of luxury, warmth and timeless elegance to the space itself. Whether you choose to incorporate it subtly or boldly, gold has the power to transform an interior into a place of beauty and grandeur. The research will discuss the very techniques of using gold color on different materials that are most often used in interior decoration. Gold color, which is often associated with luxury, opulence and sophistication, has been a popular choice for interior design as a finishing touch for centuries. It can be used in a variety of ways to improve the overall aesthetics and ambiance of a space. The gold effect is used not only for its aesthetic appeal, but also for its ability to create a warm and inviting atmosphere [1]. When used judiciously, gold accents can transform a space, making it more welcoming, refined, and elegant. Gold can be implemented in the interior in different ways, such as gilded furniture, applications on the walls in the form of gold leaves, wallpaper and various wall treatment techniques. The choice of texture and finish can affect the overall feel of a space, from classic and ornate to modern and elegant [2]. Gold is a color that has stood the test of time. It has been a part of interior design for centuries and continues to be relevant in the contemporary and ~~even~~ minimalist aesthetics. This timelessness makes gold a reliable choice for those looking for lasting style.

2. CHARACTERISTICS OF GOLDEN COLOR IN THE INTERIOR

There are several types of gold colors used in interior design, each with its own unique characteristics and applications.
Classic Gold / Classic gold, often referred to as "yellow gold", is the most traditional and recognized shade of gold. It's a warm, rich shade that brings a sense of luxury and sophistication to a space. It is used in a variety of interior elements, including furniture details, lighting fixtures and decorative accessories.
Rose Gold / Rose gold is a softer and more delicate variation of gold, characterized by a pink hue. This contemporary approach to gold has gained popularity in recent years, especially in modern and minimalist interior design. Rose can be utilized in accessories, textiles, and smaller decorative items to achieve a chic and modern appearance.

[1]jzivkovic2021.10445@politehnika.edu.rs

Champagne Gold / Champagne gold is a subtle and muted golden color with hints of beige or dark red. It exudes a sense of understated luxury and is often used in furniture upholstery, curtains and wall treatments. Champagne gold can add a touch of sophistication without overwhelming the space.
Antique Gold / Antique gold creates has a worn antique or old aged look appearance, which makinges it ideal for vintage or shabby-chic interior styles. It is often used in antique furniture finishes, decorative mirrors and ornate picture frames to evoke a sense of history and nostalgia.
Bronze and Copper Gold / Bronze and copper gold tones have a more pronaunced reddish or brownish undertone compared to classic gold. These variations can be used in "hardware" such as drawer pulls and doorknobs, as well as in accent pieces to create a warm and rustic atmosphere.
Metalic Gold / Metallic gold is a high shine, reflective gold commonly used in modern and contemporary interior design. It is popular for contemporary furniture, accent walls and glossy finishes. The reflective quality of metallic gold can enhance the effect of natural and artificial light in a given room.
Verdigris Gold / Verdigris gold combines the richness of classical gold with the patina it lacked. This unique finish is used in architectural details such as moldings and trim to create a sense of worn elegance.
Gold is most comonly applied to the surfaces by a technique of gilding, the application of gold leaf or gold foil to surfaces such as walls, ceilings and furniture. This technique adds a glossy and opulent finish to interior elements, often seen in luxurious, historic spaces.

3. DECORATIVE TECHNIQUES

Calce Cruda is a microporous decorative coating of mineral nature. The clay component, which is its integral part, creates a network structure of particles, adjusts the processing time and improves the workability of the product. Cellulose fibers strengthen the structure, thus contributing to the stronger binding with the other components. Calce Cruda makes it possible to achieve superior finishes with a wrinkled effect, soft and warm colors, while providing an elegant interior decoration. This technique is applicable on new and old binder-based plasters, gypsum and plasterboard surfaces, old paints as well as various absorbent mineral conglomerates, **Figure 1.**
Travertin is a material composed of the mineral raw materials that allows for various decorative techniques. It is commonly used to achieve the effect of natural Travertine stone. This material's composition prevents the growth of mold, algae and bacteria, has a low odor content, is non-flammable and is environmentally friendly. One of the significant advantages of this technique is durability and quality, as it is resistant to water, UV radiation and weather effects. This technique is suitable for both interior and exterior due to its versatile properties. It can be in one or more colors, matte or glossy finish, **Figure 2.**
Swahili, (a product of the Italian company *NovaColor*), is a decorative material whose collection consists of a water-based finish with metallized particles, producing an unparalleled crystal reflective effect with a refined and futuristic design. The inclusion of metallized particles allows this decorative coating to create varying and pleasing interplays of light and color reflections. It is available in two different bases: silver and gold. Swahili in gold is an excellent choice for interiors where a gilded effect is desired. Additionally, thanks to its rich collection of colors, it can be utilized in various other interior solutions, **Figure 3.**
Ottocento is a water-based technique for walls for interior decorative use. It was specially designed to provide new solutions in the field of interior decoration providing spaces with a highly refined elegance. Featuring a satin appearance, it includes reflective grains that, influenced by bestow a sophisticated elegance to the material. Utilizing cutting-edge technologies, Ottocento guarantees durability and washability. Notable characteristics of this include its ecological nature, non-toxicity, odorlessness, non-flammability, vapor-permeability and waterproofing (allowing the wall ~~can~~ to breathe), it holds European Union class 1 certificate. Over time, Ottocento maintains stable resistance, remaining unreactive to tobacco smoke, and proving resistant to impacts, scratches, and abrasion

(mold). Cleaning is hassle-free as it can be washed with water, and soap effectively removes alcohol, grease, and oil stains using a sponge, **Figure 4.**

Africa, a product of the Italian company *NovaColor* is an exclusive decorative material designed for interior surfaces, featuring a silk effect. It produces a silky surface that elicits exceptional sensations upon touch, imparting a surprisingly warm finesse to the space. The Africa decorative material introduces comfort and refinement to the interior. With its remarkable shine and warm color shades, it enables the creation of modernly decorated walls that, when combined with lighting, evoke a wonderful and unique ambiance in alignment with contemporary trends in interior design. Figure **5.**

The spatula technique is most often used in the decoration of the walls of prestigious buildings, and enhancing the modernity of structures and elevating the beauty of classic interiors. Often referred to as "fake marble", this decorative material yields similar final effects under various names and manufacturers encountered during our research. Its composition includes the finest stone dust mixed with colorants and oils imparting a shiny finish that reveals traces of the application process. The spatula decorative material resembles an opaque paste crafted from natural stone, offering a choice between matte or glossy effects. The final look and structure mimic polished stone or marble, contingent upon the execution technique, **Figure 6.**

Hoblio, product of the Italian company *Candis*, is a particularly pleasant decorative material for interior decor from the Antiche Terre Fiorentine line, developed to give the walls of a room a pleasant and charming look. It combines the beauty and durability of a wall that should last over the years. In terms of aesthetics, Hoblio offers different solutions: gold, silver bases, which reproduce light effects and shadows, as well as a final look reminiscent of sand dunes in the desert created by the wind. The characteristic of this decorative paint is that it is completely water-based, of moderate vapor permeability, and that it is an organic product, which tells us that the raw materials were carefully selected, **Figure 7.**

Antiche Terre Fiorentine Vintage (product of the Italian company *Candis*) is a decorative material that belongs to the "Classic" group of products in the Antiche Terre Fiorentine line. Vintage coating offers a wide range of harmonious colors that allow for creating an elegant ambience. Vintage is available in eight different color families: Vanilla, Coral, Amber, Sea Breeze, Rose, Lagoon, Parchment and Forest. These bases also contain small amounts of pearl micro-pigment, which gives the decorative paint on the wall the appearance of a soft and slightly shiny surface, the so-called. "Pearl effect". Vintage is a decorative material that is completely water-based, semi-transparent, ecological and consists of carefully selected raw materials. **Figure 8.**

Tuscania Antica (product of the Italian company *NovaColor*) is a decorative material designed as a special coating, with the aim to create creative solutions for interior spaces and achieve unique effects by combining color, shape and light. This decorative material is formulated to avoid color washes and decorative stains, typical of the Italian historical heritage. Gradual darkening of shading is easily contained thanks to the natural transparency of the use of pigment and the application of several layers of the same or different color. The surfaces aquire an antique effect or the effect of an old wall [3]. **Figure 9.**

4. GLASS

Gold-colored lighting fixtures, such as chandeliers, lamps and other elements, can serve as focal point in the room. The reflective surfaces of golden lighting create a soft, warm glow, creating a pleasant and inviting atmosphere. The type of gold used as a finishing touch to lighting fixtures in interior

design can greatly affect the overall look and feel of a space. Different gold finishes offer different aesthetic possibilities and combine well with different interior design styles.
The choice of gold finish for lighting fixtures should be align with the overall design concept of the room and the ambiance we want to create. Finishing should be in accordance with the color palette, furniture and decor of the space itself. Whether polished, satin, antique, champagne, metallic, rose gold, verdigris gold or gilded, choosing the right gold finish can enhance the aesthetics and atmosphere of an interior, making fixtures both functional and visually appealing.
Creating the golden color of glass involves different techniques and processes, depending on the desired outcome. Gold glass can add a touch of elegance and sophistication to windows, mirrors and glassware. Gold pigmentation in glass is achieved by adding real gold, in the form of gold chloride or gold nanoparticles, during the glass making process. [4] Gold is a unique and valuable material that gives glass a rich and warm metallic gold color, creating a luxurious and opulent aesthetic.
Gold chloride (AuCl) is a gold compound used in the glass industry to create gold pigmentation. It is added to the glass melt during the manufacturing process. Gold chloride decomposes at high temperatures, releasing pure gold atoms that are evenly dispersed throughout the glass. This dispersion results in a characteristic golden color. The concentration of gold chloride used can be varied to achieve different shades of gold in the glass, from pale gold to deep and lustrous tones.
In recent technological advances, gold nanoparticles have been used to achieve gold pigmentation in glass. These nanoparticles are extremely tiny particles of gold suspended inside the glass. They can produce vivid and uniform gold colors in glass with the added benefit of improved transparency and reduced cost compared to using gold chloride.
Gold pigmented glass is especially prized for its luxurious appearance and is often used in architectural applications, stained glass, decorative glassware and artistic glass sculptures. Its warmth and glow make it a popular choice for adding a touch of opulence to a variety of design elements. The gold pigmentation process allows glass manufacturers to create a wide range of gold shades, meeting the diverse needs and preferences of artists, architects and designers.

5. METAL

Gold pigmentation on metal objects is most often achieved by various methods of coating, coating or alloying. Unlike glass, where gold chloride or gold nanoparticles can be added directly to achieve a golden color, metals are not usually pigmented with elemental gold. Instead, gold finishes or colors in metal objects are created using alternative techniques.
Some metal objects are coated with a gold-colored finish, which does not necessarily contain real gold. These gold-tone coatings can be made from a variety of materials, including brass, copper, or other alloys thereof, which are treated to mimic the appearance of gold. Although they may resemble the color of gold, they do not contain real gold. Some metals, such as white gold or rose gold, are created by alloying gold with other metals such as silver, copper or palladium. These alloys can result in a wide range of gold colored metal objects with different shades [5]. For example, rose gold contains a higher percentage of copper, which gives it a pink or pink hue. In certain applications, gold-colored powder or paint can be applied to metal surfaces to achieve a gold finish. These products may contain metallic pigments or other colors that create a golden appearance when applied and dried.
In architectural and interior design, gold veneer is sometimes used to cover metal surfaces to achieve a golden appearance. Veneers are thin layers of real gold adhered to a metal base, creating a golden finish.
It is important to note that the quality and durability of gold pigmentation on metal objects can vary depending on the method used. Gold plating offers the appearance of real gold, but may require maintenance over time. Gold-colored coatings will not have the same longevity or authenticity as gold plating or gold alloys. The choice of method depends on factors such as cost, aesthetics and intended use, and it is important to consider the specific application and desired level of gold appearance when dealing with metal objects.

6. WOOD

Gold pigmentation in wood finishes does not usually involve the use of elemental gold, as gold is not soluble in the solvents or chemicals commonly used in the production of wood moldings and finishes. Instead, gold pigmentation in wood is achieved by using pigments, dyes or metal powders that mimic the appearance of gold.

Metal powders, often made from materials such as bronze, brass or aluminum, are added to wood finishes to create a metallic effect. These powders can provide a gold-like appearance when combined with a clear or tinted wood finish. They are especially popular in woodworking and fine furniture making. *Paints and stains* that are specially formulated to achieve a gold or metallic effect can be used on wood. These products may contain pigments that create a metallic sheen or golden hue when applied to wood. They are often used in the craft and woodworking industry for decorative and artistic purposes.

Gold glaze is a transparent, colored finish that can be applied over a base coat of paint or stain. Gold glazes contain metallic pigments that provide a shimmering, golden effect while allowing the underlying grain of the wood to show through. Glazing is commonly used in finishing furniture and cabinets. *Fake finishing techniques* - sponge, wear or patterning. These methods involve applying layers of paint, glaze, and metal powder to simulate the appearance of gold. Faux finishes can be highly customized and artistic. When choosing a method to achieve golden pigmentation in wood, it is important to consider factors such as the level of authenticity, the desired gloss, the type of wood and the use. While some techniques, such as the use of metal powder or gold leaf, can provide a more authentic look of gold, others, such as metallic paints and stains, can offer a shimmering metallic effect without the expense and complexity of real gold [6].

5. STONE

Gold pigmentation in natural stone does not usually involve the use of elemental gold as it is expensive and impractical for this purpose. Achieving the appearance of gold in natural stone is often achieved through the use of pigments, minerals or coatings that mimic the appearance of gold.

Certain natural stones, such as granite or quartz, may naturally contain *mineral inclusions* that give them a golden or metallic appearance [7]. For example, quartz with pyrite inclusions may have a golden or brassy appearance. Although this is not a traditional pigment, it is a natural way for the gold color to appear in the stone. To enhance or change the color of natural stone, *pigmented sealants or coatings* can be applied. These products may contain pigments, including metallic powders or mica, which create a golden or metallic sheen on the surface of the stone. [8] This technique is often used to achieve specific aesthetics on countertops and floors. Skilled artisans can create *faux gold* finishes on natural stone using *painting techniques* that mimic the appearance of gold. Faux finishes often involve the use of metallic paints, glazes and artistic techniques to create a golden appearance on stone surfaces. *Gilding* is a technique in which thin sheets of real gold leaf or gold foil are applied to the surface of a natural stone to create the appearance of real gold. Gilding is a labor-intensive and artistic process often used in architectural applications and fine art. In some cases, a *custom-colored epoxy* or *resin* can be used to achieve a gold-like appearance in natural stone. This method is particularly relevant in applications where stone surfaces need to be repaired or restored. When choosing a method to achieve golden pigmentation in a natural stone, it is important to consider factors such as the type of stone, surface finish, desired level of authenticity, and intended use of the stone. Pigmented sealers, coatings and tinted resins can be applied to different types of stone to achieve a golden color, while mineral inclusions and gilding can be used in certain situations to achieve a certain aesthetic. The choice depends on the unique requirements of the individual project and the effect we want to achieve.

5. CONCLUSION

A team of designers from *Boca Do Lobo Studio* from Portugal, who create timeless pieces of furniture, said: "*Owning furniture in gold symbolizes wealth and prosperity. Our talented designers and master craftsmen create every piece of furniture that represents jewelry for the home*" [9].
The research in this ~~e previous~~ work shed light on the multifaceted role of the color gold in interior design. During the study, it was found that gold is not only a shade, but also a versatile element that has the potential to elevate and enhance interior spaces in numerous ways. Finally, the application of gold color in interior design goes beyond mere aesthetics. It serves as a means of expressing opulence, warmth and timeless elegance in interior spaces. As the study shows, it is a versatile tool that designers and homeowners can use to create stunning and luxurious environments. The findings here not only provide valuable insights for interior designers, but also inspire further research into the interplay of color and ambience in the realm of design. Gold, in all its richness, continues to shine in the world of interior design, enriching spaces with its enduring appeal.

USE OF COPPER IN INTERIOR DESIGN

Sara Todorović[1], The Academy of Applied Technical Studies Belgrade

Abstract: *Copper is one of the oldest elements known to humankind throughout its development. Since ancient times, copper has been esteemed for its exceptional value and practicality. From ancient cultures using it for the crafting of weapons and tools to the creative masters of the Renaissance employing it in the creation of refined artistic works, copper has left an indelible mark on the history of human creativity. Throughout the centuries, its application has expanded into various domains, including architecture, art, and interior design, leaving a legacy that continues to inspire and enrich our contemporary culture and aesthetics. Through research, we have examined the rich history of copper as a material that has shaped human history and continues to define our present, through its ubiquitous role in creating inspiring and functional interiors. We have engaged in the analysis of copper properties, as well as its various applications in different parts of interiors. Additionally, we explored the global impact of this element on interior design.*
Keywords: design, copper, interior, furniture, properties

1. INTRODUCTION

In recent decades, copper has become an indispensable material in interior design, bringing warmth, luxury, and subtle charm to modern spaces. Its diverse use spans a wide range of interiors, from kitchens and bathrooms to living rooms and commercial areas. The exceptional adaptability of copper allows designers to create different styles, from modern minimalist to classic traditional, adapting to diverse preferences and client demands. By combining subtle copper tones with various textures and materials, designers craft rooms that exude authenticity and elegance. This study explores the role of copper in contemporary interior design, considering how this refined material shapes spaces, adding a touch of luxury and warmth that leaves a lasting impression on observers and space users.

2. PROPERTIES OF COPPER

Copper is a chemical element with the symbol Cu (from Latin Cuprum) and atomic number 29. The period of history from the 5th millennium to the 3rd millennium BCE, during which copper was extensively used in various fields, is referred to as the Copper Age. By mixing copper and tin, bronze, a hard alloy that gave its name to the subsequent era, the Bronze Age, was obtained, replacing the Chalcolithic period [1]. This element is characterized by many significant properties, which we will analyze individually.

High Conductivity

Copper is characterized by exceptional electrical conductivity, making it a valuable material in various industries. Its ability to efficiently conduct electric current allows for a wide range of applications in different interior aspects, from functional elements to decorative details [2].

[1]stodorovic2021.10419@politehnika.edu.rs

When it comes to interior design, the high conductivity of copper opens the door to diverse creative possibilities. The incorporation of copper electrical installations enables the efficient distribution of electrical energy in a space, ensuring optimal functionality of electrical devices and lighting. By using copper conductors in interior installations, designers can ensure a stable and safe flow of electrical energy, minimizing power losses and ensuring the reliable operation of electrical systems. For this reason, copper is often used in the production of various lighting elements, such as chandeliers, lamps, and wall sconces, due to its ability to create warm light and accentuate the beauty of the interior. Its high conductivity allows for the efficient flow of current through these elements, simultaneously providing an aesthetically appealing glow that enriches the room's ambiance.

Corrosion resistance

Copper's resistance to corrosion is a key characteristic that makes it an extremely prevalent material in interior design. Its ability to retain its original properties in various humidity conditions and chemically aggressive environments allows for a wide range of applications in spaces such as kitchens, bathrooms, and other areas exposed to moisture and changing conditions [3].

In the context of interior design, copper's corrosion resistance enables the creation of durable and aesthetically appealing furniture pieces. When used in kitchen design, copper is often applied in the fabrication of sinks and faucets, providing long-lasting luster and preserving its aesthetic form despite the daily challenges of exposure to water and chemicals. Its ability to maintain its shine and physical characteristics makes it a popular choice among interior designers aiming to create rooms that are both functional and aesthetically attractive.

In bathroom design, copper is frequently used in the fabrication of shower cabins, sinks, and other bathroom elements that require a material resistant to moisture and chemical substances. Copper's corrosion resistance allows for the preservation of the aesthetic appearance and functionality of these elements over an extended period despite exposure to a humid environment, simultaneously providing a sense of luxury and sophistication that enhances the overall experience of being in a particular space.

Simple Design

Copper stands out with its exceptional flexibility and ease of shaping, making it a suitable material in furniture design. Its ability to easily adapt to different shapes and textures allows designers to create diverse aesthetic effects and functional elements within interiors.

When it comes to interior design, copper's property of easy shaping enables the creation of unique furniture pieces and decorative elements. Designers can use copper to craft elegant lines and refined forms in furniture such as chairs, tables, and dressers. Its flexibility allows for the creation of intricate details and reliefs on the surface of furniture, adding a touch of luxury and sophistication to the space [4].

Aesthetic Appeal

The aesthetic appeal of copper is a unique characteristic that makes this metal irreplaceable in interior design. Its distinctive reddish color and natural sheen, reminiscent of the so-called rose gold effect, create an atmosphere of warmth, luxury, and authenticity.

When used in interior design, the aesthetic appeal of copper is showcased through various decorative elements and details. Integrated into lighting design, copper can create a refined and elegant ambiance, providing warm light that further accentuates the texture and color of the room. Its gleaming shine creates a visual effect that enriches the interior, making a pleasant space that captures attention and stands out in the environment.

Recyclability of Copper

The recyclability of copper is a key characteristic that makes it an environmentally friendly material in interior design. Its ability to be recycled and reused enables a reduction in the exploitation of

natural resources and contributes to a sustainable approach in design, making it a desirable choice in creating functional and sustainable interiors.

3. WAYS TO USE COPPER IN INTERIOR DESIGN

Copper is a versatile metal that is increasingly used in various aspects of interior design. Its ability to be easily shaped, aesthetic appeal, high conductivity, and corrosion resistance make it a suitable resource for use in interior design. We will list some ways in which copper can be used in furnishing spaces:

COPPER DETAILS

Copper details in interior design can include various objects and elements made from copper materials. The process of creating these details typically involves a series of steps such as cutting, shaping, welding, grinding, polishing, and finishing to achieve the desired functional and aesthetic quality. These processes are often carried out using specialized tools and techniques, and craftsmanship plays a crucial role in creating high-quality copper details in interior design.
Copper details may encompass:
Handles and Hardware: Copper is often used to craft handles, knobs, and hardware for furniture, cabinets, and other pieces. These components can be handmade or machine-fabricated, shaped from copper rods or sheets, and then processed to achieve the desired form and texture.
Lighting: Copper is used in the creation of various types of lighting, including lamps, chandeliers, wall sconces, and other lighting elements. These pieces are often crafted by combining copper elements with other materials such as glass, wood, or fabric to achieve the desired aesthetic and functional effect.
Decorative Items: Copper is also used to create various decorative objects such as vases, bowls, and other ornamental elements. These items are typically shaped from copper sheets or rods and then processed to achieve a specific shape, texture, and shine.

KITCHENS

Copper provides the kitchen with a warm and rustic aesthetic that adds a touch of luxury and elegance to the space. Its natural shine and reddish color create an appealing contrast with other materials used in the kitchen. When it comes to designing kitchens, copper is often used in the production of sinks, faucets, kitchen hoods, cookware, or decorative elements in the kitchen. This material can add contrast and warmth to the space, creating a pleasant atmosphere for cooking and gathering. Some ways in which copper can be used in kitchen design include:
Sinks and Faucets: As previously mentioned, copper is extremely resistant to corrosion, making it a durable material for kitchen elements such as sinks, faucets, and cookware. Copper's resistance to wear and damage contributes to creating a kitchen that retains its original appearance and functionality over an extended period of use. It is used to manufacture sinks and faucets, which are often produced by combining copper sheets and copper rods. These elements are shaped according to specific dimensions and shapes, then welded and processed to achieve the necessary strength and aesthetic effect. Copper sinks and faucets often undergo grinding and polishing processes to achieve a high shine and a smooth texture that highlights the metal's natural brilliance.
Cookware or Kitchen Accessories: Copper is used to make kitchen accessories such as stove lids, hoods, decorative panels, and countertops. These elements are typically made from copper sheets that are cut, shaped, and processed according to specific dimensions and design requirements. After being shaped, these elements are often polished to achieve the desired shine and texture.

FURNITURE

In interior design, copper is often used to create various pieces of furniture that emphasize the aesthetic value of the space and provide unique sophistication. These furniture pieces include:

Tables: Copper is frequently used to craft different types of tables, including dining tables, console tables, and coffee tables. Tables with copper elements typically have copper legs or frames combined with glass or wooden tops, creating elegant and modern furniture pieces.
Chairs: Copper is also used to make various types of chairs such as barstools, dining chairs, and armchairs. Chairs designed with copper often feature copper frames or details combined with fabric or leather, providing comfort and elegance simultaneously.
Beds: Copper is used to create elegant beds with copper frames or details that add sophistication and warmth to the bedroom. Copper beds often have a unique design that combines the rustic appeal of metal with the comfort and luxury of fabric.
Shelves and Dressers: Copper is frequently used for crafting shelves, dressers, and other storage elements that add functionality and style to the space. These shelves often have copper frames or details combined with wooden or glass shelves, providing a practical solution.
Mirrors: Copper is used to create decorative frames for mirrors that highlight the sophistication of the space. Copper mirror frames often have a rustic appearance that adds warmth and authenticity to the space, emphasizing the value and character of the interior [5].

WALL DETAILS

The use of copper in wall details contributes to the creation of elegant, rustic, and sophisticated interiors. Copper is often used to craft various decorative elements that add texture, depth, and visual appeal to the walls. These elements can be used as decorative coverings, panels, reliefs, or ornamental details.
Copper Panels: Copper panels are commonly used as decorative coverings on walls, providing warmth and luxury to the space. These panels are typically made from copper sheets that are shaped according to specific dimensions and design requirements. After shaping, copper is further processed to achieve the desired texture and shine, giving the walls an authentic look that highlights the sophistication of the space.
Copper Reliefs: Copper is often used to create reliefs that add depth and texture to the walls. These reliefs are crafted either manually or mechanically, shaping copper according to specific design schemes and patterns. After shaping, copper undergoes processes such as patination or oxidation to achieve the desired visual effect that emphasizes the texture and details of the relief.
Decorative Copper Details: Copper is also used to craft various decorative details such as decorative plates, moldings, and wall ornaments.

4. GLOBAL IMPACT OF COPPER ON INTERIOR DESIGN

The global impact of copper on interior design is reflected through diverse cultural interpretations and regional preferences shaping various aesthetic, functional, and stylistic approaches. Different cultures and geographic areas worldwide have specific traditions, values, and preferences influencing how copper is used in interior design. Here are a few examples of how copper usage differs on certain continents:
Asia: In countries like India, China, and Japan, copper is traditionally used in crafting decorative elements such as vessels, candles, and reliefs. These pieces reflect the rich history and culture of these regions, highlighting sophistication and elegance through intricate engravings and textures.
Europe: In European interior design, copper is often a key element in creating rustic, elegant, and luxurious interiors. Countries like Italy, France, and Spain have a rich tradition of using copper in crafting furniture, decorative details, and architectural elements that emphasize the authenticity and opulence of the space.
North America: In the United States and Canada, copper is frequently used in contemporary and industrial design approaches, adding sophistication and modern elegance to spaces. Copper is often integrated into kitchen, bathroom, and residential designs, emphasizing their functionality and aesthetic value.

Africa: In African interior design, copper serves as a crucial element highlighting traditional aesthetics, culture, and artistic heritage. In countries like Morocco, Egypt, and South Africa, copper is often used in crafting traditional vessels, artistic sculptures, and decorative details reflecting the authenticity and identity of local communities.

Through these examples, it becomes evident that the use of copper in interior design varies globally, reflecting specific cultural, historical, and sociological influences shaping aesthetic and functional preferences in different regions and parts of the world. Integrating copper into various interior design styles and traditions provides spaces with a unique appearance, emphasizing the importance of culture and local identity in creating inspirational and authentic interiors.

5. CONCLUSION

Research has shown that copper, through its ability to be shaped into different forms and textures, allows designers to create diverse interior styles tailored to the specific requirements of clients and market preferences. Its functionality, especially in kitchens and bathrooms, enables the creation of spaces that simultaneously meet the aesthetic and practical needs of users.

Furthermore, the research emphasizes the importance of sustainability and the environmental friendliness of copper, making it a desirable choice in the context of the growing awareness of environmental protection. The recyclability of copper contributes to reducing the exploitation of natural resources and minimizing the negative impact on the environment, highlighting its role in sustainable interior design.

Finally, the research clearly demonstrates that copper has a comprehensive impact on creating aesthetically appealing, functional, and sustainable interiors. Its numerous advantages, coupled with creative applications in interior design, make it an irreplaceable resource that brings elegance, warmth, and authenticity to every space. Through further research and the use of innovative approaches, new perspectives for using copper in interior design can be explored, creating spaces that reflect harmony between functionality, aesthetics, and sustainability.

ROAD SAEFTY MANAGEMENT CAPACITY REVIEW – USE OF TAILOR-MADE CHECKLISTS

Dejan Jovanov[1], The Academy of Applied Technical Studies Belgrade
Daniel Pavleski[2], MoTC PIU
Kosta Jovanov[3], Novius d.o.o.

Abstract: *During Road Safety Management Capacity Reviews, researchers can employ a variety of approaches and assessment tools. Various checklists are used to make review approaches as efficient and unified as possible. This paper presents and discussesthe merging of different approaches with accompanying checklists into a single tailor-made checklist that extends any of the single approaches and provides researchers with a broader range of information for future interventions.*
Keywords: Road Safety Management Capacity Review, Checklists

1. INTRODUCTION

Prior to the implementation of any road safety interventions, it is essential to conduct a comprehensive Road Safety Management Capacity Review (RSMCR). The Road Safety Management Capacity Review (RSMCR) is crucial for gaining an in-depth understanding of the current state of road safety within a country, whether at the national or local level. It serves as a tool for conducting a thorough gap analysis between current road safety practices and the best international practices. Furthermore, the RSMCR aids in identifying adequate interventions that can be implemented to enhance road safety performance.
The use of different checklists is a common method for evaluating the current state of road safety in road safety assessments. If checklists are difficult to read and comprehend or fail to include important issues for review, problems with implementation will occur. These problems could possibly result in the absence of crucial information, consequently leading to a lack of interventions that might improve road safety. This paper presents and discusses various RSMCR checklists and proposes how they might be merged to some extent.

2. RSMCR APPROACH/METHODOLOGY

Several approaches (methodologies) are used for RSMCR at the national level, with the one promoted by the World Bank (WB) being the most prevalent. The aforementioned approach is founded on the guidelines provided by the Global Road Safety Facility (GRSF) pertaining to Road Safety Management Capacity reviews and Safe System projects [1]. The Guidelines comprise a total of 12 supporting checklists. The notion of review relies on the expertise of highly experienced reviewers who are regarded as having a profound understanding of road safety management. This is necessary due to the presence of complex questions that may be challenging to comprehend and implement. In some cases, checklists may exhibit a more generalised nature, lacking specific and clear instructions for implementers. Some questions have the potential for several interpretations,

[1] djovanov@atssb.edu.rs
[2] daniel.pavleski.piu@mtc.gov.mk
[3] kostajovanov98@gmail.com

leaving space for different points of view. This is why it is imperative to incorporate supplementary questions and expand initial checklists in order to obtain a comprehensive and unified assessment of the road safety situation within the country, regardless of who is tasked with implementing the RSMCR methodology. The process of merging different checklists should be approached with caution in order to avoid a possible repetition of issues/questions.

2.1 About WB GRSF RSMCR

The RSMCR is an activity initiated by the World Bank that aims to gain a holistic and detailed understanding of the road safety management capacity within the researched country. The ultimate objective of this assessment is to provide assistance to the government, typically the Ministry of Transport, in developing a national Road Safety Strategy and corresponding Action Plans, that are designed to improve road safety performance within the country.

2.2 Steps in RSMCR

The Guidelines promotes several steps during RSMCR:

1. Set review objective
2. Prepare for review
3. Appraise results' focus at system level
4. Appraise results focus at interventional and institutional level
5. Assess lead agency role and identify capacity strengthening priorities
6. Assess road safety approach at local level
7. Specify investment strategy and identify Safe system implementation projects
8. Translate the above findings into comprehensive Action plan
9. Confirm review findings at high-level workshop
10. Finalize review report

Among specified steps, steps 3 through 6 are based on different assessments using accompanying checklists, which require an in-depth understanding of road safety management.

3. USAGE OFCHECKLISTS

3.1 WB RSMCR Checklists

Within the WB GRSF RSMCR Guidelines, the road safety management system is described through the so-called "Road Safety Pyramid" where three interrelated elements: institutional management functions, interventions, and results are presented (Figure 1—left, light blue shaded side).

The cornerstone of road safety management systems is established by seven key institutional management functions: coordination, legislation, funding and resource allocation, promotion, monitoring and evaluation, research and development, and knowledge transfer.

Interventions include several aspects such as the planning, design, operation, and usage of the road network, as well as the entry and exit of vehicles and road users to and from the network. These interventions are strategically formulated to efficiently achieve the targeted outcomes.

Results refer to the quantification of the desired results and their expression as targets, encompassing final outcomes, intermediate outcomes, and outputs. Targets define the desired safety performance endorsed by governments at all levels, stakeholders, and the community.

Checklists are part of the WG GRSF RSMCR Guidelines and are classified within 12 chapters[4]:

- Checklist 1: Results focus at system level (with 8 questions)
  - ✓ Are estimates of the social costs of crashes available?

[4] Due to the paper limitations, only a few of the first checklist's questions are presented.

- ✓ Are data on road deaths and injuries readily available?...
- Checklist 2: Planning, design, operation and use of the road network (5 questions)
  - ✓ Have comprehensive safety standards, rules and associated performance targets been set for the planning, design, operation and use of roads to achieve the desired focus on results?
  - ✓ Are the official speed limits aligned with Safe System design principles to achieve the desired focus on results? …
- Checklist 3: Entry and exit of vehicles to and from the road network (4 questions)
  - ✓ Have comprehensive safety standards, rules and associated performance targets been set to govern the entry and exit of vehicles and related safety equipment to and from the road network to achieve the desired focus on results?
  - ✓ For each category of vehicles and safety equipment (private, commercial, public, helmets) are compliance regimes in place to ensure adherence to the specified safety standards and rules to achieve the desired focus on results? …
- Checklist 4: Entry and exit of road users to and from the road network (4 questions)
  - ✓ Have comprehensive safety standards and rules and associated performance targets been set to govern the entry and exit of road users to and from the road network to achieve the desired focus on results?
  - ✓ For each category of driver (private, commercial, public) are compliance regimes in place to ensure adherence to the specified safety standards and rules to achieve the desired focus on results? …
- Checklist 5: Recovery and rehabilitation of crash victims from the road network (3 questions)
  - ✓ Have comprehensive safety standards, rules and associated performance targets been set to govern the recovery and rehabilitation of crash victims from the road network to achieve the desired focus on results?
  - ✓ For each category of post-crash service are compliance regimes in place to ensure adherence to the specified safety standards and rules to achieve the desired focus on results? …
- Checklist 6: Coordination (4 questions)
  - ✓ Are interventions being coordinated horizontally across agencies to achieve the desired focus on results?
  - ✓ Are interventions being coordinated vertically between national, regional, provincial and city agencies to achieve the desired focus on results?…
- Checklist 7: Legislation (2 questions)
  - ✓ Are legislative instruments and procedures supporting interventions and institutional management functions sufficient to achieve the desired focus on results?
  - ✓ Are legislative instruments and procedures supporting interventions and institutional management functions regularly reviewed and reformed to achieve the desired focus on results? …
- Checklist 8: Funding and resource allocation (4 questions)
  - ✓ Are sustainable funding mechanisms supporting interventions and institutional management functions in place to achieve the desired focus on results?
  - ✓ Are formal resource allocation procedures supporting interventions and institutional management functions in place to achieve the desired focus on results? …
- Checklist 9: Promotion (1 question)
  - ✓ Is road safety regularly promoted to achieve the desired focus on results?
- Checklist 10: Monitoring and evaluation (8 questions)
  - ✓ For each category of roads (national, regional, provincial, city) are sustainable systems in place to collect and manage data on road crashes, fatality and injury outcomes, and all related road environment/vehicle/road user factors to achieve the desired focus on results?
  - ✓ For each category of roads (national, regional, provincial, city) are sustainable systems in place to collect and manage data on road network traffic, vehicle speeds, safety belt and helmet wearing rates to achieve the desired focus on results? …
- Checklist 11: Research and development and knowledge transfer (4 questions)

- ✓ Has a national road safety research and development strategy been established to achieve the desired focus on results?
- ✓ Has an independent national road safety research organization been established to achieve the desired focus on results? …

- Checklist 12: Lead agency role and institutional management functions (9 questions)
  - ✓ Does the lead agency (or de facto lead agency/agencies) effectively contribute to the results focus management function?
  - ✓ Has a lead agency been formally established to direct the national road safety effort to achieve the desired focus on results?...

The hardest to understand and implement are checklists No. 2–4. Therefore, most of the additional questions were related to them.

3.2 EU Road Safety Policy and Checklists

In 2010, the European Commission published a road safety programme intended to span the following decade [2]. The primary objective of the programme was to reduce the total number of road fatalities in the European Union by 50% by the year 2020. The EU Road Safety Policy recognises seven strategic objectives.
In 2017, a project [3] funded by the EU developed road safety performance indicators, also known as checklists, which were used for the purpose of benchmarking and monitoring the following specified objectives:

1. Improve education and training of road users (in total 16 questions split in 5 categories)
   - ✓ Strategic basis
   - ✓ The quality of Pre-test learning…
2. Increase enforcement of road rules (17 questions/4 categories)
   - ✓ Cross-border exchange of information in the field of road safety
   - ✓ Enforcement campaigns…
3. Safer road infrastructure (18 questions/4 categories)
   - ✓ Strategic basis
   - ✓ Legal basis…
4. Safer vehicles (13 questions/3 categories)
   - ✓ Strategic basis for Safer vehicles
   - ✓ Vehicles of today…
5. Promote the use of modern technology to increase road safety -ITS (13 questions/4 categories)
   - ✓ Strategic basis for ITS
   - ✓ ITS Directive…
6. Improve emergency and post-injury services (13 questions/3 categories)
   - ✓ Emergency services
   - ✓ Monitoring of road accidents and consequences…
7. Protect vulnerable road users (13 questions/4 categories)
   - ✓ Powered-two-wheelers
   - ✓ Pedestrians, cyclists…

The EU Road Safety Policy Framework 2021–2030 [4] prioritises the Safe System Approach (SSA) and Key Performance Indicators (KPIs). Nevertheless, it is important to acknowledge that the seven policy objectives continue to hold significant value for the majority of LMICs[5].
The only potential concern relates to the lack of a road safety management objective. The reason for it can be attributed to the nearing completion of the formation of the RSM in EU countries, hence making the inclusion of such a chapter redundant in the second decade.

[5] Low and middle-income country

3.3. Global Road Safety Plan and UN Decade of Road Safety Action Checklists

The United Nations declared the Decade of Action for Road Safety 2011–2020 in March 2010. In September 2020, the UN passed a resolution titled "Improving Global Road Safety." This resolution launched the second Decade of Action for Road Safety 2021–2030. The primary objective of this programme is to reduce road traffic fatalities and injuries by at least 50% by the year 2030.
The WHO, the UN regional commissions, and other collaborating partners within the UN Road Safety Collaboration have developed a Global Plan for the Decade of Action [5,6].
The provided assessment checklists [7] pertain to the five pillars during the initial decade and the SSA components during the subsequent decade:

- Pillar 1: Road Safety Management Capacity (RSMC)
  - ✓ Implementation of UN EU road safety policy framework
  - ✓ Establishment of Lead agency and coordination mechanisms…
- Pillar 2: Safer Roads and Mobility
  - ✓ Road Safety Ownership and accountability
  - ✓ Sustainable urban planning…
- Pillar 3: Safer Vehicles
  - ✓ Minimal vehicle safety standards
  - ✓ NCAP implementation…
- Pillar 4: Safer Road Users
  - ✓ Road safety risk factors identified
  - ✓ Speed management…
- Pillar 5: Post Crash Responses
  - ✓ Pre-hospital care
  - ✓ Care in transit…

UN Decade checklists exhibit a logical and easily implementable structure, making them an ideal choice for researchers in LMICs. This checklist provides a straightforward set of questions that are user-friendly for researchers.

3.4 Compilation (Merging) of Checklists – Tailor-made Checklists

The best practice identifies the WB GRSF RSMCR Guidelines as the predominant approach/model for reviewing road management systems. Inconsistencies among researchers and practitioners have been observed throughout the implementation of guidelines and accompanying checklists. This is an opportunity to expand and improve existing checklists by including additional questions derived from other review models.These modifications have the potential to enhance the overall surveyquality and promote greater consistency in their implementation. Consequently, the process of compiling checklists involves enriching the WB checklist with additional questions from two other checklists to comprehensively elucidate every aspect of the capacity review.
Merged checklists offer a more coherent and applicable set of questions that serve as a guiding framework for researchers/practitioners throughout the review process. This also enables a more unified approach and enhances comprehension of the current road safety situation. It allows a more thorough gap analysis and ultimately guides the selection of appropriate activities that will contribute to the improvement of road safety outcomes.
Figure 1 illustrates the relationship between the WB GRSF RSMCR Guidelines checklists and additional checklists that encompass an expanded set of questions.

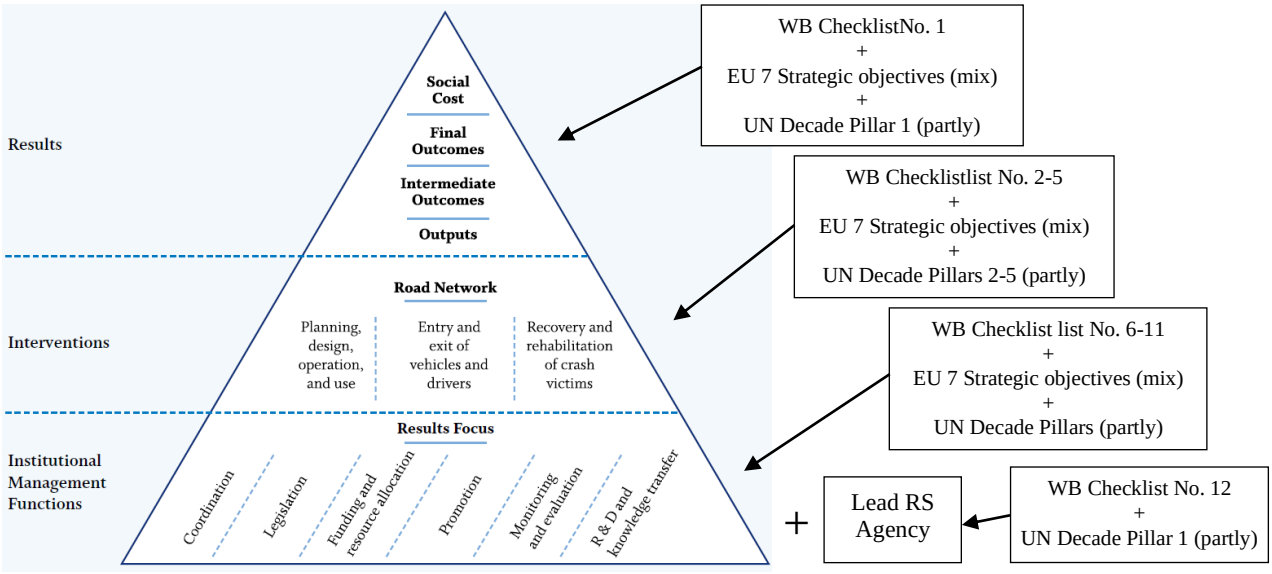

Figure 1. The Road Safety Management System

Source: *Bliss and Breen, 2013 and Project "Technical Assistance for Road Safety Management Capacity Review (RSMCR) and improvements of road safety management capacity at municipality level (Local Communities)", 2023*

4. CONCLUSION

There are several RSMCR approaches that incorporate different checklists within their framework. The authors were among researchers/practitioners who applied all approaches (checklists) and were able to identify shortcomings and propose improvements for their implementation. The significant expansion of checklists occurred within the middle part of the "Pyramid", regarding interventions. These interventions encompass the planning, design, operation, and utilisation of the road network, as well as the entry and exit of vehicles and road users to and from the road network. In order to obtain a comprehensive understanding of the current state of road safety, it was necessary to incorporate additional checklists to encompass a full spectrum of information. Furthermore, the proposed expansion of checklists has led to greater uniformity among researchers of diverse backgrounds. The proposed checklist expansion (merging) was successfully tested and implemented within recent RSMCR projects in Ukraine and North Macedonia.

This research and expansion (merging) of different checklists was successfully tested and implemented thanks to the EIB project in Ukraine[6] and the WB project in North Macedonia[7].

CONSEQUENCES OF TRAFFIC ACCIDENTS IN THE REPUBLIC OF SERBIA IN THE PERIOD FROM 2013 TO 2022 WITH PROPOSED MEASURES TO REDUCE FATAL CONSEQUENCES

Željko Ranković[1], The Academy of Applied Technical Studies Belgrade
Nemanja Deretić[2], Belgrade Business and Arts Academy of Applied Studies
Aleksandra Obradović[3], The Academy of Applied Technical Studies Belgrade

Abstract: *The degree of traffic safety is most quickly assessed on the basis of traffic safety indicators, and most often on the basis of the consequences of traffic accidents. The paper provides an overview of the number of people killed in traffic accidents in the Republic of Serbia in the period from 2013 to 2022 and a comparison of the values of those indicators between two periods: from 2013 to 2017 and from 2018 to 2022. The number of people killed in traffic accidents in the Republic of Serbia, despite many years of efforts to improve the situation, is still unacceptably high. It is particularly important to consider at which stage of the course of events the participants in traffic accidents die, i.e. whether at the scene of the accident or during transport to emergency medical centers or within a period of 30 days after the traffic accident. Based on the consideration of those three components, a proposal for preventive measures to reduce fatalities in traffic accidents during transport and during the treatment of victims of traffic accidents in the Republic of Serbia was given.*
Keywords: Traffic Safety, Traffic Accident, Traffic Safety Indicators, Fatal Consequences

1. INTRODUCTION

How to evaluate the level of traffic safety is one of the basic problems for improving traffic safety. The first method, which still occupies an important place today, is evaluation based on traffic safety indicators, i.e. based on the number of traffic accidents and their consequences. Among the consequences of traffic accidents, the indicator of the number of traffic accidents with fatalities has always had the greatest influence, that is, the number of fatalities, whose impact is evaluated in the professional literature with weights from 99 to 130 (keeping in mind that 1 is the weighting for traffic accidents with material damage). Progress in the approach to evaluating the level of traffic safety was represented by combinations of several single-criteria evaluation methods, as well as multi-criteria methods with the use of multi-criteria decision-making tools, such as the methods: Prometheus, Expert Choice, AHP or Fuzzy logic [1].

Modern views on evaluation included performance indicators of traffic safety, which in the Republic of Serbia began to be measured on the ground in 2013 in 7 groups: use of protective systems (belts and helmets), pedestrian behaviour, presence of alcohol in traffic participants, traffic violations vehicle speeds, use of child restraint systems and characteristics of emergency services after a traffic accident.The average response time of emergency medical assistance in the Republic of Serbia was investigated in 2018 for 27 police departments and ranges from 4.41 minutes (Subotica) to 21.62 minutes (Šabac). The median response time of emergency medical assistance for the Republic of Serbia is 9.71 minutes [2,3,4].

[1]zrankovic@atssb.edu.rs
[2]nemanja.deretic@bpa.edu.rs
[3]aobradovic@atssb.edu.rs

From 2017 onwards, within the Republic of Serbia, the behaviours of road users, including motorised passenger vehicle and motorcycle drivers, as well as non-motorised users like pedestrians and cyclists, have been systematically studied. Following the launch of the inaugural Traffic Safety Strategy in the Republic of Serbia for the 2015 to 2020 timeframe, a system was established to quantify the economic and financial impact of road accidents on the nation and its local communities. This provides a tangible measure which can effectively appeal to potential investors interested in enhancing traffic safety standards.

In addition to all the mentioned methods, the method for evaluating the level of traffic safety, the number of people killed in traffic accidents is the most commonly used indicator for evaluation and as an argument for taking preventive measures and actions. Persons killed in traffic accidents are considered to be: persons whose death occurred on the spot, during transport to a medical facility or within a period of 30 days after the traffic accident. If the proportion of people killed in each of the mentioned stages is observed, it can be concluded that most people are killed at the scene of the traffic accident, but a significant number are killed during transport and in the period of 30 days after the accident [3]. This data points to the need to improve emergency medical services for victims of traffic accidents.

The subject of the work is the investigation of death immediately after a traffic accident (during transport and during treatment) from 2013 to 2022. The aim of the paper is to examine the hypotheses whether there is a significant statistical difference between the two five-year periods 2013-2017 and 2018-2022. year in the distribution of fatal outcomes of traffic accidents on the spot, on the way to the hospital and within 30 days of the accident. The paper consists of four points: Introduction, Number of persons dead in traffic accidents in the period from 2013 to 2022, Proposed measures to reduce death in road traffic and Conclusion.

2. NUMBER OF PERSONS DEAD IN TRAFFIC ACCIDENTS IN THE PERIOD FROM 2013 TO 2022

For the purpose of statistical analysis, two consecutive periods were considered: the first period from 2013 to 2017 and the second period from 2018 to 2022. Understanding the distribution of these fatalities over time can offer insights into the effectiveness of traffic safety measures and interventions.In Table 1, data is displayed regarding the total number of fatalities in traffic accidents (Fatalities), the number of individuals who died on the scene of traffic accidents (Fatalities at the scene), the number of individuals who passed away during transport to a medical facility (Fatalities en route to hospital), and the number of individuals who subsequently died within 30 days as a result of traffic accidents (Fatalities within 30 days) by year for the period from 2013 to 2022.The basic descriptive parameters (Mean, StDev, Sum, and Median) for the observed periods 2013-2017 and 2018-2022 are provided in Table 2.

In the analysis of the number of fatalities in traffic accidents in the Republic of Serbia over two consecutive five-year periods, the use of the Mann-Whitney U test was chosen as an alternative to the T-test for independent samples. This choice was motivated by several key reasons. Firstly, given that each period contains only five values, the assessment of normality and homogeneity of variances can be unreliable, making traditional parametric tests less suitable. Additionally, the Mann-Whitney U test, as a non-parametric method, does not make assumptions about the normality of data distribution, making it more robust in this context.Finally, this test demonstrates greater resilience to potential outliers that could disproportionately affect the results of the T-test, especially when dealing with small samples.Taking everything into account, the Mann-Whitney U test proved to be the optimal approach for comparing the number of fatalities in the mentioned periods, providing reliable and relevant statistical conclusions.

Source: *Authors' research*

Variable	Mean	StDev	Sum	Median
Fatalities 2013-2017	594.20	41.60	2,971	599
Fatalities 2018-2022	529.60	24.50	2,648	534
Fatalities at the scene 2013-2017	354.40	24.80	1,772	345
Fatalities at the scene 2018-2022	309.80	20.61	1,549	315
Fatalities enroute to hospital 2013-2017	84.80	23.10	424	81
Fatalities en route to hospital 2018-2022	57.00	6.78	285	56
Fatalities within 30 days 2013-2017	155.00	28.90	775	154
Fatalities within 30 days 2018-2022	162.80	5.45	814	163

The results of the Mann-Whitney U test are provided in Table 3.

Table 3. Results of the Mann-Whitney U test for comparing medians for the periods 2013-2017 and 2018-2022 (Test of $\eta 1 = \eta 2$ vs $\eta 1 \neq \eta 2$)
Source: *Authors' research*

Variable	n	Median	Point estimate $\eta 1 - \eta 2$	W	p-value
Fatalities 2013-2017	5	599	59	38	0.0367*
Fatalities 2018-2022	5	534			
Fatalities at the scene 2013-2017	5	345	36	40	0.0122*
Fatalities at the scene 2018-2022	5	315			
Fatalities enroute to hospital 2013-2017	5	81	23	39	0.0216*
Fatalities enroute to hospital 2018-2022	5	56			
Fatalities within 30 days 2013-2017	5	154	-9	25	0.6761
Fatalities within 30 days 2018-2022	5	163			

Note: * p-value is less than the usual significance threshold of 0.05, hence there is sufficient evidence to reject the null hypothesis. In other words, there is a statistically significant difference between the two consecutive periods.

Between 2018 and 2022, there was a noted decline in the total number of fatalities in traffic accidents compared to the period from 2013 to 2017, where the number decreased from 2,971 to 2,648, representing a drop of 10.87%. During the same years (2018-2022), the number of individuals who lost their lives at the accident scene reduced from 1,772 to 1,549, indicating a

decrease of 12.58%. In that span, there was also a noticeable decline in the number of individuals who passed away while being transported to the hospital, with the figure dropping from 424 to 285, a stark decrease of 32.78%. However, in the period from 2018 to 2022, there was an observed rise in the number of individuals who died within 30 days due to injuries from traffic accidents, increasing from 775 to 814, marking an increase of 5.03%.

The number of fatalities was divided in the analysis into two consecutive five-year periods based on the timing or timeframe of their death after the traffic accident. To analyse trends in the number of fatalities from traffic accidents across two consecutive five-year periods (2013-2017 and 2018-2022), the following hypotheses were set:

- H0: There is no significant difference in the distribution of fatalities in traffic accidents (Fatalities at the scene, Fatalities enroute to hospital, Fatalities within 30 days) between the two specified five-year periods;
- H1: There is a significant difference in the distribution of fatalities in traffic accidents (Fatalities at the scene, Fatalities enroute to hospital, Fatalities within 30 days) between the two specified five-year periods.

To test the set hypotheses, the Chi-square test for independence was used. This test allows for the comparison of the distribution of fatalities from traffic accidents between the two five-year periods and determining if there are significant differences in the distributions across the three categories of fatalities. The results of the Chi-square test for independence indicated a statistically significant difference in the distribution of fatalities across the two consecutive five-year periods according to categories (Fatalities at the scene, Fatalities enroute to hospital, Fatalities within 30 days). The Pearson Chi-Square value was 24.697 with 2 degrees of freedom (DF = 2), and a p-value less than 0.001 ($p < 0.001$). Similar results were obtained using the Likelihood Ratio Chi-Square, which was 24.794 with 2 degrees of freedom (DF = 2) and a p-value less than 0.001 ($p < 0.001$). In the distribution of fatalities across the two consecutive five-year periods according to categories, the most notable decrease was in the frequency related to the variable "Fatalities enroute to hospital", from 14.27% (2013-2017) to 10.76% (2018-2022). Meanwhile, the frequency increased for the variable"Fatalities within 30 days", from 26.09% (2013-2017) to 30.74% (2018-2022). The frequency for the variable"Fatalities at the scene" remained nearly unchanged, 59.64% (2013-2017) and 58.50% (2018-2022).

3. PROPOSED MEASURES TO REDUCE DEATH IN ROAD TRAFFIC

This paper does not include measures to reduce the number of people killed in traffic accidents on the spot (58.5% of all traffic accident fatalities), which are a consequence of the traffic conditions that preceded the traffic accident and elements of active and passive safety of vehicles, roads and participants in a traffic accident.

In the Republic of Serbia, from 2018 to 2022, 10.76% of traffic accident victims died during transport to a health facility. Additionally, 30.74% died within 30 days of the accident. This accounts for a total of 1,099 people killed in traffic accidents over five years. These figures suggest that non-traffic factors in the prevention of traffic accidents have been largely overlooked. This oversight is particularly significant considering that "Care after a traffic accident" is recognized as Pillar 5 in the safety management of traffic, as outlined in the Global Plan of the Decade of Action for Road Safety 2021-2030 [5]. Measures to improve traffic safety management within Pillar 5 are systematized in five levels: Legislation (improvement of standards for data collection during response and investigation after a traffic accident), Enforcement (supervision of rescue services and investigators who analyse a traffic accident), Education (service training first aid and rescue assistance), Technology (necessary equipment and modern equipment technologies) and International regulatory support, which is based on consolidated resolution by WP.1 and standards.

By implementing the above four groups of measures and international regulatory support, it is possible to achieve a reduction in fatalities in traffic accidents. Within the "Legislation" group of measures, it is necessary to improve standards and procedures, as well as their implementation. The

implementation of the EN 1789 standard (Medical vehicles and their equipment - Road ambulances) is particularly important. In addition to the application, the criteria for how emergency medical services for rescuing victims of traffic accidents, in addition to the basic type of Patient transport ambulances (Types A1 and A2), should also be equipped with ambulance vehicles of the following categories: Emergency ambulances (Type B) and Emergency ambulances (Type C). Emergency ambulances (Type B) are the most seen type of emergency ambulance. Mobile intensive care unit (Type C) is a type of ambulance which is commonly seen in the movement of high-acuity patients between hospitals. It provides adequate space for not only the medical equipment commonly seen in ambulances, but also to accommodate hospital equipment, such as ventilators, during transport [6].

A completely different approach, which can also significantly reduce the number of fatal consequences in the period after a traffic accident, is the establishment of emergency medical assistance during the so-called "Golden hour" [7]. The "Golden hour" is the term often used in trauma or emergency care to suggest that an injured or sick person must receive definitive treatment within the first 60 minutes from the time of injury or appearance of symptoms. It was believed that once this time has lapsed, the risk of death or long-term complications will significantly increase. During road traffic accidents, intervention done in the first few minutes might determine if the person will live or die. The main principle in managing the victim here is to stabilize their Airway, Breathing, and Circulation and carry them to the nearest hospital. If this is not possible, a "scoop and run" approach rather than "stay and play" is encouraged. This means rather than wasting time giving improper first aid at the site of injury (and searching for help in vain), it is better to get the victim to the hospital as soon as possible. That being said, the potentially life and limb saving interventions (a tracheostomy, an epinephrine injection, intravenous fluids, splinting the broken bones, and collecting amputated toes/fingers in ice and carrying them along with the patient) [8,9]. Activities to save the life of a traffic accident victim within the "Golden hour" are shown in Fig. 1.

In the Republic of Serbia, there were projects to create an emergency medical service based on the "Golden hour" principle, with the provision of helicopter transport of severely injured victims of traffic accidents within a radius of 100 km, but, unfortunately, that idea has not been realized to date. In the Republic of Serbia, there are all the preconditions for the return of the Helicopter Service to the roads of Serbia, which was abolished in 1990.

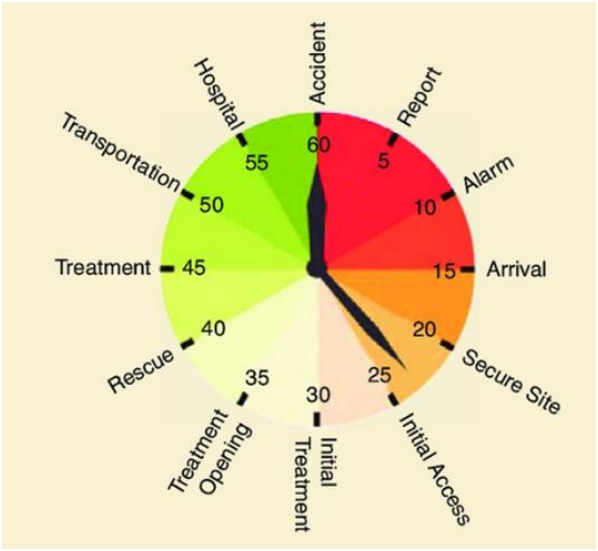

Figure 1. "Golden hour" in a car accident
Source: *Martinez F., Toh C., Cano J., Calafate C., Manzoni P.: Emergency Services in Future Intelligent Transportation Systems Based on Vehicular Communication Networks*

In the area of "Implementation" it is not only necessary to introduce the supervision of the rescue services, but it is more important to improve the coordination of those services. Within the field of "Education", the training of the population in terms of first aid, the training of all subjects in the

chain of information from the scene of the accident to the rescue services, and especially the specialist training of persons in medical institutions and ambulances of all three categories (A, B and C). Within the field of "Technology", it is necessary to improve the equipment in medical institutions and vehicles, i.e. to have in vehicles of type B and C the same equipment that will be able to be used in the field, that is, to have reliable sources of electricity and technical gases necessary for providing assistance to victims of traffic accidents.
In the Republic of Serbia, the Rulebook defines the necessary equipment for medical institutions and emergency medical assistance, including the equipment in standard emergency medical assistance vehicles of health centres, transport vehicles and special medical vehicles [10].

4. CONCLUSION

The number of fatalities has a dominant effect on the amount of damage that the state has as a result of traffic accidents. That number can and should be reduced, both in terms of persons who died at the scene of a traffic accident, as well as after the accident, in transport and during treatment. Given that, the goal of the work is directed towards measures to reduce death, especially in transport and during treatment, i.e. after the accident, it can be concluded that the share of deaths of participants in traffic accidents is about 41.5% of the total number of people killed in traffic accidents in the R. of Serbia.
The proposed measures are, in accordance with the document Global Plan of the Decade of Action for Traffic Safety 2021-2030, systematized in five levels: improvement of legislation, improvement of application, improvement of education of subjects and procurement, application of modern technologies and equipment and international regulatory support. The measures of equipping medical facilities and emergency vehicles with the necessary equipment for more advanced care and monitoring of the condition of the injured (type C vehicles) and the establishment of a system for providing assistance to victims of traffic accidents according to the "Golden Hour" model were particularly highlighted.

STATISTICAL ANALYSIS OF TRAFFIC ACCIDENTE ON STATE ROADS IN THE WORK ZONE ON THE TERRITORY OF THE REPUBLIC OF SERBIA FOR THE PERIOD FROM 2014 TO 2021

Aleksandra Obradović[1], The Academy of Applied Technical Studies Belgrade
Dalibor Pešić[2], Faculty of Transport and Traffic Engineering, University of Belgrade
Željko Ranković[3], The Academy of Applied Technical Studies Belgrade

Abstract: *Globally, road traffic accidents cause almost 1.3 million deaths and around 50 million serious injuries each year – making it the leading cause of death for children and youth in the world (WHO, 2021). As the number of motorized traffic developments has increased over time, so has the demand for better and safer roads. In order for the state to respond to the existing demands, which are almost reaching saturation, it is necessary to provide all vehicles with the appropriate capacity of roads, which leads to the need for the reconstruction of existing ones. In most cases, when carrying out works on certain sections of the road, there is no alternative direction to which traffic flows can be diverted, so in that case, the work zone becomes a potentially dangerous place. The part of the work zone that is the most risky for the occurrence of traffic accidents, especially with fatal consequences, is the construction site itself. The transition from the normal traffic regime, without interruptions and unusual situations, to the traffic regime in the work zone must be gradual, clearly marked and noticeable. The aim of this work is to present the results of statistical processing of data from the Database of the Agency for Traffic Safety, on the basis of which it is necessary to investigate which attributes, in the capacity of the road factor, can affect the occurrence of a traffic accident in the work zone on state roads. The paper will show the relationship between the attributes of traffic accidents in the work zone.*
Keywords: traffic safety, road works zone, database, statistical analysis

1. INTRODUCTION

Managing a system or process means taking management measures to bring the current state of the system closer to the target (desired) state (Vujanić, et al., 2011). As the number of motorized traffic developments has increased over time, so has the demand for better and safer roads. In order for the state to respond to the existing demands, which are almost reaching saturation, it is necessary to provide all vehicles with the appropriate capacity of roads, which leads to the need for the reconstruction of existing ones. In most cases, when carrying out works on certain sections of the road, there is no alternative direction to which traffic flows can be diverted, so in that case, the work zone becomes a potentially dangerous place. The part of the work zone that is the most risky for the occurrence of traffic accidents, especially with fatal consequences, is the construction site itself.
The transition from the normal traffic regime, without interruptions and unusual situations, to the traffic regime in the work zone must be gradual, clearly marked and noticeable. In the Republic of Serbia, there is a Rulebook on how to regulate traffic on roads in the work zone, which clearly defines what is meant by safely marked work zones, from the traffic aspect. The road as one of the traffic safety factors affects vulnerable traffic participants.

[1]aobradovic@atssb.edu.rs
[2]d.pesic@sf.bg.ac.rs
[3]zrankovic@atssb.edu.rs

According to road classification, highways are the safest, while city streets are the least safe. On open roads for mixed traffic, the risk of an accident is three times higher, while on city streets it is six times higher. According to world experience, the road itself or in combination with other factors is the cause of approximately one third of all traffic accidents. The aim of this work is to present the results of statistical processing of data from the Database of the Agency for Traffic Safety, on the basis of which it is necessary to investigate which attributes, in the capacity of the road factor, can affect the occurrence of a traffic accident in the work zone on state roads. The paper will show the relationship between the attributes of traffic accidents in the work zone.

2. METHODOLOGY

For work purposes, a database was created with the help of data obtained from the Agency for Traffic Safety for the period from 2014 to 2021. The created database consisted of all traffic accidents that occurred in the work zone for the period from 2014 to 2021. 394 traffic accidents were analyzed and 9 attributes were shown for each. When selecting attributes, it is necessary to clearly define those attributes that are necessary for the analysis of traffic accidents. Also, errors in the data can often occur in large databases, so before the very beginning a check of the existing data was carried out, which included a logical check of the entered data, as well as the completeness of all information necessary for further analysis.

The presented results were processed with the help of the software program for data analysis and processing SPSS Statistics version 26.0. The mentioned program works according to the principle of numbers, that is, it is necessary to assign a specific code (code) to the received data, which the program will be able to process and recognize.

Given that the subject of this paper is the analysis of traffic accidents in the work zone on state roads, the attributes related to the type of accident that occurred, the category of the road, whether the accident occurred in the settlement or outside the settlement, characteristics and condition of the roadway, lighting were analysed. At the time of the accident, as well as the existence of street lighting as well as a group of influential factors.

For further statistical analysis, the attributes related to the type of accident, road category and TA type groups are shown as independent variables, while the attributes related to settlement/non-settlement, road condition, road characteristics, street lighting, lighting, groups of influential factors viewed as dependent versus independent variables.

In order to determine the strength of the relationship between the mentioned divisions, several statistical analyses were conducted at different intersections of the obtained data (descriptive analysis, non-parametric tests and correlation).

Descriptive analysis was used as the simplest display and analysis of data, which calculates, displays and describes the characteristics (parameters) that represent the attributes of traffic accidents. Descriptive data analysis is suitable for the initial presentation, because it shows the importance of the topic of the work, as well as the obtained results, in the simplest and most transparent way. With the help of descriptive analysis, the paper shows the mean value and mean standard deviation of the attributes related to the type of accident, road category, groups of traffic accident types and groups of influencing factors.

After descriptive analysis, Spearman correlation testing between attributes was conducted to show the strength of relationships. The values that can be obtained are in the range from -1 to 1, which means that if they are negative, then by influencing the increase of one attribute, the value of the other with which it is correlated decreases, and if the value is positive, changing the value of one attribute proportionally it increases the value of the other with which it is correlated. If the correlation value between two attributes is 0, it means that there is no correlation between them.

3. RESULTS AND DISCUSSION

For the period from 2014 to 2021, 394 traffic accidents (TA) were analysed in the work zone on state roads, of which 62.7% were traffic accidents with material damage, 33.0% TA with an injured person and 4.3% TA with a dead person. The mean value of the analysed database represents the central value of the observed attribute in relation to its analysed elements, while the standard deviation represents how much on average the elements deviate from the mean value of the attribute, i.e. in what range the data can appear. The mean value of the type of accident is 2.58, and based on the standard deviation, we can see that the obtained data can most often appear in the range from 2.01 to 3.

Based on this analysis, we can come to the conclusion that the largest number of traffic accidents that occurred in the work zone for the analysed period resulted in an injured person or property damage. When it comes to the road category, based on the obtained values (1.58±0.72), the most traffic accidents occur on higher-ranked sections (state road IA and IB order). The analysis of groups of types of traffic accidents also recorded accidents with pedestrians, which are very specific in such traffic accidents (state road and work zone), that is, they are considered very rare in the literature. Also, based on the processed literature, the importance of marking and visibility of the workers themselves, who are pedestrians, in the work zone is pointed out and discussed. Even if the work zone itself is not adequately marked, it is necessary to mark the workers and provide adequate visibility to the drivers themselves in order to further reduce the number of traffic accidents in the work zone on state roads where vehicles move at high speeds. When we look at groups of influencing factors, the main influencing factor is the influence of the driver, while the next factor is the influence of the road. Because of the data obtained in this way, it is necessary to further analyse the elements of the road and the environment in order to see their correlation with the occurrence of traffic accidents in the work zone.

When it comes to the work zone, the most traffic accidents were recorded on the section of the IA state road, which represents the section of the highest rank. The largest percentage of the mentioned traffic accidents resulted in material damage, as well as the fact that they occurred on sections outside the settlement. The largest number of traffic accidents in the work zone, which occurred on sections of the settlement, were recorded on the IB state road. Also, the highest percentage of traffic accidents resulted in material damage.

By analysing the group of types of traffic accidents in the work zone on state roads, it was expected that the number of traffic accidents involving pedestrians was the lowest, but traffic accidents involving pedestrians were recorded, resulting in the death of a person. Also, these accidents occurred on state road IA and IB, where higher speeds are allowed than on other state roads, which additionally shortens the driver's reaction time, as well as increases the length of braking when an obstacle is detected. Traffic accidents with one vehicle represent the most common group of types of traffic accidents, as well as traffic accidents with at least two vehicles without turning.

Table 1 shows the values of the Spearman correlation coefficient between the attributes defined as independent and all other attributes. The highest positive correlation is achieved between the attributes related to TA type groups and the group of influencing factors (0.337), as well as between the road category and pavement characteristics (0.331), while the highest negative correlation is achieved between the attributes related to the TA type group and street lighting (-0.284).

There is almost no correlation between the attributes related to the type of accident and the characteristics of the pavement, as well as the road category and street lighting.

Table 1. Value of the Spearman correlation coefficient

	Road condition	Pavement characteristics	Street lighting	Groups of influencing factors
Type of accident	0,024	0,008	-0,047	0,099
Type groups	0,032	0,162	-0,284	0,337
Road category	0,239	0,331	0,002	-0,060

4. PROPOSED MEASURES FOR IMPROVING TRAFFIC SAFETY IN THE ROAD WORK ZONE

Due to the observed problem, it is necessary to adequately mark the road work zone. This approach increases the level of safety of all traffic participants, as well as road contractors. Given that the most common influence of traffic accidents is the human factor, it is necessary to place frontal, vertical and/or horizontal obstacles at the approach to the work zone itself, which would further increase the visibility of the work zone, as well as provide additional notice to drivers that they are encountering, finding or passing through the zone of works on the section. Also, the importance of street lighting in the occurrence of traffic accidents in the work zone has been observed, so in addition to the obstacles, it is proposed to install flashing lights that would increase the level of illumination in the work zone. In addition to the installation of light signals, adequate equipment and contractors are necessary to make them more visible to drivers. The following photos show an example of the contractor's adequate equipment.

The basic proposal of the measure refers to the application of Intelligent Transport Systems (ITS) in traffic, which would enable better coordination and self-management of all actions in the work zone, thus improving the level of service in dynamic traffic. Also, if there are no conditions for the installation of changeable traffic signals, it is suggested to install a traffic light that would stop and allow vehicles alternately in the work zone. As the most common type of traffic accident with a single vehicle, using ITS would provide drivers with all the necessary information in a timely manner, which would reduce vehicle collisions, i.e. the most common type of traffic accident.

As another form of notification to drivers in traffic that they are encountering a work zone, in addition to adequate vertical signalling, the proposed measure would refer to the installation of vibrating strips, as well as the marking of dividing lines, where a sound would be produced every time a tire passes over a colored part of the line, which would was an additional warning for all drivers.

5. CONCLUSION

On the territory of the Republic of Serbia for the analysed period from 2014 to 20201, the most traffic accidents occurred during daylight hours, due to reckless actions by drivers in traffic accidents with at least two vehicles - without turning. Driving on the part of the road where works are being carried out is one of the most dangerous traffic situations because:

- Before the start of the area where the work zone is located, there may be traffic congestion, as well as the movement of vehicles according to the start/stop principle,
- There is a change in the traffic regime - driving through the construction zone is always a "bottleneck",
- It leads to a big loss of time if the capacity of the section is filled, which can lead to a decrease in concentration and nervousness among drivers,
- If there is very little saturation of the traffic flow, a traffic accident may occur, because the driver does not expect a dangerous situation on the road.

Due to increasing demands, even a small intensity of works on the road leads to a change in the traffic flow and a new service. One of the most important factors in the work zone is the competent authorities. The competent Ministry is responsible for traffic regulation at the national level, while the local self-government is responsible for traffic affairs at the local level. In order to improve the level of traffic safety in the work zone, in 2016 the competent Ministry adopted the Rulebook on the manner of regulating traffic on roads, as well as the Public Company "Roads of Serbia", which has a contract with the competent Ministry for the maintenance and management of state roads. Which in the same year published the document Technical instructions for marking the zones of work on the maintenance of state roads in the Republic of Serbia. Everything that is defined by the mentioned documents, and refers to marking and warning with temporary traffic signals in the work zone, it is necessary to constantly monitor and check the adequacy of its application so that the observed omission can be changed or supplemented in time in order to prevent the occurrence of a traffic accident.

The number of traffic accidents, which resulted in a person being killed or injured during the previous years, constantly leads to the conclusion that it is necessary to educate all traffic participants, as well as to increase the level of control of violations and negligent actions in the work zone. It is necessary to work to ensure that warning signs for marking obstacles on the road are always in an adequate place marked with adequate traffic signals, because if the work zone is, for example, on a highway, it is necessary to place repeating signs, of larger dimensions, due to the high speeds that are allowed on the mentioned sections. The local community can greatly contribute to increasing the level of safety in the work zone, because it can demand that the Investor has adequate project documentation for the execution of road works, and that the Contractor marks temporary traffic signals in the road work zone in accordance with the project documentation. Inadequate temporary traffic signals lead to the invisibility of the road works zone, which can lead to the collision of a vehicle in a convoy due to inappropriate speed, a head-on collision with a physical obstacle if the work zone is located in the traffic lane in which the vehicle moves, aggressive driving to compensate for lost time, which represents only some of the causes of traffic accidents in the road works zone.

ANALYSIS OF SAFETY OF CYCLISTS IN TRAFFIC IN THE CITY OF SMEDEREVO FROM 2018 TO 2022

Lazar Kocić[1], Faculty of Transport and Traffic Engineering, University of Belgrade
Aleksandra Obradović[2], The Academy of Applied Technical Studies Belgrade

Abstract: *In the Republic of Serbia, on average, on an annual basis, about 60 cyclists are killed in traffic accidents, and about 1600 cyclists are injured. Every eleventh person killed in traffic is a cyclist and every fourteenth person injured is also a cyclist. Cyclists are most often killed by passenger cars, then by trucks (trucks), and a significant percentage of deaths are also due to their own carelessness or accidents and falling off their bicycles. The purpose of this work is to examine the causes of traffic accidents involving cyclists in the territory of the city of Smederevo with the help of data from the Database of the Traffic Safety Agency. The paper will show locations, critical points, as well as the main causes of traffic accidents involving cyclists in the city of Smederevo.*
Keywords: *traffic accidents, cyclist, critical points*

1. INTRODUCTION

Cyclists are often killed in traffic. There are several reasons for that. The key problem is that cyclists are the most vulnerable category in traffic, because they suffer serious injuries at relatively low speeds. This is because they have no protection. A helmet (if they have one) and shields cannot protect them from being hit by a car. The speed of vehicles involved in traffic accidents with cyclists plays an important role, because the consequences are significant. Bicycle drivers are hard to see for other road users because they are very small in comparison to the size of cars, trucks, etc. This is especially pronounced in night conditions, conditions of low visibility (fog or rain), and if they do not have appropriate lights and clothing. This is an obligation from ZoBS, Art. 81, paragraph 5that every bicycle should have a red flashing light at the rear and white at the front. Also, the bicycle rider should wear bright clothing, i.e. clothing with fluorescent, reflective details. Cyclist safety also depends on age. Younger cyclists are physically fitter, have faster reflexes and can react much more skillfully if they find themselves in trouble. Elderly drivers have reduced powers of observation, mobility and often cannot react in time. Children are a category that, apart from experience and routine, also lacks speed and reflexes. Safety is also affected by the traffic environment. Most cyclists move on the road, because there are few cities and municipalities in the Republic of Serbia that have enough and safe cycling paths. Car drivers do not look favorably on cyclists in traffic. Cyclists are seven times more likely to die than car passengers. This is confirmed by the official data of thehttps://www.abs.gov.rs/. Also, men suffer more than women.

2. SAFETY OF CYCLISTS IN TRAFFIC IN THE REPUBLIC OF SERBIA IN THE PERIOD FROM 2018 TO 2022

The key problem when it comes to the safety of cyclists in traffic is their vulnerability, given that even at relatively low speeds they often suffer serious bodily injuries, mainly because their only

[1]lkocic@ atssb.edu.rs
[2]aobradovic@atssb.edu.rs

protection is their clothing. The speed of vehicles involved in a collision with cyclists plays an important role, when the severity of the consequences of the accident is in question. Cyclists are often hard to see for other road users compared to cars. Poor visibility of cyclists is a particular problem in nighttime visibility conditions, especially if the bicycle is not equipped with proper lights (white light on the front and red light on the back of the bicycle) and if the cyclists do not wear bright clothing, i.e. clothing with retroreflective materials. Traffic accidents involving cyclists, due to their great vulnerability, often result in fatalities. On average, in the period from 2018 to 2022, about 1,515 accidents were registered in the Republic of Serbia during the year in which one of the participants was a cyclist. Of all recorded accidents in the Republic of Serbia, 7.57% were cyclists. On average, about 48 cyclists are killed and about 1,468 cyclists are injured in TA in the period from 2018 to 2022 (Figure 1) [1].

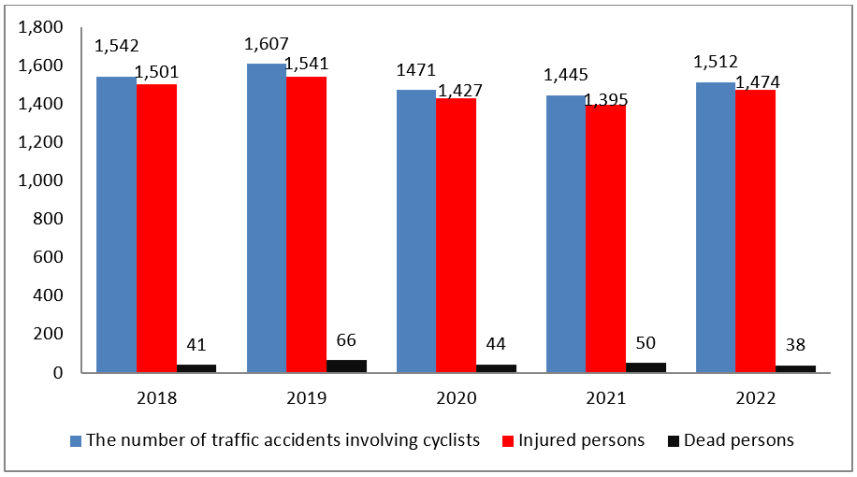

Figure 1. Number of traffic accidents involving cyclists in R. Serbia, as well as the number of dead and injured cyclists in the period from 2018 to 2022
Source: *Agency for Traffic Safety, Republic of Serbia, https://vvv.abs.gov.rs/*

3. SAFETY OF CYCLISTS IN TRAFFIC IN THE PERIOD FROM 2018 TO 2022 IN THE CITY OF SMEDEREVO

In the observed five-year period, a total of 50 traffic accidents involving cyclists occurred, of which 3 traffic accidents resulted in fatalities and 47 traffic accidents resulted in injuries, of which 11 resulted in serious bodily injuries and 36 with minor injuries. In Figure 3.1, it can be seen that there is a trend of decreasing the number of traffic accidents with injured persons in which cyclists participated. The total number of dead cyclists is 3, which is 6% of the total number of people killed in traffic accidents in the city of Smederevo in the observed period, while the number of injured cyclists is 47, which is 3% of the total number of people injured in traffic accidents in the city of Smederevo (Figure 2) [2, 3].

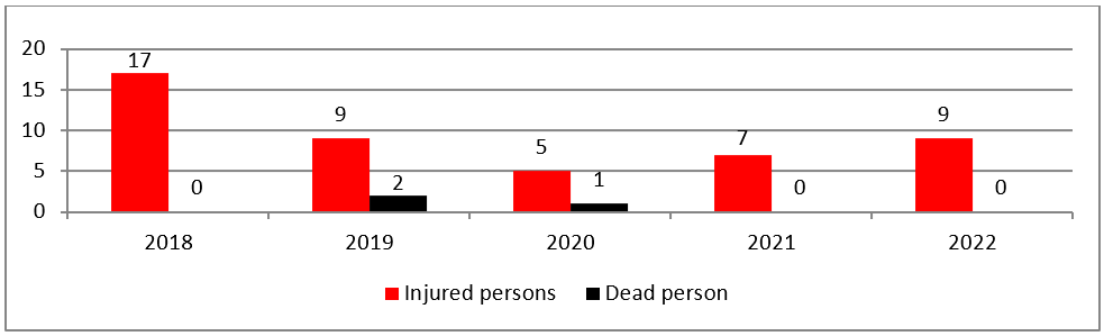

Figure 2. Number of injured and dead cyclists in the city of Smederevo, in the period from 2018 to 2022
Source: *Agency for Traffic Safety, Republic of Serbia, https://vvv.abs.gov.rs/*

In the observed five-year period, the most injured cyclists in the territory of the city of Smederevo were between the ages of 46-64 and 65+ (Figure 3).

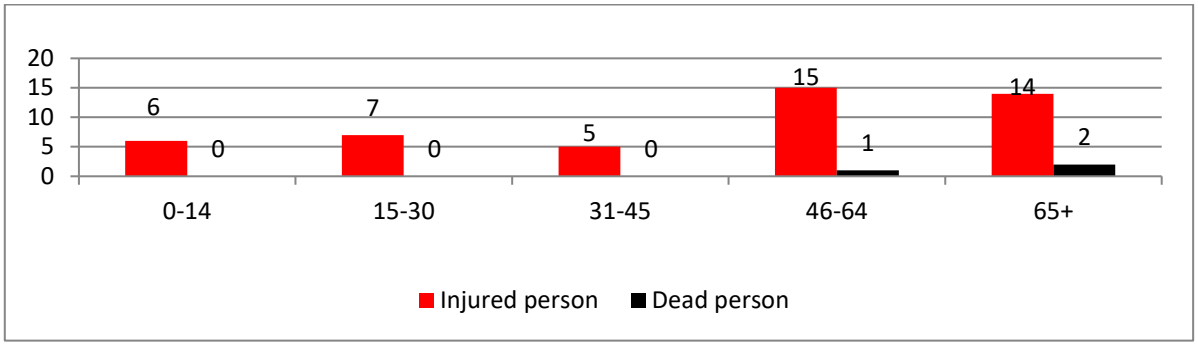

Figure 3. The number of injured and dead persons by old groups in the city of Smederevo, in the period from 2018 to 2022
Source: *Agency for Traffic Safety, Republic of Serbia, https://vvv.abs.gov.rs/*

On average, about 67% of fatal traffic accidents involving cyclists occurred outside the settlement, and about 33% of fatality occurred in the settlement. When it comes to road accidents with injuries, and in which cyclists participated, suffering is more pronounced in the settlement (89% of road accidents with injured cyclists occurred in the settlement, ie 11% outside the settlement), Figure 4 [3].

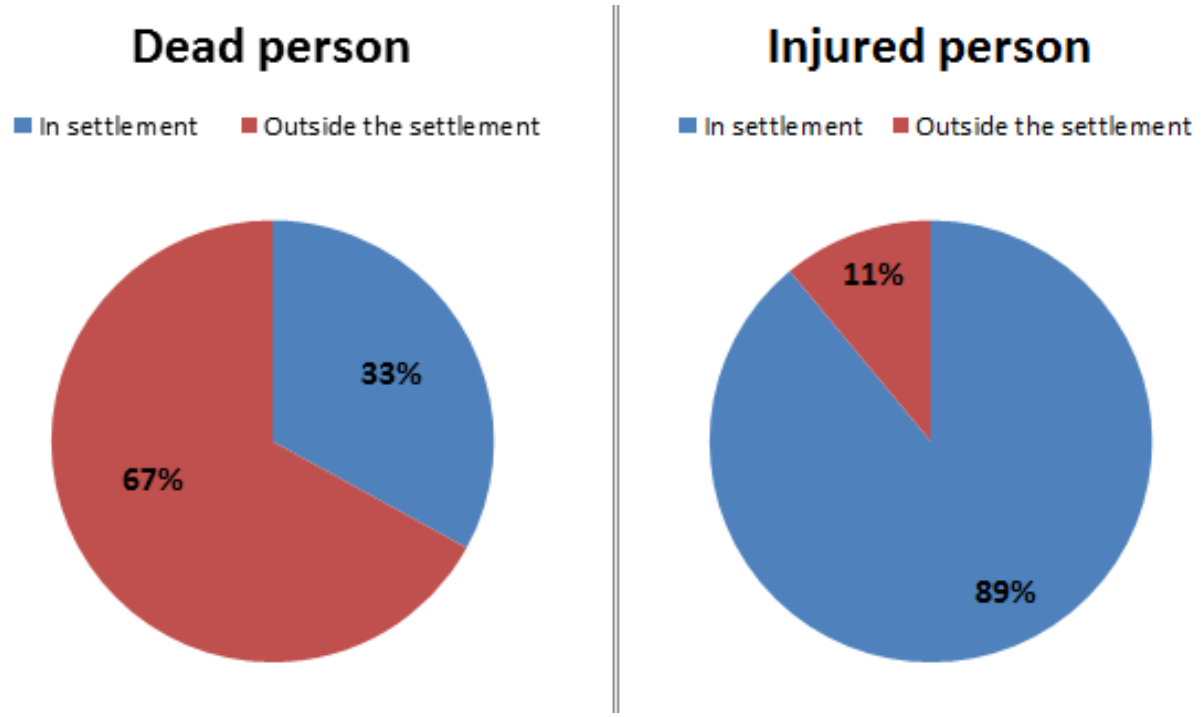

Figure 4 Distribution of traffic accidents with fatalities and injuries involving cyclists in the settlement/outside the settlement, in the period from 2018 to 2022
Source: *Agency for Traffic Safety, Republic of Serbia, https://vvv.abs.gov.rs/*

The places where traffic accidents with dead cyclists occurred in the city of Smederevo are shown in Figure 5, two cyclists died outside the settlement, while one cyclist died in the settlement [3].

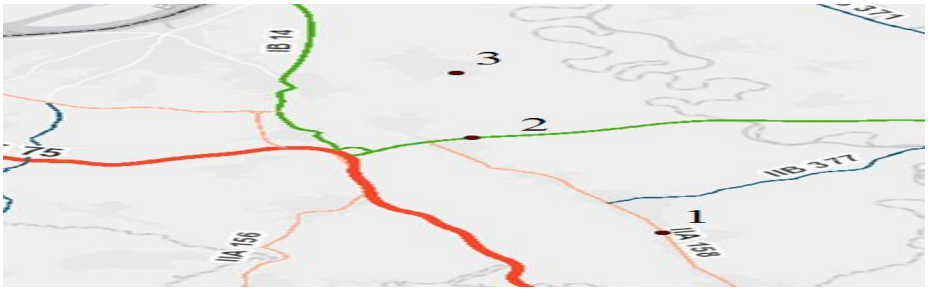

Figure 5. Places of traffic accidents with dead cyclists in the city of Smederevo, in the period from 2018 to 2022
Source: *Agency for Traffic Safety, Republic of Serbia, https://vvv.abs.gov.rs/*

Traffic accidents with dead cyclists occurred during a sudden change in the direction of movement, unadjusted speed for traffic conditions and road conditions, lack of a bicycle path or lane in the settlement and when driving under the influence of alcohol.
In the observed five-year period, the most traffic accidents with injured cyclists occurred in the settlement on the road (71%) and intersection (29%). As many as 49% of traffic accidents with injured cyclists happened in the very center of the city. Figure 6 presents traffic accidents with injured cyclists as well as critical points 1 and 2 in the city of Smederevo [3].

Figure 6. Places of traffic accidents with injured cyclists and critical points in the city of Smederevo, in the period from 2018 to 2022
Source: *Agency for Traffic Safety, Republic of Serbia, https://vvv.abs.gov.rs/*

The largest number of traffic accidents with injured cyclists at critical points 1 (intersection 17. October) and critical points 2 (state road IB 14 row) were caused by non-compliance with traffic regulations, properties of the intersection itself, as well as malfunctions of bicycle lights (white front light and red rear light), (Figure 7).

Figure 7. Critical Point 1 and Critical Point 2
Source: *https://www.google.rs/maps/*

4. CONCLUSION

The city of Smederevo does not have a single bicycle path, which is a big problem for both the safety of cyclists and other road users. Based on the data collected in this work, the biggest problem in the city of Smederevo is insufficiently illuminated roads and intersections, as well as defective bicycle lights (front white and rear red). Which leads to misjudgment of motor vehicles when catching up with bicycles, thus leading to a traffic accident with a stiff face. The causes that lead to traffic accidents with cyclists in the city of Smederevo, as well as in other cities of the Republic of Serbia, are exceeding the permitted speed of motor vehicles, failure to yield the right of way cyclists, as well as the lack of infrastructure or infrastructure in very poor condition. If there is no adequate infrastructure and if the conditions for the safe movement of cyclists are not provided, cyclists can be endangered in traffic, primarily by motor vehicles. Since protective helmets and light-reflecting vests are not mandatory for cyclists, as an alternative, cyclist associations propose the construction of more separate paths for cyclists in all cities of the Republic of Serbia, the introduction of the concept of bicycle streets in which cyclists would have priority, the expansion of zones 30 and slow traffic zones, more frequent controls speeds in cities and the introduction of speed cameras, technical measures to slow down traffic, allowing bicycles to move in two directions in some one-way streets, regulating the movement of bicycles with yellow strips, if there is no bicycle path as an alternative, and defining a mandatory safe distance for overtaking cyclists by motor vehicles vehicles. In order for cyclists to be as safe as possible in traffic in the city of Smederevo, and in the entire Republic of Serbia, apart from work on improving the cycling infrastructure, emphasis should be placed on the correctness of bicycle lights. Only about 10% of cyclists in the entire Republic of Serbia use front (white) and rear (red) lights according to regulations.

THE LENGTH OF DILEMMA ZONE AT SIGNALIZED INTERSECTIONS

Biljana Ranković Plazinić[1], The Academy of Applied Technical Studies Belgrade
Aleksandra Obradović[2], The Academy of Applied Technical Studies Belgrade

Abstract: *Yellow traffic light at a signalized intersection is a time period during which drivers decide whether to stop the vehicle or to proceed through the intersection, according to their perception is that decision is safe or not. The aim of this paper is to investigate at what distance to the stop line drivers have a "dilemma" related to which decision they will make.This space is called "dilemma zone". The research is conducted at one approach of the signalized intersection that operate in fixed-time mode with flashing green signal.The sample was made only of vehicles caught between the stop line and camera situated at the distance of 82 m in the moment of yellow signal activation. The results show that dilemma zone is 15 m longand it is situated between 6 m and 21 m to the stop line. Also, it was found that professional drivers are less likely to proceed through the intersection and speeding drivers are more likely to take risky behaviour.The obtained results are compared with the results of other researchers. The paper ends with the most significant conclusions and discussion of research limitation and future research guidelines.*
Keywords: Dilemma Zone, Traffic Lights, Intersection, Yellow Signal

1. INTRODUCTION

Signalized intersections are common in cities with high-volume road traffic. With the expansion of traffic-actuated mode of traffic light operation the flashing green signal has been increasingly removed from signal plans due to the efficiency. So, drivers are informed about signal change when the yellow signal turns on. This short time period of three seconds presents the period during which a driver has to decide whether to continue through the intersection or to brake until he/she stops. According to Low on Road Traffic Safety of the Republic of Serbia [1], the yellow traffic light means that it is forbidden for vehicles to go through the intersection, except when they cannot safely stop in front of the traffic light. Hence, it is up to drivers to decide is it safe to stop the vehicles or not. There are many factors influencing this decision.
The aim of this paper is to investigate at what distance to the stop line drivers have a "dilemma" related to which decision they will make. This space is called "dilemma zone" and it is well known in the literature (Figure 1).
The paper is structured as follows. In the next chapter the relevant literature is reviewed. In Chapter 3 the research methodology is presented. Chapter 4 presents the results of analysis. The paper ends with conclusions and guidelines to the future research.

[1]brplazinic@atssb.edu.rs
[2]aobradovic@atssb.edu.rs

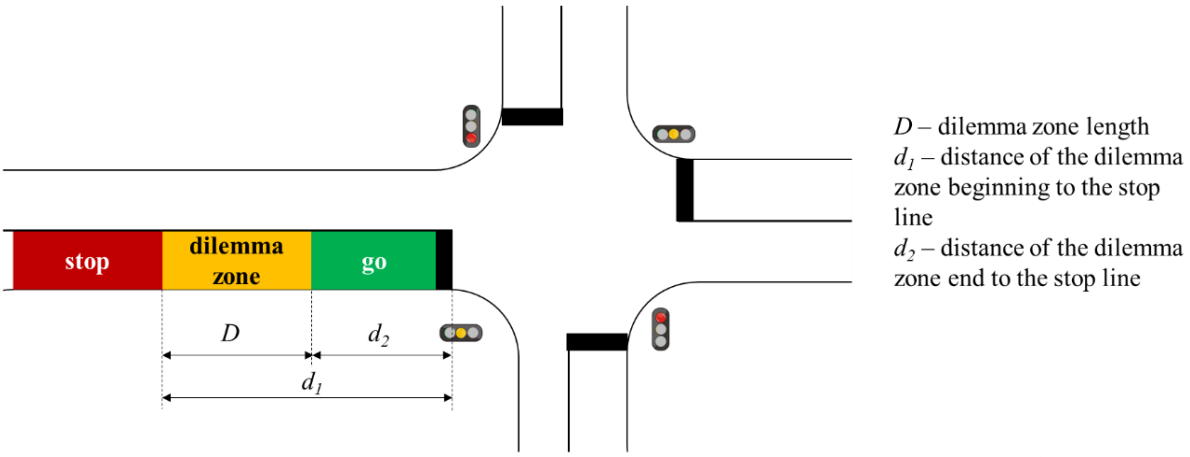

Figure 1. Dilemma zone position

2. LITERATURE REVIEW

Driver behaviour in dilemma zones was investigated both in homogeneous traffic conditions (traffic flow composed mainly of passenger cars) and mixed traffic conditions (traffic flow composed of different-type vehicles) [2]. According to the research results, the most significant factors influencing the decision made by driver in dilemma zone are: approaching speed [2, 3], distance to stop line [3], flashing green signal presence [3], driver age and gender [4], vehicle type [5] and cycle length [5].
There are also papers dealing with the estimation of road safety risk in dilemma zone. For example, Sharma et al. found that drivers base their decision on the acceleration required to pass through the intersection without conflict, not on the deceleration [6]. When it comes to the traffic light operation efficiency, Wu et al. found that the number of vehicles in dilemma zone is more sensitive to the signal coordination [7].

3. RESEARCH METHODOLOGY

3.1 Research site selection

The site was selected by applying the following criteria:

- signalized intersection with an approach that is situated on theat least 150 meters-long road segment (entrance or exit of vehicles is not possible),
- the intersection approach is suitable for camera recording (no obstacles, high visibility of vehicles and current traffic signal).

The research was conducted in Belgrade and a part of Braće Jerković street was selected as the research site (Figure 2). Its position is between two intersections: Svetozara Radojičića – Vladimira Mitrovića – Braće Jerković – Dragice Končar and Svetozara Radojičića – Ignjata Joba. The length of the analysed road segment is 255 m, measured from the centre of the first intersectionto the centre of the second one. The research included only one approach at four-leg intersection Svetozara Radojičića – Vladimira Mitrovića – Braće Jerković- Dragice Končar – this is the approach Svetozara Radojičića. Table 1 presents some important characteristics of the intersection and analysed approach.

Figure 2. Selected research site

Table 1. Characteristicsof intersection and analysed approach

Traffic light operation mode	fixed-time
Environment	urban
Speed limit	50 km/h
Yellow signal duration	3 s
Flashing green signal	yes
Speed limit at the analysed approach	50 km/h
Direction allowed from the analysed traffic lane	left and through

3.2 Research method

The research was conducted by day, during the peak time period, from 15 h to 17 h. The weather was fine, with no precipitation. Only left traffic lane on the selected approach was chosen for research becausea bus stop is situated at the right traffic lane before the intersection. Figure 3 illustrates the applied method of data collection. One camera recorded the position of vehicles 166 m in front of stop line. Another one, installed 82 m in front of stop line, recorded the position of vehicles at its location and in the moment when yellow signal turns on, as well as whether the vehicle made red light violation. The approaching speed was calculated based on travel time required to travel the road segment between cross sections situated 166 m and 82 m in front of the stop line. The positions of vehicles when yellow signal turns on are estimated based on the road markings (the distance between two continuous parts of median lineis5 m and the distance between the stop line and the first “empty” part of the median lineis measured too). The sample was made only of vehicles caught between the stop line and second camera situated at the distance of 82 m in the moment of yellow signal activation. The following data were extracted from video recordings: approaching speed, vehicle type, distance of vehicle to the stop line in the moment of turning

yellow signal on, whether the vehicle decide to cross the stop line during the yellow signal and whether the driver made red light violation.

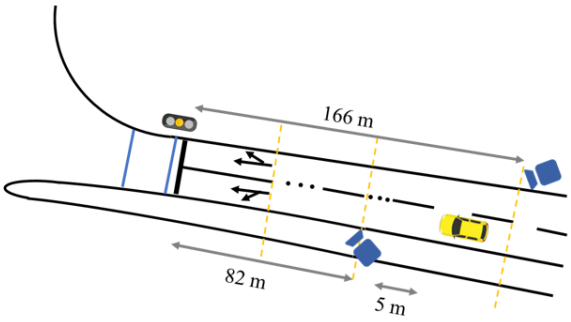

Figure 3. Layout of data collection equipment

4. RESULTS

Results of the research are based on 62 recordings of vehicles at the research site. According to the obtained data, 17,7% (11) of drivers decided to go through the intersection when the yellow signal was active and 82,3% (51) decided to stop. No driver made red-light violation.
The intersection is characterized by mixed traffic because of public transport lines and numerous construction sites at the vicinity. Table 2 shows drivers' decisions by vehicle types. As expected, drivers of heavy vehicles are lesslikely to take risky behaviour unlike passenger car and light commercial vehicle drivers. Those results are just indicative because of small share of buses and commercial vehicles in the sample.

Table 2. Drivers' decisions by vehicle type

Vehicle type	% drivers who decided to go
Passenger car	18,2
Bus	0,0
Light commercial vehicle	25,0
Heavy commercial vehicle	0,0

Figure 4 shows drivers' decisions (stop or go) in relation to the distance to the stop line and approaching speed. Dilemma zone boundaries were determined by analysing at what distance to the stop line 85% of drivers decided to cross the stop line and at what distance to the stop line 85% of drivers decided to stop. Having in mind that some researchers use 90% as a reference, boundaries were also calculated in this way in order to enable the comparison. It turns out that dilemma zone is situated between 6 m and 21 m to the stop line when taking into account the decisions of 85% of drivers. Hence, it is 15 m long. If the criterion of 90% of drivers is adopted, the dilemma zone is 22 m long and it is situated between 5 m and 27 m to the stop line.

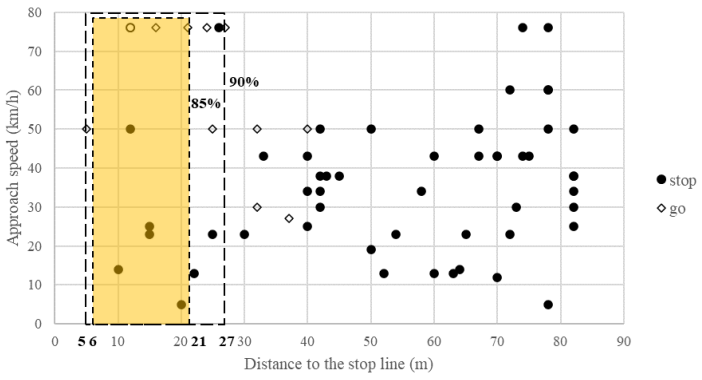

Figure 4. Drivers' reactions to yellow signal

Higher speedsat the moment of yellow signal activationare more related to decisions to go through the intersection than lower speed. Speeding drivers are generally more likely to take risk at the intersection in comparison with no-speeding drivers (Table 3).

Table 3. Drivers' decisions by speed overrun

Speed overrun	**% drivers who decided to go**
No speed overrun	11,4
Up to 10 km/h	0,0
More than 20 km/h	62,5

5. DISCUSSION

Although the most research paper refer to dilemma zone in terms of distance to the stop line, measured in meters, there are also some researches dealing with time to the stop line, measured in seconds [8]. This method takes the approaching speed of vehicle and comfortable deceleration into account [5]. Zhang et. al. made the review of research results for dilemma zone boundaries in terms of distance (ft) from the stop line in relation to the speed [9]. Their beginning is in range from 52 m to 65 m from the stop line while their end is in range from 30 m to 44 m from the stop line. Those values are results of relatively old studies, conducted in the period from 1963 to 1994. In comparison with the results of this paper, it could be concluded that the length of dilemma zone is similar, but now a days its distance is closer to the stop line. Better braking abilities of modern vehicles could be the reason. Also, drivers are previously informed about signal phase change by flashing green signal, so it is possible that different results would be obtained at the intersection without it.

Risky behaviour during yellow signal could lead to road accidents. One measure to overcome the safety problem of drivers in dilemma zone is to install a countdown timer which displays the remaining green time and assist drivers in making decision by providing them with timely information. This measure is already implemented in cities of China [9].

6. CONCLUSION

The results of this paper indicate that dilemma zone is very close to the stop line and the presence of flashing green signal could be one of influential factors. Speeding drivers are more likely to proceed through the intersection. Therefore, the approaches of signalized intersections that are characterized by high percent of speeding drivers are more at risk of red-light violation and traffic accident. Traffic calming measures at those approaches should be tested from this perspective.

The results of conducted pilot research are only indicative for conclusions. In order to get more precise results, it is necessary to enlarge the sample, especially in mixed-traffic condition, and to conduct the research in different conditions and environment (for example, by day and by night, actuated traffic light operation mode and fixed-time mode without flashing green signal, exclusive and mixed traffic lane etc.), as well as to measure time and distance in a more precise way. In terms of traffic safety, it would be useful to model driver behaviour related to red-light violation.

ROLE OF THE RESCUE COORDINATION CENTRE IN LAND IN CASE OF AIRCRAFT ACCIDENTS

Kristina Milic[1], Civil Protection Directorate, Ministry of Interior

Abstract: *Aircraft accidents are rare but very serious accidents that require quick and efficient coordination of rescue operations to save lives and minimize damages. The rescue coordination centre in land in the Republic of Croatia has a key role in coordinating and managing all aspects of the search and rescue operation. The aim of the paper is to investigate the role of the Rescue Coordination Centre in land in the Republic of Croatia in situations of uncertainty in the search for a missing aircraft. The key tasks and responsibilities of the coordination centre will be analysed, as well as the procedures used for effective search and rescue management. The paper presents the results of research aimed at the participants of the aircraft search and rescue system in the Republic of Croatia, to collect data on the current state of the aircraft search and rescue system and recommendations for improving the capabilities of the Rescue Coordination Centre in land, in part of training the staff, updating plans and procedures and the use of modern technologies for communication and monitoring the situation in the field.*
Keywords: Rescue, coordination, centre, aircraft accidents

1. INTRODUCTION

Aircraft accidents are challenging and often tragic events with potentially serious consequences for passengers, crew and the environment. In such crisis situations, a quick, coordinated and effective response can significantly influence the outcome of the accident and save lives. A key link in the organization and implementation of rescue in aircraft accidents in land is the Rescue Coordination Centre (here and after: RCC) in land.

The RCC in land is the central hub for the management and coordination of rescue operations in the event of aircraft accidents. His role includes receiving and analysing accident reports from the field, managing resources, communicating with relevant agencies, coordinating search and rescue unites (here and after: SRU), and providing support to accident investigators. The RCC in land plays a key role in providing emergency assistance and organizing all aspects of response to the accident.

The main goal of this paper is to introduce the audience with the important role of the RCC, the challenges and lessons learnt with each implemented exercise or emergency occurred. Hypothesis: Rescue Coordination Centre is the key coordination hub in aircraft accidents.

1.1. System of ASAR in the Republic of Croatia

System of Aircraft Search and Rescue in the Republic of Croatia (here and after: System) is based on international standards and regulations established by the International Civil Aviation Organization (here and after: ICAO), the European Aviation Safety Agency (EUROCONTROL) and International Maritime Organization (here and after: IMO).

The System is carried out in the manner regulated by the Regulation on the conditions and methods of conducting aircraft search and rescue (Official Gazette 129/11) and special regulations which

[1]kristinamulic@gmail.com

regulates search and rescue activities at sea, in the area of responsibility for search and rescue of the Republic of Croatia (SRR RH), i.e. in the area of flight information (FIR) Zagreb with established lateral boundaries in accordance with ICAO doc. 7754 (Air Navigation Plan) and the Air Traffic Act (Official Gazette 96/09, 84/11, 54/13, 127/13, 92/14).
The main responsibility for the air traffic security system is on the Ministry of Transport, Sea and Infrastructure which is obligated to achieve communication with international organizations and represent the area of search and rescue in relation with the international standards. Search and rescue system is divided into two Rescue Coordination Centres – RCC in land with the responsibility of Ministry of the Interior, Civil Protection Directorate and Maritime RCC – Rijeka for the seaside with the responsibility of Ministry of Transport, Sea and Infrastructure [1].
Till the 2009, when the new Air Traffic Act enter into force, the Ministry of the Interior was responsible for conducting aircraft search and rescue activities. 2009, aircraft search and rescue responsibilities have been transferred to National Protection and Rescue Directorate. Based on the Regulation of the Government of the Republic of Croatia on the conditions and methods of aircraft search and rescue (Official Gazette 129/11), National Protection and Rescue Directorate started to develop the aircraft search and rescue system. The Regulation stipulates that the aircraft search and rescue system, must be based on the standards and recommended practice from the Annex 11 „Air traffic services“ and Annex 12 „Search and rescue“ of the Convention on International Civil Aviation and the manual Doc. 7333 – AN/859 International Civil Aviation Organization (IAMSAR Manual). On 2019 National Protection and Rescue Directorate was integrated into the Ministry of the Interior and Civil Protection Directorate was established, as a carrier of the responsibilities for further development of the aircraft search and rescue system.
In accordance with the Regulation on the conditions and methods of aircraft search and rescue, RCC is the structured organizational unit within the Civil Protection Directorate which is operative, personnel and material technically trained to accept warning message from the various organizational and individual stakeholders, analysis, processes and distribute message in order to conduct search and rescue activity by being operational 24/7 [2].
The System is composed of various, crucial institutions which are carrying important role in the emergency. Air Traffic Control is the primary point in warning system by reporting the disappearance of aircraft from the radar. Ministry of the Interior, the Civil Protection Operational Centre at the Directorate of Civil Protection, performs the role of the RCC in land which conducts coordination of resources and institutions in aircraft search and rescue, such as Directorate of Police, the Croatian Civil Aviation Agency, the Croatian Mountain Rescue Service, the Ministry of Défense, the Croatian Army through the Command Operations Centre of the Armed Forces of the Republic of Croatia by activating helicopters for purposes of searching, the Croatian Red Cross, the Ministry of Health and the Institute for Emergency Medicine, the State Hydrometeorological Institute, the Croatian Institute of Public Health, the Croatian Firefighters Association and numerous of other entities. These entities work together to ensure quick and coordinated action in case of aircraft search and rescue.
Search and rescue activities includes the use of various techniques of searching by using aircraft and unmanned aerial vehicles (UAV), the use of civilian and military radars, satellites, infrared cameras and other technologies to find aircraft and survivors. Search and rescue operation are carried out in the field, including medical assistance and treatment of the injured.

1.2. International standards

The Republic of Croatia has been a signatory of the International Convention on Civil Aviation since 1992 and is thus obliged to implement the standard and guidelines established by the ICAO, which includes the area of search and rescue in the event of an aircraft accident. The Republic of Croatia cooperates with other countries in the region and participates in international initiatives for the purpose of improving the search and rescue system [1].

In accordance to international standards, the Republic of Croatia is obliged to integrate Appendix 12 „Search and Rescue“ into its legislation. Regulations related to the system of search and rescue of buried vessels, as well as the use of aircraft for search and rescue purposes, are regulated by various international conventions that determine the conditions and manner of using aircraft for search and rescue purposes, such as the Chicago Convention, the Convention on the High Seas, the International Convention for Safety of Life at Sea (SOLAS), the Convention on maritime search and rescue. Aviation as a transport branch has the best regulated legal sector compared to other transport branches.
In order to implement Appendix 12 „Search and Rescue“ in legislation of the signatory states to the ICAO the International Manual for Aviation and Maritime Search and Rescue (IAMSAR) was created and published by the ICAO and the IMO.

2. ROLE OF THE RCC INLAND IN AIRCRAFT ACCIDENTS

The basic role of the RCC is to receive and evaluate information in the event of an aircraft accident, make and implement decisions on initiating search and rescue activities. RCC activates in the moment when it is triggered by Air Traffic Control, 112 county centre or by getting the information from the eyewitness [4].

2.1. Coordination and Communication

Coordination and communication play a vital role in aircraft search and rescue operations. These elements are critical for ensuring the swift and effective response to an emergency, the safety of both victims and rescuers, and the successful resolution of the situation.
To achieve impeccable coordination, there is a need for multi-agency collaboration because search and rescue operations often involve multiple agencies and organizations. Knowing the structure of a coordination in search and rescue activities, helps to establish a clear organizational structure with designated roles and responsibilities for search and rescue personnel, such as the role of Search Mission Coordinator (here and after: SMC), On-scene Coordinator (here and after: OSC), Aircraft Coordinator (here and after: ACO). Coordination involves identifying and dispatching the appropriate resources, including aircraft, ground teams, medical personnel, and equipment, based on the specific needs of the search and rescue operations.
Communication begins with receiving and decoding distress signals, which can arrive from various sources, including aircraft's emergency locator transmitter (ELT)[2], radar, or satellite communication systems. By developing crucial communication plan and standard operational procedures, among rescue unites and implementing the modern technologies into search and rescue activities such as communication platform for exchanging information between teams (Next Generation Incident Command System – NICS), Starlink for the areas without telecommunication network, can provide effective and successful result in search and rescue operations. One of the most important communication strategies is developed Media and Public Relations communication. Effective communication with the media and families of the victims is important for providing accurate information and managing public expectations during search and rescue operations.

2.2. Stakeholders in the search and rescue operations

The Coordination in search and rescue activities is established in three different levels; Search and Rescue Coordinator (here and after: SC), SMC and OSC.
SC is responsible for establishing, staffing, equipping, and managing the search and rescue system on the national level which includes legal and funding support, establishing RCC, Rescue Sub-Centres (here and after: RSC's), developing search and rescue policies, coordinating search and

[2] Emergency Locator Transmitter (ELT) – determines the right position of an aircraft in distress via COSPAS SARSAT satellite system.

rescue trainings, within its search and rescue region (here and after: SRR). The responsibility for conducting search and rescue operations is on the SMC which is the most qualified person in the RCC [4].
OSC is designated by SMC to facilitate support by two or more search and rescue units which are working together on the same mission. OSC will sometimes conduct the duties of the SMC if the communication could not be established with the RCC and if the OSC has better overview of the distress situation [3].
Special role of coordination is designated to ACO. In complex distress situation when the mission must be extended to other search and rescue facilities, ACO is designated by SMC or if it is not practicable by the OSC to coordinate airborne resources in defined geographical area.

2.3. Rescue Sub-Centres (RSC)

In accordance with Regulation on the conditions and methods of conducting aircraft search and rescue (Official Gazette 129/11), Rescue Sub-Centres (here and after: RSC) are the Civil Protection County Offices. In the Republic of Croatia there are five of the Civil Protection County Offices which heads are in distress situation designated as the OSC.
Main role of RSC is that in the event of an aircraft accident, receive and evaluate information, make and implement decisions on initiating search and rescue, and lead and coordinate search and rescue activity within their jurisdiction. RCC may some or all responsibilities designate to the RSC, including communications, search planning, arrangements for search and rescue facilities if it is more appropriate to conduct the effective coordination of search and rescue activities [3].

3. TRAINING AND EXERCISES

Training and exercises are crucial components of aircraft search and rescue activities. They ensure that search and rescue personnel are well prepared to respond effectively to emergencies, handle various scenarios, and coordinate efforts across different agencies. In accordance with Appendix 12 „Search and Rescue“and the International Manual of Maritime and Aviation Search and Rescue, training must be carried out for each of the roles defined by the before mentioned SMC, OSC, ACO, RCC staff and search and rescue units (here and after: SRU) [4].
Those components are not only enhancing the skills and readiness of search and rescue personnel but also help identify areas in need of improvement. Developing a productive training program and implementing the realistic Exercises are essential for maintaining a high level of preparedness in aircraft search and rescue, which is vital for the safety of passengers and crew in emergency situations.

3.1. Requirements for RCC staff

Personnel of the RCC consists of the trained and capable of planning and coordinating search and rescue activities. The number of personnel at the RCC depends on other duties, traffic density, seasonal conditions, meteorological and other search and rescue region conditions. RCC staff could be variously trained by attending specialized trainings, conferences, on-the-job training, analysing international standards and documents dedicated to aircraft search and rescue activities, search and rescue incident analysis, search planning and operations management [4].
In accordance with IAMSAR Manual edt.2022, vol.2, it is required that the RCC staff are working in 24/7 with established duty work, knowledge of the English language, means of plotting, establish communication with Air Traffic Control, know action plans, standard operational procedures, having ability to perform information management with recognition of priorities.

3.2. Exercise cycle

In accordance to Appendix 12 „Search and Rescue“, member states of the ICAO are obliged to conduct aircraft search and rescue exercises. There are three types of exercises that are carried out in search and rescue operations: communication, coordination and full-scale exercises to validate communication procedures of the participants included in the aircraft search and rescue system as well as verification of operational procedures and capabilities. At the end of the exercise, an analysis of the exercise is carried out with representatives of the participants (management and exercise group), in accordance with the goals set by the exercise. The goal of the analysis is to identify deficiencies in the operational implementation of activities during the simulated aircraft search and rescue operation and to identify lessons learned [4].

4. CONCLUSION

The role of the RCC in land in the event of aircraft accidents is of paramount importance in ensuring the safety and effectiveness of search and rescue activities. RCC serves as the central hub for coordinating efforts and resources from various agencies and organizations to respond to aircraft emergencies. The efficient functioning of the RCC significantly contributes to the success of search and rescue operations in the aftermath of aircraft accidents. It ensures that the response is well organized, timely, and focused on saving lives and mitigating the impact of the incident. Challenges and complexities are inevitable, but with the dedication and professionalism of the RCC staff, these challenges can be effectively addressed. Ultimately, the dedication, coordination, and communication of the RCC personnel contribute to the safety and security of aviation, further emphasizing the vital role they play in land-based rescue and recovery operations followed by aircraft accidents.

TRENDS OF ARTIFICIAL INTELLIGENCE IN AVIATION: CYBER SECURITY OF ADS-B SYSTEM

Dejan Kožović[1], BenAir
Dragan Đurđević[2], Academy of National Security

Abstract: *Since the beginning of the 21st century, aviation has been in a process of continuous transformation. The development of advanced Information Communication Technologies (ICT) and their very fast and mostly safe adoption has led to a huge increase in innovation and automation in the aviation. The approved relevant innovations, which include consolidated technologies, among other things, refer to additional values related to the Aviation industry 4.0 – industry based on Artificial Intelligence (AI) technologies, i.e. by increasing automation and data exchange, including cyber-physical systems, Internet of Things (IoT) and cloud computing. However, AI application in aviation is faced with certain challenges, which primarily relate to very high safety requirements, sofor now, AI is used as support, and the future will show how AI will be used in safety-critical aviation operations. Indeed, every new improvement in customer service/increase in the efficiency of aviationoperations opens up space for cybercriminals to take advantage of that new technology. Surely, in the non-safety-critical area, AI must be deployed rapidly and aggressively obtaining benefits and knowledge. This paper reviews of various advantages/disadvantages of AI including its applicationsin the fields of aviation cyber security, particularly for improving the security of the Automatic Dependent Surveillance – Broadcast (ADS-B) system.*

Keywords: Artificial Intelligence, Machine Learning, Cyber Security, ADS–B Aviation System

1. INTRODUCTION

The aviation industry has always been at the forefront of technological innovation, constantly pushing the boundaries to make air transport safer, more efficient and more accessible. From the earliest pioneer flights to the present day, aviation has undergone many technological revolutions, each contributing to the evolution of safer air travel. The latest revolution is the rise of AI and its potential to transform the world of aviation [1].

Namely, modern AI techniques can play an important role in the development of intelligent systems (for example smart airports or smart aviation). In the civil aviation industry, the concept of □smart□ is based on the most modern applications of the digital industry, such as the integration of devices and IoT, sensors in physical systems, the use of AI, as well as large amounts of data in the □cloud□, in order to achieve an improved user experience on reliable and sustainable way, with maximum operational efficiency, safety and security.

Various international organizations, such as European Union Aviation Safety Agency (EASA), which cooperates with all stakeholders in the aviation industry, are working very intensively and proactively on mapping the development path of AI, i.e. the approval and implementation of AI systems in aviation while maintaining the highest standards of safety, security and environmental protection [2]. In doing so, different AI techniques and approaches are considered: machine learning (data-driven AI), approaches based on logic and knowledge (symbolic AI), statistical

[1] dejankozovic@gmail.com
[2] djurdjevic.dragan@gmail.com

approaches and combined use of all three previous approaches (hybrid AI). With all this, it is necessary to analyse the trustworthiness of the AI application, i.e. assessment of safety and security in accordance with thedeveloped ethical guidelines for the use of AI.

On the other hand, a giant step in modernizing ATM (Air Traffic Management) and improving the quality of aviation operations is the introduction of ADS□B, a multi-parameter system for air traffic surveillance [3]. As the ADS□B surveillance system does not involve a pilot or controller, it is considered as an automatic system, i.e. intelligence system. Its operation is dependent as the input is made available to the air traffic control system based on data coming from the GPS receiver of the aircraft. As a result of ADS□B broadcast protocol, immediate aircraft position, velocity, direction aswell as some other data including aircraft identification number, source, and destination are sent to nearby aircraft and ground stations over unencrypted datalink on a regular basis. Thus, ADS□B increases the safety of air traffic, enables an increase in situational awareness, as well as provides improved reports on meteorological conditions, traffic capacity, avoiding possible collisions in the air, etc. However, ADS□B has a very simple "free to air" protocol, which is its essential drawback: this system is vulnerable to various types of cyber-attacks, such as eavesdropping, jamming, message modification, message injection, i.e. spoofing [4]. Between those major design vulnerabilities of ADS□B, spoofing is the most sinister because the targeted receiver cannot detect a spoofing attack and therefore cannot warn users that its navigation solution is untrustworthy. Moreover, even if not fully successful, spoofing usually will inject hazardously misleading information and create significant Position, Velocity, Time errors. In fact, ongoing advances in compact, cost-effective software-defined radio (SDR) technologies are already lowering the barrier to conducting various types of malicious activities. Hence given the impending scope and scale of ADS□B adoption, it is imperative to consider the full range of cybersecurity threats here and devise effective mitigation strategies.

So, while vulnerable, ADS–B is not blindly exposed to defenceless cyber-attacks; attacks can be mitigated by applying various countermeasures for cyber security protection [5], such as techniques based on broadcast/message authentication and location verification. Recently, various techniques build on models of machine learning, such as Long Short−Term Memory (LSTM) networks, SODA-DNN (Deep Neural Network), fuzzy logic, etc., also have been proposed.

In addition, pilots are also trained to detect and solve problems in each phase of flight. However, due to possible more sophisticated forms of cyber-attacks, a proactive approach is necessary, increasing the robustness of the ADS□B system against different types of cyber-attacks. So, AI, or machine learning (ML), as a subset of AI, allows us to create intelligent systems that can provide advanced assistance solutions to human end users, optimise aircraft performance, improve ATM and in turn enhance safety in ways that were previously unimaginable. However, the deployment of AI in aviation brings a number of new challenges, including security and privacy, technology, cost, acceptance and regulations.

2. IMPACT OF ARTIFICIAL INTELLIGENCE ON AVIATION CYBER SECURITY

2.1.Advantages of AI technology

Multiple domains of the aviation sector will be impacted by AI emerging technology. The air transport system is facing new challenges: increase in air traffic volumes, more stringent environmental standards, growing complexity of systems, greater focus on competitiveness, for all which AI could provide opportunities.

The latest developments in AI technologies applied in the aviation industry (from production and maintenance, through aircraft and air traffic management, to innovative services for passengers) offer numerous benefits, related to [2]: a) design of aircraft parts, predictive maintenance and operability (for example, Boeing 777 is the first aircraft that was completely computerized in the design phase), b) optimization of fuel consumption, c) assistance to pilots in air operations and controllers in air traffic management (AI and ML models can be used to analyse a large amount of

data obtained from various sources and aviation systems, helping pilots to make adequate decisions, such as on an alternative route in case of bad weather conditions, g) assessing the environmental impacts (for example, AI enables route optimization and thus reducing CO_2 emissions, as well as the development of machine learning algorithms on based on ADS−B data, which could be used to estimate fuel consumption practically every flight), d) air traffic management (the ATM area foresees important applications of AI/ML, and some have already been introduced in support of ATC (Air Traffic Control) operations; by analysing data on meteorological patterns, configuration, congestion in air traffic and other factors, AI and ML models could support the optimization of flight routes in order to reduce flight time, fuel consumption and thus costs) f). passenger identification (trained AI systems, biometric scanners and facial recognition technologies can be used for quick and simple identity verification, as well as criminal activity detection), e) user experience (many airports and airlines are introducing more efficient ways to check in passengers, such as using mobile devices, e.g. Personal Digital Assistants for electronic ticketing, check-in and immigration clearance), h) pilot training, z) Unmanned Aerial System (UAS), i.e. drones (for example AI and ML models will be necessary to safely conduct UAS operations in case of unforeseen/emergency situations, as well as the effective implementation of U-space), i) detection and mitigation of cyber-attacks (latest developed techniques based on ML algorithms, such as deep learning model), etc.

A particularly significant application of AI is in the field of aviation cyber security. The effective response of the pilot to some unforeseen event, at low flight altitudes, and especially in some of the critical phases of the flight, requires a quick and efficient reaction of the pilots, who are taught to always have a way out. However, in cyber security, AI makes the response faster and more efficient. AI, i.e. machine learning techniques can be used as potential solutions for detection of avionics anomalies, achieving security of data link communications, as well as security certifications. In this context, as pointed out by Gustafsson P. (OBE, chief exec of Darktrace, a global leader in AI cyber security), ″As the aviation industry battles new threats targeting the technologies which are so critical to its business operations, the role of AI in containing and fighting back against these attacks has never been more important.″ [6]. Thus, Darktrace is based on three technology products: Detect,Respond and Prevent, which are based on ″self-learning″ AI; Darktrace separate technologies also learn from each other: each continuously inputs data into others, improving its own capabilities as well as the system's threat protection capabilities. Namely, Darktrace Respond uses Detect contextual understanding to take the optimal action (response) to mitigate the threat. The adaptability of this response is essential: a cyber-attack can come in any number of configurations, and Respond can adapt its actions accordingly. So, by using AI that takes action at machine speed, offering effective and proactive measures, as well as ″clear-sky visibility″, airlines/security teams can be confident in their ability to prevent an attack, i.e. to be/remain protected from cyber-attacks.

2.2. Machine learning approach to cyber security in ADS-B aviation system

The introduction of the mentioned ADS–B system (data link, ADS−B Out and ADS−B In applications) provides ATC and pilots with numerous benefits, such as real-time precision, shared situational awareness, advanced applications that increase safety and efficiency (in the air and on runways), as well as reducing costs and harmful effects on the environment. Now that ADS-B Out is a required standard (ADS-B In remains an optional mode), and the fact that ADS-B broadcasts the messages as unencrypted plaintexts, the most important issue is the cybersecurity of ADS–B.

ADS–B system is vulnerable to various types of cyber-attacks, such as eavesdropping (message interception), jamming (flooding) and spoofing. The latter is very dangerous and causes particular concern because affects the confidentiality and integrity of ADS-B: in spoofing, false signals are inserted into the "victim's" receiver, and the targeted receiver cannot detect the attack, norwarn the user about unreliable navigation solutions. Namely, spoofing attack is achieved by the combination of both message injection and message deletion, and the malicious hacker must eavesdrop the 1090 MHz channel (the data link which support ADS–B to enhance interoperability, regulatory and legacy purposes) in order to interpret the messages and to interfere with the required message.

In particular, potential attacks that could be carried out from the air, using UAS/drones forthe purpose of hijacking or security distraction in airspace surveillance, pose a major risk. Also, the integration of UAS and ADS−B represents a particular challenge, because in this case electronics oflower quality can be used, and the systems do not require rigorous maintenance. Because of this, there may be an unintentional transmission of wrong ADS−B data, and without a mechanism to solve these problems, unverified ADS−B data could pose a significant danger to air traffic.

Therefore, the development of robust and effective countermeasures against cyber-attacks on the ADS−B wireless communication protocol is of particular importance. To test the integrity and credibility of the received ADS-B messages, various techniques are proposed, from cryptographic and techniques that use location verification, to the most recently developed methods that are based on ML algorithms, such as, the deep learning model. For the detection of cyber-attacks on wireless aviation systems (e.g. the very dangerous spoofing attack on ADS-B), two basic machine learning approaches can be used. One is based on the classification and verification of the characteristics of certain legitimate users based on stored patterns, while the other is based on anomaly detection, whereby the parameters of the system's normal state are learned over time, and deviations from these patterns are marked as an anomaly (a potential security problem).

Thus, one of the most recently proposed methods for detecting spoofing (from the ground or from the air) [7] is a method based on the Strategic Options Development and Analysis − Deep Neural Network (SODA−DNN) detector, which consists of a message classifier and an aircraft classifier. The SODA−DNN detector allows the ground station (equipped with an ADS-B receiver, computer resources, an adequate database of received authentic ADS-B messages, etc.), to analyse each incoming message based on the characteristics of the PHYlayer (IQ samples and phases) and to note suspicious message. The message, which is not malicious, is forwarded to the aircraft classifier, which uses the phases of the received messages as input; by comparing the ICAO address with the requested one, the detector can detect a spoofing attack. To test the characteristics of the proposed detector system, it is necessary to analyse a large number of real data, i.e. have adequate equipment (ADS−B receiver and ADS-B spoofer). It should be emphasized that application of SODA−DNN allows the detection of spoofing attacks with a very high probability and a very small proportion of false alarms, which is a significant improvement over other state-of-the-art detectors.

The other/second approach [8] is based on the detection of anomalies in ADS−B messages, i.e. detection of false/manipulated ADS−B messages sent by an attacker/compromised aircraft, by analysing a series of messages and assessing their credibility. As the flights most often take place on similar routes, an LSTM (Long Short-Term Memory) encoder-decoder model, based on previous (legitimate) flights for a given route, is used and trained. Using such a model, each aircraft can independently evaluate received ADS−B messages and identify deviations from the legitimate flight path. However, the causes of anomalies in ADS−B messages can be of different nature, so their identification is only one segment in the detection of cyber-attacks. Also, very careful setup and testing of the model (calibration) is necessary to avoid false positive results.

Finally, besides the above mentioned anti-spoofing techniques, different and increasingly sophisticated ML algorithms are designed, such as neural networks, support vector machine and hybrid techniques. These different ML as well as fuzzy logic methods are proposed in the challenges of identifying and categorizing large amounts of aircraft flight data, thanks to the availability of ADS−B transponders in commercial aircraft, as well as the increase in the number of ground stationsthat provide public access to their data. These large amounts of air traffic data can be useful in a widerange of ATM analyzes that rely on operational data and statistics [9].

2.3. Some challenges of AI applications in aviation sector

Although AI technologies offer significant benefits, it can introduce new vulnerabilities and open space for cybercriminals to take advantage of this improved technology. Therefore, it is necessary to understand these new vulnerabilities (e.g. data corruption, data poisoning) and define their specific

security controls (technical or organizational). Nowadays, it is already observed that malware adaptsits behaviour depending on the operating environment. Furthermore, researchers have demonstrated the potential of a new class of AI-driven malware (e.g. DeepLocker) [2]. Cyberattacks undertaken using AI are likely to be more effective (more adaptive and autonomous), by developing AI's ability to bypass conventional detections based on system rules. Therefore, it is necessary to develop adequate countermeasures. Thus, the state-of-the-art research related to cyber-attacks based on intentional/malicious use of AI technologies significantly contributes to understanding the actions of attackers (they are constantly changing and improving their attack strategies), as well as contributingto the development of adequate defences against attacks.

Also, in future, some of the main challenges related to the application of AI in aviation, whichrequire further consideration and development guidelines, are the verification standards of AI-basedsystems and components, knowledge and data management (the need for a quality knowledge base), architecture selection models and algorithms, then, dealing with limitations in the predictability and comprehensibility of AI application behaviour (considering the model complexity), implementation of AI models in security systems (optimization of the trained model and the model embedded in the target platform), management of joint operational authorizations in new types of human-AI alliances, etc.

In all of this, the essential prerequisites for the safe development of any system, including theone with built-in AI, are the characterization of AI, i.e. safety and security assessment as well as ethics. Also, a very important aspect of future AI regulations is the level of "human oversight" in theapplication of AI. In this regard, different levels of AI application have been identified: 1) human assistance, 2) human-AI integration, and 3) advanced automation.

Advances in AI technologies are predicted to cause the AI market in the aviation industry to grow exponentially. However, it is also a fact that investing in this technology is very expensive, which is one of the primary drawbacks of its application. The necessity of numerous testing and certification by relevant organizations/regulators are key processes in the application of AI in aviation, which is why it will take time for AI to be implemented globally. Particular scepticism of experts regarding the future use of AI, i.e. by generating the concept of autonomous flight for e- Enabled planes, caused the mentioned plane accidents with fatal outcomes (in 2018 and 2019), of thesame type of plane, Boeing 737 MAX 8, because of which the Boeing company was under great pressure.

Also, and no less significant is the fact that for the successful application of AI, aviation needstrained staff who understand the issues and development process and can interact with experts both in academia and in specialised consulting companies. Extensive training programmes need to be put in place at all levels.

At the end, the most recent revolutionary invention in aviation, created by the consolidation of AI and robotics, is a humanoid robot (Pibot pilot), which is capable of independently controlling the flight process, and which was developed by the Korea Institute of Advanced Science and Technology. Taking advantage of AI, Pibot is designed to support the pilot in extreme situations, andit is expected that the full functionality of this pilot robot will be realized in the coming years.

3. CONCLUSION

Although various intelligent aviation systems will be created and the new ICT solutions for increasing the security of information and networks, as well as for the detection of cyber threats to aviation systems, including ADS–B, it is unequivocal that a human decision, based on previous knowledge, experiences and abilities, is necessary for successfully solving critical situations. Therefore, it is necessary to raise awareness of cyber-attacks through periodic training of pilots, as well as cabin crew, in order to establish a ″collective″ awareness of cyber threats, as well as training on general decision-making skills (pilots should be trained to control unforeseen and unexpected events and troubleshooting).

On the other hand, just through the AI technology, we can see significant changes in the world of aviation. Although at the beginning, these changes are already being seen, and advanced AI technologies, such as auto-pilot functions, are drastically changing the future of the airline industry. However, the idea of AI completely replacing humans/pilots is still in its infancy. But, we can conclude – adequate use of AI will significantly improve the operation and business in the aviation industry sector.

THE IMPORTANCE OF LOW-COST AND DIFFERENTIATION STRATEGIES FOR THE BUSINESS OF TRAFFIC COMPANIES

Saša Marković[1], The Academy of Applied Technical Studies Belgrade
Svetozar Sofijanić[2], The Academy of Applied Technical Studies Belgrade

Abstract: *There are numerous strategies that traffic companies use depending on the results of the analysis of the external and internal environment. At the business level, there are two primary sources of competitive advantage: low costs and differentiation. Cost leadership strategy implies the ability of an individual business to gain a competitive advantage on the basis of lower costs and lower prices for the same quality. Through lower costs and lower sales prices, it will ensure a greater market share and a greater scope of traffic services. A cost advantage exists if the company has a lower cumulant cost of activities from the value chain compared to its direct competitors.*
Differentiation strategy represents a business approach to make the business of a traffic company unique and different from the competition, with the aim of standing out from the majority and providing reasons for potential customers to choose a differentiated product compared to the competition's products. Through a differentiated offer, the traffic company ensures a greater market share, a greater volume of services, and even in conditions when the differentiated product (service) has a higher price compared to the competition.
Keywords: low cost strategy, differentiation strategy, traffic business, business offer

1. INTRODUCTION

There are different definitions of strategy in the literature. Michael Porter defines strategy as a competitive position, i.e. "a conscious choice of different activities with the aim of delivering (providing) a unique mix of values". In other words, the company must know its competitors and the market in which it operates in order to be able to determine business guidelines in the future [6].
There are numerous strategies that companies use depending on the results of the analysis of the external and internal environment. The concept of "5 competitive forces" (Entry possibility, Customer power, Threat of substitutes, Supplier power and Rivalry of competitors) represents a significant method of analyzing the immediate environment in terms of opportunities and threats from the environment, that is, the strengths and weaknesses of foreign companies. Understanding the threats and opportunities that the company faces, along with its strengths and weaknesses, is a prerequisite for solving the dilemmas posed by the cascade of strategic choices. Strategy can be understood as a way to neutralize threats (and weaknesses) and turn them into advantages, as well as to take advantage of opportunities (and strengths) [1, pp 560].
At the business level, there are two primary sources of competitive advantage: (1) low costs and (2) differentiation. One of the basic strategies implemented by traffic companies is the low cost strategy (Cost leadership strategy or Low cost strategy). This type of strategy implies the ability of an individual business to gain a competitive advantage based on lower costs and lower prices for the same quality. Through lower costs and lower sales prices, it will ensure greater market share, greater volume of sales and servicing (production), greater effects of the wrong experience and, on

[1] smarkovic@atssb.edu.rs
[2] ssofijanic@atssb.edu.rs

that basis, lower costs again. A cost advantage exists if the company has a lower cumulated cost of activities from the value chain compared to its direct competitors [1, pp 878].
In addition to the strategy of low costs, the strategy of differentiation is a business approach to make the business of a traffic company unique and different from the competition, with the aim of standing out from the majority and providing reasons for potential users to choose a differentiated service compared to the services of the competition [1, pp 565].

2. LOW COST STRATEGY

Low costs represent one of the sources of the company's competitive advantage. Also, costs are related to the level of differentiation, another source of competitive advantage, since a differentiated competitor is not free to increase differentiation costs indefinitely. If the increase in costs fails to overcome the costs of differentiation, the differentiated competitor will be unable to financially valorise the competitive advantage [2, pp 139].
In choosing a strategy, each competitor must take into account its relative cost position. Low costs are the premise of value creation which reduces threats caused by competitive forces (degree of competition, consumer power, supplier power, threat of entry and substitutes). There are several reasons why different competitors providing the same services have different costs. The most important reasons include: (1) differences in capacity size that cause the effect of (dis)economies of scale, (2) the existence and intensity of the experience curve effect, (3) location rent (differences in access to service factors and location) and (4) frequency and the character of technological changes. It used to be thought that the size of the capacity had a decisive effect on the costs level. As seen from the previous review of factors, size is only one of the cost-reducing factors. A change in the approach to service factors, as well as the use of opportunities offered by modern information technology, enable the creation and maintenance of a competitive advantage that is not based solely on the size of capacity. Cost reduction today is decisively influenced by the organizational structure (decentralized and thin), management concept (holistic approach supported by software) and reward system (reward based on value created) [1, pp 560].
According to some authors, the prerequisites for the successful implementation of a low-cost strategy in traffic companies are as follows:
1. Access to capital for significant investments,
2. Efficiency of the service system,
3. The possibility of professional improvement of the production process,
4. Procurement of raw materials and materials at a lower price,
5. Low labour costs,
6. Effective sales and service billing.

If costs are so important, how do you track their movement? Expenses are monitored through the so-called "cost drivers". They are structural determinants that affect the costs of an activity. The costs of an activity are affected by several cost drivers. Cost drivers reflect the connections and relationships that exist between activities within the enterprise and between the enterprise and its environment. The cumulative cost of essential discrete activities determines the relative cost position. An advantage in costs exists if the company has a lower cumulative cost of activities from the value chain compared to its direct competitors [3, pp 187-213].
The first step in cost driver analysis is to allocate costs to individual activities in the value chain. The performance of each activity in the value chain involves certain costs caused by capital investments and working capital. The entry of inputs into the value chain causes a certain type of cost in each activity in the value chain through operating costs and fixed assets (capital investments). The need to tie funds to activities reflects the fact that the value of funds in activities and the efficiency of their use affect the costs of performing activities.
A low-cost strategy is a price-based, widespread marketing strategy. Companies that implement this type of strategy must be particularly efficient in engineering tasks and service delivery. Because

traffic companies using this strategy focus on a large market, they must also be able to minimize marketing and research and development (R&D) costs. On the other hand, individual traffic companies may become so focused on keeping costs low that they overlook the necessary changes in service or marketing. A low-cost strategy can be more difficult in a dynamic environment because some of the costs that traffic companies can minimize are research and development costs or marketing research costs - costs that the company may still have to incur to remain competitive [4, pp 597] .

A low-cost leader can gain significant market share by enabling a stronger position vis-à-vis suppliers and competitors. This strategy is particularly effective in the traffic area where there is limited opportunity for product differentiation and where customers are very price sensitive.

Two or more traffic companies competing for low-cost leadership can engage in price wars that drive profits to very low levels. Ideally, a business using a low-cost strategy will develop an advantage that cannot be easily copied by others. Low-cost leaders must also maintain their investments in state-of-the-art equipment or face the possible entry of more profitable competitors. Major changes in technology can drastically change business processes so that previous investments in business technology are no longer favourable [7].

3. DIFFERENTIATION STRATEGY

A traffic company that has a unique offer is not forced to accept prices (*price taker*), but has the opportunity to set prices (*price setter*). Namely, the demand for unique products and/or services depends on the price of the product, not on the ratio of supply and demand. The rule applies here: higher price, lower costs and vice versa. A traffic company that provides a unique traffic service, services the entire market, and the demand depends on it. Unlike branches with a homogeneous product or service, in branches with a differentiated product or service, the price is determined by the production or service company [1, pp 565].

Differentiation strategy represents a business approach to make the business of a traffic company unique and different from the competition, with the aim of standing out from the majority and providing reasons for potential customers to choose a differentiated service compared to the competition's services. This definition is closely related to competition in business, which Michael Porter defined as the struggle to achieve a profitable, unique position in the market [8]. This usually involves highlighting a significant difference between the business and its competitors. That difference must be recognized and appreciated by potential consumers. Also, Michael Porter believes that there are only two ways to gain a sustainable competitive advantage. One way is low cost, while emphasizing the similarities they share with their main competition: “We're just as good as our competition, but we cost less.” Unfortunately, unless businesses have a sustainable cost advantage, they can't hold on for long and implement this strategy. There is always a danger that another company (competitor) will lower the lowest price of the competitor's company. The strategy of low costs also exposes the company to the consumer's belief that all products and services are the same (commoditization) and to a much wider range of competitors [5, pp 210].

Porter's second (and more effective) way is to set the company apart, that is, to be different from the competition in a way that is important and relevant to potential customers. According to the definition above, this refers to a differentiation strategy. A point of differentiation can be broad-based and set the company apart from the rest of the industry or more narrow appealing to a niche market. This approach is often referred to as a focused or concentrated strategy. It is difficult to achieve the development of a broad-based differentiation strategy, in which one traffic company is significantly different from the industry as a whole. Even if it manages to pull it off, the question is what is stopping a competitor from imitating such an approach? This is why many businesses choose to compete with a focused strategy. In a focused strategy, the company concentrates its diversity, and thus its appeal, on a narrower audience (niche market).

There are great advantages to using a differentiation strategy in traffic companies. Some of them are [9]:

1. Price does not have to be the only strategic instrument. Since the company has distinguished itself from the competition, the potential consumer does not have to reduce his choice only to the dimension of costs, but also recognizes other differences in relation to the competition.
2. Greater attractiveness of the traffic service within the target group is created. This makes it easier to generate interest and increase sales.
3. The service has no direct replacement. Differences attract more potential customers. The lack of direct comparability forces the potential customer to focus on the unique value of the service difference.
4. Loyalty to the service (and to the company) increases. The value of the difference and the lack of comparable substitutes result in greater loyalty to the company.
5. It is possible to increase the prices of services. Assuming that the company's differentiator is one that adds value and is not available elsewhere, the company is in a position to increase the cost of the service.

According to numerous authors, differentiation strategy represents a big challenge for companies due to the following potential problems [9]:

1. In the long run, it is difficult to build differentiation on service characteristics. Any feature (or function) of a service that is significant and currently popular is easily copied. (for example, as soon as Snapchat Stories came to life, first Facebook, and then all other social networks, copied them). Even when a service has some truly innovative features, it will take time for the competition to reach that level of service. Therefore, differentiation should not be based only on the characteristics of the service, especially since there are consumer beliefs that all services are the same (commodization). Almost all smart phones have great screens. It wasn't always this way, but mobile phone manufacturers can no longer build or maintain a competitive advantage based on screens alone. They might be able to do this based on battery life, but even if a better battery is made (which will likely increase the overall cost of production), even such success will be very limited in time. The competition will produce the same battery very soon.
2. Markets are becoming increasingly saturated. Never before have there been so many brands as there are today. The barrier to entering the market and opening new businesses has never been lower.
3. Over time, competitors become increasingly similar. The greater the competition, the stronger the commitment to differentiation should be, however, the opposite is generally the case. Constant comparison and benchmarking lead to similarities between products, and competitors become less differentiated over time. As the number of products within a category multiplies, the differences between competitors become less and less visible, almost non-existent.

4. SUCCESSFUL EXAMPLES OF STRATEGIES IN TRAFFIC COMPANIES

There are numerous examples of companies in the world that implement a low-cost strategy using different instruments and methods, depending on internal opportunities (and weaknesses) and external opportunities (and threats). In the context of this work, we cite several examples of traffic companies. Although the above examples belong to air traffic companies, the low cost and differentiation strategies applied by these companies can easily be applied to companies dealing with other types of traffic.

RyanAir [10] is probably one of the most famous examples when it comes to implementing a low cost strategy. Founded in 1984, Ireland's budget airline (with a fleet of 469 aircraft including subsidiaries) carries more international passengers than any other airline in the world.

The company's competitive advantage strategy is based on their intention to outperform competitors by providing air travel services at the lowest possible unit costs. This is achieved in a variety of ways, including:

- significant bargaining power with suppliers, which helps the company to keep its operating costs at a low level;
- small variety of aircrafts (mainly Boeing 737-200), which allows them to purchase spare parts in large quantities;
- negotiating power with airport operators, demanding low landing, take-off and maintenance fees, in addition to flights to less popular airports;
- lack of differentiation services such as loyalty schemes, free food, in-flight entertainment, airport lounges, premium cabins, etc.

Emirates [11]. While airlines such as Ryan Air and Wizz Air have chosen a low-cost strategy as a competitive advantage, other companies in the industry are looking for ways to differentiate themselves. For this reason, an example of a differentiation strategy is the Emirates. Based in Dubai, Emirates is the national airline and carrier of the United Arab Emirates. The company operates about 3,600 flights per week to more than 150 cities in 80 countries. However, what really differentiates them is not the number of flights or the countries they go to, but:

- Exceptional customer service. Narrow spaces between seats, no entertainment and a limited choice of food and drinks, Emirates does not exist. The company provides exceptional service and merchandise to its passengers, taking care of them throughout the flight. Even Economy Class, the cheapest of their offerings, includes: high-quality, regionally inspired meals from the flight's destination; digital entertainment during the summer with over 4,500 movies to choose from; excellent customer service and catering; Free drinks; Wi-Fi on the plane.
- Latest technology. An important part of Emirates' differentiation strategy is the fact that they invest heavily in the latest technologies available in the market. From using advanced navigation technology for their aircraft to providing the best in-flight entertainment, their commitment to innovation is a fundamental part of the customer-centric experience.

5. CONCLUSION

From the above, it can be concluded that a low-cost strategy can help achieve a competitive advantage in the market. Traffic companies that implement a low-cost strategy have first of all created the preconditions for the successful implementation of the strategy, namely: access to capital for significant investments, efficiency of the servicing system, the possibility of professional improvement of the servicing process, supply of vehicles and spare parts at a lower price, low labour costs and efficient placement services. Such companies can gain significant market share enabling a stronger position vis-à-vis suppliers and competitors. This strategy is particularly effective for organizations in industries where there is limited services differentiation and where customers are highly price sensitive.

The low-cost strategy carries with it certain risks and dangers. Two or more firms competing for low-cost leadership can engage in price wars that drive profits to very low levels. Ideally, a business using a low-cost strategy will develop an advantage that cannot be easily copied by others. Low-cost leaders must also maintain their investments in state-of-the-art equipment or face the possible entry of more profitable competitors. Major changes in technology can drastically change servicing processes so that previous investments in servicing technology are no longer profitable. Finally, businesses can become so focused on keeping costs low that they may overlook necessary changes in processing services or marketing.

The strategy of differentiation is one of the most widely applied generic strategies in practice. Companies that implement this strategy use different ways and instruments of differentiation with the main goal of being different from the competition. Which instrument will be used depends on the results of the market research as well as on the research of one's own company, that is, on the current possibilities, the traffic company itself, and the market, i.e. company environment.

ANALYSIS OF THE COMPETITIVENESS OF LOGISTICS PROVIDERS IN THE AREA OF THE WESTERN BALKAN COUNTRIES

Svetlana Živanović[1], The Academy of Applied Technical Studies Belgrade

Abstract: *It often happens that the critical factors of competitiveness are difficult to recognize or are incorporated within other segments, so companies or countries are not able to recognize them in a timely manner. It is for this reason that it is important to have adequate instruments both at the state level and at the global level, which will enable the monitoring and continuous improvement of performances that lead to the strengthening of competitiveness. Given the fact that competitiveness is related to many factors and that the logistics services market is extremely complex, it is difficult to compare different countries in terms of competitiveness and logistics performance. Namely, it is necessary to determine which performances are important to monitor, collect a large amount of data, and then process, analyze, and propose potential directions for improvement. However, the World Bank has introduced two important instruments for monitoring these indicators, namely the Logistics Performance Index and the Global Competitiveness Index. Based on the data published on a biannual basis, which are included in the report, one can easily assess the position on the market, the competitiveness of countries, as well as the directions for improvement. Therefore, the aforementioned indexes were considered in the paper in order to create a complete picture of the logistics services market in the area of the Western Balkan countries.*
Keywords: Competitiveness, Logistics performance, Logistics providers, LPI, GCI

1. LOGISTICS PERFORMANCE INDEX

Globalization and increased competitiveness have led to logistics becoming one of the key elements of international trade. Since logistics includes many factors, activities, and functions, the challenge is to be competitive in the market and to have a level of efficiency that meets the needs of users. Logistics is one of the most important elements of national competitiveness. Quality logistics services and infrastructure promote the exchange of goods between countries [1, 3].
In developing countries, certain aspects of logistics are not sufficiently developed, which causes an increase in costs and hinders the efficient movement of goods across borders. The reasons are numerous, from insufficiently developed infrastructure to complex customs procedures and excessive bureaucracy. It is precisely for this reason that it is complex to develop a unified model for measuring the logistics offer of a country. A tool that has proven to be useful is the Logistics Performance Index (LPI), published by the World Bank for an average of 150 countries (depending on the year). This index enables the analysis of key differences between countries, providing an overview of customs procedures, logistics costs, infrastructure, timeliness, and other dimensions of logistics service quality [1, 5]. Below are the key dimensions of the LPI index [1, 2, 4]:

- Efficiency of the customs clearance process (i.e., speed, simplicity, and predictability of formalities) by border control agencies, including customs;
- Quality of trade and transport-related infrastructure (e.g., ports, railways, roads, information technology);
- Ease of organizing shipments at competitive prices;
- Competence and quality of logistics services (e.g., transport operators, customs brokers);

[1]szivanovic@atssb.edu.rs

- Ability to track shipments;
- Timeliness of shipments arriving at their destination within the predicted or expected delivery time.

The Logistics Performance Index (LPI) is an interactive benchmarking tool created by the World Bank to help countries identify the logistics challenges and opportunities they face. In addition, the LPI report also provides potential guidelines, i.e., what the observed countries can do to improve their performance. The last report available on the World Bank website is from 2023. Although the data was planned to be published for two years, the previous report was published in 2018 due to the impact of the COVID-19 pandemic. According to the LPI index, the countries of the Western Balkans are partially logistically developed [2, 4].
Table 2 provides an overview of the LPI and the ranking of the countries of the W. Balkans in the period from 2014 to 2023. The largest increase in LPI in the observed period was achieved by North Macedonia, from 117th position to 57th. The country with a negative growth trend is Serbia. The leader in terms of rank on the LPI list among the countries of the Western Balkans is Croatia [2, 4].

Table 1. LPI index for the countries of the Western Balkans
Source: *https://lpi.worldbank.org/*

	in 2023		in 2018		in 2016		in 2014	
Country	Rank	In total	Rank	In total	Rank	In total	Rank	In total
Croatia	43	3.30	48	3.12	51	3.16	55	3.05
Serbia	73	2.80	68	2.83	76	2.76	63	2.96
BiH	61	3.00	78	2.76	97	2.60	67	2.88
Montenegro	73	2.80	94	2.65	123	2.38	81	2.75
Albania	97	2.50	98	2.62	117	2.41	/	/
N. Macedonia	57	3.10	99	2.62	106	2.51	117	2.50

The country received the best rating for the timeliness of shipment delivery; Croatia is the leader in this category with a rating of 3.4. The countries of the Western Balkans mostly received the lowest score for customs procedures. Certainly, this is expected considering the average time the vehicle is held during customs formalities, which is often between 4 and 5 hours. The inefficiency of the customs procedure significantly affects other attributes of the logistics service, primarily the timeliness of delivery [2, 4].

Table 2. LPI index for Western Balkan countries by category (2023)
Source: *https://lpi.worldbank.org/*

Country	Customs	Infrastructure	International shipments	The quality of the logistics offer	Timeliness	Shipment tracking
Croatia	3.0	3.0	3.6	3.4	3.2	3.4
N. Macedonia	3.1	3.0	2.8	3.2	3.5	3.2
BiH	2.7	2.6	3.1	2.9	3.2	3.2
MNE	2.6	2.5	2.8	2.8	3.2	3.2
Serbia	2.2	2.4	2.9	2.7	3.4	2.9
Albania	2.4	2.7	2.8	2.3	2.5	2.3

The LPI index showed another shortcoming of the mentioned countries, namely the quality of the infrastructure. According to the assessment, the infrastructure is the least developed in the territories of Serbia and Montenegro. The quality of the logistics offer is the best in Croatia, followed by North Macedonia and Bosnia and Herzegovina. Regarding the organization of international shipments, the countries are quite uniform. This means that international commodity flows are

taking place on the territory of the listed countries, but the question is how complex their organization is. Shipment tracking is also not at a satisfactory level. It is a fact that modern monitoring and reporting systems are insufficiently used in the countries of the Western Balkans [2,4].

2. GLOBAL COMPETITIVENESS INDEX

The World Economic Forum defines competitiveness as a set of institutions, regulations and other factors that determine the level of productivity of countries. The indicator of the level of competitiveness is called the Global Competitiveness Index (GCI) and deals with measuring the average of several microeconomic and macroeconomic components that are individually evaluated on a scale from 1 to 7. All measured indicators are grouped into twelve segments and reflect different aspects complex economic realities. The indicators are grouped into three units: the basic factors of the managed economy, the efficiency of the managed economy and the innovations of the managed economy.
The following (Table 4) shows the competitiveness index of the countries of the Western Balkans for 2019. For each country, the overall ranking is shown, as well as the ranking of each key element of the GCI. In addition, the ratings for the mentioned categories are also shown. Scores are from 1-100 and represent the sum of individual scores for each subgroup (scores from 1-7) [6].

Table 3. GCI of Western Balkan countries by category

Country	*Croatia*		*Serbia*		*BiH*		*Montenegro*		*Albania*		*North Macedonia*	
GCI 2019	Rank	Rating	Rank	Rating	Rank	Rating	Rank	Rating	Rank	Rating	Rank	Rating
IN TOTAL	**63**		**72**		**92**		**73**		**81**		**82**	
Basic factors of the managed economy												
Institutions	77	51.8	75	52.5	114	44.4	53	57.3	76	51.9	84	50.7
Infrastructure	32	78.2	51	73.8	84	63	83	63.6	98	57.7	75	66.9
Macroeconomic stability	43	90	64	75	64	75	104	70	104	70	82	74.8
Health and basic education	47	85.7	76	79	73	80.3	65	81.2	46	85.9	64	81.3
The efficiency of the managed economy												
Higher education and training	69	63.5	55	68.2	82	60	53	68.7	50	69	83	59.8
Commodity market efficiency	86	53.2	73	54.6	108	49.6	42	59.4	75	54.4	110	48.6
Labor market efficiency	94	56	54	62.1	107	53.3	26	67.7	38	65.3	82	58.3
Development of the financial market	63	61.9	82	57.4	80	57.9	44	68	102	53.3	83	57.3
Technological preparedness	60	60.7	77	52.6	80	51.6	57	62.9	75	52.9	70	57.6
Market size	78	50	74	51.8	101	42.3	134	28.8	111	39.6	109	39.7
Innovations of the guided economy												
Business sophistication	101	54.6	54	63.1	117	51.1	50	64	63	61.8	65	61.2
Innovations	73	37.8	59	40.2	117	28.4	69	38.3	110	29.8	97	31.8

A higher score reflects a country's greater success in a particular category. The best-ranked country in the Western Balkans is Croatia, followed by Serbia, Montenegro, Albania, and North Macedonia. The lowest-ranked country in the observed category is Bosnia and Herzegovina. The category in which countries received the lowest individual score is innovation and business sophistication. Namely, based on the results, it can be concluded that countries do not sufficiently follow and implement modern business trends. The market size category also supports the mentioned fact.

In terms of infrastructure, a positive picture can be seen for Croatia and Serbia. One of the reasons is certainly the membership in and the process of accession to the European Union. Namely, before its official accession to the EU, Croatia had to fulfill many conditions, and one of them was the quality of its infrastructure, which the mentioned country significantly improved. Given that Serbia is also in the process of joining the Union, it is clear that it is necessary to work on improving the infrastructure network, which is reflected in the GCI assessment. However, the LPI values show that the performance in terms of infrastructure is still not at a satisfactory level. The countries of the Western Balkans are generally rated poorly in terms of institutions. In this category, the sections dealing with corruption and bureaucracy are particularly poorly rated. Namely, it was observed that bureaucratic forms, laws, and other by-laws are often a "stumbling block" for many companies. It was observed that many activities within the institutions are carried out lapurlatistically.

In terms of health and basic education, the countries are correctly listed. This is to be expected, considering that in most of the listed countries, primary education is compulsory. However, the problem is reflected in another category, namely higher education and training. The percentage of highly educated people in these countries is still at a devastating level. This is also influenced by personnel training, which is insufficiently conducted, and as one of the reasons, the previously mentioned small percentage of highly educated people can definitely be singled out. Namely, managers who are insufficiently educated are unable to recognize the value of training and encourage employees to continuously develop. In terms of macroeconomic stability, Croatia is once again ranked the best. Of the listed countries, it stands out for having the highest average income per capita and the lowest unemployment, but also for the fact that there is little political turmoil.

3. CONCLUSION

Through the monitoring and analysis of Logistics Performance Indicators and Competitiveness Indicators, some of the basic shortcomings of the countries of the Western Balkans were observed, due to which they are limitedly competitive on the markets and logistically underdeveloped. The analysis of both indices gave similar results. The best in the region in terms of both indices is Croatia, which can be explained by the fact that it has been part of the European Union for ten years and that in the process of accession it significantly improved various segments with the intention of becoming a full member. However, Croatia, as well as other countries in the Western Balkans, should continue with continuous growth and development in various aspects. Starting with infrastructure, administration, logistics, market expansion, development of new products and services, education, and staff training.

It is necessary for companies to seriously devote themselves to the development of logistics solutions, the introduction of innovations, digitization, and the construction of system support for business. The lack of manpower will initiate faster development and the introduction of solutions based on new technologies and automation. It is necessary to work on solutions that replace human labor in the execution of the work itself. Such solutions are already widely used around the world. On the other hand, it is necessary to introduce standards, procedures, and work procedures that companies do not have or have adopted but do not implement. It is necessary for the growth and development of companies to be planned and controlled. This requires specific knowledge and skills, so it is necessary to invest in acquiring knowledge and training employees.

SELECTION OF LOGISTICS PROVIDER IN THE FIELD OF E-COMMERCE

Svetlana Živanović[1], The Academy of Applied Technical Studies Belgrade
Gordana Radivojević[2], Faculty of Transport and Traffic Engineering, University of Belgrade
Milorad Kilibarda[3], Faculty of Transport and Traffic Engineering, University of Belgrade

Abstract: *Through the cooperation of business entities, it is possible to maximize the advantages and minimize the risks of business. Therefore, especially in the last decade with the expansion of e-business, the execution of certain logistics activities is increasingly left to specialized logistics service providers. Choosing a logistics provider is a complex task. It is necessary to know the system well and define the criteria for choosing a provider accordingly. In addition, it is necessary to apply adequate methods for solving this task. In this paper, a model for the selection of a logistics provider in the field of e-commerce was developed using the AHP (Analytic Hierarchy Process) method.*
Keywords: logistics, providers, e-commerce, AHP method

1. INTRODUCTION

In the period of globalization, gaining a competitive advantage is possible through the cooperation of business entities, with the aim of dividing tasks, risks, responsibilities, as well as specialization in the execution of certain business activities. Development of the information sector, communications and traffic has brought a series of changes in supply chains. One of those changes is the transfer of logistics jobs to specialized logistics service providers. In the beginning, tasks related to warehousing, transportation and customs formalities were left to logistics providers. Due to the numerous advantages of doing business in such a way which are primarily related to the rationalization of logistics costs, the provision of better service, greater specialization of personnel, an increasing number of activities were entrusted to the providers. After the expansion of electronic commerce, providers of logistics services in the field of e-commerce appeared on the market. This type of provider, by applying knowledge and information technologies, strives to provide the user with complete logistics solutions. The aim of this paper is to develop a model for the selection of logistics providers in the field of e-commerce.

2. LOGISTICS PROVIDERS

Expansion of market competition led to increased cooperation between companies, shared responsibilities and divided jobs and tasks, next to the specialization of their own activities. Therefore, the need to hire a provider often arises. Products and product quality are becoming more and more uniform and therefore, competitive advantage can only be achieved in the field of logistics service. Looking for a way to increase profits, quality and minimize risks, companies are increasingly turning to partnerships and outsourcing certain activities [3]. Logistics providers are companies that specialize in providing logistics services. The development of logistics also influenced the development of logistics providers. Therefore, different forms of logistics providers

[1]szivanovic@atssb.edu.rs
[2]g.radivojevic@sf.bg.ac.rs
[3]m.kilibarda@sf.bg.ac.rs

appear over time, from 1PL (First Party Logistics) to the 5PL (Fifth Party Logistics) model [14]. The main task of the 5PL provider is related to the mapping and reengineering of the entire supply chain in the field of e-commerce. The 5PL provider tries to coordinate the work of other providers in the field of electronic commerce (e-commerce) by applying knowledge and information technologies and thus offering complete logistics solutions. This type of provider does not own physical assets in the form of means of transport, warehouses, etc. Its business is mostly focused on web business, which implies that all participants in the supply chain receive information precisely from the 5PL provider and on that basis perform part of the activities within the supply chain. It is essential that the 5PL provider manages the information adequately, but also the system for integration of information received from the downstream providers needs to be reliable. The information has to be updated and available in real time. For this reason, 5PL providers have recognized the importance of digital transformation and, through the concept of IoT (Internet of Things), collect data from various sources of the supply chain [7].

3. E-COMMERCE

Electronic business means the provision of services and the exchange of goods and information through electronic systems (most often the Internet). In a broader sense, electronic business includes any form of business activity that is performed using electronic systems. The most common forms of business activity are: purchase, sale, distribution, marketing, supply chain management, money transfer, servicing, development, etc. The advantages of using e-commerce compared to traditional commerce are numerous. Some of the advantages from the seller's point of view are [6]:

- faster identification of the target market,
- global availability,
- increasing competitiveness,
- the possibility of a faster reaction to the customer's requests,
- faster turnover of capital and
- reduction of documentation in paper form

The advantages of e-commerce from the customer's point of view are primarily the convenience of shopping (the so-called armchair shopping), but also [6]:

- the seller's response time is shorter,
- easier access to information,
- faster delivery than in the case of commercial sales and
- easier price comparison of services and products of different companies

The biggest drawback of e-commerce, from both the seller's and the buyer's perspective, is related to data control and protection. Other disadvantages are [6]:

- the possibility of a delivery error,
- the possibility that delivery will not occur,
- the seller may misrepresent himself,
- reduction of direct contact between seller and user,
- sharing confidential information (address, account number, etc.) etc.

4. AHP METHOD

The AHP method was defined by Saaty in the 1980s and is used as a tool in multicriteria analysis. A complex problem is decomposed into a larger number of factors, among which a hierarchy is established. At the highest level of the hierarchy is the goal, then the criteria within which a large number of sub-criteria can be found, and finally, the alternatives [5, 13]. The application of the AHP method can be presented in four steps. The first step involves structuring the problem, the next step involves forming a decision matrix. In the third step, it is necessary to define the priority of each element in relation to the higher level of the hierarchy. In the last step, all priority values are synthesized. Below, the steps are described in more detail [4, 12]. During the application of the

AHP method, the expert can add or eliminate hierarchical levels and elements depending on the impact they have on the achievement of the defined goal [10, 11].
The second step involves the formation of a decision matrix. It is assumed that there are elements of the same hierarchical level. It is necessary to compare them in pairs in order to determine their importance for achieving the defined goal. For comparing pairs of elements, experts most often use the Saaty scale [10, 12]. The expert defines the values for the elements of the square matrix $A = [a_{ij}]_{nxn}$, where for each a_{ij} based on the rule of reciprocity is valid [12]:

$a_{ij} = \frac{1}{a_{ji}}$ for $\forall i, j = 1, \ldots n \; i \; a_{ij} = 1 \; za \; \forall i = j$, where n is the number of criteria. (1)

In the third step, the priority of each element is defined in relation to the higher level of the hierarchy (w_{ij}). Priority w_{ij} shows the importance of alternative i in relation to criterion j, where $i = 1, \ldots m$ and $j = 1, \ldots n$ where m represents the number of alternatives [4].
The last step entails the synthesis of all priority values in order to obtain the priority of each element in relation to a predefined goal. W_i is the priority of alternative i and is determined as [4]:

$W_i = \sum_{j=1}^{n} c_j w_{ij}$ (2)

where c_j is the priority of criterion j, and w_{ij} is the priority of alternative i in relation to criterion j.
A significant characteristic of the AHP method is that during the evaluation of the elements of the hierarchy, the consistency of the expert's reasoning can be checked side by side, and thus the correctness of the obtained weight values and ranks of alternatives and criteria can be monitored. This is done by monitoring the consistency index CI. The index measures the deviation of n from λ_{max} where λ_{max} represents the highest eigenvalue of the decision matrix. If $CR \leq 0.10$, it means that the evaluations of the decision makers are consistent, that is, that the deviation in the experts evaluations is less than 10%. The consistency index is calculated as [4, 12]:

$CI = \frac{\lambda_{max} - n}{n-1}$ (3)

Based on the presented relations, the CR consistency ratio is calculated. The consistency ratio represents the quotient of the consistency index and the random consistency index RI [12]:

$CR = \frac{CI}{RI}$ (4)

The AHP method is applied in various fields, and it has also found its place in logistics. It is used for the selection of logistics providers, solving location problems, improving the quality of logistics services, etc. The AHP method can be combined with QFD, COPRAS, TOPSIS and other methods [1, 2, 8, 9].

5. MODEL FOR SELECTING A 5PL PROVIDER

In this paper, the criteria and alternatives for selecting a logistics service provider in the field of e-commerce are analyzed. After that, a hierarchy was established, that is, the structuring of the problem was carried out, which is shown in Figure 1.

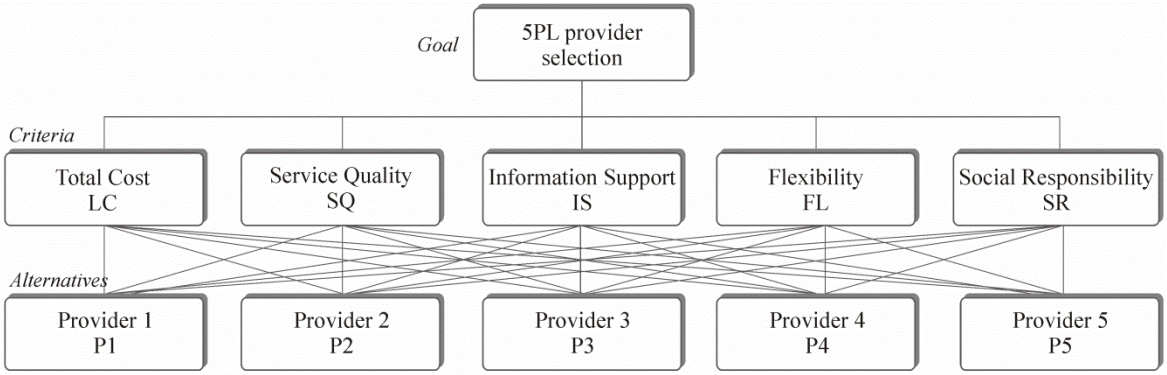

Figure 1. Hierarchical structure of the model for selecting a logistics provider

At the highest level within the presented hierarchical structure is the goal - the logistics provider selection in the field of e-commerce. On the second level, there are the criteria on the basis of which

the logistics provider is selected, namely: logistics costs, service quality, information support, flexibility and social responsibility. On the third level there are five alternatives, that is, five logistics providers that are shown in Figure 1.

6. NUMERICAL EXAMPLE

The model for choosing a logistics provider was tested on a concrete example that includes $n = 5$ criteria and $m = 5$ alternatives. The criteria are logistics costs (LC), service quality (SQ), information support (IS), flexibility (FL) and social responsibility (SR), and the alternatives are providers P1, P2, P3, P4 and P5. The input data for the application of the AHP method were obtained by surveying experts.

Table 1 shows the criteria comparison matrix and the calculated priorities for each criterion. The table shows the values of λ, CI and CR. The value CR is less than 10%, which means that the priority vector can be accepted.

Table 2 shows the comparison matrices of providers in relation to the criteria and values of local priorities for each provider. Global priorities are calculated based on the obtained values of local priorities. Table 3 shows the local and global priorities for each provider. The output results of the proposed model include the importance of all criteria and proposed alternatives. Figure 2 shows the values of importance of criteria and alternatives graphically.

Table 1. Comparison matrix and priorities of criteria

	P5	1/3	1/3	1/4	1/5	1	0.066
	λ_{max} =5,220		CI =0.055		CR =0.050		

Table 3. Local and global priorities of criteria and alternatives

	LC	SQ	IS	FL	SR	
	0.105	0.393	0.299	0.132	0.071	← W ↓
P1	0.062	0.398	0.399	0.177	0.246	0.323
P2	0.118	0.175	0.188	0.115	0.246	0.170
P3	0.388	0.175	0.097	0.395	0.283	0.211
P4	0.211	0.157	0.091	0.207	0.158	0.150
P5	0.221	0.095	0.225	0.106	0.066	0.147

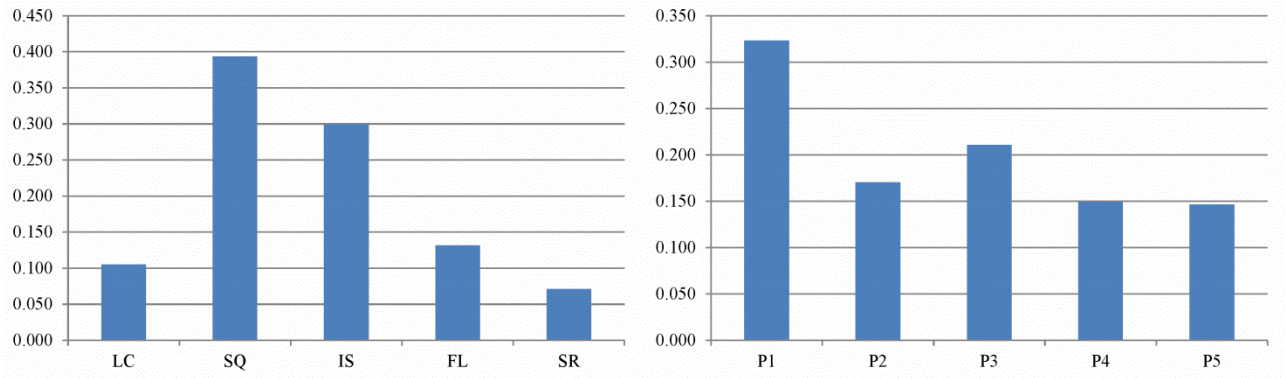

Figure 2. Importance of criteria and alternatives

Analysis of the results indicates the following conclusions:

- The most important criterion is service quality – SQ (39.3%) and the least important is social responsibility – SR (7.1%).
- The provider ranking is P1, P3, P2, P4 and P5.
- Provider P1 is the best because it is rated best by experts according to the most important criteria (SQ and IS).
- Other providers have approximately similar scores for all criteria.

7. CONCLUSION

There is increasing interest in the application of different methods for selecting logistics providers, and in recent years the focus has been on the expanding e-commerce sector. It is important to emphasize that there is no universal tool for selecting logistics providers. The criteria are chosen depending on the needs and way of functioning of the observed system. In addition to the AHP method, it is possible to apply other methods, and often a combination of several methods is applied.

Fulfilling the increasingly complex demands of customers and maintaining a position in the market is a real challenge. Therefore, companies increasingly decide to entrust part of their activities to specialized logistics service providers - logistics providers. Choosing an adequate provider is a

complex task, and a wrong assessment can affect many aspects of business, primarily the end user's dissatisfaction with the service or product. Therefore, it is necessary to choose reliable business partners, but also to monitor your own system in order to determine which features the provider should have in order to fulfill all requirements.

MARKET RESEARCH AIMED TOWARDS THE ANALYSIS OF THE POSSIBILITY OF LAUNCHING AN OPERATIONAL START UP IN THE FIELD OF LCL (LESS THAN CONTAINER LOAD) TRANSPORT AT THE PORTS OF BARI AND/OR TARANTO (ITALY)

Class[1] "Tecnico Superiore della Lorisitca per la GDO" biennio 2022-24, ITS Logistica Puglia Bari, Italy
Michele Minenna,[2], ITS Logistica Puglia Bari, Italy
Natasa Gojkovic Bukvic[3] ITS Logistica Puglia Bari, Italy

Abstract: *The competitive advantage of the Less Container Load (LCL) solution consists in a significant reduction in transport costs, compared to the booking of a complete container or air transport but it's notable that today, within the Italian territory, the main LCL departure hubs are predominantly located in Northern Italy. Therefore, the purpose of this market research done by ITS Logistics Class 2022-2024 GDO was the analysis of a possible start-up of an LCL shipping service in Southern Italy at the Ports of Bari or Taranto, as well as its possible implications in terms of growth of the territory, implementation of innovative technologies and environmental sustainability. Its statistical survey showed that the creation of an LCL service located at the Port of Bari is in total harmony with the current demands of the neighboring markets (Apulia, Basilicata, Campania),with the leading product sectors being wine and agri-food. It has also been shown that there would be wide room for opportunity with the introduction of cold chain in LCL service. But on the other hand, statistical tecniques we used demonstrated the absolute need to spread the concept of LCL and also made evident that there is still a remarkable chunk of the market which does not appear to be educated on the subject.*
Keywords: Market research, LCL, Southern Italy, Start up

1. INTRODUCTION - PREMISE

In the field of transport systems which make use of containers, the acronym LCL (Less than Container Load)is the term which identifies, in the field of logistics, the frequent shipment type of "partially loaded containers", also known as "groupage": the load coming from different senders, suitably consolidated and grouped, stowed in a standard container, is sent for shipment by sea.The competitive advantage of the LCL solution therefore consists in a significant reduction in transport costs, compared on the other hand to booking a full container (FCL - Full Container Load) or Air Transport [1]. By a visual scrutiny of the geographical location of the service, it should be noted that within the Italian territory as of today, the main LCL departure hubs are mainly located in northern Italy. The purpose of this market research therefore consists in analyzing the possibility of launching an LCL shipping service at the Ports of Bari or Taranto, as well as to evaluate the possible implications in terms of growth of the territory, implementation of innovative technologies and environmental sustainability [2].

2. METHODOOGICAL APPROACH OF THE RESEARCH

The phase of identifying the statistical collective was preceded by a qualitative-quantitative analysis which defined the categories of operators active in the field of international shipments and the producers operating in the agri-food, mechanical, pharmaceutical, fishing, chemical, construction. It has been here for proceeded to extrapolate 600 names of Companies located in the regions of Apuglia and Basilicata (Italy) from the main sources available on the net, together with their relative classification by product sector and cataloguing of the significant salient data. An appropriate verification and reclassification work was then carried out on the selected collective through Excel spreadsheets and use of the functions: VLOOKUP, COUNTIF, COUNTVALUES. Upon completion of the aforesaid phase, the sample purified by analysis was obtained, consisting of 400 statistical units. For the purposes of an efficient outcome in the administration of the questionnaires and data collection processes it was therefore decided to proceed with the drafting of two groups of Google Forms made available to the interviewer, for the registration of the primary sources. The group of questions to be submitted was distributed as follows: 18 questions for the category of producers and 13 questions for the category of shippers. For the purposes of greater efficiency of the process, specific guided logical paths were identified during the drafting of the questionnaires, also aimed at collecting data useful for marketing and profiling activities as well as the feasibility study for its own sake, also through the proposal of some open-ended questions. The administration of the questionnaires was carried out through the method of the outbound telephone call preceded by an e-mail explaining the initiative, with indication of the person in charge of the processing of sensitive data, also in compliance with the provisions in force regarding privacy pursuant to Italian law 675/96 “Text Unico” of 2003. The consent to participate in the survey also constituted the consent to the processing of data. To encourage broad acceptance and understanding of the survey, the aforementioned email was accompanied by a graphic and captioned representation of the initiative in the form of "storytelling" **(Figure 1)**.

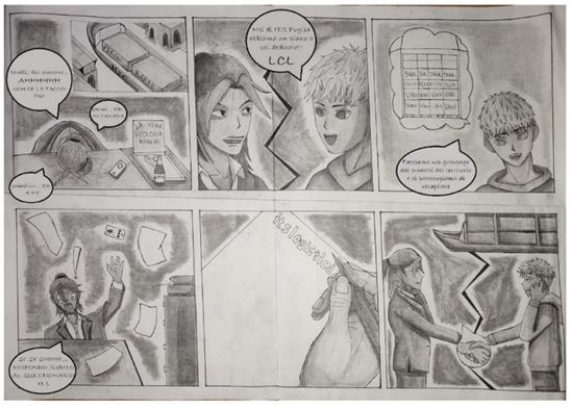

Figure 1. Storytelling board

The effective yield at the end of the administration phase, carried out in about 6 hours with 26 active operators including interviewers and co-opted, produced a total of 96 complete interviews (corresponding to about 1/4 of the total statistical collective).The data reclassification was subsequently carried out through the use of Excel sheets extracted from Google Forms and the built-up of the Pivot tables. With a view to improving the quality of the survey, it was deemed necessary to resort to statistical inference for the estimation of inclusive oscillation intervals of the processed percentage data. The Confidence Interval was opted and supported by the calculation of the corresponding percentage of reliability through the use of the Mean Squared Deviation and the application of an appropriate correction factor K for widening the aforementioned interval, for the purposes of being able to ensure the survey the strongest correspondence to the real data **(Figure 2).**

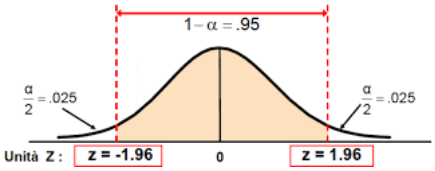

Figure 2. Mean Squared Deviation

As a useful guide tool in support of the interpretative phase, the SWOT Analysis technique was used for a more precise assessment of the aspects related to strengths, limitations, opportunities and threats.To complete and summarize the data analysis and the interpretation phase, a canvas of the "Value Proposition" type was also drawn up.

3. OUTCOME, ANALYSIS AND INTERPRETATION OF DATA PRODUCERS SECTION

The data elaborated highlights a mainly qualitative factor of the sample interviewed, characterized indeed by the substantial totality of companies that have shown a marked capacity for resilience against the critical phase of the Covid-19.
From the point of view of financial analysis, the figure is therefore assumed to be plausibly correlated to more than satisfactory balance sheet ratios.
More than half of the sample analyzed was found to be operating in the agricultural sectors of viticulture and agri-food.
The data is comforting for the purposes of our study since it is closely related to a stand-out interest, subsequently shown by this sample, in willing to receive further useful information on the subject. In fact, the characteristic peculiarity of the distribution of the local wine and agri-food sector in general is well placed, in a strategic perspective, to the use of the LCL mode of transport [3].
The analysis highlights the strong vocation of the local productive fabric, in Puglia in particular, to export to foreign markets. These destinations, as will be highlighted below, are mainly directed towards Asian routes (**Figure 3**).

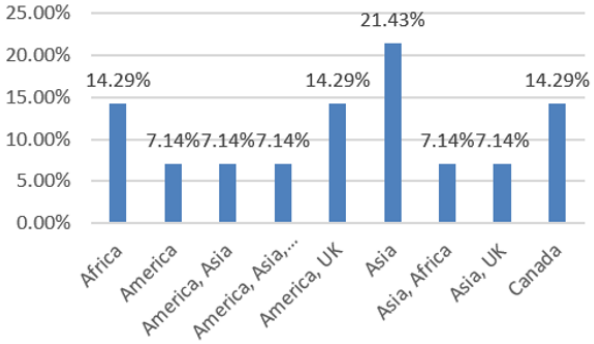

Figure 3. Which macro geographical area do you predominantly cover up with your shippings?

Table 1. Range of confidence for Figure 3 results

	Range of confidence		
Africa	4,93%	**14,29%**	33,88%
America	0,00%	**7,14%**	20,91%
America, Asia	0,00%	**7,14%**	20,91%
America, Asia, etc	0,00%	**7,14%**	20,91%
America, UK	4,93%	**14,29%**	32,99%
Asia	10,46%	**21,43%**	43,36%
Asia, Africa	0,00%	**7,14%**	20,91%
Asia, UK	0,00%	**7,14%**	20,91%
Canada	4,93%	**14,29%**	32,99%

The previous three questions goal was to extract useful information aimed at understanding the size and propensity of manufacturing companies to resort to professionals in the transport sector and the perception of the level of satisfaction with the service offered [4].
The figure shows a greater tendency to outsourcing the service to multitransport operators, as confirmed later in a specific control question reserved for shippers in the second module (**Figure 4**).

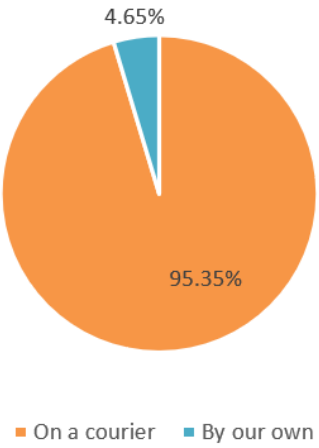

Figure 4. Do you ship by your own means or you rely on a courier?

Table 2. Range of confidence for Figure 4 results

	Range of confidence		
On a courier	92,14%	**95,35%**	100,00%
By your own	1,44%	**4,65%**	7,86%

With reference to the latter aspect, an economic-financial assessment aimed at identifying the specific turnover/outsourcing ratios of the service would be worthy of further study.[5] As a particularly peculiar feature for the purposes of the survey, we evaluated the market share of producers who direct exports to non-EU countries. It was therefore noted that over 32.56% of the interviewees carry out activities towards this destination, even if they do not have a foreign branch (**Figure 5**).

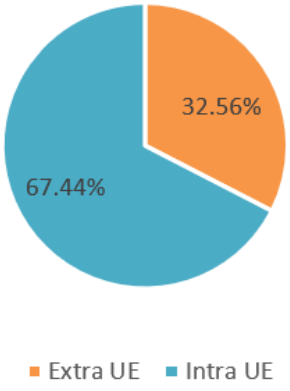

Figure 5. Where do you mainly export your products to?

Table 3. Range of confidence for Figure 5 results

	Range of confidence		
Extra UE	25,41%	**32,56%**	39,70%
Intra UE	60,30%	**67,44%**	74,59%

With reference to the assessment of the degree of interest in a possible temperature-controlled consolidation and transport service, it was found that over 1/3 of the sample expressed their consent.
The survey also highlights the presence of a large portion of the market that intends to increase the production quotas for export in the near future. For the purposes of the survey, the data is of particular interest since a demand for more qualified and innovative services seems to emerge distinctly in the field of freight forwarding activities.

4. SHIPPERS SECTION

As part of the questions administered to professional transport operators, it was decided to investigate the existence of opportunities to expand the range of services offered by them, currently lacking in the LCL transport sector. The data show that 48 operators declared themselves willing to receive updates on the subject in the future, also with reference to a highly specific service such as 'under controlled temperature' LCL transport (**Figure 6**).

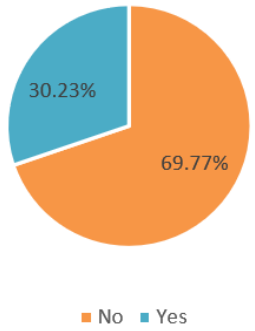

Figure 6. Do your transportations need to be under controlled temperature?

Table 4. Range of confidence for Figure 6 results

	Range of confidence		
No	62,76%	**69,77%**	76,77%
Yes	23,23%	**30,23%**	37,24%

Data analysis reveals that the main actor towards which strategically concentrate the LCL transport service is Asian, properly integrated with intermodal transport systems. For the purposes of the survey, the data reveals that the port of Bari is the most appropriate location for the establishment of an LCL service hub. It is hoped that in the short period the adjustments relating to the extension of the draft limits of this infrastructure will be definitively completed.

5. CONCLUSION

This statistical survey, performed by the scientific method, demonstrates with plausible truthfulness that starting of an LCL freight transport service located at the Port of Bari is in total harmony with the current service requests of the neighboring markets (Puglia, Basilicata, Campania).
The reference product sectors of maximum instance are included in the wine and agri-food sectors.
In terms of the innovative quality of the system, it has been shown that there are ample margins of opportunity with the introduction of the 'under controlled temperature' LCL service.
For the purposes of an effective territorial distribution of the service, the absolute need also emerged to set up an effective commercial and consultancy network aimed at the specific dissemination of the LCL shipping service since it is evident that there are stilllarge market shares that are not educated on the subject. To this end, it is desirable to draw up an appropriate marketing plan for which the use of the Value Proposition method should be proposed.

Abstract: *Freight pickup and delivery processes are increasingly based on the concept of crowd logistics. One of the most well-known vehicle routing problems based on this concept is the Vehicle Routing Problem with Occasional Drivers (VRPOD). The first paper describing this problem was published in 2016. Since then, this problem has begun to attract more and more attention from researchers around the world. Until now, many papers related to this problem have been published. In this paper, we make a detailed review and analysis of papers published between 2016 and 2020 that dealt with this vehicle routing problem.*
Keywords: Vehicle Routing Problem, Occasional Drivers, Crowd Logistics

1. INTRODUCTION

The concept of last mile refers to the stage of the shipment when delivery occurs. Last mile also involves all the tasks necessary for the arrival of the parcel to the recipient. This is the last step of the entire distribution chain, hence the importance of last-mile delivery.The last mile delivery has always attracted the attention of researchers. The reason for this is primarily the large costs that these activities generate. The common practice for the implementation of the last mile delivery in the market is to use specialized companies that deal with it. The development of modern information technologies has led to the increasing use of alternative ways of realizing the distribution of goods to users. In recent years, companies and researchers have been paying more and more attention to the possibilities of hiring ordinary people who can provide certain services in the field of logistics. In this way, we came to the relatively new concept of crowd logistics, which implies the engagement of a large group of individuals in the realization of logistics activities.
One of the forms of crowd logistics in distribution problems is the inclusion of occasional drivers who can make part of the deliveries instead of companies that deal with it professionally. Hiring occasional drivers with certain amounts of compensation can lead to an overall reduction in costs for companies. Whether the goods should be sent using occasional drivers or their own vehicles, and what the routes should look like in those cases, are some of the most important questions that companies are looking for answers to. One of the vehicle routing problems, the solution of which would provide answers to the questions posed, is the vehicle routing problem with occasional drivers (VRPOD). Within this paper, we analysed the literature between 2016 and 2020 in which the authors treatedthe VRPOD.
The remaining part of the paper is organized as follows: in the second part of the paper a description of the vehicle routing problem with occasional drivers is given, in the third part an overview of the relevant literature is presented, and in the last, fourth part concluding remarks are shown.

[2]ivana.jovanovic@sf.bg.ac.rs
[3]m.selmic@sf.bg.ac.rs

2. VEHICLE ROUTING PROBLEM WITH OCCASIONAL DRIVERS

The VRPOD is a problem on the network $G = (N, A)$, where N represents the set of nodes and Arepresents the set of links. The set$C$ consists of users who submitted service requests. Each request is characterized by the amount of goods q_i that the regular vehicle or occasional driver needs to deliver. The user's request should be realized either by a regular vehicle or by an occasional driver, whereby only one visit to the user is allowed. Occasional drivers can fulfiljust some of the customers' requests. Information on whether an occasional driver can fulfil a request is given as input data. Taking into account the costs of the regular vehicles deliveries, and compensation for the occasional drivers' deliveries, it is necessary to determine the best plan for the realization of the stated requirements in order to minimize the total costs.
For the considered problemArchetti et al. [1] proposed a mathematical formulation in which, in addition to the introduced notations, the following are also used:
K – the set of the occasional drivers,
c_{ij} – the cost for travelling the regular vehicle from the node i to the node j,
p_{ik} – the compensation to occasional drive k for making delivery to the customer i,
β_{ik} – equals 1 if the occasional driver k can serve the customer i,
Q – the capacity of the regular vehicle,
x_{ij} – a binary variable equals 1 if the regular vehicle going from the node i to the node j, otherwise equals 0,
y_{ij} – a variable that represents the quantity of the load that regular vehicle carries from the node i to the node j,
z_i – a binary variable equals 1 if the customer i will be served by the regular vehicle, otherwise it equals 0,
w_{ik} – a binary variable equals 1 if the customer i will be served by occasional driver, otherwise it equals 0.

The mathematical formulation of the problem can be presented as follows [1]:

Minimize

$$F = \sum_{(i,j)\in A} c_{ij}x_{ij} + \sum_{i\in C}\sum_{k\in K} p_{ik}w_{ik} \tag{1}$$

subject to

$$\sum_{j|(i,j)\in A} x_{ij} = \sum_{j|(j,i)\in A} x_{ji} = z_i \qquad \forall\, i \in C \tag{2}$$

$$\sum_{j|(0,j)\in A} x_{0j} - \sum_{j|(j,0)\in A} x_{j0} = 0 \tag{3}$$

$$\sum_{j|(j,i)\in A} y_{ji} - \sum_{j|(i,j)\in A} y_{ij} = \begin{cases} q_i z_i & \forall\, i \in C \\ \sum_{i\in C} -q_i z_i & i = 0 \end{cases} \tag{4}$$

$$y_{ij} \le Q\, x_{ij} \qquad \forall\, (i,j) \in A \tag{5}$$

$$y_{i0} = 0 \qquad \forall\, i \in C \tag{6}$$

$$w_{ik} \le \beta_{ik} \qquad \forall\, i \in C, k \in K \tag{7}$$

$$\sum_{i\in C} w_{ik} \le 1 \qquad \forall\, k \in K \tag{8}$$

$$\sum_{k\in K} w_{ik} + z_i = 1 \qquad \forall\, i \in C \tag{9}$$

$$x_{ij} \in \{0,1\} \qquad \forall\, (i,j) \in A \tag{10}$$

$$z_i \in \{0,1\} \qquad \forall\, i \in C \tag{11}$$

$$w_{ik} \in \{0,1\} \qquad \forall\, i \in C, k \in K \tag{12}$$

$$y_{ij} \ge 0 \qquad \forall\, (i,j) \in A \tag{13}$$

An objective function (1) represents the total cost to make the deliveries to the customers. It includes the cost for delivering with regular vehicles and the occasional drivers.Constraint (2) defines that the variable z_i will have value 1 if the regular vehicle is going to serve the customer i. Also, this constraint ensures that the vehicle after visits the customer i must leave it. Constraint (3) guaranties that all routes of the regular vehicles that starts from the depot must finish at the depot. Constraint (4) ensure that customer demands will be satisfied, and it prevents subtours. Constraint (5) takes care about the regular vehicle capacity. According to Constraint (6) the regular vehicles must return empty to the depot. Constraint (7) guaranties that the occasional driver is going to serve the customer only if he/she can do that. Constraint (8) defines that the occasional driver can serve only one customer. Constraint (9) ensure that one customer can be served only by the regular vehicle or the occasional driver. Constraints (10)-(13) define the decision variables.

3. LITERATURE REVIEW

The first ideas about hiring ordinary people to make deliveries, rather than professional companies, appeared in Walmart and Amazon [2, 3]. However, authors of [1]were the first to define the vehicle routing problem with occasional drivers. As we mentioned in previous section these authors proposed a mathematical formulation of integer programming for the considered problem. They also developed a multi-start heuristic to solve defined problem. Performed numerical examples showed that the solutions obtained by heuristics deviate very little from the optimal ones, which are obtained by solving integer programming models with professional software. The authors also pointed out the importance of analyzing the determination of the compensation offered to occasional drivers in order to realize certain deliveries.

Generally speaking, all relevant papers from this area could be divided into three groups: papers that takes into account dynamic occasional drivers, papers that analyze problems with time windows and the one that considered the green vehicle routing problem with occasional drivers.

The vehicle routing problem with dynamic occasional drivers is considered in [4]. In this variant of the problem, occasional drivers appear to be available to fulfill requests in a stochastic manner. At the moment when new drivers come forward to fulfill some requests, the company should consider changing the previous delivery plan because the new plan would be more profitable. For this problem, the authors proposed a new mathematical formulation of the problem. Also, the authors have given a way to avoid symmetry that can occur so that it is possible to solve examples of larger dimensions.

In [5] a multistage stochastic model for the vehicle routing problem with dynamic occasional drivers was proposed, and compared with a two-stage stochastic model from [4]. The proposed multistage stochastic model takes into account the dynamic behaviour of occasional drivers where in various stages information about availability of particular driver may or may not be accessible to decision maker in the company using occasional drivers.

The next few papers dealt with the scheduling problem with occasional drivers and time windows. For the considered problem, the authors of [6] proposed a mathematical formulation. The objective function consists of three parts and represents the total costs that need to be minimized. The first part of the objective function represents the costs related to the company's vehicles, the second part includes the costs when performing tasks by occasional drivers and the third part includes the costs of occasional drivers when they do not perform tasks. The authors generated instances based on well-known instances for VRPTW. The tests were performed using CPLEX 12.5 software.

Same type of problem as in [6] was analyzed in [7]. The focus was on the application of the developed model in the distribution of bread. The model was tested on a small example, where three scenarios were discussed depending on the amount of compensation for occasional drivers. The author used the LINGO 11.0 software to solve mixed integer problems.

Lalang et al. [8] considered a vehicle routing problem with occasional drivers and multiple depots and time intervals. Within this paper, the authors proposed a mathematical formulation in which the objective function represents the sum of the total costs of shorting the company's vehicles and the

total costs of moving the vehicles of occasional drivers. This objective function needed to be minimized. The constraint set guaranteed that the assumptions of the model would not be violated. For testing, the authors used the LINGO 11 software, which uses the branch and bound method to solve mixed-integer programs. The tests were performed in three scenarios. These scenarios differ in relation to the costs of fulfilling requests from the occasional drivers. The tests were performed on a small example that has two bases and eight users.

Unlike assumption from [1] that occasional drivers will always accept to make deliveries for certain compensation amounts, the authors of [9] used a certain probability for this acceptance. The probability of acceptance is directly related to the compensation amount (the higher the compensation amount, the higher the probability that the occasional driver will accept to make the delivery). The amount of compensation is fixed and does not depend on the location of the occasional driver, nor on his final destination. The authors considered the problem as a bi-level model and proposed a heuristic algorithm to solve it. They tested the algorithm on the example which consists of a depot and 15 users.

The pickup and delivery problem with time windows and occasional drivers was solved in [10]. These authors based their work on the problem analyzed in [1]. For the considered problem, they proposed two mathematical formulations of mixed integer programming. The first mathematical formulation was based on the work of [11], and the second used variables for flows of several types of goods. Within the description of the mathematical formulations, the authors indicated how reduction tests and symmetry avoidance tests (breaking symmetry) could be performed for this problem. They also analyzed the impact of different compensation costs of occasional drivers on the optimal solutions. Additionally, the authors proposed a model for parameter optimization in compensation schemes. The tests were performed on the examples used by [12] for the pickup and delivery problem with time windows.

The authors of [13] applied Variable Neighbourhood Search (VNS) metaheuristic to solve VRPOD problem with time windows and multiple deliveries previously proposed in [6]. The authors performed several computational tests on various network sizes using CPLEX 12.5. Besides testing on small-size instances, which were addressed in the previous paper, VNS was also implemented to solve large-scale networks. In comparing small-size instances with previous work, authors performed test with up to 15 customers and five occasional drivers for which an optimal solution can be obtained using CPLEX. Large-scale instances included 25, 50 and 100 customers, and up to 10, 15 and 29 occasional drivers respectively. Authors showed that VNS outperformed CPLEX in terms of effectiveness and efficiency.

Same group of authors [14] used the similar model as in their previous paper [6] – VRPOD with time windows (VRPODTW), but they evaluated the impact of occasional drivers on the amount of CO_2 produced, as well as the total cost which consist of routing and fuel cost, cost of compensation to occasional drivers and cost of the occasional drivers when it does not make the delivery. The model was tested on the same instances as in [6] using CPLEX 12.5 software. When comparing the results of VRP using conventional vehicles and using occasional drivers, their study concluded significant benefits when using ODs instead of conventional vehicles, both in cost reduction as well as environmental impact.

VRPOD with time windows and transhipment nodes (VROPDTN) was formulated in [15]. In this variant of VRPODTW authors considered intermediate depots in the transportation network. Occasional drivers can choose if they will pick up the shipment in the central depot, or in the intermediate. Total cost that aimed to be minimized consists of conventional vehicles' cost and occasional drivers' compensation. Authors used VNS metaheuristics for solving small-size and large-size instances generated from Solomon benchmarks. The model was solved with CPLEX 12.7 software, then the VNS was used on same instances, and the results were compared. In both small-size and particularly large-size instances, VNS outperformed CPLEX.

Marcina and Guerriero [16] considered the green vehicle routing problem with occasional drivers. These authors developed a new mathematical formulation in which the objective function has seven parts: the recharging costs, the energy consumption costs, the total diesel cost, the routing costs (for

electric vehicles and internal combustion commercial vehicles), the cost of compensation of the occasional drivers for the delivery service and the cost of the occasional driver when it does not perform the delivery service. The authors made tests using the 30 instances proposed in the literature for the electric vehicle VRP with time windows (these instances are based on Solomon's instances for VRP with time windows). The authors concluded that occasional drivers influence significant reduction of emissions: 79 % for the instances with 5 customers, 52 % for the instances with 10 customers, and 73 % for the instances with 15 customers.
An environmentally friendly vehicle routing problem with regular and occasional drivers, taking into account their behavioral control characteristics was studied in [17]. These authors proposed a multi-criteria optimization model that has four objective functions. The first function, which is minimized, represented the total energy consumed during the realization of the routes. The second function represented the maximum speed, and it is maximized. The third objective function was the total energy consumption for all routes. This function was minimized. The fourth objective function, the total costs of a given vehicle routing plan, taking into account both regular and occasional drivers was also minimized. The authors tested the model on a small example taken from the literature.

4. CONCLUSION

The concept of crowd logistics is becoming increasingly popular. One of the most important optimization problems based on this concept is the vehicle routing problem with occasional drivers. This routing problem involves delivering part of the shipments through conventional means, using vehicles from a professional delivery company, while the other part is handled by hiring occasional drivers. The implementation of deliveries in this manner is gaining increasing attention because it can lead to various benefits, such as cost reduction, decreased fuel consumption, and reduced emissions of exhaust gases, etc.
In this paper, we provide an overview of the studies in which this problem was analysed. A total of 13 papers were analysed, ending in 2020. In future research, we will analyse papers that are not covered in this overview.

APPLICATION OF PROBABILITY AND STOCHASTIC ANALYSIS TO TRAFFIC IMPROVEMENT

Marina Milovanović Aranđelović[1]*, The Academy of Applied Technical Studies Belgrade*

Abstract: *Of great importance for improvement, traffic planning, traffic safety and traffic regulation are certain areas of mathematics such as applied probability and stochastic analysis, within which various binomial, Poisson, exponential, log normal, generalized logarithmic distributions, as well as stochastic processes are studied, and in within them Markov processes and chains. In this paper will be presented some further application in traffic improvement.*
Keywords: traffic improvment, applied probability, stochastic processes, Markovs chains.

1. INTRODUCTION

In technique and technology both deterministic and stochastic models are known. Deterministic problems, from our point of view, are considered as equations for expected values of random processes and phenomena. Problems which arise in the description of expected values consist in the fact that expected values need satisfy stability both in traditional presentation of continuous variation of solutions on given data and in stability or instability of scenaria of behaviour of random phenomena. In the present exposition for solutions of problems in the traditional presentation concerning stability, equations for dispersion are derived. These equations are obtained with the help of Focker-Planck-Kolmogorov equation and equations for random fields derived in paper [1,2,3]. Equations for differential entropy which permit analysis of stability of scenaria of behaviour of radnom phenomena are also given. Entropy posses an amazing property: with its help it is possible to predict occurence of this or that event in advance. Besides that, the theme of finding maximum of the entropy and results of investigation of behaviour of random phenomena which result from that maximum is also addressed here.

2. FOCKER-PLANCK-KOLMOGOROV EQUATION FOR PROBABILITY DENSITY

The basis for obtaining stochastic analogues of deterministic problems, corresponding to ordinary differential equations with technical thematics, is the Focker-Planck-Kolmogorov equation for probability density (denoted by PD). *P(t,C),* written without the term, responsible for spasmodicity. It has the following form:

$$\partial P(t,C)/\partial t = -\partial(A(t,C)P(t,C))/\partial C + 0,5B\partial^2 P(t,C)/\partial C^2 \quad (1)$$

where*A(t,C),*is the drift coefficient (function of sources (sinks)), *B* is the coefficient ofdiffusion of random Markov process. Let *t* stands for time and *C/T,* be the real characteristic of random process. In synergetics [1] there is a notion of the control parameter. Under its influence the whole random process adjusts, despite the action of other factors. Such a control character in this exposition of stochastic phenomena is the drift coefficient.

[1]mamilovanovic@atssb.edu.rs

Depending on the choice of functional dependence of this coefficient on expected values different interpretations of the described systems will be obtained. Some material constants appear in differential equations for expected values. These quantities often have quite distinguished random character, occasionally not depending on the basic characteristic of the process. Most often they satisfy the normal distribution law with different drift coefficients and determine the shift of scenaria of behaviour of a radnom object. Beside that, in space-time fields the particular role is played by boundary conditions, which independently on inside state of the object, may have independent time behaviour. This behaviour, which has several shifts of analytic form of the drift coefficient, will influence the change of scenaria of behaviour of the described space object. The expected value (mathematical expectation) we introduce in the following notation.

$$M^{(1)}(t) = \int_{-\infty}^{+\infty} CP(t,C)dC \tag{2}$$

The initial moment of the second order, we denote as:

$$M^{(2)}(t) = \int_{-\infty}^{+\infty} C^2 P(t,C)dC \tag{3}$$

We denote by

$$\sigma^2(t) = M^{(2)}(t) - (M^{(1)}(t))^2 \tag{4}$$

the dispersion. We introduce the differential entropy in the following way:

$$S(t) = \int_{-\infty}^{+\infty} P(t,C)\ln P(t,C)dC \tag{5}$$

The equation for expected value corresponding to the PD*P(t,C)*, in the classical representation is obtained from equation (1) as:

$$dM^{(1)}(t)/dt = \int_{-\infty}^{+\infty} A(t,C)P(t,C)dC \tag{6}$$

In this case, in order to find the expected value one has to solve tho problem for PD. In this exposition the drift coefficient is proposed to be given as

$$A(t,C) = Cf(M^{(1)}(t))/M^{(1)}(t) \tag{7}$$

Then the equation for expected value will fully correspond to the differential equation in deterministic formulation:

$$dM^{(1)}(t)/dt = f(M^{(1)}(t)) \tag{8}$$

The equation for dispersion is:

$$d\sigma^2(t)/dt = 2(\int_{-\infty}^{+\infty} CA(t,C)P(t,C)dC - \int_{-\infty}^{+\infty} CP(t,C)dC\int_{-\infty}^{+\infty} A(t,C)P(t,C)dC) + B \tag{9}$$

With the drift coefficient in the form (8), the equation for dispersions obtains the form convenient for investigation of stability of solutions of differential equations for expected values in deterministic formulation (8):

$$d\sigma^2(t)/dt = 2(f(M^{(1)}(t)/M^{(1)}(t))\sigma^2(t) + B \tag{10}$$

The equation for the change of differential entropy is:

$$dS/dt = \int_{-\infty}^{+\infty} (\partial A(t,C)/\partial CP(t,C))dC + 0,5B\int_{-\infty}^{+\infty} \ln P(t,C)(\partial^2 P(t,C)/\partial C^2)dC \tag{11}$$

Under the choice of the drift coefficient in the form (3), the equation for differential entropy is as follows:

$$dS/dt = f(M^{(1)}(t))/M^{(1)}(t) + 0,5B\int_{-\infty}^{+\infty} \ln P(t,C)(\partial^2 P(t,C)/\partial C^2)dC \tag{12}$$

If the moment of diffusion of the Markov process is equal to zero, $B = 0$, then equations (10) and (12) may be solved without finding PD, which is the essential advantage of the method for investigation of random phenomena proposed here.

Equation (6) with $B \approx 0$allows one to find minimal and maximal values of the dispersion, which is important in the search for recommendation for experiment planning and the analysis of experimental data. Equation (8) allows with $B \approx 0$ to determine moments of extremal values of $S(t)$, and also dependence of jumps of the derivation of differential entropy under a change of scenaria of evolution of a random phenomena.

In the case of the dependence of PD on two random variables$P(t,C,T)$, it satisfies multidimensional Focker-Planck-Kolmogorom equation:

$$\partial P(t,C,T)/\partial t = -\partial(A_C(t,C,T)P(t,C,T))/\partial C + \partial(A_T(t,C,T)P(t,C,T))/\partial T + \\ +0,5B_C\partial^2 P(t,C,T)/\partial C^2 + 0,5B_T\partial^2 P(t,C,T)/\partial T^2. \quad (13)$$

Expected values satisfy equations:

$$dM_C^{(1)}(t)/dt = \int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} A_C(t,C,T)P(t,C,T)dCdT \quad (14)$$

$$dM_T^{(1)}(t)/dt = \int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} A_T(t,C,T)P(t,C,T)dCdT \quad (15)$$

The dispersion is in this case described by equations:

$$d\sigma_C^{(2)}(t)/dt = 2(\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} CA_C(t,C,T)P(t,C,T)dCdT - \\ -M_C^{(1)}\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} A_C(t,C,T)P(t,C,T)dCdT) + B_C; \quad (16)$$

$$d\sigma_T^{(2)}(t)/dt = 2(\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} TA_T(t,C,T)P(t,C,T)dCdT - \\ -M_T^{(1)}\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} A_T(t,C,T)P(t,C,T)dCdT) + B_T; \quad (17)$$

$$d\sigma_{CT}^{(2)}(t)/dt = \int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}(TA_C(t,C,T)P(t,C,T) + CA_T(t,C,T)P(t,C,T))dCdT - \\ -(M_T^{(1)}dM_C^{(1)}/dt + M_T^{(1)}dM_C^{(1)}/dt). \quad (18)$$

For

$$A_C(t,C,T) = a_{11}C + a_{12}T \quad A_T(t,C,T) = a_{21}C + a_{22}T \quad (19)$$

the dispersion is determined by the following system of equations:

$$d(\sigma_C^2(t))/dt = 2a_{11}\sigma_C^2 + 2a_{12}\sigma_{CT}^2, + B_C \quad t > 0 \quad (20)$$

$$d(\sigma_T^2(t))/dt = 2a_{21}\sigma_{CT}^2 + 2a_{22}\sigma_T^2, + B_T;\ t > 0 \quad (21)$$

$$d(\sigma_{CT}^2(t))/dt = a_{21}M_C^{(2)} + a_{12}M_T^{(2)} + (a_{11} + a_{22})M_{CT}^{(2)} - \\ -(a_{21}(M_C^{(1)})^2 + a_{12}(M_T^{(1)})^2 + (a_{11} + a_{22})M_C^{(1)}M_T^{(1)}) = \\ = a_{21}\sigma_C^2 + a_{12}\sigma_T^2 + (a_{11} + a_{22})\sigma_{CT}^2;\ t > 0. \quad (22)$$

From these equations one may obtain classical stability conditions for the solution of systems of ordinary deterministic differential equations by Lyapunov, in the case.

$B_C=0$, $B_T=0$ and one can also predict instability for arbitrary coefficients on the right-hand side if $B_C \neq 0$, $B_T \neq 0$. The described results are given in [1]. Equation for the variation in time of differential entropy

$$S(t) = \int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} P(t,C,T)\ln P(t,C,T)dCdT \quad (23)$$

has the form:

$$dS/dt = \int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}[(\partial A_C(t,C,T)/\partial C + (\partial A_C(t,C,T)/\partial T]P(t,C,T)dCdT + \\ +0,5B_C\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}[\ln P(t,C,T)\partial^2 P(t,C,T)/\partial C^2]dCdT + \\ +\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}[\partial A_T(t,C,T)/\partial T + (\partial A_T(t,C,T)/\partial C]P(t,C,T)]dCdT + \\ +0,5B_T\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}[\ln P(t,C,T)\partial^2 P(t,C,T)/\partial T^2]dCdT. \quad (24)$$

If$B_C=0$, $B_T=0$, then equation (20) (assuming (15)) obtains the following form:

$$dS/dt = a_{11} + a_{12} + a_{21} + a_{22}. \quad (25)$$

Depending on the sign of the sum ($a_{11}+a_{12}+a_{21}+a_{22}$) one obtains linear in time the increase of entropy, if $a_{11}+a_{12}+a_{21}+a_{22}>0$, or linear decrease if $a_{11}+a_{12}+a_{21}+a_{22}<0$, and for the entropy $a_{11}+a_{12}+a_{21}+a_{22}=0$ remains constant and equal to its initial value.

3. FOCKER-PLANCK-KOLMOGOROV EQUATION FOR STOCHASTIC FIELDS

Let us write equations for stochastic fields. The equation for PD, describing random field of concentration has the form:

$$\partial P(t,x,C)/\partial t - D\partial^2 P(t,x,C)/\partial x^2 = -\partial(A(t,x,C)P(t,x,C))/\partial C + \\ +0,5B\partial^2 P(t,x,C)/\partial C^2. \quad (26)$$

The equation for expected value:

$$M^{(1)}(t,x) = \int_{-\infty}^{+\infty} CP(t,x,C)dC \quad (27)$$

$$\partial M^{(1)}(t,x)/\partial t - D\partial^2 M^{(1)}(t,x)/\partial x^2 = \int_{-\infty}^{+\infty} A(t,x,C)P(t,x,C)dC \quad (28)$$

If the drift coefficient has the special form

$$A(t,x,C) = Cf(M^{(1)}(t,x))/M^{(1)}(t,x) \quad (29)$$

then the equaion for expected values obtains the classical form of a deterministic equation:

$$\partial M^{(1)}(t,x)/\partial t - D\partial^2 M^{(1)}(t,x)/\partial x^2 = f(M^{(1)}(t,x)) \quad (30)$$

The equation for dispersion:

$$\partial\sigma^2(t,x)/\partial t - D\partial^2\sigma^2(t,x)/\partial x^2 = 2D(\partial M^{(1)}(t,x)/\partial x)^2 + \\ +2[\int_{-\infty}^{+\infty} CA(t,x,C)P(t,x,C)dC - M^{(1)}(t,x)\int_{-\infty}^{+\infty} A(t,x,C)P(t,x,C)dC] + B \quad (31)$$

Under conditions (27) equation for dispersion is as follows:

$$\partial\sigma^2(t,x)/\partial t - D\partial^2\sigma^2(t,x)/\partial x^2 = 2D(\partial M^{(1)}(t,x)/\partial x)^2 + \\ +2[f(M^{(1)}(t,x)/M^{(1)}(t,x)]\sigma^2(t,x) + B. \quad (32)$$

The equation for differential entropy:

$$\partial S(t,x)/\partial t - D\partial^2 S(t,x)/\partial x^2 = \int_{-\infty}^{+\infty}\partial A(t,x,C)/\partial C P(t,x,C)dC + \\ +0,5B\int_{-\infty}^{+\infty}\ln P(t,x,C)\partial^2 P(t,x,C)/\partial C^2 dC - D\int_{-\infty}^{+\infty}(1/P(t,x,C))(\partial P(t,x,C)/\partial x)^2 dC. \quad (33)$$

Under conditions (23), the equation for entropy transforms into the form:

$$\partial S(t,x)/\partial t - D\partial^2 S(t,x)/\partial x^2 = [f(M^{(1)}(t,x)/M^{(1)}(t,x)] + \\ +0,5B\int_{-\infty}^{+\infty}\ln P(t,x,C)\partial^2 P(t,x,C)/\partial C^2 dC - D\int_{-\infty}^{+\infty}(1/P(t,x,C))(\partial P(t,x,C)/\partial x)^2 dC. \quad (34)$$

The equation for description of wave fields is:

$$\partial^2 P(t,x,C)/\partial t^2 - c^2\partial^2 P(t,x,C)/\partial x^2 = \\ = -\partial(A(t,x,C)P(t,x,C))/\partial C + 0,5B\partial^2 P(t,x,C)/\partial C^2 \quad (35)$$

The equation for expected values:

$$\partial^2 M^{(1)}(t,x)/\partial t^2 - c^2\partial^2 M^{(1)}(t,x)/\partial x^2 = \int_{-\infty}^{+\infty} A(t,x,C)P(t,x,C))dC \quad (36)$$

Under conditions (23), the equation obtains the well-known form of a deterministic equation for expected values:

$$\partial^2 M^{(1)}(t,x)/\partial t^2 - c^2\partial^2 M^{(1)}(t,x)/\partial x^2 = f(M^{(1)}(t,x)) \quad (37)$$

The equation for dispersion:

$$\partial^2\sigma^2(t,x)/\partial t^2 - c\partial^2\sigma^2(t,x)/\partial x^2 = 2[c(\partial M^{(1)}(t,x)/\partial x)^2 - (\partial M^{(1)}(t,x)/\partial t)^2] + \\ +2[\int_{-\infty}^{+\infty} CA(t,x,C)P(t,x,C)dC - M^{(1)}(t,x)\int_{-\infty}^{+\infty} A(t,x,C)P(t,x,C)dC] + B. \quad (38)$$

Taking into account formula (26) equation (34) may be rewritten as:

$$\partial^2\sigma^2(t,x)/\partial t^2 - c\partial^2\sigma^2(t,x)/\partial x^2 = 2[f(M^{(1)}(t,x))/M^{(1)}(t,x)]\sigma^2(t,x)] + \\ +2[c(\partial M^{(1)}(t,x)/\partial x)^2 - (\partial M^{(1)}(t,x)/\partial t)^2] + B. \quad (39)$$

4. STOHASTIC MODELING IN TRAFFIC IMPROVEMENT

Stochastic models of traffic flow are used in a variety of applications, e.g., traffic state estimation, travel time reliability, and traffic control. A main source of uncertainty in traffic dynamics is heterogeneity among drivers. This is captured using parametric uncertainty, resulting in stochastic microscopic models. These, in turn, are used to develop probabilistic traffic relations and stochastic models of traffic dynamics. Hence, the relevance of the compilation and consideration of practical aspects, as well as the mathematical solution of the problems of modeling the traffic flows of the metropolis, which will be considered in papers [4,5].

Classical mathematical models of continuous traffic flows considered Descartes's coordinates as real numbers. In probabilistic modes Descartes's coordinates will be considered as random variables. Let $C(X_1,X_2,X_3)$ be random vector which Descartes's coordinates X_1, X_2 and $X_3$are random variables. They determine probabilty of particle position in spatial motion.In probabilistic mathematical model of continuous traffic flows, path of spatial or planar motion can be described by equation (1), where t is time elapsed from start of motion. So, traffic flow can be considered as stohastic process, which probability density is given by equation (1). Its expected value is define by equation (8) and dispersion by (9) for one-dimensional case. For multi-dimensional case, expected value is given as solution of system of equations (14) and (15) and dispersion can be obtained as solution of system of equations (16), (17) and (18). Also, traffic flow can be considered as random field. In this case, its expected value can be obtained by (37) and dispersion can be obtained by(38).

5. CONCLUSION

In this paper some new formulations of problems of stochastic description of random and deterministic mathematical models given in [1] are presented. The basic assumption is the following: a solution of a deterministic problem is the expected value of its stochastic analogue. Topicality of the problem consists in the fact that deterministic problem does not allow to reveal neither the stability of a stochastic phenomena, nor a change in scenario of its development. Proposed equations allows one to investigate stability of solutions for expected values from the analysis of the dispersion. The use of differential entropy permits to find moments of change of a

scenario of evolution of random phenomena and reveal repercussions of the achievement of maximal entropy. Presented theory can be applied in analysis of some mathematical models of traffic improvement given in [4,5].

IMPROVEMENT OF TRAFFIC SAFETY ON THE CHOSEN INTERSECTION IN THE TOWN OF PANCEVO

Jelena Vajović[1], The Academy of Technical Vocational Studies
Marina Stevanović[2], The Academy of Technical Vocational Studies

Abstract: *Traffic safety management is important in order to reduce the number of injured participants in traffic accidents and thus reduce the total damage for the society or local government caused by traffic accidents. Participation in traffic requires competence, knowledge, skills and safe behaviour which depends on traffic culture of traffic participants. In this work, possible measures and suggestions concerning traffic safety are presented. According to total number and consequences of traffic accidents in the Republic of Serbia, it can be observed that the number of injured as well as the number of casualties in traffic accidents has the decreasing trend until 2020 and in majority of traffic accident there was merely material damage. 27% of all traffic accidents happen on intersections. Taking into consideration the huge number of incidents on intersections, possible improvements can be divided into two groups: infrastructural solutions and advanced solutions. The advantages of infrastructural solutions are based on the fact that traffic participants can observe the situation on an intersection better. On the example of the concrete intersection in the town of Pancevo, suggestions for the improvement of traffic safety are given.*
Key words: traffic safety management, traffic accident, intersection

1. INITIAL CONSIDERATIONS

It was proven in many researches that the traffic safety mostly depends on human factor, internal sources of behaviour and individual reaction of drivers in different situations on the roads. Participation in traffic requires competence, knowledge, skills and safe behaviour which depends on traffic culture.

Law regulating traffic safety on roads contains important news in the domain of possible traffic safety improvement in the country, in local governments, in municipalities and cities (towns). On local level it is necessary to make strategies concerning traffic safety, to write annual plans concerning traffic safety and to monitor traffic safety. Consequences of traffic expansion development are the increasing number of vehicles, roads, density of traffic flow etc.

Huge number of different vehicles use the same roads. Difference of vehicles participating in traffic is clearly observed on intersections which connect urban and rural areas.

In the context of huge number of incidents on intersections, there are two possible solutions of this problem: infrastructural solutions and advanced solutions. Infrastructural solutions are based on sensors located near intersections. Sensors detect approaching vehicles and in the case of possible accident, the system generates warning light signals which drivers can see. The advantages of infrastructural solutions are based on the fact that traffic participants can observe the situation on an intersection better.

The goal of the research is traffic analysis on intersections, especially on ones with traffic lights and to give suggestions for the improvement of traffic flow based on functional, economic and ecological aspect.

2. TRAFFIC SAFETY ANALYSIS IN THE TOWN OF PANCEVO FROM THE YEAR 2018 TO THE YEAR 2022

Total number of traffic accidents during this period in the town of Pancevo was 1.713, which is 1% of total number of traffic accidents in the Republic of Serbia, while the total number of casualties is 1.722, which is approximately 2% of the total number of casualties in traffic accidents in the Republic of Serbia.
While analysing the basic parameters of traffic safety on the territory of the town of Pancevo during this period, it can be seen that in the year 2021 there was the largest number of both traffic accidents and casualties. The total number of traffic accidents in the year 2021 was 490, which is 1,4% of the total number of traffic accidents in the Republic of Serbia in the above-mentioned year, while the total number of casualties in the same year was 387, which is 1.9% of the total number of casualties in this year.

3. TRAFFIC SAFETY ANALYSIS ON THE CHOSEN INTERSECTION FROM THE YEAR 2018 TO THE YEAR 2022

The Miloša Obrenovića street connects the centre of Pancevo with Tesla settlement and continues onto the Bavaništanski road, which connects the town of Pancevo with Bavaniste. The Prvomajska street continues onto the Stevana Šupljikca street and those two streets are major part of the bypass, i.e., the section of the European road E-70 which passes through the town of Pancevo.
The road E-70 is the international road of class A and it begins in Spain and finishes in Georgia and is 5.114km long. Apart from Serbia, this road passes through France, Italy, Slovenia, Croatia, Romania, Bulgaria and Turkey.
On figure 1 there are spots of traffic accidents based on the consequences on the observed intersection the Prvomajska – the Stevana Šupljikca – the Bavaništanski road – the Miloša Obrenovića.

Figure 1. Spots of traffic accidents on the observed intersection from year 2018 to year 2022
Source: *http://bazabs.abs.gov.rs/smartPortal/saobNezgode*

Total number of traffic accidents on intersections in the town is 665, which is 39% of total number of traffic accidents in the town of Pancevo. Total number of traffic accidents on the observed intersection (26) is 4% of total number of traffic accidents on intersections in the town of Pancevo.
Total number of traffic accidents during the observed period on the observed intersection is 26, which is 18% of total number of traffic accidents on the streets that this intersection consists of.

Total number of casualties on the observed intersection is 28, which is 19% of total number of casualties in traffic accidents on the streets that this intersection consists of.
While analysing the types of traffic accidents on the observed intersection, it can be concluded that during the period of 5 years there were 14 traffic accidents with at least two vehicles – turning or crossing, 7 traffic accidents with at least two vehicles – without turning and 3 traffic accidents with one vehicle. Traffic accident in which some participants die is in the group of traffic accidents with at least two vehicles – turning or crossing.
The most common groups of influential factors that can cause traffic accidents on the observed intersection are: drivers' wrong execution of actions in traffic, drivers' reckless actions, drivers' mistakes due to bad psychophysical condition, carelessness, distraction and mistakes due to inadequate visibility, i.e. a complete experience of the road and traffic. The largest number of traffic accidents (9), which caused minor bodily injuries of some participants, were caused by drivers' wrong execution of actions in traffic. The largest number of traffic accidents (6), which caused material damage, were caused by drivers' reckless actions and these actions also caused the death of some participants in traffic accidents. While analysing the influential factors it can be concluded that the largest number of traffic accidents was caused by drivers' wrong execution of actions in traffic (14) and by drivers' reckless actions (13).
It can be concluded that the majority of traffic accidents happened on intersections regulated by traffic lights working properly and the number of such traffic accidents is 14. Traffic accident which caused the death of some traffic participants happened on intersection regulated by traffic lights at the moment when there was only yellow flashing light on, which happens very often and it is shown on figure 2.

Figure 2. Traffic lightswith yellow flashing light on the chosen intersection

Since the observed intersection is huge and accesses to it are not at the right angle there is the problem of poor visibility when accessing it from some streets. The poorest visibility, especially during night, observing from the stop line is in the Miloša Obrenovića street and it is shown on figure 3. From the above-mentioned stop line, there is also poor visibility from the Stevana Šupljikca and the Prvomajska streets. There is poor visibility from the Stevana Šupljikca street due to residential building and some greenery, while there is poor visibility from the Prvomajska street due to sharp angle compared to the stop line and due to advertising sign and tall protective fence.

Figure 3. Intersection access from the stop line in the Miloša Obrenovića street

4. MEASURES AND SUGGESTIONS

Traffic on the observed intersection is regulated by traffic lights, which allow alternating vehicle passing from the Stevana Šupljikca and the Prvomajska streets and at the same time from the Miloša Obrenovića street and the Bavaništanski road. In the case when traffic lights do not work or there are only yellow flashing lights, drivers rely on traffic signs.
Due to the huge number of vehicles on city roads there is the problem of traffic regulation. Roads and their surrounding areas as well as the road conditions directly influence drivers and their vehicles. Surrounding areas influence the consequences of traffic accidents while the road conditions influence traffic safety. The observed intersection, the Prvomajska – the Stevana Šupljikca – the Bavaništanski road – the Miloša Obrenovića, is one of the busiest intersections in the town of Pancevo. This intersection belongs to corridor E70 in Pancevo. Since this road connects many European countries, it is very important for the strengthening of trade, economy, material goods and as such directly influences people's lives.
The idea of this work is to implement some measures for the improvement of traffic safety on the observed intersection and its relieving as well as the improvement of traffic conditions.
Measure suggestions:

- Zebra crossings replace with footbridges and so lower the number of conflict points
- Lanes for opposite directions physically separate
- Place traffic lights controlled by artificial intelligence, technology which can prioritize and thus regulate traffic on intersection
- Place cameras which record speed limit of vehicles
- Upon completion of road works on the road Bubanj Potok – Vinča – Pančevo, redirect cargo traffic onto the above-mentioned road and so decongest the observed intersection
- Make roundabout at the place of the observed intersection

Cameras which record speed limit have advanced functions for traffic safety improvement. They offer the solution which can repress violation of traffic regulations, speeding and improper parking and stopping. Intelligent cameras have multiple advantages: increased security, detection of potential danger and warning the competent services, recording videos and data in real time, increased effectiveness for counting and classification of vehicle types. The main goals of cameras is to make it easier for competent services to fully understand every traffic situation.
Nowadays, roundabouts are used more often. Essential parts, number of lanes and the diameter of the circle directly influence the vehicle speed, traffic safety and reduce waste of time. At roundabout intersections there is no privileged direction, which means that neither direction has high speed. The main advantage of roundabout is there are no conflict points. The usage of roundabouts equals main and side direction as far as importance is concerned. Apart from reducing waste of time, roundabouts have higher throughput. On figure 4, there are current solution and suggested solution in the form of roundabout intersection.

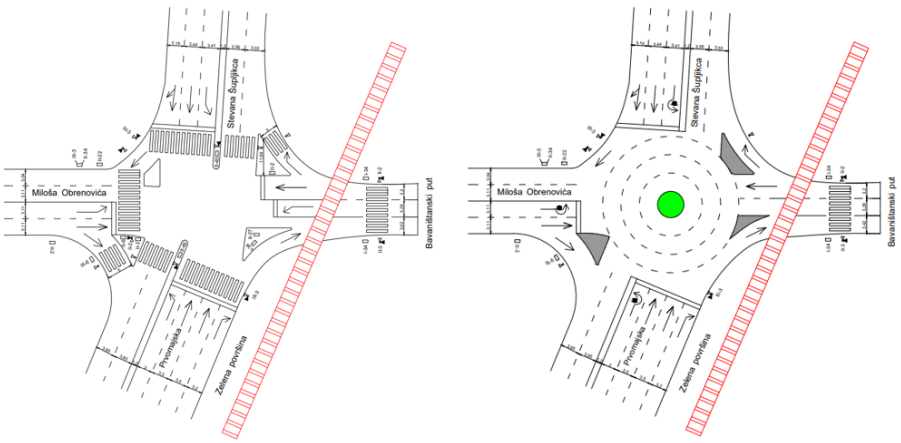

Figure 4. Current solution and suggested solution in the form of roundabout intersection

The way that roundabout intersections influence traffic safety improvement and their importance on intersections with huge number of traffic accidents, can be seen in professional literature used for this work [7, 8, 9, 10, 11].
Much more space is needed for roundabout intersections compared to classical intersections. Traffic regulation with multiple accesses is more effective when implementing roundabouts. Geometry of intersection with unfavourable angles of leg intersection makes such an intersection busy during morning and afternoon rush hour. Above-mentioned characteristics can be seen on the observed intersection. The suggestion of changing this intersection into roundabout intersection, in near future can make this intersection convenient and safe.
Knowledge as prerequisite for safe and secure driving a vehicle makes driving rational and quality, and the key word is prevention, i.e., investment into traffic safety.
Huge traffic density can lead to its slowing down, which can cause traffic participants to become nervous, increase in fuel consumption, longer travel time etc. The best tool is vehicle speed management, functioning of the road network and promotion, in media and in driving schools, of driver training with the goal to improve traffic safety on roads.
Some of many problems on the chosen intersection are as follows: in the situation of conditional turning of vehicles to the right, drivers must give way to pedestrians and vehicles, vehicles in direction the Bavaništanski road – the Miloša Obrenovića street when turning to the left must give way to vehicles from the opposite direction etc. The above-mentioned problems can lead to huge number of conflict points that influence the effective traffic flow through this intersection and are shown on figure 5.

Figure 5. Photo documentation of problems on the chosen intersection

5. CONCLUSION

The Republic of Serbia is one of the countries which, in its regulations, implements modern procedures for traffic safety improvement on roads. Law on road traffic safety prescribes implementation of independent projects for controlling traffic safety on roads mainly on state roads according to predetermined frequency, while for other roads it can be done if there are realistic possibilities. In practice, it means that controls will be rarely conducted although the practical researches imply that the risk of traffic accident is not on the negligible level.
Law on road traffic safety brings some innovations for traffic safety improvement, which is basically the research goal of this work. Taking into consideration the importance of factors: participant – vehicle – road – surrounding area, regardless the position and road rang, prevention is of the utmost importance on spots of higher risks.
Taking into consideration advantages and disadvantages, as well as desirable and undesirable situations on roundabout intersections, it is necessary to carefully plan their implementation. It is important to consider their influences on security, capacity, ecology and aesthetics. It is important to analyse and evaluate all previously mentioned influences. For project evaluation should be used

the method of gain – expenses. Gain considers security and functionality, while expenses consider building and maintenance.

Roundabout intersections are safer and provide higher traffic flow compared to classical intersections. They secure continuous driving and fit well with the surrounding area. Advantages for the chosen intersection are higher level of security, shorter waiting time at access points and lower maintenance costs. Ecologically, they are more acceptable since they lower energy consumption and harmful gases emissions. Quality of roundabout intersections improves over time and security level and traffic quality become higher.

BIOLOGICAL CONTROL AS AN EVOLVING TECHNOLOGY IN PEST MANAGAMENT

Tatjana Sekulić[1] , The Academy of Applied Technical Studies Belgrade
Zlata Živković[2], The Academy of Applied Technical Studies Belgrade
Marija Perkunić[3], The Academy of Applied Technical Studies Belgrade

Abstract: *Biological control involves the use of populations of natural enemies to suppress pests populations to lower densities, either permanently or temporarly. Natural enemies are the fundamental resource of biological control, mainly represented by two major groups: parasitoids and parasit insects. When pests are to be controlled over large areas, the only long-term affective approach is introduction of natural enemies. There are two types of permanent biological control: classical and new association. When biological control is used to temporary suppress pests in production area, three approaches are available: conservation control, augmentation, and application of biopesticides. In recent decades, the increase use of biological control is due to its safety, species specific and permanent action on the target agriculture pests. Unlike the use of chemical pesticides, this method is environmental friendly, with no effects on human health. The aim of these paper is to review different major strategies of biological control of pests used in agriculture and nature ecosytems like farms, green houses, garden and forests.*
Keywords: Biological Control, Natural Enemies, Pest Populations

1. INTRODUCTION

Biological control has long been considered as a potential alternative to pesticidal strategies for pest management. Predators and parasitoids, as well as entomopathogenic nematodes and microbes, are main tolls for biological control, and have been in action for a long time in the history of agriculture [1]. Biological control agents of weeds include herbivores and plant pathogens. Predators are mainly free-living species that directly consume a large number of preys during their whole lifetime. Insect parasites (parasitoids) are smaller than their host and develop inside, or attach to the outside, of the host's body. Pathogenic microorganisms include bacteria, fungi, and viruses. They kill or debilitate their host and are relatively host-specific. Populations of some aphids, caterpillars, mites, and other invertebrates are sometimes drastically reduced by naturally occurring pathogens, usually under conditions such as prolonged high humidity or dense pest populations.

Biological control method has been actively practiced for more than 100 years and the history of biocontrol and its successes, has been extensively reviewed in literature. Interest in biological control has increased over recent decades for many reason [2]. First, insect pests continue to cause severe damage to crops globally, estimated to be at least $470 billion per year [3]. Second, the human population growth, combined with increasing per capita demands for protein, require that losses from pests and other causes (including human wastage) are addressed so that food availability is doubled in coming decades [4; 5]. Third, the availability of insecticides is threatened as a number of arthropod pests have developed resistance to one or more pesticides leaving growers to search for alternative

[1]tsekulic@atssb.edu.rs
[2]zzivkovic@atssb.edu.rs
[3]mperkunic@atssb.edu.rs

management strategies [6]. Accordingly, agricultural intensification efforts should be based on ecological principles rather than greater reliance on non-renewable resources [7]. The primary factors affecting adoption of biological control are efficacy, predictability, and cost [8].
Biological control of pest dated back to 16th century in China. They were the first to use natural enemies to control insect pests in the third century, for the control of citrus insect pest such as *Tesseratoma papillos* Drury (Hemiptera: Tesseratomideae) using nests of the ant *Oecophylla smaragdina* Fabricius (Hymenoptera: Formicideae) in Canton [9].
In the second half of the 20th Century, following the Green Revolution biological control has resurfaced with renewed force in recent years, especially by the adoption of integrated pest management (IPM) programs. These programs were implemented as a consequence of the anappropriate use of agrochemicals, which led to a number of problems, such as insect and mite resistance to insecticides and acaricides, as well as environmental contamination [10].
The aim of these paper is to briefly describe the history of the major forms of biological control review different strategies of biological control of pests used in agiculture and nature ecosytems like farms, green houses, garden and forests.

2. STRATEGIES OF BIOLOGICAL CONTROL

There is a long history of seeking to increase the efficacy of biological pest control by predators and parasitoids, as well as entomopathogenic nematodes and microbes [1]. Ant colonies have been traded and the movement of ants between tree crop canopies facilitated by bamboo poles for 100s of years [11]. Biological control efforts against plants and insects have different histories, and since the 1800s, 'classical biological control' efforts to suppress exotic pests have involved importing their natural enemies; though this practice is increasingly under scrutiny to avoid effects of introduced agents on non-target, native species [12]. During the 1900's, insect biological control against environmental pests develop as an independent goal [11]. This practice continues to grow in popularity though the costs to farmers are often significantly higher than the use of insecticide applications.
Biological control can be approached by two means: permanent suppresion of pests and temporary [13]. When the goal is a permanent control which targets non-native invasive species over large areas, the only feasible method is classical biological control. If the target is a native pest (or an exotic species of unknown origin), and the natural enemies released against it come from a different species, the approach is called new association biological control. When biological control is used to temporary suppress pests in production area, three approaches are available: conservation control, augmentation, and application of biopesticides [13].

2.1. Classical biological control

Classical biocontrol is defined; as the intentional introduction of an exotic (non-native), usually co-evolved biological control agent for permanent establishment and long term pest control [8]. This is usually done by government authorities. In recent years, classical biological control has come under increasing scrutiny for its nontarget effects.
Many of the important arthropod pests of agriculture and natural areas are non-native invasive species [14]. For example, in the USA, 35% of the 700 most important insect pest are invasive species. Since 1888, natural enemy introductions have provided complete or partial control of more than 200 pest arthropod and 40 weeds [15,16]. Rapid suppresion of an invasive plant by an introduced insect is illustrated by the case of the floating fern *Azzola filiculoides* Lamarck (Salvinales, Salivinaceae) [17]. *Azolla filiculoides* (red waterfern) is a floating fern native to South America which has invaded aquatic ecosystems in South Africa. Thick mats of *A. filiculoides* on dams and slow-moving water bodies cause economic losses to water-users. Among those most seriously affected were farming (71%), recreational (24%), and municipal (5%) users. The frond-feeding weevil *Stenopelmus rufinasus* Gyllenhal (Coleoptera: Curculionideae) was released as a biological control agent at the

end of 1997. Within 3 years, the weevil had reduced the weed population to the point that it was no longer considered a problem in South Africa.
Introduced as a method classical biological control has major advantages over other forms of control because it is self-maintaning and less expensive over the long term. They are usually conducted by public institutions, using public resources to solve problems for the common good [13].

2.2. New association biological control

This term appiles if the target pest is a native species or an invasive species of unknown origin [13]. Natural enemies are collected from a different species that are related either taxonomically or ecologically to the pest. *Peristenus digoneutis* Loan (Hymenoptera: Braconidae) was introduced to the eastern USA for biological control of the tarnished plant bug, *Lygus lineolaris* Palisot de Beauvois (Hemiptera: Miridae), and has since spread through much of the northeast [18]. New association biocontrol differ from classical in two ways. First, the ecological justification (restoring disturbated ecosystems to pre-invasing conditions) for classic biological control is missing when native species are targetied. The second way is that, by definition, natural enemies are not located by finding the pest overseas and collecting its natural enemies. One has to select surrogates from another biogeographic region that are enough like the pest (based on taxonomy, ecology, morphology, etc.) to have natural enemies that would attack the pest [13].

2.3. Conservation biological control

The discipline of conservation biological control has evolved rapidly over the last two decades [1]. This type of control include modification of the environment or existing farming practices to protect and enhance the abundance and diversity of the natural enemy community in order to reduce the effect of pests. Ecosystem manipulation involves increasing the species diversity, and this approaches provide natural enemies with resources such as nectar, pollen, alternative prey and alternative hosts and operate to reduce pest densities through out the enhancement of natural enemies.
Research has been done on myriad arthropod pests, including species with high levels of insecticide resistance such as *Chilo suppressalis* Walker (Lepidoptera: Crambidae) and *Helicoverpa armigera* Hubner (Lepidoptera: Noctuidae) [19]. As an example of conservation biological control, alternative habitats for natural enemies are provided, in the form of ‘beetle-banks’ in Britain or ‘sown seed strips’ in Switzerland incereal crops [2]. These practices are highly successful and are among the few documented uptakes of a biocontrol option in temperate open-field arable agriculture [20].
Studies show that the conservation of natural enemy species richness sometimes weakens, or has no affect, on biological control. This approach is likely to be true for many native insect pests, but is not true for weeds, nor it is usually true for invasive insects unless a programe of classical biological control has imported effective specialized natural enemies. Conservation method depend on knowing how effective a particular practice will be under local conditions, and as so can be implemented on individual farms. This requires extensive local research in farmer’s fields.

2.4. Augmentation biological control

Augmentation is the periodic release of a natural enemy that does not occur in sufficient numbers to keep a pest below damaging levels. The practice of augmentation is based on the knowledge or assumption that in some situations there are not adequate numbers or species of natural enemies to provide optimal biological control. It can be used when natural enemies are missing (as in green housees), or arrive too late for new plantings (some row crops), or are too scarce to provide control (in large monocultures).
There are two general approaches to augmentation: inundative releases and inoculative releases [2]. Inundation, or mass release, involves releasing large numbers of natural enemies for immediate reduction of a pest population. It is a corrective measure; the expected outcome is immediate pest

control. In practice, releases are often repeated if pest populations were not all present in a susceptible stage during the previous application, if new pests disperse into the crop, or if the crop is long lived, increasing the length of time it could become infested [21]. Therefore, it may be used int he field and in greenhouse as seasonal release [22]. For example, *Eretmocerus eremicus* Rose&Zolnerowich (Hymenoptera: Aphelinideae) must be released weekly for continuous suppresion of whiteflies in greenhouse. The utilization of some microbial insecticides, such as those containing *Bacillus thuringiensis* Berliner (Bacilales, Bacilaceae), is also inundation. Inoculation on the other hand; involves releasing small numbers of natural enemies at prescribed intervals throughout the pest period, starting when the pest population is very low. The natural enemies are expected to reproduce themselves to provide more long-term control. However, the expected outcome of inoculative releases is to keep the pest at low numbers, and it is more of a preventive measure [2].

2.5. Biopesticides

Biopesticides are naturally occurring formulations made from the living organisams that control pests by non toxic mechanisms and in ecofriendly manner. The science of biopesticide is still considered to be young and evolving. Biopesticide is gaining interest because of its advantages associated with the environmental safety, target-specificity, efficacy, biodegradability and suitability in the integrated pest management programs. Global production of biopesticides has been estimated to be over 3,000 tons per year, which is increasing rapidly, and about 90% of the microbial biopesticides are derived from just one entomopathogenic bacterium *Bacillus thuringiensis* [23]. *Bacillus thuringiensis* is the most commonly used biopesticide globally. It is primarily a pathogen of lepidopterous pests like American bollworm in cotton and stem borers in rice. When ingested by pest larvae, this bacteria releases toxins which damage the mid gut of the pest, eventually killing it. Main sources for the production of this biopreparations are the strains of the subspecies *kurstaki*, *galeriae* and *dendrolimus*. Certain soil bacteria, algae, fungi, plants and insects possess the unique ability to produce hydrogen cyanide (HCN), which plays an important role in the biotic interactions of those organisms. In particular, cyanogenic bacteria have been found to inhibit the growth of various pathogenic fungi, weeds, insects, termites and nematodes. Thus, the use of HCN-producing bacteria as biopesticides offers an ecofriendly approach for sustainable agriculture.

3. CONCLUSION

Biological control of pest is the non-chemical way in which we use of pathogens, predator and parasitoid in purpose for killing pest, reducing their populations or eliminating them completely from our farms, garden and forest. It is environmentally friendly and increase productivity and safety of the consumers. Statistical data shows that, unfortunately, farmers have been slow to adopt biological control as part of their pest management practice. For example, biological control is practiced in just 5% of the estimated 741,290 acres of greenhouses worldwide. The primary factors affecting adoption of biological control are efficacy, predictability, and cost.

Classical biological control is a powerful tool for suppression of invasive species of plants and insects in natural and agricultural ecosystems. It will play an increasingly important role in restoration of ecosystems and biodiversity, because it provides a mechanisam to permanently suppress invaders over large landscapes without long-term resource commitments and for that reason it makes it sustainable. However, for biological control to be fully utilized, it is essential for the users to have insects available whenever they are required, in order to use them in inoculative (classical biological control), inundative (applied biological control), or seasonal inoculative releases (biological control in protected crops) to control the target pests.

Conservation method depend on knowing how effective a particular way of practice will be under local ecological conditions on the field, and as so it is appropriate for individual agroecosystems. Augmentation is limited principally by costs, agent availability and quality, and field effectivness of the reared organisams. Costs limit the use of reared natural enemies when the natual enemy is

inexpensive to rear, the crop has high cash value, or cheaper alternatives such as insectides are not available.

In recent years, microbial antagonists are used for the control of pest and diseases. Typical example abounds on the *Bacillus thuringiensis* which are toxic to many species of pest insects. However, while present in the market place for over 65 years, currently make up less then 1% of insecticide use.

As a conculsion there is a need to develop better and more widely applicable strategies that will allow the promise of conservation biological control to be realized more widely in global agriculture. Key to achieving this objective is to find a predator which may consume multiple species of prey in addition to plant foods (e.g., pollen).

Biopesticide is one of the promising alternatives to manage environmental pollutions. Since the environmental safety is a global concern, we need to create awareness among the farmers, manufacturers, government agencies, policy makers and the common men to switch-over to biopesticides for the pest management requirements.

Abstract: *Agriculture has played a vital role throughout human history since ancient times, as it is essential for the survival of the human species. Many changes occurred during this period, from the domestication of animals and plants to the systematic use of crop rotation and other advances in agricultural practices. The last innovation a few decades ago was the increased use and production of pesticides, which drastically increased agricultural productivity, as diseases and pests were more effectively controlled. Agriculture today is considered to be experiencing a new evolution called Smart farming, which is based on information and communication technologies that include unmanned aerial vehicles (UAVs), unmanned ground vehicles (UGVs), image processing, machine learning, big data, cloud computing and wireless, sensor networks (VSN). With the world's population constantly growing and currently numbering more than 8 billion people, it is estimated that food production will need to double by 2050. Smart agriculture aims to increase productivity and improve the quality of the final product while reducing production costs by using the latest technologies and enable the sustainability of environmental resources through the optimal use of pesticides and chemical fertilizers.*
Keywords: smart farming, sustainability, environmental resources, agriculture

1. INTRODUCTION

Agriculture is essential to human survival as it provides food for the growing world population and play important role in economic development. Contrarily, agriculture is the primary cause of environmental degradation because it is thought to be a major contributor to climate change, freshwater scarcity, fish die-offs, soil fertility degradation, the environment and soil pollution, landscape changes, and loss of biodiversity and ecosystem at all levels [1,2,3,4,5]. The predominance of annual plants cultivated in monocultures is one of the traits of conventional agricultural production. These crops cause ecological degradation, soil erosion, and an increase in pests and weeds that have adapted to the crop [4]. Due to the development of resistance, which arises as a concurrent issue in monocultures, large quantities of various active ingredients of pesticides are needed to control them. The need for agricultural output has expanded dramatically in response to the growing global population, which has resulted in extensive pesticide use and the development of artificial fertilizers

in conventional agriculture. The quality and fertility of the soil have decreased as a result of the usage of these chemical agents in agricultural fields. Several million people worldwide are going without food, and at the same time, the environmental resources are becoming more and more polluted. The challenges of preserving soil fertility, water scarcity in endangered regions of the world, pests and illnesses that harm crops and livestock, and increasingly strict criteria for food quality and safety can all be observed from a for mentioned information, demonstrating the need for an integrated approach. [4,6]. The current phrase in the agricultural industry is "smart farming," which aims to replace conventional methods with creative ones based on information and communication technologies (ICT) [7]. Smart agriculture is one of the new perspective technologies [8]. Technologies like Unmanned Aerial Vehicles (UAVs), Unmanned Ground Vehicles (UGVs), Image Processing, Machine Learning, Big Data, Cloud Computing, and Wireless Sensor Networks (WSNs), are expected to bring significant changes in conventional agriculture [7].

2. STATE OF CONVENTIONL AGRICULTURE AND SUSTAINABLE AGRICULTURE

Over the last several decades, the rapid growth in technological innovations have led to profound structural changes in the agricultural sector, including a transition from smallholder mixed farms toward large-scale specialized industrial production systems [2,9]. Agricultural sector faces many challenges to ensure possible improvements in production sustainability in ways that promote food security, poverty reduction and improved public health [2]. Agriculture is both affected by climate change and an important contributor to greenhouse gas (GHG) emissions. Total emissions on agricultural land in 2019 amounted to 10.7 billion tons of carbon dioxide equivalent (Gt CO_2eq) of GHG released into the atmosphere in 2019. [10]. Agriculture contributes nearly 11% of global greenhouse gas emissions [11]. One of the biggest problems facing crop production are plant diseases and pests. Historically, many plant diseases caused by various phytopathogenic microorganisms have led to catastrophic losses, such as the Irish famine (1845), the Great Bengal famine (1943), the southern maize leaf blight epidemic (1970), and coffee rust (1970). Until recently, only chemical pesticides were used to control harmful agents, largely due to their cost-effectiveness [12, 13]. Intensive use of pesticides caused surface and ground water pollution. Groundwater is much more serious problem because pesticides do not degrade there as rapidly as in other environments, ground-water is commonly used for irrigation and for drinking by man and domestic animals [14]. With an increasing human population under a decreasing per capita agricultural land globally, optimizing productivity while maintaining the preservation of soil health and the protection of environmental quality is a key challenge [11]. Sustainable agriculture, unlike conventional agricultural production, produces abundant food without depleting the earth's resources or polluting its environment. For the sustainable maintenance of agriculture, the dynamic nature of soil is of primary importance [15, 16, 17]. 95% of our food is produced by plants growing in soil (FAO, 2020). Soil content is regulated by numerous aspects such as various biotic and abiotic factors, soil moisture, nitrogen, phosphorus and potassium content, organic carbon and others. Wise soil management means increases organic matter [18].

3. SMART FARMING AND SUSTAINABILITY

Smart agriculture with Internet of Things and Wireless Sensor Network is a transformation from traditional farming to smart farming [19, 20, 21]. The global agricultural development trend known as "smart agriculture" uses IoT sensors and near- and remote sensing techniques to monitor crop conditions at various growth stages. In order to practice smart agriculture, a significant amount of crop health data must be collected and processed. The health of plants is influenced by a number of variables, including temperature and water content. With the help of vast amounts of data from various sources and different parts of the field, such as soil nutrients, the abundance of pests and weeds, the amount of chlorophyll in plants, and some weather conditions, smart agriculture enables a farmer to precisely know what parameters are needed for productive crops, where these parameters

are needed, and in what amounts at a specific moment in time. It is necessary to analyze all the data gathered in order to generate agronomic advice. For instance, the amount of chlorophyll content in plants, depending on their stage of development, indicates the nutrients required. The qualities of the soil where the plant is placed, along with the weather forecast, are integrated with this information. The amount of a specific fertilizer that should be applied to that plant the following day is calculated using all the data that has been gathered. To increase yields, farmers must receive agronomic information at the proper time and be sure to follow its suggestions [19]. According to Shafi et al. (2019) the main objective of smart agriculture is to produce surplus yield by optimizing the resources such as water, pesticides, fertilizers, etc., for resource optimization. Inputs for crop production can be managed by smart agriculture in an environmentally sustainable manner. Smart agriculture can target rates of fertilizer, seed, and chemicals for soil and other conditions by applying site-specific knowledge [22]. All of factors point to the fact that smart agriculture can help production agriculture become more environmentally friendly by using fertilizers and pesticides only when and where they are truly necessary. Environmental advantages of precision agriculture result from more focused input utilization that lowers losses from excess applications as well as from reductions in losses owing to nutrient imbalances, weeds, insect damage, reduction in pesticide resistance development [22, 23]. Unmanned aerial vehicle (UAV) aircrafts are used to spray pesticides in order to minimize the health issues that might arise when doing it manually, which is one method of implementing smart agriculture. UAVs can be utilized in places where labor and equipment are difficult to employ. They are equipped with the cameras and sensors for crop monitoring and sprayers for pesticide spraying. A UAV is an aircraft which can flight without a human pilot and controlled by the radio channel. A technical analysis of UAVs in smart agriculture is to analyze their applicability in agriculture operations like crop monitoring, crop height Estimations, pesticide Spraying, soil and field analysis. Their hardware implementations are solely based on important factors such as weight, flying range, payload, configuration, and costs [23]. A traditional agricultural environmental monitoring system supplies electricity and transmits data by cable. It is particularly challenging to obtain information about the agricultural environment in real time because to the challenging installation of power lines, high investment prices, etc. Systems for monitoring the agricultural environment using wireless sensor networks have been developed to increase crop output while reducing pollution and environmental deterioration. In this way, researchers can achieve real-time remote monitoring of agricultural land in the control room, according to temperature and air humidity, light intensity, soil moisture and soil pH and other agricultural information for making correct decisions. The monitoring system for the agricultural environment is made up of several dense wireless sensor nodes that are dispersed across the agricultural environment. Different sensors can be used on farmland depending on the needs, creating a self-organized network to track changes in values like temperature, humidity,CO_2 concentration, soil pH value, and light intensity. Remote monitoring terminal through GPRS processes and analyzes the collected data, and then the data will be displayed in the form of curves, graphs and report forms and also written into database, through which completes browse and inquire the current information [24]. In the area of smart agriculture, there is also the potential to investigate various deep learning (DL) models for spotting insects in pictures. Different DL-based object detection algorithms exist for identifying outdoor insect pests. To guarantee healthy crop growth, early pest insect identification is essential, because this lowers the likelihood of yield loss and enables the adoption of precise treatments that have positive environmental and economic effects [25]. Intensive development of the Internet of Things (IoT) technologies enabled different novel applications, including smart agriculture systems. IoT technologies serve as the technical foundation for smart agriculture networks. IoT includes the basic communication infrastructure and range of services, such as local or remote data acquisition, cloudbased intelligent information analysis and decision making, user interfacing, and agriculture operation automation. Such capabilities have the potential to change the agriculture sector, which is now one of the least efficient in our economic value chain. Currently, integration of wireless sensors and the IoT in smart agriculture can raise agriculture to levels which were previously unimaginable. IoT can help to improve the solutions of many traditional farming issues, like drought response, yield optimization, land suitability, irrigation,

and pest control. Soil mapping creates the possibility to sow different crop varieties in a specific field to better match soil properties such as seed suitability, time to sow, planting depth, as some are deep rooted and others less so. Additionally, combining the growth of several crops may result in more intelligent agricultural practices that make the greatest use of available resources [16, 27]. The accuracy of new IoT-based fertilizing methods helps to estimate the amount of nutrients needed while requiring minimum labor requirements. In order to make agriculture sustainable it is considered that in the future IoT will be involved in all operations, which includes water and energy use, crop transportation, alerts on the operation and maintenance of agricultural machinery, etc. Implementation of such a system in the field can help to improve the yield of the crops and overall production and enable the long-term sustainability of agricultural land and other environmental resources.

4. CONCLUSION

The goal of advancing agriculture is essential given the global trend toward new technology and their deployment. The majority of the research that has been conducted thus far shows that smart agriculture-based practices have a significant impact on sustainability and productivity. The goal of smart agriculture is to provide decision-support systems based on a variety of crop-related factors, such as soil nutrients, soil water content, wind speed, sunshine intensity, temperature, humidity, chlorophyll content, etc. Due to high costs, lack of internet access, and a lack of application knowledge among farmers, there are still restrictions on the conversion and adoption of smart agriculture today, but breaking beyond conventional methods and thinking, the use of wireless sensor networks in monitoring agricultural environments has the potential to significantly increase crop production's efficiency and dependability as well as protection environmental protection in the future.

VARROA DESTRUCTOR, THE PARASITIC MITE OF *APIS MELLIFERA*: A REWIEW

Zlata Živković [1], *The Academy of Applied Technical Studies Belgrade*

Abstract: *Honey bees are the primary commercial pollinators across the world. Long before written history was created, The western honey bee, Apis mellifera L. was a very valuable socio-economic resource for people. It has been carried throughout the world for hundreds of years for the purpose of producing honey and pollination. A. mellifera is a social insect that lives in a colony where the queen, workers and drones are interdependent and cannot survive alone, so the colony can be considered as one organism. The number of honey bees has been declining globally in recent decades. In addition to climatic factors that affect the biology and ecology of bees, the main reason for the reduction in the number of colonies is harmful agents, among which diseases, parasites and pesticides stand out. Perhaps the most harmful parasite mite that infects honey bees globally is Varroa destructor (Mesostigmata: Varroidae). Varroa is an invasive species that has spread globally since switching from its original host, the Asian honey bee (Apis cerana) (Hymenoptera: Apidae), to the Western honey bee (Apis mellifera) (Hymenoptera: Apidae). It now attacks honey bees on nearly every continent where apiculture is practiced and present the most important ectoparasite of Apis mellifera.*

Keywords: Varroa destructor, mite, honey bees, Apis mellifera, pollination.

1. INTRODUCTION

Honeybees are insects that come under order Hymenoptera and family Apidae. Based on morphometric, behavioural and biogeographical studies, 26 subspecies have been identified. *Apis mellifera* are found all over the world and their native range extends across Africa, Asia, and Europe. Distribution of *Apis dorsata* extends from Pakistan to Indonesia across the Indian subcontinent. The distribution of *Apis florea* is often limited to warm regions, ranging from Pakistan to Sri Lanka. *Apis cerana* was more commonly found in tropical and subtropical regions of Asia than in temperate regions. Because of their hidden nesting habits, only *A. cerana* and *A. mellifera* have been domesticated by man among all the *Apis* species [1, 2]. The western honey bee, *Apis mellifera*, has been globally transported for hundreds of years for honey production and pollination and has been of enormous socio-economic value to humans long before the beginning of written history. The oldest records of honey hunting date back to prehistoric cave paintings [3, 4, 5]. Based on the fossil record, the first signs of social bees appeared about the same time as some of the earliest flowering plants that needed insect pollination [3]. In addition to exhibiting sophisticated behavioral features like sociality, language, labor division, and remarkable capacities for learning and memory, honeybees also have a complex social structure. Honeybee females can grow into either workers or into morphologically different, reproductively active queens, a phenomenon known as polyphenism [1]. The honey bee *Apis mellifera* is a social insect which lives in a colony where the queen, workers and drones are interdependent and cannot survive alone. The colony can be considered as one organism (Figure 1). The colony has a one year developmental cycle which is dependent on some external factors such as season, geography, beekeeping practices, etc. [6]. The queen, the only reproductive person in each colony, is responsible alone for laying the eggs that hatch into workers (females) and

[1]zzivkovic@atssb.edu.rs

drones (males). Despite being sterile, workers collaborate on all actions related to colony upkeep, defense, food foraging, and brood rearing. Although worker honey bees have the same physical characteristics, each individual is specialized in carrying out particular behavioral tasks within the colony [7].

Throughout history, honey bees have benefited man both for food and their ability to increase crop yield via pollination [8]. Next to pollination, honey production is the second biggest benefit humans get from bees. Honey is a complex nutritional sweetener composedmainly of carbohydrates and water, and it also contains small amounts of other compounds, such as organic acids, minerals, vitamins, enzymes, proteins, amino acids. Its is usually consumed in natura, and as a food ingredient but has been also employed in both human and veterinary medicine [9]. Nowadays, the benefits of plant pollination exceed all other economic benefits that modern beekeeping has through the production of honey, propolis, wax and more. A number of important horticultural crops depend increasingly on controlled honey bee colonies which help in pollination in modern agriculture.

Figure 1. Colony of bees

2. MEET THE ENEMY: THE PARASITIC BEE MITE - *VARROA DESTRUCTOR*

The process of honey bee pollination is essential to ecosystem health and agricultural production optimization [10]. The honey bee, of all insect species, is most crucial to the pollination of agricultural crops. Only 15-20% of pollination is carried out by other mediators, such as bumblebees, solitary bees, butterflies, etc., compared to 80–85% by bees. With their activities, these insects affect not only the maintenance of plant communities but also entire ecosystems. In modern commercial beekeeping, bees face numerous enemies in the form of diseases and pests. This number has increased in recent decades. International transport, export or import of bees and/or their products increased the possibility of introducing different pathogens (parasites, bacteria, viruses and fungi) into bee colonies. Arguably the most destructive parasite mite attacking honey bees globally is hemophagous honey bee mite *Varroa destructor* (Mesostigmata: Varroidae). *Varroa* is an invasive species that has spread globally since switching from its original host, the Asian honey bee *(Apis cerana*) (Hymenoptera: Apidae), to the Western honey bee (*Apis mellifera*) (Hymenoptera: Apidae). *Varroa* was first reported in Africanized honeybees in Brazil in the early 1970s. It is presently regarded as the main danger to apiculture [11,12]. *Varroa destructor* is an obligatory parasite, spending its entire life in the bee's nest [13]. High levels of *Varroa* infestation, particularly in the absence of mite management techniques, can cause varroosis throughout the colony and ultimately colony loss. Because it can multiply within both worker and drone cells, allowing populations to grow quickly, *Varroa* has become an effective parasite of *A. mellifera* [14,10]. The *Varroa destructor* mite is the largest threat to apiculture worldwide and has been responsible for devastating losses of wild honeybee populations in Europe and North America [14]. *Varroa jacobsoni,* on the other hand, has comparatively little influence on the colonies of its native host, *A. cerana,* owing, at least in part, to the fact that the mite can only breed when a male brood is present. In contrast, *V. destructor* can reproduce on both male and female brood, which results in an extended reproductive season and increased numbers of *V.destructor* mites,

which parasitize both adult bees and their larvae in the hive [10]. *Varroa* mites enter brood cells inhabited by mature bee larvae prior to worker bees sealing comb cells with wax. Here, they will eventually feed on the hemolymph and fat bodies of host pupae [15]. Parasitism of honey bees by the *V. destructor* reduces the body weight and water content of young bees, there is a reduction in the size of the drones and their reproductive capacity, which directly affects the bee population, i.e. the entire colony. Additionally, *Varroa* affects foragers' ability to fly, locate, and navigate, which reduces their efficiency in gathering the resources necessary for colony development. Certain haplotypes of *V. destructor* parasitizing *A. mellifera* transmit various bee-related viruses. The quantity of viral infection rises in the spring and summer as the *Varroa* population grows within the colony. High levels of *Varroa* infestation can lead to colony-wide varroosis and eventually colony death, especially when no control measures are taken against the mites [12]. High *Varroa* parasitization impacts bees at the individual level, causing bees to exhibit lower weight, decreased learning capacity, and shorter lifespan (Figure 2).

Figure 2. Colony of *Varroa destructor* on the bottom of the hive

3. VARROA'S EFFECTS COMBINED WITH ADDITIONAL COLONY STRESSES

Because of their crowded living conditions and the potential that closely related nestmates would have similar vulnerabilities against particular pathogens, social insects are particularly vulnerable to parasites and diseases. Among the social insects, parasites and diseases that affect honey bees are exceptionally varied, and disease-related problems have been linked to both decreased productivity and colony failure [16]. *Varroa* can interact with other biotic and abiotic stressors, including viruses, pesticides, other parasites and diseases, and environmental conditions. Exposure to pesticides, poor forage, mite parasites, and pathogens has resulted in high annual death of colonies in the USA, Europe, and other parts of the world [17]. Climate change means that honey bee colonies must endure longer durations of brood raising and foraging due to longer warm seasons. A longer brood time increases the number of *Varroa* reproductive cycles, perhaps leading to an increase in the mite population. In order for pathogens and pests to persist in a host population, they must be spread past one colony to another. Usually, inter-colony transmission happens when honeybee workers "drift"- that is, leave their home colony and join a foreign colony. Colonies with high *Varroa* infestation had a significantly enhanced acceptance of drifters, although they did not send out more drifting workers. Since *Varroa*-infested colonies show an enhanced attraction of drifting workers, and not only those infected with Varroa and its associated pathogens, infestation by Varroa may also facilitate the uptake of other pests and parasites [18]. Nosema infection reduces the effectiveness of bee defences against

the mite [19]. Nosemosis or Nosema disease is caused by two species of microsporidian parasites (a type of spore forming fungus) called *Nosema apis* and *Nosema ceranae*. Nosemosis is one of the most serious adult honey bee diseases and has high prevalence in honey bee colonies [17, 20]. Iportant bacterial pathogen (*Paenibacillus larvae* subsp. *larvae*) cause of the disease American foulbrood which is infectious disease of the larval stages of the honey bee Apis mellifera. The disease is also important from the point of view of international trade, so the import or export of bee colonies is allowed under certain, controlled conditions [16].
If mite populations develop undetected, untreated and infested honey bee colonies usually collapse within a year. Beekeepers check adult honey bees and their offspring for varroa mite infestations using a variety of techniques. These methods include counting mites on traps and on such colony contents as hive debris on the bottom boards, brood, as well as the bodies of captured worker bees. Collecting data foroptimally timing acaricide applications and effectively controling mites requires sampling such hive contents [15]. The "sugar shake" is a straightforward, non-destructive technique for gathering samples of varroa mites that are present on adult honey bees' bodies. This method consists only of dusting live bees' bodies with powdered sugar. *Varroa* mites will rapidly lose adhesion to the powdered sugar, which causes them to become permanently detached from their host bees' tarsal pads. The powdered sugar will quickly clog the tarsal pads of varroa mites. On this way, they lose adhesion and become permanently dislodged from host bees. For the purpose of controlling varroa mites in both conventional and organic honeybee colonies, organic acids that are mostly generated from plant components and essential oils are commonly utilized. Formic acid and oxalic acid are the most often used organic acids with strong acaricidal action [15,21]. Oxalic acid is applied via spraying and sublimation methods. It is a component of honey that occurs naturally, is safe for beekeepers to use, highly effective against the Varroa mite, and leaves no residue behind. However, other research indicates that mites have a high chance of becoming resistant to oxalic acid [22].

4. CONCLUSION

There has been a dramatic decline in the number of cultivated honey bees and wild bees in Europe during the last few decades. The reasons for the decline are varied and include habitat loss, pests and diseases, and excessive use of agrochemicals. At the same time, more crops are cultivated that require pollination. *Varroa destructor* is one of the biggest biological threats to the health of western bees (*Apis mellifera*) worldwide. The mite is a big problem for beekeeping and the search for new control methods is constantly in the focus of researchers and beekeepers. The most common applications in the control of *Varroa* are acaricides. However, acaricides can have harmful side effects on individual bees as well as entire colonies. Beekeepers routinely use chemical treatments to control this parasite, although overuse and mismanagement of these treatments have led to widespread resistance in *Varroa* populations. As a result, and to prevent the development of resistance to acaricides, they must be administered at the lowest effective dose. The application of toxic active products each season can be reduced by increased mite monitoring and the use of less persistent, low-residue acaricides. The need for a sustainable solution to the threat of the *Varroa* mite is essential for the economic viability of beekeeping and agriculture, as well as for bee health, conservation and ecosystem services. The special importance of healthy bee colonies refers to pollination as the primary benefit that humans and agriculture derive from bees. The constant education of agricultural producers, in terms of pointing out the importance of bees, and the preservation of the entire biodiversity is of exceptional importance.

RESEARCH ON THE PHOTOSYNTHESIS RATE IN THE SPECIES *SALVIA OFFICINALIS IN VITRO* AND *IN VIVO*

Dorin Dumitru Camen[1], Faculty of Engineering and Applied Technologies, University of Llife sciences, Timisoara, Romania
Mădălina Elena Dumitrașcu[1], Faculty of Engineering and Applied Technologies, University of Llife sciences, Timisoara, Romania
Maria Mihaela Moatăr, Faculty of Engineering and Applied Technologies, University of Llife sciences, Timisoara, Romania

Abstract: *Salvia Officinalis is an aromatic perennial plant, native to southern Europe and Asia Minor. It is cultivated as a culinary plant and as a plant of great medicinal importance, officially listed in the Pharmacopoeias of many countries around the world. Salvia Officinalis is a subshrub, originally from the Mediterranean region, with a height of 30-80 cm. The stem of this plant is erect, bushy, branched, at the base being lignified. It is covered with a grey-brown bark. The research focused on determining the photosynthetic rate in this species, using variants cultivated both in vivo and in vitro. The evaluation was carried out over a period of 49 days. For the variant cultured in vitro, we used the MS culture medium. The experimental results show significant differences between the experimental variants. Also, the processing of the results allowed us to establish the optimal technologies regarding the rate of photosynthesis both in the species cultivated in vitro and in vivo.*
Keywords: *Salvia Officinalis, in vitro*, in vivo, photosynthetic rate, medicinal plant

1. INTRODUCTION

The species is heat-loving, emerging above 10˚C, preferring hot summers and mild, short winters. On the other hand, Salvia is not picky about the type of soil, it can be found even on calcareous and sandy areas. Studies have shown that to establish the culture of Salvia, a well-cultivated land is needed. Plowing is done right after clearing the land of the previous plant, then harrowing is done in the direction of plowing [1]. Sowing is carried out in November or early spring. Care works consist of manual or mechanical weeding. In the spring, the work is carried out which consists in the removal of lignified stems, called rejuvenation work, which lead to the appearance of young shoots, with large leaves, helping to increase the harvest [2]. After the second year of cultivation, plant rejuvenation procedures are carried out in the spring, the stems are cut 8-10 cm compared to the soil. This procedure must be repeated after each year, at a distance of 10-12 cm [3]. Numerous studies have demonstrated the benefits of vitamins B1 and C, found in the composition of the leaves. The leaves of this species contain a volatile oil, represented by thuil, salven, terpenes, thujone and sabinol. We also find tannins, potassium salts, bitter principles, polyphenols, glycosides and resins. In Romania, the cultivation of *Salvia Officinalis* is a risky one, being restricted by the winter period when the temperatures are negative. In this case there is a high risk of freezing [4]. The nature of the active principles it contains and the complex chemical composition give this plant

[1] taranmadalina90@yahoo.com

carminative, estrogenic, choleretic, and antiseptic properties. Studies have shown that *Salvia* has a hypoglycemic effect, a calming effect on the nervous system. Thanks to the phytoestrogenic compounds it contains, it helps balance the body of menopausal women and regulates menstruation [5]. Numerous studies have shown that this plant acts in conditions such as: hepatobiliary disorders, poor blood circulation, fights nervousness, hypertension, mental depression, hepatitis, jaundice, abdominal bloating, vascular diseases, poor blood circulation, prevents heart attack, disorders of the menstrual cycle, ovarian dysfunction, diabetes, headaches, fatigue, paralysis, asthma, chronic bronchitis, bactericidal action on Koch barium [6].
On the other hand, this plant is used as a raw material in the manufacture of detergents and fine soaps. *Sage* is included in the recipes of creams, shaving lotions and colognes. The essential oil is often used in perfumeries in combination with lavender, citrus and rose oils[7].
The photosynthesis process takes place at the level of the leaves, which is why, in this area of the plant, the substances necessary to initiate the cycle so necessary to maintain life must be transported. Carbon dioxide is captured through extremely small pores, which are called stomata [8]. Oxygen is released, at the end of the process, also through these holes. Water is absorbed through the roots and transported to the leaves through the vascular tissue system of the plant [9]. Sunlight rays are absorbed by chlorophylls - green pigments, located at the level of chloroplasts, which are the seat of photosynthesis in plants [10]. Following thorough research carried out over the last 50 years with the help of radioactively labeled carbon isotopes, it was possible to discover the mechanism thorough process by which plants synthesize organic compounds from mineral salts in the presence of aluminum and chlorophyll [11]. These researches revealed the fact that photosynthesis takes place in the form of a chain of successive reactions that require light conditions in the first stages (Robin Hill phase) and dark conditions in the following stages (F.F. Blackman phase) [12]. Devices to measure photosynthesis, based on chlorophyll fluorescence, have been in development since the early 1990s. EARS, of Delft, the Netherlands, was the first company to develop a portable instrument [13]. The plant is composed of cells, which contain a large number of green grains, the chloroplasts. In these chloroplasts there is a folded membrane, consisting of proteins and lipids, the thylakoid [14]. Embedded in the thylakoid there are clusters of several hundreds of chlorophyll-molecules, the so-called photosystems [15]. These provide the energy for the photosynthesis reaction. They function as antennae that capture light particles or photons. Photosystems absorb mainly blue and red light, while green light is scattered.

2. MATERIAL AND METHOD

Photosynthetic capacity was determined with the EARS Plant Photosynthesis Meter (PPM) which measures the photosynthetic light utilization of plants. The measurement is based on chlorophyll fluorescence, a very weak optical signal emitted by the plant, but which can be detected by the machine. Due to its light weight, the instrument is very suitable for use in the laboratory and in the field. In addition, long measurement series can be performed automatically. For this reason, PPM has a wide range of applications in research, education and practice. The plant material for "*in vitro"* and "*in vivo*" multiplication was represented by the seeds of the medicinal plant species *Salvia Officinalis.*

3. RESULTS AND DISCUSSIONS

The F test shows that both the in vivo or vitro culture mode and the time period have a very significant effect on the photosynthesis rate [$p<0.001$]. There are very significant differences between the ratings of each factor, and the interaction of the factors is insignificant (Table 1).

Table 1. Analysis of variance on the effect of culture mode and determination period on photosynthesis rate in *Salvia Officinalis*

The source of variation	GL	SP	S2	Sample F	
Total	17	1366.278			
Culture mode	1	180.500	23.8897		0.0004 ***
Determination period	2	1067.111	533.556	70.6176	0.000***
Culture mode × Determination period	2	28.000	14.000	1.8529	0.1989 ns
Error	12	90.667	7.556		

Coefficient of variation: 4.34%

According to the coefficient of variation, it follows that the rate of photosynthesis has a small variation, cv<10% [cv = 4.34%]. Regarding the effect of the culture mode on the rate of photosynthesis in Salvia Officinalis, it can be seen from the data in Table 2 that the rate of photosynthesis varied from 60.2% in the in vitro mode to 66.6% in the in vivo culture mode. The result obtained in the in vitro culture mode having a very significant negative statistical assurance.

Table 2. Experimental results on the influence of culture mode on photosynthesis rate in *Salvia Officinalis*

Culture mode	Mediate photosynthesis rate [%]	Difference from the witness	The meaning
Culture mode 1 – *vivo*	66.6	mt	
Culture mode 2 – *vitro*	60.2	-6.3	000

DL 5% = 2.82% DL 1% = 3.96 DL 0.1% = 5.60

Table 3. Experimental results on the influence of the determination period on the photosynthesis rate in *Salvia Officinalis*

Determination period (days)	Mediate photosynthesis rate [%]	Difference from the witness	The meaning
Period 1 - 21 days	54.8	mt	-
Period 2 - 35 days	61.8	7.0	***
Period 3 - 49 days	73.5	18.7	***

DL 5% = 3.45% DL 1% = 4.85 DL 0.1% = 6.85

From the point of view of the influence of the determination period on the photosynthesis rate, values between 54.8%-73.5% were obtained. Compared to the control, the photosynthesis rate registered very significant increases, an increase of 7.0 at 35 days and 18.7% at 49 days, respectively.

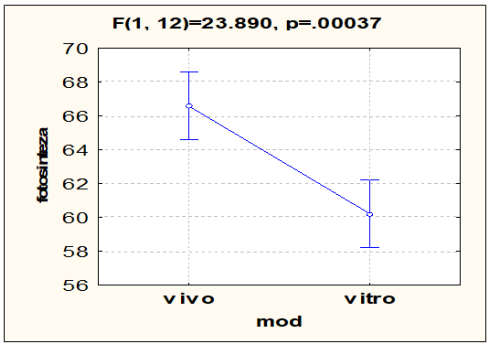

Figure 1. Influence of in vivo or *in vitro* culture mode on photosynthesis rate in *Salvia Officinalis*

The in vivo culture mode is clearly superior to the *in vitro* culture mode in terms of the rate of photosynthesis.

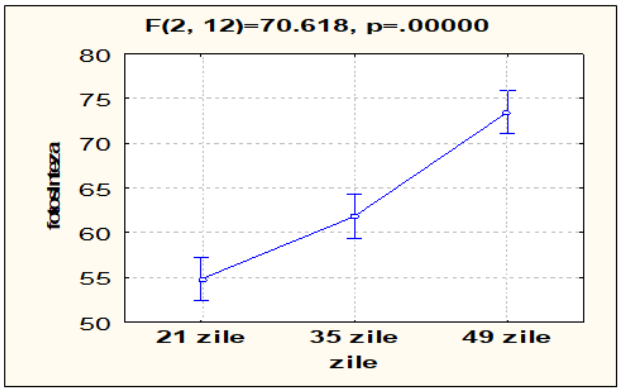

Figure 2. Influence of time on photosynthesis rate in *Salvia Officinalis*

The analysis of the photosynthesis rate over time highlights the fact that it is between 54.8 - 73.5%. At 49 days and at 35 days, the highest percentage of photosynthesis resulted, being far superior to the 21-day period.

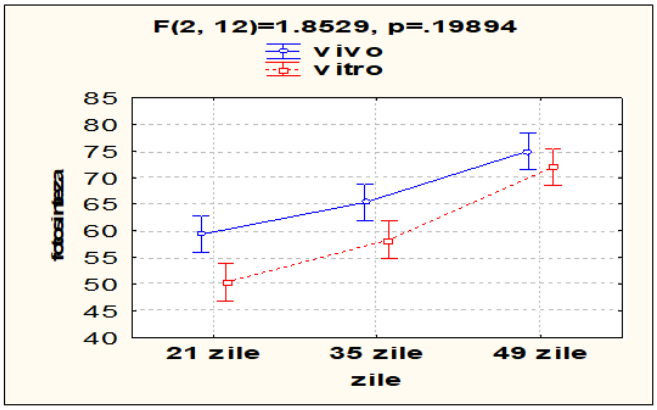

Figure 3. Influence of the interaction of culture mode and time period on photosynthesis in *Salvia Officinalis* species

Regardless of the time steps, the highest percentage of the photosynthesis rate was recorded in the in vivo culture mode. At 49 days, the values obtained on the two modes of in vivo and in vitro culture are similar, that is, they belong to the same homogeneity class.

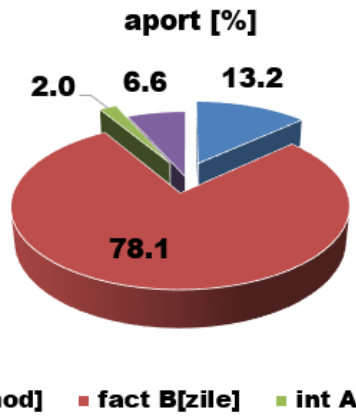

Figure 4. Contribution of culture mode factors, time period and their interaction to photosynthesis rate in *Salvia Officinalis*

4. CONCLUSIONS

In conclusion, the in vivo culture mode is superior to the *in vitro* culture in terms of the photosynthesis rate, a percentage of 66.6%, compared to 60.2%.
On the other hand, the best results were obtained during the period of determining the photosynthesis rate at 49 days, in a proportion of 73.5%, followed by the time period of 35 days with a percentage of 61.8%. Regarding the rate of photosynthesis, at the determination period of 21 days we had the lowest results, a percentage of 54.8%.
The culture method contributes to the photosynthesis rate in proportion of 13.2%, the factor represented by the number of days on which the determinations were made in proportion of 78.1%, and their interaction with 2.0%

Jelena Bošković [4], Univeristy Metropolitan

Abstract: *Climate change seriously threatens food security worldwide, causing extreme weather conditions and reducing agricultural productivity. Increased temperatures and greenhouse gas emissions are the main drivers of these changes. While increased CO_2 concentration can enhance plant growth, elevated temperatures and other factors offset these benefits. Therefore, it is essential to consider adaptation measures, including the development of climate-tolerant crop varieties and innovations in agricultural practices to preserve food security in a changing climate. Smart agriculture involves the use of advanced technologies such as climate, soil, and plant monitoring sensors, IoT devices that enable the connectivity of various aspects of agricultural production, and data analytics for decision-making. These technologies enable farmers to better understand environmental changes and respond quickly to unpredictable climatic conditions.*
Keywords: climate, climate change, agriculture, adaptation strategies, biodiversity

1. INTRODUCTION

Global climate change has reached a serious threat level for global food security and the nutrition of the world's population. The effects of these changes are becoming increasingly apparent, jeopardizing the sustainability of agriculture and food supply stability. The main factor responsible for this situation is the increased emissions of greenhouse gases, leading to global warming and the greenhouse effect. Rising surface temperatures on Earth have a range of serious consequences, including extreme weather events like droughts, floods, and storms, as well as altered precipitation patterns. These climate factors continually reduce the productivity of various agricultural crops, resulting in lower yields and reduced food quality. Increased temperatures also shorten the growing seasons, directly impacting crop yields. Global temperatures are expected to continue rising, leading to more frequent and prolonged heatwaves, further negatively affecting agricultural production [1,2,3,4].

Changes in temperatures and precipitation patterns have a significant impact on planting, crop yields, and phenological characteristics. Climate change and its unpredictable variability present real threats to agriculture and global food security. The increased concentration of CO_2, a significant greenhouse gas, has a complex impact on agriculture. On the one hand, it can accelerate plant growth and increase productivity through enhanced photosynthesis. However, these benefits are offset by increased temperatures, which lead to higher plant respiration, increased

[1]astevanovic@atssb.edu.rs
[2]vera.popovic@ifvcns.ns.ac.rs
[3]mjevtic@atssb.edu.rs
[4]jelena.boskovic@metropolitan.ac.rs

evapotranspiration (loss of water through plants), increased pest occurrences, changes in weed flora, and shortened crop durations. All these changes make agriculture more vulnerable to climate impacts. In light of these challenges, it is clear that concrete steps need to be taken to mitigate the negative effects of climate change on agriculture and food security [5, 6].

A key approach in this context is the development of heat-tolerant crop varieties and the implementation of innovations in existing agricultural practices. These adaptation strategies play a crucial role in reducing the harmful consequences of climate change on global food security and are essential steps towards preserving food supply stability in a changing climate. The agricultural sector faces serious challenges in the context of the need to adapt to climate change. With the expected growth of the world's population to nine billion by 2050, there is a need to ensure an adequate food supply and other basic needs. However, limited arable land for expansion and increasingly frequent extreme weather events due to climate change pose significant threats to agriculture. Various technologies and practices have been developed worldwide to facilitate agriculture's adaptation to climate change. These include improved weather forecasting, water conservation, drip irrigation, sustainable soil management, livestock improvement, and changes in crop varieties and planting systems. Some of these approaches require financial investments, while others require changes in practices and increased awareness among farmers. Technological strategies for adapting to climate change in agriculture are based on agroecological principles and encompass diverse scientific technologies from climatology, biology, and agronomy. They also focus on social and institutional capacity-building processes for adaptation. These technologies include climate change planning, sustainable water and soil management, sustainable crop and livestock management, sustainable agriculture systems, capacity building, and the involvement of relevant stakeholders. Instead of technologies that tend to homogenize the natural environment and agricultural production, those that promote diversity and environmental conservation are preferred. Most of these technologies are already known and applied, but they are adapted based on specific conditions and needs caused by climate change. Agroecology as a multidisciplinary approach, explores the sustainability of agricultural systems and promotes biodiversity conservation. This approach provides a useful framework for selecting and implementing technological solutions in agriculture, considering a comprehensive assessment of factors that affect their efficiency and ecological integration. Making informed decisions about appropriate technological solutions requires taking into account specific local contexts, including social and cultural norms, to achieve the optimal impact on system sustainability. When it comes to adapting agriculture to climate change, it is especially important to emphasize the preservation of water resources and the promotion of sustainable irrigation methods. Introducing improved plant genetic varieties, precise monitoring of weather conditions, and the application of precision agriculture play a crucial role in addressing the challenges brought about by climate instability. Through collaboration between farmers, researchers, and authorities, an integrated approach can be developed to ensure the resilience of agriculture to climate change and contribute to global food security. Adapting to climate change in agriculture requires a systematic approach that encompasses various technological and social aspects to achieve sustainable solutions [7].

Impact translates from climate to the environment, to the productive sphere, to economic and social dimensions, bringing a range of additional risks on availability of food, on access to food and utilization of food, as well as on the stability of these characteristics, for both farm and non-farm households [7].

2. THE IMPACT OF CLIMATE CHANGE ON AGRICULTURE AND ADAPTATION STRATEGIES

Climate change has a significant and profound impact on the agriculture sector worldwide. Increasing global temperatures, altered precipitation patterns, and more frequent extreme weather events pose serious challenges to food producers. Maintaining the sustainability of agriculture and global food security requires the implementation of diverse adaptation strategies. These strategies need to be quantified using modeling approaches to better understand and predict the potential

effects of climate change on agriculture. To address these challenges, farmers and scientists are collaborating to develop adaptation strategies. This includes adjusting planting dates to maximize crop potential and reduce losses due to unfavorable weather conditions [5]. Optimal plant densities are also being researched, as higher plant density can offset yield losses. Genetic selection and technology play a crucial role in adapting agriculture to climate change. Developing crop varieties that are tolerant of higher temperatures, drought, and unpredictable rainfall becomes imperative. Scientists are focusing on selecting genotypes that better withstand stress and developing genetically engineered varieties that are more resilient to climate change. Innovations in agriculture are also of vital importance. Precision agriculture, the use of satellite monitoring, and automated irrigation systems can significantly optimize resource utilization and reduce food production losses. Given the changing climate conditions that lead to reduced water availability for agriculture, preserving water resources is imperative. Efficient irrigation systems and water recycling become key to sustainable food production. Furthermore, precise nutrient management can enhance crop resilience through improved fertilizer efficiency and reduced greenhouse gas emissions. Farmer education plays a crucial role in successfully addressing climate change. Farmers need training on the latest techniques and practices to better cope with changes and manage their resources more efficiently. At the policy and regulatory level, governments and international organizations must recognize the urgency of the issue and adopt policies that support sustainable agriculture and the reduction of greenhouse gas emissions. Addressing climate change in agriculture requires a comprehensive approach and collaboration across different sectors. Preserving the future of agriculture and global food security demands thoughtful and effective measures to safeguard our planet and ensure an adequate food supply for future generations.

3. PRECISION AGRICULTURE AND ITS ROLE IN CLIMATE CHANGE ADAPTATION

Precision agriculture plays a crucial role in adapting to climate change. With changing climate conditions, farmers face increasing challenges in preserving crop productivity and sustainability. This modern agricultural practice utilizes advanced technology, including GPS, sensors, drones, and satellites, to enable precise resource management such as water, fertilizers, and pesticides. This approach reduces resource overuse and economic costs, which becomes increasingly important in the context of growing climate change unpredictability. Several key ways in which precision agriculture can help in adapting to climate change include: GPS (Global Positioning System, sensors, drones, satellites, crop adaptability, early warning of damage, sustainable practices, precision agriculture [8].

The combination of these technologies allows farmers to better understand and respond to climate change, increasing agriculture's resilience to extreme weather conditions, droughts, floods, heatwaves, and other challenges brought by climate change.

4. BIODIVERSE AGRICULTURE, OR "ECOLOGICALLY INTENSIVE AGRICULTURE"

Biodiverse agriculture, also known as "ecologically intensive agriculture," is a key aspect of modern agriculture focused on the sustainable preservation of biodiversity within agricultural ecosystems. Like natural ecosystems, agricultural ecosystems depend on the diversity of plant and animal species to achieve sustainable productivity, fertility, and resilience to external changes and disruptions. The concept of biodiverse agriculture relies on a high level of biological diversity within agricultural systems to achieve sustainable productivity and resilience, while also contributing to environmental protection and reducing the need for chemical agents. This approach plays a crucial role in addressing current climate changes as it promotes ecosystem services and reduces the need for chemical agents. However, while this concept is of fundamental importance, its complexity has not yet been fully understood, making its regulation challenging. In the context of ensuring global food supply, careful consideration should be given to protecting valuable ecosystems and their biodiversity. In the food production sector, priority should be given to the

restoration and preservation of ecosystems, requiring long-term planning and fundamental changes in economic, production, and development strategies. It is also necessary to restructure food systems to achieve a neutral or positive impact on the environment while ensuring healthy nutrition and food security. Low-impact strategies must become a priority.

Agroecology, as an approach that promotes sustainable agricultural production and biodiversity conservation, provides a useful framework for selecting technology adapted to local needs. In making informed decisions about the appropriate technological options, it is essential to consider local contexts, including social and cultural norms. To support the decision-making process, the application of a community-based adaptation (CBA) framework is proposed, involving various stakeholders and enabling participatory planning, monitoring, and implementation of adaptation activities. Additionally, setting criteria for prioritizing adaptation technologies, taking into account ecological sustainability, access to climate change information, water, carbon, and nutrient cycles, economic aspects, cultural diversity, scaling, and institutional integration. Adaptation in agriculture requires a comprehensive approach, encompassing technical and social aspects to preserve productivity while protecting the environment. An impact assessment of climate change provides a scientific basis for the development of adaptation strategies that can mitigate the negative effects of climate change on agricultural crops. Biodiversity, including genetic diversity, species diversity, and ecosystem interactions, enhances ecosystem resilience to changing conditions and environmental stresses. Genetically diverse populations and species richness have a higher potential for adapting to climate change. Therefore, the use of native and locally adapted plants and animals is promoted, as well as crop and livestock variety selection.

5. AGRICULTURE ADAPTED TO CLIMATE CHANGE

In order to effectively address the challenges of climate change in the context of agriculture, it is necessary for farmers to adopt an approach that involves the development or transformation of their agricultural systems. This approach involves replacing old procedures and practices with new agricultural methods and techniques that are in line with the requirements of climate change [9,10]. Agriculture adapted to climate change (ACC) can be described as a comprehensive approach to agricultural management aimed at achieving sustainable growth in agricultural productivity and income, addressing food security and climate change issues, directing agricultural development to achieve climate change mitigation and adaptation goals, and efficiently managing agricultural growth [11,12,13,14,15]. ACC encompasses a wide range of adaptive measures and practices aimed at reducing the impact of climate change, sustainably increasing agricultural productivity (in the context of food, fibers, and fuels production), reducing greenhouse gas emissions, increasing agricultural resilience to climate change, and promoting national food security and development goals [12,13,16,17]. ACC doesn't only address ecological aspects but also takes into account social and economic aspects to achieve comprehensive benefits and reduce compromises, including institutional, political, and technological practices [15]. ACC activities involve a combination of traditional agricultural practices that have evolved over time and innovative agricultural technologies that are widely recognized and promoted. This includes approaches such as agroforestry, conservation agriculture, biodiversity-based agriculture, water management, and sustainable land management practices or technologies [15,18,19]. At the farm level, the implementation of ACC measures depends on the socio-economic environment influenced by institutional patterns, resource availability, and climatic conditions. Using different methods allows farmers to synergize ACC practices and technologies, increasing farm productivity while addressing interconnected challenges [13,19,20]. While it is desirable to achieve all the set ACC goals, in the real world of agriculture, compromises between productivity, sustainability, and climate change mitigation will be necessary. Today, the concept of ACC plays a crucial role for many organizations dealing with the intersection of climate adaptation and agriculture. ACC provides guidance for identifying successful models of agricultural production among different approaches. Any agricultural technology that surpasses conventional practices can contribute to achieving ACC goals

and be recognized as climate-sustainable [21]. Currently, existing directions for ACC development include (i) the application of advanced internet technologies to ensure information security in agriculture; (ii) the improvement of crop structures and management methods; (iii) the provision of "Internet + weather" services; (iv) the improvement of the quality of agricultural services; and (v) the development and application of agricultural weather disaster insurance [12]. These concepts and strategies will enhance environmental protection, support sustainable agricultural progress, and reduce the impact of climate change.

Climate change represents a significant and serious threat to global food security and agricultural sustainability. Rising temperatures, altered precipitation patterns, and increased greenhouse gas concentrations significantly affect plant productivity, reducing yields and food quality. These effects are becoming increasingly evident and are expected to continue in the future. To preserve global food security, urgent measures to adapt to climate change are necessary. This includes developing crop varieties tolerant to high temperatures and implementing innovations in agricultural practices to mitigate the negative effects of climate change on food production. It is also important to work on reducing greenhouse gas emissions to slow down global warming and mitigate the climate impacts on agriculture. Sustaining the world food supply system requires a multidisciplinary approach involving farmers, researchers, government and international organizations to develop strategies and solutions to address this serious threat and ensure an adequate and safe food supply for the growing global population [22, 23].

6. CONCLUSION

Climate change poses a serious threat to the agriculture sector and global food security. Rising temperatures and increased CO_2 concentrations in the atmosphere can have complex effects on plant growth and productivity while simultaneously increasing the number of pests and weeds. Additionally, the microbial population in the soil can also be affected by climate change, which can impact the availability of nutrients for plants. Climate-smart agriculture is becoming crucial for adapting to these new conditions, but it requires innovations and changes in agricultural practices. It's also important to understand the economic consequences of climate change in agriculture, including the costs of adaptation and reduced yields. To address these challenges, serious global steps are needed to reduce greenhouse gas emissions and slow down temperature rise. Additionally, local and regional initiatives for adapting to climate change in agriculture are becoming increasingly important to preserve food security and sustainable agricultural production.

INFORMATION SYSTEMS IN ORGANIC AGRICULTURE – A REVIEW

Aleksandar Stevanović [1], The Academy of Applied Technical Studies Belgrade
Goran Nestorović[2], The Academy of Applied Technical Studies Belgrade
Vera Popović[3], Institute of Field and Vegetable Crops, National Institute of the Republic of Serbia

Abstract: *Organic agriculture is becoming an increasingly significant component of the global food system, with a focus on environmental sustainability and product quality. Information systems and technologies play a crucial role in supporting organic production, environmental conservation, and the production of safe and healthy safe food. The application of precision agriculture, utilizing cutting-edge technological systems, enables pest and disease monitoring and management, efficient water and energy management, digital product identification, the use of Geographic Information Systems (GIS) for crop planning, and blockchain technology for supply chain transparency. Through these applications, information systems and technologies significantly contribute to reducing the negative environmental impacts of agriculture, increasing productivity, and ensuring healthy safe food with greater nutritional benefits in organic farming. This symbiosis of science and technology in organic agriculture helps create more sustainable agricultural systems that can meet the needs of current and future generations.*
Keywords: organic agriculture, information systems, environmental sustainability, healthy food

1. INTRODUCTION

The dynamics of global population growth and the need to ensure a larger quantity of high-quality food, combined with the imperative of preserving the environment and resources, are key factors shaping the development of technologies in the field of organic agriculture. Organic agriculture is a holistic production management system, which promotes and enhances agro-ecosystem health, including biodiversity, biological cycles, and soil biological activity [1-10]. Faced with the challenges of the modern era, the agricultural sector must address a dual task: increasing productivity and ensuring long-term sustainability. It is evident that Information Technology (IT) plays a pivotal role in enhancing productivity in organic agriculture, with the ultimate goal of benefiting agricultural producers [11-15]. Specifically, the application of precision agriculture, using cutting-edge satellite-guided and automated technology systems, along with Geographic Information Systems (GIS), significantly contributes to yield improvement. Simultaneously, these technological advances promote efficient resource utilization, thereby reducing negative environmental impacts. In this light, the integration of new technologies into organic agriculture becomes essential for enhancing the production of safe and healthy safe food and represents the potential for sustainable sector development.

Contemporary trends in information technology development offer organic agriculture a unique opportunity to improve its operations, increase production efficiency, and minimize the negative impact on the environment. Given the specific requirements for producing environmentally friendly

[1]astevanovic@atssb.edu.rs
[2]gnestorovic@atssb.edu.rs
[3]vera.popovic@ifvcns.ns.ac.rs

products to meet the global demand for organic agricultural products, the main direction of its development lies in the introduction of innovative methods and technologies into the production process.

Despite global challenges in the agricultural sector, the prospects for organic production development through digitization are promising. The use of information systems in organic agriculture is driven by the need to increase its efficiency and manageability, improve product quality, and align with the requirements of organic agriculture standards in the green economy. They enable the automation of many routine processes and informed decision-making [16].

2. APPLICATION OF INFORMATION TECHNOLOGY FOR EFFICIENT RESOURCE AND PROCESS MANAGEMENT IN ORGANIC AGRICULTURE

Organic agriculture represents a specific branch of agricultural production that requires a special management system to ensure sustainable and environmentally-friendly production. The implementation of Enterprise Resource Planning (ERP) and Customer Relationship Management (CRM) systems can significantly enhance the efficiency of managing all aspects of organic agriculture, including the management of material and financial resources. One of the key systems for managing organic agriculture is FarmERP. This system encompasses a range of functions crucial for organic farms, including yield tracking and analysis for various crops. These systems allow farmers to gain a better understanding of yield dynamics and make informed decisions. Additionally, FarmERP includes crop planning systems, taking into account crop rotation and their mutual location, which is crucial for preserving soil health. Furthermore, the system provides soil condition monitoring and offers agronomic recommendations for the care of different crops, considering optimal sowing times and agronomic operations. FarmERP also includes cost tracking systems, essential for monitoring the costs of major material resources such as seeds, fertilizers, and fuel. FarmLogs is another important cost management tool in organic agriculture. This system allows tracking all costs associated with organic production, including fertilizers, seeds, labor, fuel, and other factors. It also enables monitoring of soil conditions, such as pH values, moisture, and nutrient levels. Based on this data, FarmLogs provides recommendations based on successful agronomic practices, taking into account natural, climate, and weather conditions, as well as crop characteristics. ERP systems like SAP ERP provide a comprehensive solution for automating business processes in organic production. These systems enable the planning of agricultural tasks and resources, efficient management of business operations, and the optimization of the overall business of organic farms. Additionally, the information system FarmOS supports farmers in managing organic production. This system includes crop and crop rotation planning, weather monitoring, financial accounting, and nutrient management. FarmOS also allows tracking mineral and organic fertilizers, organizing pest control, and provides documentation necessary for compliance with organic agriculture standards. The implementation of ERP and CRM systems, such as FarmERP, FarmLogs, SAP ERP, FarmOS, and others, plays a crucial role in optimizing organic agriculture management. These systems provide better control over all aspects of production, help reduce costs, improve product quality, and contribute to the sustainability of organic agriculture [17-19].

3. ADVANCED INFORMATION SYSTEMS FOR ENSURING COMPLIANCE WITH ORGANIC AGRICULTURE STANDARDS

In the modern context, the use of information systems has become a key component in achieving compliance with stringent organic agriculture standards. These standards encompass various aspects, including the production, labeling, and certification of organic products, as well as requirements for ecological and socially sustainable agricultural practices. In this context, digital solutions play a crucial role in facilitating the compliance process for farmers and providing them with tools to monitor and document all relevant aspects. Information systems enable farmers to

track all stages of organic product production, starting from agricultural activities such as the use of fertilizers, pesticides, and cultivation techniques that comply with organic standards. They allow for efficient monitoring of the flow of raw materials and products throughout the supply chain, contributing to transparency and the reliability of the organic chain. One of the key aspects of information systems for compliance with organic agriculture standards is simplifying the certification process. These systems enable farmers to collect, organize, and store all the necessary information and documentation required for certification. This includes data on inputs used, tracking production processes, and records of previous annual production cycles. All this information streamlines the certification process and facilitates effective communication with certification bodies. Additionally, information systems provide farmers with tools to monitor compliance with environmental and social standards [20-24].

4. IMPLEMENTATION OF SCIENTIFIC INFORMATION SYSTEMS FOR MONITORING AND MANAGING RISKS IN ORGANIC AGRICULTURE

Scientific-level information systems provide essential tools for monitoring and managing risks in the context of organic agriculture. These systems enable farmers to effectively track variables such as climate change, plant and animal diseases, as well as soil and water quality. Through this comprehensive data analysis, farmers can identify potential risks and take appropriate measures to minimize crop losses and enhance product quality. Information systems for risk monitoring and management in organic agriculture can include various components, including meteorological stations to monitor weather conditions, automated irrigation systems to reduce moisture-related risks, disease control information systems, and market analytics tools to optimize resources and reduce market risks. Integrating these information systems into a unified platform allows farmers to efficiently collect, analyze, and predict risks, enabling them to make strategic decisions to improve the sustainability and stability of organic agriculture [25, 26].

5. INFORMATION SYSTEMS ENABLING STATISTICAL DATA MANAGEMENT AND BIG DATA ANALYSIS

This process encompasses all relevant aspects of agricultural production and is based on the application of precision agriculture systems, including the use of GPS technology, field sensors, technology-equipped machinery, storage, and satellite imagery. Integrated systems for monitoring the health and movement of animals, as well as physiological parameters, are also included. This comprehensive set of data includes a significant amount of unstructured information that is crucial for making informed decisions and optimizing agricultural processes. An example of such a system is AgSquared, a software platform that is entirely based on cloud technologies. This platform enables collaboration among various stakeholders in the agro-industry, including managers, agronomists, tractor operators, and farm workers. This approach provides constant access to key information, allowing for improvements in productivity, profitability, sustainability, and efficiency at any time and in any location within the agricultural sector. [27].

6. LAND MONITORING INFORMATION SYSTEMS

Land monitoring information systems are crucial in modern agriculture. They enable precise monitoring of soil fertility and quality, helping farmers choose suitable crops and apply optimal cultivation methods. The use of digital technologies enhances the productivity and sustainability of agricultural systems while preserving the natural balance. These systems allow for precise control of nutrients in the soil, reducing the use of fertilizers. They also improve product quality and reduce the risk of diseases and drought. Digital land monitoring systems provide rapid information on soil health, aiding in crop protection. These systems also support organic agriculture and the preservation of the natural balance by measuring various soil parameters [27].

7. INFORMATION SYSTEMS FOR PLANT CONDITION MONITORING

Organic agriculture requires the monitoring and control of plant conditions to achieve healthy growth and a good yield. Information systems play a crucial role in this process. The system for monitoring and controlling soil moisture uses sensors to measure moisture and provides irrigation recommendations. Additionally, a system for monitoring soil nutrients is important for the sustainable use of nutrients. These systems monitor the content of nitrogen, phosphorus, potassium, and other elements, recommending doses of organic fertilizers. Information systems are also used for early detection of pests and diseases through sensors, including infrared cameras or pest detectors. This allows for rapid interventions without the need for pesticides. Data collected from these systems are processed and sent to farmers, enabling them to optimize processes and improve productivity in organic agriculture. Overall, information systems enable the early detection of problems in organic agriculture, thereby improving yields and product quality [28].

8. INFORMATION SYSTEMS FOR ANIMAL CONDITION MONITORING

In organic agriculture, information systems for monitoring animal conditions play a crucial role. These systems encompass various technological solutions for precise monitoring and management of animal health and movement. One of the key technologies is the RFID identification system, which uses microchips embedded in animals. These microchips enable tracking animal movement and essential health parameters such as body temperature and pulse. Such monitoring allows farmers to effectively track each animal, which is essential for reproduction and rapid response to health issues. In addition, there are systems for monitoring animal health status, which serve to prevent diseases and the spread of infections among animals. These systems use databases of diseases and data analysis tools. Furthermore, feed control systems play an important role in ensuring proper animal nutrition while adhering to organic agriculture standards. These systems monitor and manage food and additives usage. There are also systems for monitoring physiological parameters such as hormone levels, pheromones, and body temperature. These data are crucial for determining the optimal breeding times and the overall health of animals in organic agriculture. All of these information systems enable farmers to efficiently manage farms, reduce negative environmental impacts, and adhere to organic agriculture standards [29].

9. COMMUNICATION INFORMATION SYSTEMS

Organic agriculture is a certified system, well controlled by authorities, so it would a strategy for gathering and analyses of data could be of great value to reinforce the implementation of organic agriculture as a health indicator, in any country or region, where organic agriculture certification already exists. Information systems play a crucial role in improving communication among various stakeholders in organic agriculture, including farmers, consumers, and other interested parties. These systems contribute to building more reliable and transparent relationships among participants in the organic market. By using information systems, farmers are facilitated in tracking changing market demands and consumer needs, allowing for production adaptation. Additionally, information systems provide consumers with access to essential information about the origin and quality of products, which fosters greater trust in organic products. Transparency in the supply chain becomes crucial for consumers and is achieved through the use of modern information technologies. Information systems enhance communication and collaboration among all stakeholders in the organic market, ensuring better sustainability and product quality, while also promoting transparency and trust in organic agriculture [30].

10. CONCLUSION

The integration of information technology (IT) into organic agriculture brings about profound transformations and a range of key elements that shape this change. On one hand, there is the potential for significant improvement in the production of organic food and environmental preservation. On the other hand, there are certain challenges that require careful consideration. The advantages of this integration include increased productivity, reduced negative environmental impacts, the production of high-quality food, and better farm management. These factors contribute to increased profitability and long-term sustainability of organic agriculture. The challenges that accompany this change include high initial costs for implementing IT systems, the need for farmer training, regular system maintenance, and data privacy and security concerns. These challenges can be barriers, especially for smaller farms and rural areas. In essence, the integration of IT into organic agriculture has the potential to significantly enhance this branch of agriculture, but it requires careful planning and management to maximize the benefits and minimize the drawbacks. This process represents a critical point for the long-term development of organic agriculture in line with the requirements of modern society and environmental preservation.

RAISING THE VINEYARD - PRUNING AND AGRO-TECHNICAL MEASURES: A REVIEW

Vladanka Stupar[1], Academy of Applied Technical Studies Belgrade
Darko Stojićević[2], Academy of Applied Technical Studies Belgrade
Aleksandar Stevanovič[3], Academy of Applied Technical Studies Belgrade

Abstract: *The successful raising of a vineyard implies the knowledge and use of knowledge from all areas of viticultural science and technique, but also knowledge from other areas, from climatology, economics to the market. The choice of variety for establishing a vineyard depends on a large number of factors such as: climatic conditions, soil conditions, market requirements, but also the wishes of investors. Before planting a vineyard, it is necessary to carry out extensive soil preparations: soil fertility improvement, plowing the land and soil disinsection. The period of establishing a vineyard lasts at least three years. In this period special agrotechnical measures are carried out with the aim of caring for young shoots and forming the planned cultivation form. Regular pruning is the most important ampelotechnical measure that contributes to the establishment of a favorable relationship between the growth and development of individual organs of the vine, as well as between the yield and grape quality. Important agrotechnical measures for vineyard maintenance include and soil maintenance, fertilization, irrigation, protection against diseases and pests and harvest of grapes. As vineyards are raised for a longer period of exploitation, the goal of this work is to look at all the factors that affect production and, accordingly, to carefully plan each segment of vineyard raising and maintenance.*
Keywords: Viticulture, Cultivation System, Management Method

1. INTRODUCTION

Thanks to the long history and tradition, favorable agro-ecological conditions and soil characterized by good physical and chemical properties, viticulture has always been an important branch of agriculture in Serbia. According to the most recent regionalization, wine-growing Serbia is divided into 3 regions that represent geographical units and 22 regions [1]. During its development, the viticulture and wine industry went through crisis and difficult, but also glorious periods. According to the data of the Republic Institute of Statistics, of the over 100,000 ha of vineyards that Serbia had in the eighties of the 20th century, now Serbia has 20,466 ha under vines and annually produces around 30 million liters of wine. Although there is a significant decrease in the area under vineyards in comparison to the mentioned period, it is positive that new plantings are being raised with certified, clonal selection planting material and that there is a trend of increasing the number of wines with protected geographical origin. Of the total production area, grape varieties for wine production with geographical origin are grown on only 2065 ha [2]. As far as the assortment is concerned, foreign international varieties such as: Cabernet Sauvignon, Chardonnay, Sauvignon Blanc, Pinot Noir, Muscat Hamburg, Italian Riesling dominate. However, in recent years, the trend of growing international varieties is decreasing, while the growing of unique and autochthonous Serbian varieties such as: Prokupac, Tamjanika, Grašac, Seduša is increasingly important [3]. As vineyards are raised for a longer period of exploitation (economic profitability 25 years), the goal of this work is to look

[1] vstupar@atssb.edu.rs
[2] stojicevic@atssb.edu.rs
[3] astevanovic@atssb.edu.rs

at all the factors that affect production and accordingly carefully plan each segment of vineyard raising and maintenance.

2. RAISING THE VINEYARD

2.1 Environmental conditions

The successful raising of a vineyard implies knowing and using knowledge from all areas of viticulture science and technology, but also knowledge from other areas, from climatology, economics to the market [4]. Weather conditions and soil type are important factors in preparing the plot for planting. The economic importance of wine production in a certain territory is one of the most effective motives for protecting the typicality of wine [5, 6]. The vine has certain requirements in terms of climate, and a good knowledge of the climatic conditions of the locality where it is intended to be grown is necessary. Light, heat, humidity (rain, fog, dew, snow, etc.) and winds, as the main factors of climate, each in their own way affect the success of growing vines. The vine has high heat requirements. It is successfully cultivated in regions where the average annual temperature is from 9°C to 13-14°C. During the dormant period, well-ripened shoots tolerate the cold well, but the differences between varieties are very large. Each phase in the life of the grapevine takes place in certain thermal conditions, that is, when the average daily temperatures reach a certain level. Thus, in our country, the initiation of juices starts at 8-10 °C, the initiation of buds at 10-12 °C, flowering at about 18 °C, and the ripening of grapes at about 20-30 °C. Temperatures lower than 0 °C negatively affect the vine plant, depending on its age during the growing season. Active buds die already at -3 °C, shoots at -1 °C, leaves and bunches at -3 °C, winter buds at -20 °C, and old vine at -30 °C [7]. However, too high temperatures can have a negative impact on the cultivation of vines, especially in recent decades due to global warming. In the wine industry, various technological solutions are being developed to mitigate the negative effects of current global warming in order to obtain wines with a lower alcohol content [8].

The vine is a plant of the sun, but it also uses diffused light very well. Well-lit vines are healthier, grapes on them ripen faster, berries are more resistant, accumulate more sugar. The better use of light is influenced by the choice of row direction, cultivation form, pruning, green operations and other phytotechnical measures [1]. The vine is considered to be relatively drought tolerant. The amount of precipitation of 550-700 mm is generally sufficient for the normal growth of the vines. Where temperatures are higher and precipitation is lower, vineyards can be grown successfully only through the use of irrigation [1]. There are a lot of vineyards in the plains in the world, but the vine is primarily a plant of sloping terrain. Top quality wines are most often obtained from grapes from vineyards on sloping sites [4]. Exposure plays a significant role in the ripening of grapes. In the northern hemisphere, the most favorable are southern, southwestern and southeastern exposures.

Soil is one of the most important factors of wine quality. Healthy soils form the basis of sustainable viticulture, where soil characteristics directly affect the quantity and quality of wine [9]. Terroir can be defined as the interaction of all the characteristics of the ecosystem in a given place that influence the phenotype of the crop, including vines (grape varieties and rootstock), climate and soil [10]. Winegrowers in geographically defined production areas attach special importance to the preservation of soil quality, adding to thus adding value to the wine [9]. Hard and cold soils are not suitable for growing vines, because vines do poorly on them and produce grapes and wine of poor quality. For normal development and regular fruiting, the vine requires a humus content of about 3% in the root zone, a phosphorus content of 15-30 mg 100 g^{-1} of soil, potassium in the range of 20-60 mg 100 g^{-1}, and magnesium 10-20 mg 100 g^{-1} of soil [11].

The choice of variety for establishing a vineyard depends on a large number of factors such as: climatic conditions, soil conditions, market requirements, but also the wishes of investors. In addition to the selection of the grape variety, great attention should be paid to the selection of the rootstock. Considering our ecological conditions and soil characteristics, the varieties should be grafted on*Berlandieri X Riparia* [7].

2.2 Raising the vineyard

Before planting a vineyard, it is necessary to carry out extensive soil preparations. High-quality soil preparation involves more complex operations in terms of improving the mechanical and chemical properties of the soil [1]. Adequate fertilization, precisely calculated, should match the cultivated crop as much as possible. Deep plowing is done after spreading fertilizers in autumn at least three months before planting [12]. The correct arrangement of the land area is very important for the rational organization of production in viticulture. These include: determination of plots and roads, planting distance, row direction and planting schedule. The arrangement of the land area depends on: the biological requirements of the vines, the size, position and relief of the surface for the vineyard, as well as on the mechanization that will be used during the exploitation of the vineyard [7]. The distance between planting vines is determined by the biological requirements of the vines, the existing machinery and the specific cultivation form. In practice, planting with a distance of 2.7-3.0 x 0.8-1.0 m for individual or 2.7-3.0 x 1.6 m for planting coppice in pairs is most often used. It is considered that the ideal direction of the rows in the vineyard is north-south, but this direction is deviated from: if the plot is narrow and long, if the plot is on sloping ground and in regions where dominant winds blow. The length of the rows in the vineyard should be 100-120 m, maximum up to 200 m.
In our climate, vines are usually planted from autumn (end of November) to spring (mid-April). The best way of planting is planting with a water planter - hydrobur. A very effective method of raising vineyards, which is increasingly used today, is mechanical planting with the help of laser or GPS guidance. The planting depth is 35-40 cm, where the junction should be 3-4 cm above the ground. Only first-class vine grafts or scarified cuttings can be used for growing vineyards. Before planting, it is necessary to check the correctness of the grafts and use only first-class grafts. In recent times, the top parts are paraffinized, as a measure of protection against drying out. The root of the cuttings should be shortened to a length of 8-12 cm for the classic method of planting, or to 2-3 cm for planting with a hydrobur. One of the strongest shoots is cut to 1-2 visible winter buds, while all other shoots are removed. After planting, it is necessary to additionally close the holes with earth in order to reduce the drying of the moisture around the seedling.
A prerequisite for the successful formation of a breeding form is a properly placed support. When marking the planting places in the vineyard, it is necessary to mark the places for the poles. The best solution would be to place the posts before planting or immediately after planting. The stakes must be installed in the spring of the second year, usually after the beginning of the growing season. After that, the wire is placed.

3. AGRO-TECHNICAL MEASURES

3.1 Agro-technical measures in a young vineyard

The period of establishing a vineyard lasts at least three years. In this period special agrotechnical measures are carried out with the aim of caring for young shoots and forming the planned cultivation form of the sedge. The design of the cultivation form of the grapevine depends on a number of factors: agroecological, agrotechnical, organizational and technical, assortment, orientation in the production of grapes and wine, product marketability, socio-economic conditions. The designed cultivation form should ensure: the appropriate vegetative and reproductive potential of the variety, the planned yield of grapes and the planned quality of grapes [4]. In our agro-ecological conditions, the following cultivation forms are most often applied: for varieties that require short pruning - the Roajat cordunica, and for varieties that require long pruning - the Karlovci cultivation form.
In the first year, all shoots on seedlings are nurtured. It is important to strengthen the seedling as much as possible and all agrotechnical measures should be directed in that direction. These include weed control, protection against fungal diseases and water supply. In years with a normal distribution of precipitation, 1-2 waterings are needed, and in dry years even more. It is known that the above-ground and underground parts of the tree are in direct correlation. A strong increase in the number of shoots

with healthy leaves testifies to the good development of the root system [1]. In order to further encourage the development of deep veins, which are the most important for the vine, it is necessary to remove surface veins twice during the growing season, the first time in July and the second in August. Until the end of the growing season, it is necessary to do several shallow land cultivation, usually 4-6. In the following years (second, third and beyond), soil cultivation is carried out in a similar way. The use of herbicides in vineyard plantings younger than 3 years is not recommended, except for the use of some selective herbicides that are used during the growing season [4].
In the second year, the strongest shoot is selected on the stem, which is pruned to one condir with two hooks, and all other shoots are removed. During the growing season, only two shoots are nurtured, while the other shoots are repeatedly removed. Shoots are tied every 20 cm to the side of the tree so that they are as straight as possible. One of the two nurtured shoots will produce a tree. Shoot in the zone of the future tree should be removed while they are still young.
Pruning in the spring of the third year is done in such a way that one of the two nurtured shoots is removed, and the other is pruned long depending on the selected growing form. During the growing season, all green shoots are removed from the part of the shoot from which the tree is formed. The shoots that develop above the tree form a photosynthetically active green wall, and their cutting is done 30-40 cm above the last wire.
In the fourth year, the formation of the selected breeding form continues or ends. Shoots emerging from the tree are removed this year and every year thereafter. From the fourth year, the vineyard is considered to be in full fruit bearing.
During the period of formation of the growing form, the young shoots are attacked by many pests, especially owls, wireworms and green beetles. If these pests appear during this period, protection of shoots and leaves with appropriate insecticides is undertaken. Considering that the shoots grow during the entire growing season, the susceptibility of plants to diseases is very high. This particularly applies to the spread of downy mildew (*Plasmopara viticola*) and powdery mildew (*Uncinula necator*). Shoots and leaves should be protected from these diseases with appropriate fungicides during the entire growing season.
Young vine plants are particularly sensitive to low temperatures. That is why their protection is also recommended in regions where vines rarely suffer from winter frosts. In the fall of the first and second year, the basal parts of the shoots must be covered; in later years it depends on climatic conditions [4].

3.2 Agro-technical measures in full fertility

Regular pruning (pruning at maturity) is the most important ampelotechnical measure that contributes to the establishment of a favorable relationship between the growth and development of individual organs of the vine. Pruning establishes an optimal relationship between the height of the yield and the quality of the grapes and makes it possible to maintain the desired cultivation form. Full-grown pruning is done by leaving short or long root elements on the growing form of the tree in accordance with the requirements of the variety and growing form. When pruning at maturity, in order to protect against infection by tree diseases, it is preferable to make as few wounds as possible and coat the cuts with some fungicide.
Green operations in the vineyard include all measures performed on seedlings during the growing season, namely: removal of excess shoots, shortening of shoots, shortening and removal shoots of the second order, ringing of vines, thinning of inflorescences, bunches and berries and defoliation (removal of leaves).
The removal of excess herbaceous shoots is carried out at the beginning of the growing season while the shoots are still small (several cm in length). Performs several times during the growing season. During the growing season, the shoots are directed upwards and passed between the double wires. When they outgrow the last (highest) level of the wires and before they begin to bend down, it is necessary to cross them 30-40 cm above the last level of the wires, which ensures a sufficient number of leaves on the shoots. Performs 2-4 times during the growing season. Shortening and removing the

shoots of the second row prevents crowding of the trellis. During the growing season, all zappers in the cluster zone are removed, and above that zone they are shortened to 2-4 leaves [1]. Girdling or ringing is a special measure in the production of table grapes in order to obtain larger berries and earlier ripening of grapes. It is performed with special scissors by removing the bark and phloem in the form of a 2-5 mm wide ring. This measure accelerates the growth and ripening of the berries in bunches and is carried out no later than two weeks after the flowering of the vine. Thinning of inflorescences, bunches and berries belongs to special measures in the production of table grapes. For table varieties, it is recommended to remove every third inflorescence on the shoot. Defoliation implies the removal of leaves from the shoots and is applied in cold and wet years at the time of grape ripening. This ensures better ripening of the grapes and aeration of the trellises in order to reduce the risk of rot attack on the grapes.

Tillage is a necessary agrotechnical measure in the vineyard, which regulates the water-air regime, destroys weeds and pests, and introduces mineral and organic fertilizers. According to the time of execution, processing can be autumn-winter, spring and summer. Autumn-winter processing is carried out immediately after the grape harvest at a depth of 20-30 cm, while at the same time the vine trunk can be covered in areas where there is a risk of freezing. Spring processing is carried out immediately after pruning at a depth of 15-20 cm in order to preserve moisture and shred the surface layer of the soil. Summer processing is carried out during the growing season at a depth of 5-10 cm in order to fight against weeds and preserve moisture. It is carried out several times a year with a tiller, disc harrow, cultivator and other attachment machines.

Fertilization is a regular agrotechnical measure that compensates for the amount of nutrients. If ameliorative fertilization is done correctly, every year the vineyard should be fertilized with 500-700 kg ha^{-1} of mineral fertilizer (formulation example: 8:16:24, or 0:10:30) [1]. Manure is applied in cycles of 3 to 5 years with a rate of 40,000 - 50,000 kg ha^{-1}.

During the entire growing season, the vines have a great need for water, but they are greatest during the period of intense shoot growth and development of green berries, that is, from mid-June to the end of August [12]. All wine-growing regions in Serbia generally have sufficient rainfall, but in some years their distribution is irregular [11]. There are various ways of irrigation, but in practice drip irrigation is the most widely used. This method has the greatest savings in water consumption compared to other irrigation methods. The watering norm is determined based on the type of soil, the height and distribution of precipitation, the phenophase of vine development, etc. and ranges from 40-80 liters of water per 1 m^{-2} [1].

Grape harvesting is the final and very important organizational and technical part of grape production technology. As a rule, grapes are harvested when they reach full maturity, because that is when the varietal properties are most strongly expressed [4]. In addition to harvesting at full maturity, grapes can also be harvested at physiological or technological maturity, which depends on the structure of the assortment and the production purpose of the grapes (for fresh consumption, for processing into premium, quality or ordinary wines, for processing into juices and jams or for drying). The criterion for determining the ripeness of table grapes and the ripeness of wine grapes is different. In the case of table grapes, in addition to the appropriate content of sugar and acids, it must also have a beautiful external appearance and a pleasant taste and smell. Harvesting of table grapes is done on several occasions (screening harvest), considering that with table varieties, not all bunches ripen at the same time. With table varieties, the external appearance of the grapes (shape and size of the berries, color, ash and compactness of the bunch) and taste are particularly important. To determine the ripeness of wine grapes, it is important to determine the content of sugar and total acids in the grapes. Wine grapes are harvested by variety, taking into account that grapes with white and colored berries are harvested separately. Grapes are harvested once only from the main shoots and only healthy grapes that have not been damaged by gray mold (*Botrytis*).

4. CONCLUSION

Serbia has 20,466 ha under vines and annually produces around 30 million liters of wine. As far as the assortment is concerned, international high-quality varieties predominate. However, in recent years, the cultivation of unique and autochthonous Serbian varieties such as: Prokupac, Tamjanika, Grašac, Seduša has become increasingly important. The choice of variety for establishing a vineyard depends on a large number of factors such as: climatic conditions, soil conditions, market requirements, but also the wishes of investors. The period of establishing a vineyard lasts at least three years. In this period, special agrotechnical measures are carried out with the aim of caring for young shoots and forming the projected growing form of the sedge. Regular agrotechnical measures in the full yield of the vineyard include: pruning, soil maintenance, irrigation, fertilization, protection against diseases and pests, and grape harvesting. As vineyards are raised for a longer period of exploitation, it is necessary to carefully look at all the factors that affect production and, accordingly, carefully plan each segment of vineyard raising and maintenance.

CROP MODELLING: A NEW TOOLS FOR CROP PRODUCTION

Markola Saulić[1], The Academy of Applied Technical Studies Belgrade
Darko Stojićević[2], The Academy of Applied Technical Studies Belgrade

Abstract: *In an era of intense need for high yields, quality and safe food, the application of models in agricultural production can serve for successful and precise simulations and forecasts of crop yields. Crop models and decision tools are increasingly used to improve production efficiency and contributes to understanding of the real world because it helps to integrate the relevant processes of the studied system and to bridge areas and levels of knowledge. The combination of advanced technology and agriculture to improve the production of crop yield is becoming more interesting recently. For the implementation of such models for simulation crop production, it is necessary to define of problem, have correct and long-term data and create design and assesment of model.*
Keywords: Modelling, Agriculture, Crop production, Crop yield prediction

1. INTRODUCTION

In the past, farmers could estimate the weather and determine when the planting, agrotechnical measures and harvesting seasons in the field would begin using conventional methods and were relied on their long-terms experiences. Today, it is complicated to predict the weather using such a method because of global warming, which makes it difficult for farmers to predict the weather. For that reasons, in recent years, an era of intense need for high yields, quality and safe food, models have been increasingly used in plant production.
The models enable society to tackle a wide range of challenges: soil and water conservation, greenhouse effect mitigation, carbon conservation, sustainable agriculture and safe food and can serve for successful and precise simulations and forecasts of crop yields. Results of research suggest that it is a matter of urgency to model crop rotations in order to evaluate the resilience of cropping systems and their contribution to ecosystem services under changing climate conditions [1]. Modeling arose from the human need to understand the way systems function and determine their dynamic responses. It is a process of abstraction of a real system, which is obtained on the basis of a person's overall experience and way of thinking about the system he is considering [2]. Simulation models integrate knowledge from different disciplines and provide researchers with capabilities for conducting computer experiments to supplement actual experiments [3]. We reviewed the literature to understand the development of the model as a modern tool for accurate simulations and forecasting of crop yields.

2. DATA SET FOR CROP MODELING

Crop models and decision tools are increasingly used in agricultural field to improve production efficiency. The combination of advance technology (GIS, GPS, IoT, drones) and agriculture to improve the production of crop yield is becoming more interesting recently. Due to the rapid development of new higher technology, crop models and predictive tools are expected to become a key element of smart agriculture [4]. First, the farmer will mark the location of their agriculture area

[1]msaulic@atssb.edu.rs
[2]dstojicevic@atssb.edu.rs

in polygons shape. Then the remote sensing device will take periodic land pictures and save it as time-series data. The monitoring process uses sensors to find out real-time of the condition of the agricultural area. The collected data will be stored in a database and it will be processed and used as input in decision making od model and its assessment (Figure 1) [5]. Setting the aims of a model generally takes much time, especial in long-term and multidisciplinary researches and was estimated to occupy 5% to 50% of the total time spent in large-scale predictive modelling efforts [6].

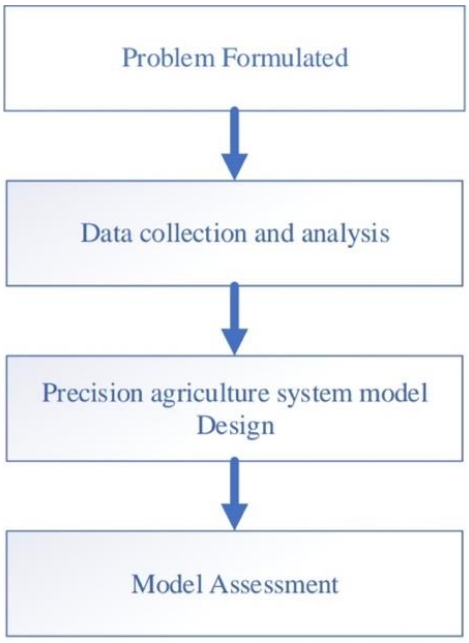

Figure 1. Research metodolgy
Source: [5]

Until today, a lot of approaches and modelling techniques have been in existence and the most crop models which were based as an linear relationship between variables and crop production. linear method such as linear regression is insufficient to show the interactions of the factors and crop yield. Although the collection of multi-year series of data and their unification into a single database is much more complex than with one-year trials, it is recommended to take into account long-term data as many factors as possible [7]. For the implementation of such models, it is necessary to have correct and continuous data, and when processing the results, it must be assessed whether the data of all years can be included in a unic combined analysis or it they need to be transformed, adjusted and divided into more or less homogeneous groups [8]. Today, it considered that Neural networks have replaced and removed the shortcomings of linear regression and become a new technology which provides assorted solutions for the complex problems in agriculture researches [9].

3. VALIDATION AND CALIBRATION OF MODEL

Back in 1977 Penning de Vries described the terms „*Evaluation*“, „*Validation*“ and „Verification“ „Evaluation“ Is the broadest term to describe the action of judging the value of a model and may be used for comparison of model output with real world data and for judgement of practical utility. „Validation“ is used as evaluation with emphasis on usefulness and relevance of the model, whilst „verification“ is used for evaluation with emphasis on truthfulness [6]. Model calibration is the process of adjusting influential model parameters and inputs within their reasonable ranges. The aim of calibration is that the model results are realistic with available observed data. During model validation, the accuracy of the model predictions is evalu- ated by comparison to additional and independent observed data. For some model support, a quality control program has been developed to reads model out-put and compares it with observed data to perform simple checks and it will sucesful used as a tool to start before they conduct calibration and validation [11].

4. ADVANSES IN CROP MODELIG

The first complex model to simulate the effects of soil erosion on soil productivity was *The Environmental Policy Integrated Climate (EPIC) model* developed in the early 1980s [12]. EPIC model was used to evaluate soil erosion impacts, and over time, modified to address numerous other environmental problems [11]. Later, the Agricultural Policy Environmental eXtender (APEX) model was developed an results of extensive biophysical/environmental/hydrological model and has a GIS (geographic information system) interface tool [13]. Similar to EPIC, APEX is a flexible and dynamic tool that can be used to estimate the impacts of land management, conservation practices, or climate on a wide range of environmental indicators; soil carbon sequestration; pesticide aplication; nutrient cycling and other APEX enhancements include a groundwater (shallow aquifer) submodel, spatial rainfall generator, landscape representation of conservation or best management practices, feedlot manure management, and simulation of different grazing density and manure deposition scenarios [14]. Models are updated daily and formating dana changed, but the approach is still the same. The DSSAT crop modeling can help to understand the interaction between genotype, environment and management, providing opportunities for data analytics for strategic and actionable decisions. The DSSAT are used to provide ultimate portability and as a result, a user can easily simulate crop growth, development, and yield for different crops for the same field while making only minor changes to the input files that are crop specific, such as variety selection, planting date, or plant density (Figure 2) [15].

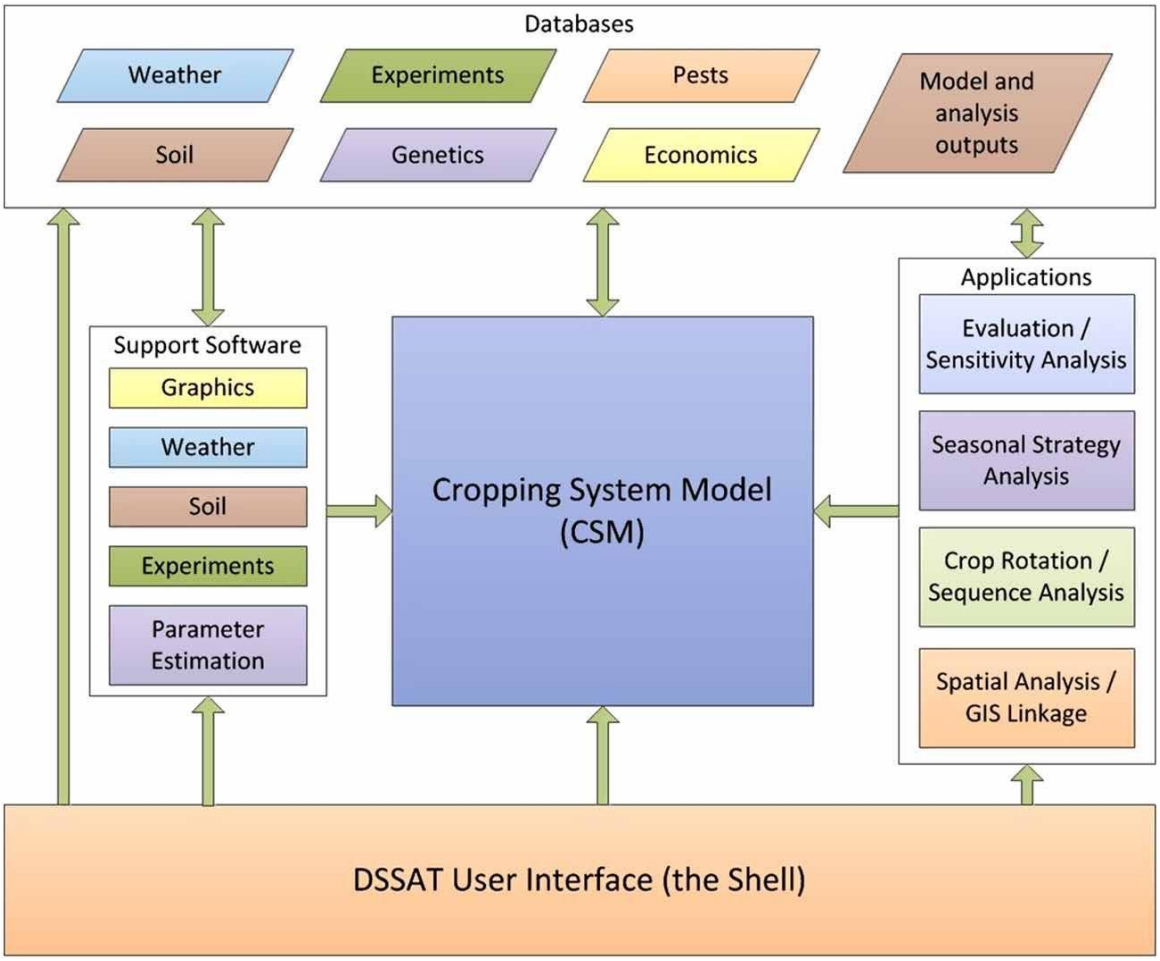

Figure 2. The DSSAT crop modeling ecosystem.
Source: [15]

The aim of the modelinig is to determine the crop yield a by considering dataset with some features which are important or related to crop production such as temperature, moisture, rainfall, humidity etc., and land factors like soil pH, soil type and production of the crop in previous years [16].

5. CONCLUSSION

The current agricultural production system is challenged with weather and climate extremes and variability and economic risks. There is pressure to grow more and healthy food. Development of models seems to have peaked in the last few years models has evolved and are now used by researchers world-wide and have become a successful tool for precise simulations and forecasts of crop yields. A major drawback is that most research still includes only a few of the many factors that affect crop yields in farmers fields but such kind of models cannot simulate real and relevant yields. To implement the model, it is necessary to have correct and continuous data and design and evaluation of the model, craate Model design and knowledge of adequate validation and calibration of the model.

BASIC CONCEPTS OF ANN MODEL AND ITS APPLICATION IN AGRICULTURAL RESEARCH

Darko Stojićević[1], The Academy of Applied Technical Studies Belgrade
Markola Saulić[2], The Academy of Applied Technical Studies Belgrade

Abstract: *Modelling in the era of intensive agricultural production has become of crucial importance because in this way the occurrence of a factor or problem is simulated and thus enables timely reaction and problem solving. It is necessary to know and choose the right model, to know its advantages and disadvantages, to constantly improve and innovate it. One of the generally accepted models in agricultural research is Artificial Neural Network (ANN) i.e. Model of neural networks. In a real sense, ANN are one of the best solutions in s dynamic population of weed species in arable soil. Today, it considered that Neural networks have replaced and removed the shortcomings of linear regression and become a new technology which provides assorted solutions for the complex problems in agriculture researches. ANN have replaced recent methods and techniques in many applications, are often used in combination with other methods, and are often the only tool to solve tasks and search for solutions.*
Keywords: Artificial Neural Network (ANN), agriculture research, modeling

1. INTRODUCTION

Even 50 years ago it was concluded that many models are scientifically interesting, others are utilised to predict and their results are applied in other fields, and some models are largely used for instructive purposes. But all models have some value in each of these fields and contributes to understanding of the real world [1]. The agricultural system is extremely complex because it handles situations involving massive amounts of data that are caused by various sources. A lot of techniques and approaches have been used to identify any interactions between factors that that affecting yields with the crop performances [2]. Agricultural research takes into account a wide range of variables, such as crop and cultivar, temperature, rainfall, and light intensity, as well as postharvest handling and storage, fertilizer applications, and cultural techniques, land factors like soil pH, soil type and production of the crop in previous years [2,3]. But, collecting multi-year series of data and combining them into a single database is much more complex than with one-year trials [4]., it is recommended to take into account long-term data as many factors as possible [5]. One of the generally accepted models which can support a long-term data series is Artificial Neural Network (ANN). The paper presented the basic concepts of Artificial neural networks, and the aim was to review research and achievements in the application of ANN models.

2. ARTIFICIAL NEURAL NETWORK

Although Artificial neural networks have been around for quite some time: for the first time introduced in 1943 by neurophysiologist Warren McCulloch and mathematician Walter Pitts. The early successes of artificial neural networks led to the widespread belief that we would soon be talking to truly intelligent machines. In the early 1950s, the greatest influence on the development of neural

[1]dstojicevic@atssb.edu.rs
[2]msaulic@atssb.edu.rs

networks was the work of Marvin Minsky, who constructed the Snark neurocomputer (1951). However, this computer did not achieve significant results, and computer Mark is considered the first real neurocomputer by Frank Rosenblatt and Charles Whiteman. In the 1960s, it became clear that it would not be easy, financial support was diverted for development and diverted to other parties. In the early 1980s, new architectures were found and better training techniques were developed, which reawakened occupation connectionism - study of neural networks [6].
ANN are biologically inspired computer programs designed to simulate the way in which the human brain processes information. They are digital representations of human brains, and just like people, ANNs learn (or are trained) by experience with suitable learning exemplars, not by programming. In order to learn, neural networks look for patterns and connections in the data. An average brain contains 100 billion neurons, each of which has 1000–10 000 connections with other neurons. On the other hand, Artificial neural networks rarely have more than a few hundred or a few thousand PE (artificial neurons or processing elements), so in complexity are thus still far beyond the creative capacity of the human brain (Figure 1.) [7].

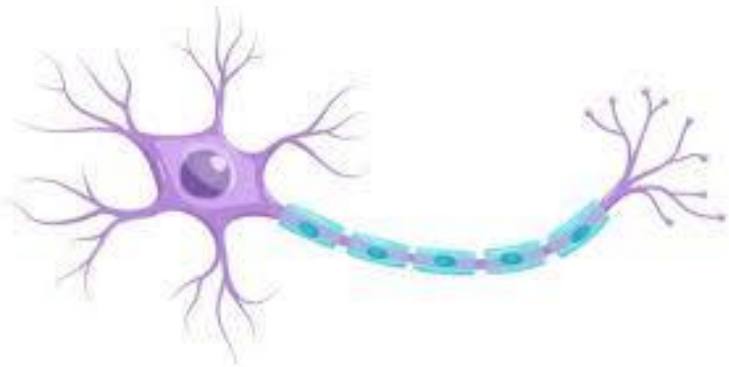

Figure 1. Neuron cell
Source: https://biologydictionary.net/cell-body/ [8]

3. ARCHITECTURE OF ARTIFICIAL NEURAL NETWORK

ANNs model have replaced recent methods and techniques in many applications, are often used in combination with other methods, and are often the only tool to solve tasks and search for solutions. For the application of the model in practice, a large database (at least from 2-10 years) is necessary in order to perform a relevant simulation for a given problem, i.e. to obtain reliable answers to questions within a certain problem in agricultural production [9]. It has the ability to help solve difficulties based on a large series of long-term data, striving for long-term solutions. ANN is suitable for data series where simplification is unacceptable, which often happens in long-term research [10]. The second important use case of ANNs in wireless networksis data analytics.To implement such models, it is necessary to have correct and continuous data, and when processing the results, it must be assessed whether all data can be included in a single combined analysis or it need to be transformed, adjusted and divided into more or less homogeneous groups. Becouse that, experiments of this type are classified as long-term ecological research (Long Term Ecological Research - LTER) [11]. Artificial neural networks consist of a large number of neurons. which are grouped into layers through which the network is connected to the environment. The first layer is input in which data is presented to the network, and each data input corresponds to an input variable. In the output layer, network outputs are calculated. Between the first and last layer are hidden layers (Figure 2.) For the successful application of ANN, it is necessary to collect as much data as possible. The type of data depends on the task that the network will perform. Data preparation includes normalization and scaling to avoid the negative effect of dominant values. The first step in building ANN is planning, then designing, training, testing and exploiting [12, 13].

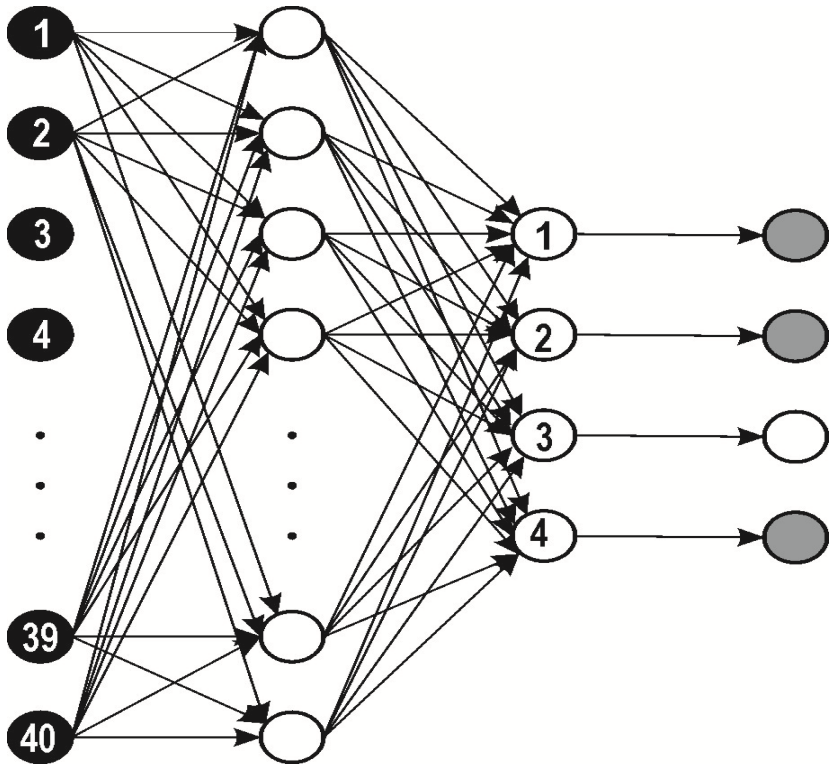

Figure 2. Architecture of artificial neural network
Source: [13]

4. APPLICATION OF THE ANN MODEL

Artificial neural networks has a general application in many evaluation areas: cost estimation, robotics, fault diagnosis, process management, quality control, etc. Presently, ANN has become a well-liked method to most authors because of its ability of prediction, forecasting and classification in biological science fields and medicine. Since there are a lot of factors which influence crop production, the use of ANN in predicting crop yield is very ussual. ANN is often used to predicted Soil and Soil-Plant Hydrology, in sensing technologies, biomass Factor, controlled environment [2]. ANN model performed extremely well in agriculture research for predicting dynamic population of weed species in arable soil [14]. Based on the ANN model and long-term data analyzis crop management, it was concluded that the greatest effect on the size of the total weed seed bank in soil with a share of 64.17% was the interaction of crop rotation + fertilization, followed by the triple interaction crop rotation+fertilization+sampling depth with a share of 30.52% and with the smallest share of only 5% interaction crop rotation+sampling depth [15]. Thus, the model clearly shows that the soil weed seed bank depend on several factors, that is, their interaction, namely the cropping rotation, fertilizer, depth of soil sampling and slightly less than the sampling time [16]. Also, with ANN model, it is possible to predict the yield, because it is determined by weather conditions, pest control and harvest plans. Today, the yield can be predicted with an accuracy of 86% [17]. by sensing various parameter of soil and also parameter related to atmosphere: type of soil, PH, nitrogen, phosphate, potassium, organic carbon, calcium, magnesium, sulphur, manganese, copper, iron, depth, temperature, rainfall, humidity [18].
Research of Alizamir and Sobhanardakani (2017) presents a new method for predicting heavy metal concentrations (As, Cu, Pb, and Zn) in the groundwater resources based on ANN and ICA (Imperialist competitive algorithm) [19]. This research is also agreed by the authors who believe that heavy metal concentrations in the environment can be more reliably predicted using strong statistical algorithms based on a set of physical and chemical characteristics, and ANNs are one of the successful computer modeling methods in modeling and predicting environmental characteristics [20, 21]. (Figure 3).

Source: [21]

5. CONCLUSSION

Modeling is of crucial importance for designing and evaluating integrated agriculture, and for this it is necessary to choose the most adequate model. The combination of artificial intelligent and agriculture is and will become a more interesting area of research in the near future. A conclusion has been made that ANN has better explained yield variability rather than other methods. Undeniably, the application of ANN to precision agriculture plays a crucial role in future evaluation of the concept of precision agriculture as a sustainable means of meeting world's food demands. However, further research about the ANN impacts towards crop yield production must be conducted to ensure sustainability of future food needs. More researches towards dynamic modelling of precision farming in agriculture using neural networks are needed in the future.

APPLICATIONS OF MOLECULAR MARKERS IN ANIMAL GENETICS AND BREEDING: A REVIEW

Milica Blažić[1], The Academy of Applied Technical Studies Belgrade

Abstract: *Molecular markers play an important role in genetics and animal breeding because they enable the maximization of the selection process for those traits that are not easily observable, have low heritability or cannot be quantified. The application of methods based on DNA polymorphism in animal breeding has multiple advantages over the previous, conventional methods, bearing in mind the specificity, accuracy and simple possibility of application. The most commonly used types of molecular markers in genetics and animal breeding are: RFLP (Restriction fragment length polymorphism), RAPD (Randomly amplified polymorphic DNA), AFLP (Amplified fragment length polymorphism), SNP (Single nucleotide polymorphism) markers and microsatellites. They have found application in the genetic diversity conservation, parentage testing, sex determination, identification of disease carriers, the process of transgenesis, as well as Marker-Assisted Selection - MAS. This paper provides a brief review of the aforementioned molecular markers, their advantages and disadvantages, as well as their applications in genetics and animal breeding.*
Keywords: Farm animals, DNA polymorphism, Selection, MAS

1. INTRODUCTION

The main goal of a breeders is to select an animal with superior genetic potential to be the parent of the next generation. Traditional breeding methods are based on selecting animals based on their phenotype. The external characteristics of animals on the basis of which selection is made are called morphological or phenotypic markers, such as body shape, coat color, udder shape, skin structure or anatomical characteristics. The oldest are markers in breeding and they are used in practice whenever possible. However, very often they can lead to a bad assessment when it comes to the genetics of domestic animals because they are based on the subjective judgment of the breeder [1]. Also, most morphological markers are limited by gender, age-dependent and significantly influenced by the external environment [2]. With the development of methods of analytical biochemistry and molecular biology, newer markers have been developed - molecular markers. They made it possible to obtain indicators of the specificity of the organism at the molecular level, that is, at the level of protein and nucleic acid molecules. They are divided into: genetic and biochemical markers. Genetic markers (GM) are any genetic characteristic of an organism that helps to identify it [3]. In a narrower sense, they are genes or sequences of DNA molecules with a known location on a chromosome that are associated with a specific gene or trait. GM can be a short DNA sequence that includes changes in a small number of nucleotides, such as Single Nucleotide Polymorphism - SNP, or a long one, such as mini and microsatellites [1]. Biochemical markers are compounds such as proteins (isozymes), hormones, antibodies. However, their application is limited because they show a low degree of polymorphism and are not genetic material, but are products of gene expression, so they are significantly influenced by environmental factors. Genetic markers are based on nucleotide sequence mutations within an individual's genome and are the most reliable markers available. They are not affected by environmental factors and generally do not have pleiotropic effects on Quantitative Trait Loci – QTL [2]. Genetic markers

[1]mblazic@atssb.edu.rs

have been increasingly used in genetics and animal breeding studies in recent years. Thus, the term Smart Breeding is used to describe breeding strategies supported by molecular markers. The development of molecular markers has enabled selection according to genotype, not phenotype, which makes them a powerful tool in animal breeding. Genetic markers can be used to measure the genetic response to selection in the breeding of farm animals. Genetic response to selection is a change in allele frequency at a specific place in the genome as a result of selection for a given quantitative trait. The improvement of the genetic characteristics of farm animals is traditionally done by artificial insemination. Animals with changes that better suited production conditions were selected for further breeding. This process led to changes in the allele frequencies of the genes that were observed. Recently, molecular markers are used in the mapping of QTLs on commercial animal farms, the main goal of which is to improve the efficiency of artificial selection in the so-called Marker-Assisted Selection - MAS, i.e. selection with the help of markers. The efficiency of artificial selection in animal husbandry would be greatly improved with the use of MAS and subsequent mating of selected lines. In order to achieve this, it is necessary to initially analyze the genotypes at hundreds of marked places, as well as monitor the phenotypic characteristics of hundreds and even thousands of individuals, with the fact that the number of analyzed markers would be significantly reduced in the next generation. With the availability of a dense map of markers and the appropriate cost of genotyping, genetic selection methods based on molecular markers can provide faster gains than would be expected using selection methods based on phenotype and pedigree [4]. The paper provides a brief review of some of the most commonly used molecular markers as well as some aspects of their application in animal genetics and breeding.

2. CLASSIFICATION OF MOLECULAR MARKERS

Molecular markers used to identify DNA polymorphisms in animal breeding are classified into three main groups based on the method used for their identification: 1) Molecular markers based on the hybridization method; the most commonly used type of this group of markers is Restriction Fragment Length Polymorphism (RFLP); 2) DNA markers based on Polymerase Chain Reaction – PCR, include: Random Amplified Length Polymorphic (RAPD) markers, Simple Sequence Repeats (SSR) markers or microsatellites and Amplified Fragment Length Polymorphisms (AFLP) markers; 3) DNA markers based on DNA chip and sequencing such as Single Nucleotide Polymorphism (SNP) marker [5]. Below is a brief description and application of the mentioned molecular markers.

- **Restriction Fragment Length Polymorphism - RFLP**: Differences in the size of DNA fragments that resulted from the degradation of DNA molecules by restriction enzymes are designated as restriction fragment length polymorphism (RFLP). These were the first molecular markers used in the construction of genetic maps. There may be many RFLP loci in two genotypes, cultivars or breeds. RFLP occurs both due to the occurrence of point mutations within the recognition sequences for restriction enzymes, usually by single nucleotide substitutions that remove the restriction site, and when duplication, insertion or deletion of a sequence occurs in the region between two restriction sites. Also, they can arise due to inversions, translocations and transpositions in the areas of restriction sites [3]. They are used to determine gene mutations as well as to find the place of the gene on the chromosome that is responsible for the occurrence of a certain disease [6]. RFLP markers were the first molecular markers used for genetic typing, better known as genetic fingerprinting profiling or testing [1]. Most RFLP markers are co-dominant (both alleles in heterozygous samples are detectable) and highly locus-specific. Also, their advantage is that they are highly reproducible, and the same combination of probe and enzyme applied to the same samples gives identical results in different laboratories. The disadvantages of this method are: the need for a large amount of isolated and pure DNA, it is time-consuming and technically demanding [3].
- **Randomly Amplified Polymorphic DNA - RAPD**: The PCR-based RAPD technique has been one of the most widely used techniques for DNA marker development in the last decade. The principle of the RAPD technique implies that one short (about 10 nucleotides in length),

oligonucleotide primer that binds to many different loci on the DNA molecule, is used to amplify random sequences from a complex DNA template [3]. This means that the amplified fragment of the DNA molecule obtained by PCR depends on the length and size of both the primer and the target genome. The main advantage of the RAPD technique is that it does not require prior sequencing of DNA molecules and provides a quick and efficient survey of DNA sequence polymorphisms at a very large number of loci [1]. The RAPD technique was used to assess genetic differences within or between taxa of interest by assessing the presence or absence of each DNA sequence modification product at each locus. However, the main disadvantage of RAPD technique is that RAPD primers are very sensitive to PCR conditions which can lead to poor reproducibility compared to other methods [5].

- Amplified Fragment Length Polymorphism - AFLP: AFLP technique is based on selective amplification of restriction DNA fragments (80-500 base pairs) obtained after degradation of genomic DNA by restriction endonucleases. The technique was originally known as Selective Restriction Fragment Amplification - SRFA [3]. AFLP markers have found the most widespread use in analyzes of genetic variability below the species level. This technique is used for identification of genetic polymorphisms, assessment and characterization of animal genetic resources, measurement of relatedness among different breeds as well as for construction of genetic maps and identification of genes of major species of farm animals [5,1]. The AFLP technique has wide taxonomic variability and can be used to examine any organism without prior knowledge of the organism's genomic makeup. The importance of the AFLP technique is also reflected in the fact that no prior information about the sequence is needed in order to construct the primers. However, the technique is expensive, technically demanding and requires a large amount of DNA molecules per reaction [2].

- Microsatellites: They represent a type of repetitive DNA, i.e. series of repeatable sequences arranged in tandems. They consist of a piece of DNA with a length of 1 to 6 base pairs that has been repeated several times in tandem. Microsatellites are also known as SSR (Simple Sequence Repeats) or STR (Short Tandem Repeats) markers, as they are the most commonly used. SSR/STR locus polymorphism is caused by variations in the number of tandem repeats [3]. They are classified as mono, di, tri, tetra, penta and hexa-nucleotide repeats, with di, tri and tetra-nucleotides being the most common choices in various molecular genetics studies. They are repeated (usually 5-20 times) in the genome with a minimum repeat length of 12 base-pairs. [1]. Due to their high abundance in the genome, extremely high degree of polymorphism and easy detection, they are very useful for various purposes: identification of animals, evaluation of animal genetic resources, determination of parentage, research of diseases, determination of genetic variability within and between races, determination of substructure of populations, reconstruction of phylogenetic relationships between populations as well as in studies on the process of domestication of animals and the migration of races. Also, they are used for mapping QTLs for production and functional traits of farm animals as well as in MAS [2]. The main disadvantages of this technique are that it is very expensive, complicated and time-consuming. Also, heterozygotes can be misclassified as homozygotes when null-alleles occur as a result of a mutation in the primer annealing sites [5].

- Single-Nucleotide Polymorphism – SNP: These are third-generation markers that were developed after RFLP and SSR techniques [7]. These are polymorphisms caused by point mutations, i.e. mutation of one nucleotide at a specific locus in the DNA sequence. These polymorphisms occur due to substitutions of individual nucleotides in the genome (transitions or transversions) or due to their insertions or deletions. Transitions are the most common (about 2/3) among all types of SNP mutations [1,3]. These are bi-allelic markers that indicate a specific polymorphism in only two alleles of the population. The majority of SNPs, generally two out of three, involve the substitution of cytosine (C) with thymine (T). Many SNP mutations do not affect the functioning of the cell, but are believed to predispose an organism to the development of a certain disease and affect how it will react to a certain drug [2]. They are used to assess genetic variability between different species and breeds of animals, as well as in genetic disease studies for different livestock species. The role of SNPs in farm animals has been very important in the study

of population structure, genetic differentiation, origin and evolution. The most important disadvantage of these markers is the low level of information obtained compared to highly polymorphic microsatellites, but this can be compensated for by using a larger number of markers [1,2].

3. APPLICATIONS OF MOLECULAR MARKERS IN ANIMAL GENETICS AND BREEDING

1) Genetic diversity conservation – The conservation of genetic diversity is important because it encourages a high level of heterozygosity in the population. Also, in order for animal populations to be able to face future changes in the environment, the existence of genetic variability is necessary. The existence of genetic diversity is necessary to ensure a long-term response to natural or artificial selection, for traits of economic or cultural importance. The primary goal of studying genetic diversity is to understand the degree of differentiation of populations within species. Population-specific genetic markers (alleles) can be generated using a number of methods for the detection of polymorphic loci. Genetic characterization of populations, races and species enables the assessment of genetic variability [8]. According to Gwakis [9] the most commonly used molecular markers for studying genetic variability at the DNA level molecules are RFLP, RAPD, AFLP, micro and minisatellites.

2) Determination of parentage: Molecular markers are used as a useful tool for determining genetic relatedness between individuals and testing parentage in segregated populations [5,8]. The concept is based on the principle of exclusion. The presence of a genetic locus on the alleles in the offspring that is not found in either of the putative parents effectively rules out a particular parental pair as the offspring's biological parents. Parentage testing using molecular markers gives a much higher probability of exclusion (> 90%), than testing with blood groups (70-90%) or some other biochemical markers (40-60%) [2]. Highly polymorphic DNA finger printing markers have been shown to be very useful for this purpose [8].

3) Sex determination of offspring: Molecular markers can be used to determine the sex of pre-implantation embryos. DNA sequences specific to the Y chromosome, such as the SRY, ZFY and TSPY genes, are used as probes. The TSPY gene was shown to be a very good male-specific marker due to the existence of a large number of gene copies [5]. Also, using PCR-based sexing methods has the advantage of being performed in less than five hours with almost 100% accuracy. They are less invasive than cytogenetic methods and can be applied in the early stages of embryo development [8].

4) Identification of disease carrier: Infectious diseases are responsible for large economic losses in animal husbandry. Most serious incurable diseases are not the result of infection by organisms that cause infectious diseases, but rather of defective genomes of certain individual animals. Certain allelic changes in the host's genome lead to its greater susceptibility or resistance to a particular disease [10]. Thus, Kingsbury [11] reported that a specific RFPL marker in the prion protein gene is responsible for variation in host response to bovine spongio-form encephalopathy (BSE) and its incubation time. DNA polymorphism that occurs within genes helps to understand the molecular mechanism and genetic control of several genetic and metabolic disorders and enables the identification of heterozygous individuals who are carriers of diseases/disorders, i.e. defective recessive alleles, but do not differ phenotypically from normal individuals. For this purpose, PCR-RFLP assay as well as microsatellite markers were used [8].

5) Transgenesis: This is a procedure in which a part, one or more genes of one organism is incorporated into the genome of another organism. According to research by Mitra et al. [10] the starting point in this process is the identification of genes of interest. For this purpose, molecular markers can serve as reference points for mapping relevant genes, which would be the first step towards their manipulation. Also, they can be used to identify animals carrying transgenes in order to reproduce them.

6) Marker-Assisted Selection (MAS): It represents the identification and use of molecular markers that are linked to genes that control traits of interest. MAS is a form of indirect selection and the most widely used molecular marker. It is irreplaceable when, in traditional breeding methods, there is no possibility of selection for important traits that are not observable or cannot be quantified. In order to get from markers to MAS, the following is needed: high-density DNA marker maps, which means many markers whose location is known, and which are spread over relatively short intervals in the genome; then, defining genes that are assumed to determine traits of interest, and testing statistical relationships between markers and traits of interest. When the defined marker is located next to, or even in the gene of interest, the next step is possible, i.e. MAS desirable traits. Desirable traits can be controlled by a single gene, such as major genes, or they are complex quantitative traits, controlled by a larger number of minor genes (QTL) and significantly influenced by environmental factors. Much of the research program is focused on the construction of maps for molecular markers and the discovery of QTLs that are required for the potential application of MAS. High linkage disequilibrium, a large population a large number of markers per chromosome, genomes containing a large number of chromosomes high heterozygote frequencies at the relevant genes and markers that are located close to quantitative trait loci (QTLs) with large effects are expected have higher response to MAS [5]. MAS can be used to detect genes responsible for certain genetic disorders, disease resistance and product quality. The use of MAS improves the longevity of animals, feather pecking, resistance to stress as well as the desired characteristic behavior [12].

4. CONCLUSION

Advances in the field of molecular biology and molecular technologies have enabled the discovery of a large number of genetic polymorphisms at the DNA sequence level, which are used as molecular markers to determine the genetic basis for the observed phenotypic variability, with the aim of improving animal breeding programs. The application of molecular markers in animal breeding programs has many advantages over conventional mehods in terms of their accuracy and specificity. They have found a wide range of applications in animal genetics: estimation of genetic distance, determination of twin zygosity and freemartinism, gene mapping, parentage testing, sex determination of pre-implantation embryos, identification of disease carriers, transgenesis and others. Overall, the improvement of farm animal species is largely achieved by the application of molecular markers. The choice of markers for different applications depends on certain factors: the degree of polymorphism, the possibility of automation of the method, the radioisotopes used, the reproducibility and the cost of the technique. Although a large number a different markers are used for different applications, it is considered that SSR markers (microsatellites) are the most common choice among available markers for various genetic studies, due to multiple alleles, cost-effectiveness and transferability.

PRECISION AGRICULTURE TECHNOLOGIES AND METHODOLOGIES USED TO CROP YIELD PREDICTION – A REVIEW

Milica Blažić[1], The Academy of Applied Technical Studies Belgrade
Markola Saulić[2], The Academy of Applied Technical Studies Belgrade
Vladanka Stupar[3], The Academy of Applied Technical Studies Belgrade

Abstract: *Pre-harvest forecasting of crop yields is essential for planning and making various decisions about the timing of harvest, processing, storage, transportation and marketing of agricultural products. Early forecasting of crop yields plays an important role in reducing hunger worldwide by assessing the availability of food for a growing world population. Traditional methods of crop yield estimation are a time-consuming, subjective and expensive process. Remote sensing as a basic element of the concept of precision agriculture provides accurate agricultural statistics one month before harvest along with the spatial distribution of different crops. Remote sensing data provide important spatio-temporal and meteorological information as well as information on the status of crops at different stages of growth. Therefore, this paper provides a brief review of basic remote sensing tools and technologies, as well as how remote sensing data can be used to crop yields prediction.*
Keywords: Remote sensing, Sensors, Vegetation indices

1. INTRODUCTION

Achieving maximum crop yield with minimum investment is the ultimate goal of farmers in their search for economically efficient agricultural production. Early detection of problems related to crop yield can go a long way in reducing loss and achieving target yield and profit. Monitoring crop growth and yield in agricultural fields is an essential procedure for food security and predicting economic returns. Some studies [1] have shown that traditional crop yield estimation methods can lead to poor estimation. In addition, these methods depend on rigorous data collection in the field, which is an expensive and time-consuming process. In the era of digital technologies, traditional agricultural management methods have been supplemented by new sensor and drive technologies and improved information and communication technologies. Based on the concept of "produce more with less", precision agriculture, also known as smart agriculture, has been used for more than 25 years to optimize the use of agricultural inputs, such as fertilizers and herbicides, thereby maximizing profits, while reducing negative environmental impacts by regulating spatial variability [2]. Crop yield prediction using precision agriculture methods can help to model the spatial distribution of site-specific yields and to investigate the factors affecting yield under different seasonal influences [3]. According to the definition of ISPA - International Society for Precision Agriculture, precision agriculture is a management strategy that collects, processes and analyzes temporal, spatial and individual data and combines them with other information, in order to support management decisions according to the estimated variability, and with the aim of better efficiency in the

use of resources as increasing productivity, quality, profitability and sustainability of agricultural production [4]. Detection is the basic element of the concept of precision agriculture. Remote sensing is described as a set of techniques that use space to monitor Earth's resources ranging from high altitudes such as satellite technologies to low altitudes such as observation from the ground for greater precision and accuracy [5]. The spectrum of electromagnetic waves (visible and infrared light, RADAR and microwaves) is used as the basis for remote sensing in order to assess its interaction with the features of the Earth [6]. Remote sensing uses a range of devices such as different types of sensors, drones, aircraft and unmanned aerial vehicles as well as cameras mounted on satellites in orbit. Sensors in fields and crops provide detailed data on soil characteristics, climate, fertilizer needs, water availability and pest infestation. Also, aerial footage captured by drones or unmanned aerial vehicles (UAVs) that can patrol fields can alert farmers to crop maturing or potential problems, as well as deviations from expected growth rates or quality. Satellites used for the purpose of precision agriculture facilitate the detection of relevant changes on the ground using satellite images [7]. This paper provides a brief review of basic precision agriculture technologies and methodologies that can be used to crop yields prediction.

2. REMOTE SENSING IN CROP YIELD PREDICTION

Remote Sensing (RS) has become one of the most important technologies in agriculture that contributes to the improvement of management practices because it provides data on the status of crops at different stages of growth. Remote sensing technology involves the collection and analysis of crop data using an instrument placed in the atmosphere or a satellite, without any physical contact [8]. It is the process of monitoring and recognizing places on Earth by measuring emitted and reflected radiation with the help of sensors [9]. Remote sensing data has several applications in agriculture, one of which is crop yield prediction.

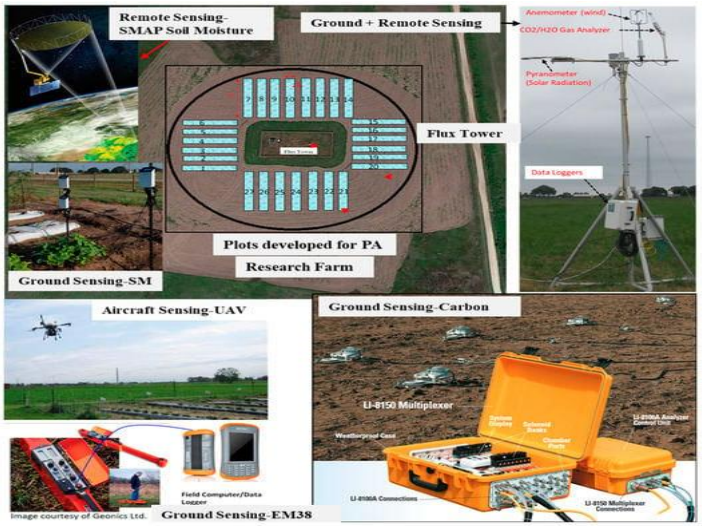

Figure 1. A typical layout for the remote, aircraft, and ground sensing systems deployed for prediction crop yield in precision agriculture. Remote sensing systems used for this purpose can be classified based on sensor platform or sensor type. Sensors are usually placed on satellites, antennas or on platforms on the ground (Figure 1). Also, more recently, antenna platforms are being used that include aircraft as well as unmanned aerial vehicles.

Ground platforms can be grouped into three categories: hand-held, field-mounted and those mounted on tractors or other agricultural machinery. Sensors used for remote sensing differ based on the spatial, spectral, radiometric and temporal resolution they offer. The spatial resolution of the sensor is defined by the size of the pixel that represents the surface of the ground, while the temporal resolution is related to the sensor platform, not the sensor itself. The time resolution for a satellite is the time it takes to complete an orbit and revisit the same observation area. Spectral resolution is indicated by the number of captured bands in a certain part of the electromagnetic spectrum [10]. Biomass and crop yield estimation usually requires the application of sensors with a higher spatial resolution [11]. Aerial platforms such as unmanned aerial vehicles generally provide higher spatial resolution images compared to satellites. As Joshi et al. [12] report, approximately 81% of crop mapping and yield forecasting studies used satellite sensors and 12% used unmanned aerial vehicles. However, drones are much more often used in yield prediction studies than crop mapping. For the purpose of crop yield prediction, both RADAR (Radio detection and ranging) and LIDAR (Light Detection and Ranging) sensors are used to obtain remote sensing data. Data obtained by RADAR systems have been used by many researchers to estimate aboveground production and crop biomass [13,14]. Debnath et al. [15] in their research, in addition to numerous applications, among other things, used LIDAR sensors to estimate biomass and crop yield.

Climate, soil properties, soil nutrients, crop nutrients, crop volume and biomass, water content, diseases, weeds, insects as well as crop variety have an impact on crop yield and agricultural production. All the mentioned factors influence the spectral characteristics of the crop, which can be evaluated through various sensors. Therefore, remote sensing offers a timely and cost-effective method for monitoring and assessing crop vitality, production and yield. The assessment of crop production using remote sensing techniques was carried out using different approaches. The earliest approach was based on the delineation of the area of a specific crop from the acquired satellite image combined with human experience for the expected yield of different local varieties of the given crop. This high accuracy of land cover classification depends on the type of satellite images used in the survey and the size of the farm under the crop. Another approach is to estimate the biophysical and biochemical parameters of the crop obtained using multiple sensors. These parameters, which are closely related to crop vitality, affect the spectroscopic characteristics of the crop, which can be measured using various remote sensing sensors. This approach is very effective; however, it sometimes requires a lengthy data collection process, which may not always be available. A third approach is to estimate crop yield through direct empirical statistical models between crop spectral characteristics measured by ground-based, airborne LIDAR and RADAR sensors as well as satellite remote sensors and observed yield. Using direct statistical empirical models with very few inputs can be the most practical and efficient method for predicting returns. The input factors for these models can be spectral factors collected by remote sensing sensors and the measured factors represent biochemical or biophysical parameters of the crop. Some of the statistical models used for this purpose are: multiple linear regression (MLR), stepwise multiple regression (SMR), generalized linear model (GLM), generalized boosted model (GBM), kernel-based regularized least squares (KRLS) [16].

3. VEGETATION INDICES IN CROP YIELD PREDICTION

One of the most important reasons for using remote sensing to obtain crop information is the calculation of vegetation indices (VI). The measured light reflected by plants in the visible, ultraviolet, and infrared parts of the spectrum is commonly used to calculate VIs that provide useful information about the conditions under which plants grow. VIs are calculated through mathematical expressions that combine the measured absorption and reflection of solar energy in many spectral bands, as a certain value would be obtained which helps to estimate crop growth, vitality, biomass, yield and chlorophyll content [10]. Each VI represents a number that quantifies plant biomass and/or vigor for each pixel in the remote

sensing image. Indices are calculated using several spectral bands that are sensitive to plant biomass and vigor. Some used VIs for crop yield prediction are: Normalized Difference Vegetation Index - NDVI, Enhanced Vegetation Index - EVI, Soil-Adjusted Vegetation Index - SAVI, Modified Soil Adjusted Vegetation Index - MSAVI [17]. The mentioned vegetation indices, their abbreviations and the equations by which they are calculated are shown in Table 1 [10]. Most VIs use information that include reflected light in the red and near-infrared part of the spectrum. A satellite with a multispectral sensor covers the visible and infrared part of the electromagnetic spectrum, which provides information for obtaining numerous VI [18]. One of the most commonly used indices for monitoring and evaluating crop yields is NDVI, which represents the ratio between the near-infrared (NIR) and the visible red part (RED) of the spectrum that plants reflect. Its values range from -1 to +1. Higher values of this index indicate that the plants are healthier, have stronger vigor and greater vigor, i.e. biomass, which will later directly affect the higher yield of the plants. EVI is similar to the NDVI index, however it minimizes the effects of soil background and atmospheric influences and uses the blue part of the spectrum to improve sensitivity to plant reflectance. It is used to determine plant health as well as water stress, especially in crops with high canopy density, where NDVI masks small variations. SAVI is a modified NDVI index, and it is used when monitoring the state of vegetation with less vigor or in the initial stages of growth when it is necessary to remove the influence of soil reflection (color and soil moisture). It is most suitable for analyzing vegetation that covers 15% or less of the total land area. MSAVI index comes to the fore when the soil is almost bare, immediately after the crop has sprouted. While other indices in the initial stages of the crop do not detect plants, this one has the function of recognizing small ones. With its help, it is possible to notice oases in the field where crop development is weaker, and the reason may be poorly done sowing, stressful conditions such as drought, extreme temperatures and precipitation. For this reason, it helps farmers in making decisions so that they can ultimately expect more and better yields [17].

Table 1. Some recently used vegetation indices for remote sensing applications in crop yield prediction
Source: [10]

Index name (abbreviation)	Definition/Equation
Normalized Difference Vegetation Index (NDVI)	$\frac{R_{NIR} - R_{red}}{R_{NIR} + R_{red}}$
Enhanced Vegetation Index (EVI)	$\frac{2.5(R_{NIR} - R_{red})}{(R_{NIR} + 6R_{red} - 7.5R_{Blue} + 1)}$
Soil-Adjusted Vegetation Index (SAVI)	$\frac{(R_{NIR} - R_{red})(1 + L)}{R_{NIR} + R_{red} + L}$
Modified Soil Adjusted Vegetation Index (MSAVI)	$\frac{2R_{NIR} + 1 - \sqrt{(2R_{NIR} + 1)^2 - 8(R_{NIR} - R_{red})}}{2}$

* NIR – near-infrared light, red – visible red light, Blue – visible blue light, L – soil conditioning index

Regardless of the variations, all designed VIs are sensitive to biochemical and biophysical parameters such as leaf chemical composition, fraction of absorbed photosynthetically active radiation, biomass and leaf area index (LAI). Remote sensing data have just been used to estimate LAI and biomass for different crops. LAI and crop biomass are considered to be two essential indicators of growth and development, and LAI is used as an input in many models to predict crop growth and yield [19]. Crop biophysical parameters obtained by remote sensing, or vegetation indices, have a strong correlation with observed crop yield and biomass, indicating their potential for application in crop yield estimation [20]. Crop yield estimation based on remotely sensed data is generally carried out in two ways. First, biophysical

parameters like LAI are used in models to predict crop yield and biomass. Second, statistical or empirical relationships are developed between remotely sensed crop parameters/indices (e.g. LAI, NDVI) and observed crop yield and biomass in a representative field. The developed statistical regression model or empirical relationship can then be used to map crop yields to the target crop field. Crop modeling is a data-intensive approach such as model input parameters, meteorological data and observed yield and biomass data. Maresma et al. [21] used a regression model-based approach to estimate the relationship between maize yield and biomass and measured spectral indices. They determined that Red-Based Indices - RBI, NDVI and Wide Dynamic Range Vegetation Index - WDRVI have the highest correlation with grain yield. A study by Fernandes et al. [22] in the prediction of corn yield showed that NDVI and Green Normalized Difference Vegetation - GNDVI had good results in terms of field variability, while Haghverdi et al. [23] found that crop yield prediction using Red-Edge Based Normalized Vegetation Index - NDVIre is more effective compared to NDVI and GNDVI.

4. CONCLUSION

Climate, soil characteristics, soil nutrients, crop nutrients, crop volume and biomass, water content, diseases, weeds, insects and crop variety are factors that affect crop yield. All the mentioned factors influence the spectral characteristics of the crops that can be evaluated by different remote sensing techniques. Therefore, remote sensing offers a timely and cost-effective method for monitoring crop conditions and estimating crop yields. Data obtained by remote sensing are used to calculate vegetation indices that are used to derive vegetation phenology and estimate various biophysical and biochemical parameters that are closely related to crop vitality and on the basis of which it is possible to estimate crop yield. Also, one of the approaches for crop yield estimation is through direct empirical statistical models between crop spectral characteristics measured by different remote sensors and the observed yield. Using direct statistical empirical models with very few inputs may be the most practical and efficient method for predicting crop yields. The input factors for these models can be spectral factors collected through various remote sensing sensors, and the measured factors represent biochemical or biophysical parameters of the crop.

Abstract: *Pruning, as the main activity during the winter dormancy of fruit trees, plays an important role in preserving the health of seedlings, high yields and obtaining high-quality fruits. Automation and robotics are widely used in many agricultural operations, however, pruning operations are usually done manually. Manual pruning is one of the most labor-intensive operations, accounting for about 20% of total labor costs and largely dependent on skilled labor. In recent years, qualified labor is in increasing shortage, and the high cost of labor is becoming a big problem for fruit production. That is why scientists around the world are paying more and more attention to robotic pruning, which represents a long-term solution to the problem of labor shortages and high costs. However, there are numerous challenges to the successful adoption of robotic pruning technologies. Robotic technology using sensors requires robust systems for perception and manipulation in changing and complex environmental conditions, as well as a precise and efficient tree branch pruning system. This paper is a review of a previous research in this field and shows the potential possibilities for automatic pruning apple with modern tree architectures, adapted to machines for automated branch pruning.*
Keywords: Apple Pruning, Mechanical Pruning, Automated Pruning

1. INTRODUCTION

Fruit production in the Republic of Serbia is to a large extent based on the use of seasonal labor. Many critical activities in the orchard are not only labor intensive, but also very sensitive to climatic conditions [1]. The lack of qualified labor represents a great risk for performing seasonal tasks in orchards [2,3]. In the future, it is critical to minimize dependence on seasonal labor for the long-term sustainability of this industry [4].
Dormant pruning of fruit trees refers to the removal of damaged parts of trees, especially unproductive shoots and branches, and is essential for maintaining overall tree health, controlling plant size, increasing fruit quality and marketable yield [1]. In most orchards, this operations is performed manually using scissors and a saws, which is a very labor-intensive operation and potentially unsafe (a cut, falls and etc.). After harvesting, pruning is the second largest labor cost in fruit tree production, accounting for 20% of total costs in full years of production (is not included the fixed investment breakdown for each year, such as land, trellis, irrigation setup and others) [5]. Researchers have been working on the mechanization of fruit tree pruning for several decades. Due to high costs and the decreasing availability of skilled labor mechanical or automated pruning is proposed [1]. Early research works in pruning focused on mass mechanical indiscriminate pruning in which the cutting

[2]stojicevic@atssb.edu.rs
[3]astevanovic@atssb.edu.rs
[4] mvasic@atssb.edi.rs

tool was passed over the wood in orchards while maintaining a certain distance from the center of the tree crown [6, 7, 8]. This type of pruning usually requires subsequent manual pruning [9]. Fence protective has been tried in the past as a supplement or replacement for selective manual pruning [1]. Ferree and Lakso [10] evaluated hedging for dormant pruning of vigorous semi-dwarf apple trees, and reported negative consequences of low within-canopy light levels and poor fruit color. These conditions resulted from a proliferation of new shoots arising from the numerous non-selective heading cuts made by the hedger [1]. Summer hedging with dormant selective hand pruning, conversely, was shown to be beneficial in creating higher light levels in the lower canopy [11].
Robotic pruning, which is selective pruning with precision cuts, typically cuts the branch with an end effector consisting of a blade and an anvil that uses a scissor motion [12]. Before cutting, the challenge is to detect the target branches and identify the predetermined cutting point. The location, orientation and dimension of the branch are the key information to perform accurate pruning, which results in a complex set of maneuvers and slows down the pruning process, so the pruning efficiency is very low [1].
Tree architecture is of paramount importance to the success of machine and automated pruning. A new orchard architecture suitable for mechanization with better machine accessibility of fruit or branches is also necessary. Different pruning strategies would be applied to the training system to meet the target apple tree system [1].
The aim of this paper is to review the contemporary architectures of apple trees and their compliance with the development of an automated pruning strategy.

2. TREE ARCHITECTURE AND AUTOMATED PRUNING.

2.1 Tree training systems

Apple orchards are evolving towards simpler, narrower, more affordable and more productive systems that are easier to mechanize and automate. Modern intensive orchard systems could provide easier detection and access to tree tops and fruits, resulting in greater potential for the application of mechanical and robotic technologies [13]. These architectures represent different training systems that create very narrow two-dimensional canopies where most branches and fruits are visible and accessible to machines [8]. These systems could increase profitability by improving yields and/or reducing labor costs.
One simplified architecture that is more amenable to mechanization than conventional orchard systems is the high-spindle wall system. In this architecture, trees are planted at smaller distances within the row of plants (1000-1300 trees ha^{-1}), and compared to classical architectures and branches, more secondary and tertiary branches are not allowed to grow [8]. A tall spindle means a conical crown where weak skeletal branches are arranged in a spiral and are getting shorter near the top. Between them there may be weak twigs and short fruitful twigs. This system for tree training is applied to fruit species grafted on weakly lush rootstocks (M.9 and M.27 for apple), as well as to apple spur types on medium lush rootstocks MM-160 and M.26. Pruning removes those branches that have an irregular position in the crown and that are too lush [14].
A super spindle is determined by its plant density. With a distance between rows of less than 3 m and a distance of trees in a row of less than 0.8 m, which gives a density of more than 4,000 trees per hectare [15]. The formation of the super spindle is similar to that of the tall spindle, except that the tree is narrower (the width at the base is up to 1 m) and during formation, the green is forced, i.e. summer pruning. Isolation of the top sapling is done in a timely manner, as well as the removal or shortening of saplings that are at a sharp angle. High-quality planting material (highly grafted and branched seedlings) and consistent architecture enable high reproductive potential and very early fertility, which in the case of apples can be up to 30 t ha^{-1} in the second year of planting.
Bi-axis is used for lusher combinations of cultivar-rootstocks, which due to their lushness do not give good results in the form of a slender spindle. The formation and maintenance is the same as with the slender spindle, with the difference that in this case two spindles are formed on one trunk. The

planting distance is 3.5 *m* x 1.8 - 2.0 *m*, which amounts to 1,500 trees per hectare, or 3,000 individual spindles. The height of the tree does not exceed 3 *m*, with the fact that each spindle is supported by a special armature, during formation, and later. Good results were obtained with more lush cultivars on weak- lush rootstocks, as well as with varieties that must have good fruit coloration [16].
The V-trellis growing system implies trees planted in one row on a support (support) inclined by 15° from the vertical. The trees are arranged alternately at a mutual angle of 30 degrees, which is why the leaf mass of the whole tree, and especially the base, is more exposed to sunlight. The formation of the cultivation form is quite similar to that of the standard spindle. The increase in the density of the assembly by planting fruit trees in the V-system is accompanied by an increase in the yield without a decrease in the quality of the fruits [14].
The Solaxe architecture partially adopts the concept of long pruning as in the case of a tall spindle, in less lush variety/rootstock combinations. With this compromise solution, it is possible to combine long pruning in the case of spindly forms and pruning of the parent tree support in solax. In the years of fruiting, a high yield and easier access to pruning are expected, as well as the possibility of converting the slender spindle into this growing form, in order to better adapt to the cultivar specifics. The planting distance depends on the lushness of the chosen cultivar/rootstocks combination and ranges from 3.5-4.0 *m* x 1.0-1.25-1.5-1.75 *m* (1,600-3,800 trees ha^{-1}) [16].

2.2 Mechanical pruning

Mechanical pruning is mainly performed in modern orchards with modern cultivation systems and large ones using mainly machines for pruning and shaping trees [17]. According to the mode of operation, the most commonly used pruning devices include reciprocating milling cutters and discs [18, 19, 20]. *Poni et al*. introduced a curtain pruner to cut upright branches, which improved pruning efficiency [21]. *Spinelli et al*. in Italy he designed a machine for pruning olives, which mainly consisted of a pruning device and a mechanism for crushing and recycling residual branches. This machine can crush and recycle residual branches during olive pruning, but it can only trim one side of the tree [22]. *Liu et al*. designed a wide-band combined pruning machine for new orchards [23] which consists of frame structure, cutting device, transmission system and hydraulic system. The cutting height range of the machine was 500–4000 *mm*, the maximum cutting diameter was 60 *mm*, the missed pruning rate was 7.3%, and the qualified pruning rate was 90.9%. The quality of the cut and the shape of the cut met the requirements for agronomic application. In 2021, *Li et al.* designed a horticultural plant pruning machine [24], whose pruning device consists of multiple cutting tools moving back and forth. It takes about 8.89 *s* to prune one horticultural plant with this machine. For tree crops, indiscriminate mechanical pruning has been investigated for various crops, such as cherry [25], citrus [26] and olive [27]. Mechanical pruning has shown some level of promise for citrus and olives. For example, medium-low vigor olive trees can be successfully controlled by mechanical pruning without compromising their yield [28]. Non-selective pruning systems are limited in their ability to provide pruning quality for some other fruit trees, such as cherry, peach and apple [29], which can lead to excessive shoot growth, leading to reduced fruit quality and yield. [30]. Therefore, mechanical pruning for fruit trees is mainly used for summer pruning with the removal of some outer shoots to increase light interception to the fruits [31].

2.3 Automated pruning

Automated pruning has not been introduced in current practice due to several important challenges. The first challenge is the complex canopy/tree structure environment. Another challenge is moving robotic parts quickly, efficiently and delicately [1]. These challenges have prevented pruning robots from achieving widespread adoption – there are no commercially available robotic tree pruning systems. In recent years, many scientists around the world have been developing and improving individual segments of automated pruning technology. In a review paper, *He and Schupp* [1] pay attention to modern apple canopy architecture for automation, defining two different pruning rules

for automated pruning and providing a summary of the sensor technologies involved in automating the pruning operation. However, the article did not include some key technological components (machine vision algorithms, manipulation and path planning) of the robotic pruning system [32]. A recent review by *Tinoco et al.* [33] focused on robotic manipulators for tree pruning and harvesting, mainly highlighting five harvesting manipulators and two pruning manipulators as case studies. In the last few years, research has been focused on the development of algorithms for automated pruning of dormant trees, in order to train the trees into the desired architecture [34, 35]. To develop a robotic pruning system, several components such as sensing or perception, mechanical manipulation, and path planning must be integrated for successful operation [32]. Path planning, pruning cut sequence, manipulation control and obstacle avoidance are also essential to the successful operation of a robotic pruning system. Machine vision systems have been developed to reconstruct tree branches for pruning, mechanical components for pruning have been investigated including manipulators [35, 36, 37] as well as end effectors [38, 39].

3. CONCLUSION

Modern intensive orchard systems are various training system architectures that produce very small, two-dimensional canopies where the majority of the branches and fruits are visible and reachable to machines. By increasing yields, decreasing labor costs, and increasing the possibilities for the use o mechanical and robotic technology, these systems could boost profitability.
Mechanical pruning is mostly done in modern orchards, mainly by pruning and shaping machines. Non-selective pruning systems are limited in their ability to provide pruning quality which can lead to excessive shoot growth and reduced fruit quality and yield. Therefore, mechanical pruning is mainly used for summer pruning with the removal of outer shoots to increase the brightness of the fruits.
Due to a number of significant obstacles, including the complicated environment of the canopy/tree structure and the slow movement of robotic parts, automatic pruning has not yet been realized. The efficient functioning of a robotic pruning system depends on path planning, cutting sequence, manipulation control, obstacle avoidance, machine vision systems and manipulators as end effectors. Further research should be directed towards the development of these systems.

Milica Blažić[3], The Academy of Applied Technical Studies Belgrade

Abstract: *Precision agriculture in vegetable farming is a transformative approach that integrates modern technology to enhance productivity, sustainability, and precision in farming practices. By utilizing various technologies such as GPS, sensors, drones, and data analytics, farmers can make informed decisions tailored to specific crops and fields. One key aspect of precision agriculture is data-driven decision-making. Farmers collect data on soil health, moisture levels, temperature, and crop growth using sensors and other monitoring devices. This data is then analyzed to determine the precise requirements of each crop, allowing farmers to tailor irrigation, fertilization, and pest control for optimal growth and yield. GPS technology assists in precise mapping and monitoring of fields, enabling farmers to manage and plan their operations more efficiently. Drones equipped with cameras and sensors can provide high-resolution images, helping identify issues like diseases, nutrient deficiencies, or pest infestations early on, enabling timely interventions. Automation plays a crucial role in precision agriculture as well. Automated machinery and equipment can perform tasks such as planting, spraying, and harvesting with precision and consistency. This not only saves labor but also ensures that tasks are carried out accurately, minimizing waste and maximizing yield. In this paper will describe the systems and equipment that can be used in growing vegetables.*
Keywords: vegetable farming, smart systems, precision agriculture

1. INTRODUCTION

'Precision Farming' or'Precision Agriculture' aims at increasing productivity, decreasing production costs and minimising the environmental impact on farming. In other words precision agriculture can be defined as a comprehensive system designed to choose risky agricultural production through the application of crop information, advanced technology and management practices. Precision agriculture is also known as precision farming, precision horticulture, site-specific farming, site-specific management, site-specific crop management, variable rate application, etc [1]. Information, technology and management are the keys to success in this production system [2]This approach considers a management system for farms that aims to increase yield or sustainability. PA can assist farmers, because it permits precise and optimized use of inputs adapted to the apparent plant status, consequently leading to reduced costs and environmental impact. Because the practise provides record trail, enhanced traceability of farm activities can be obtained that consumers and administration increasingly require [3].The steps can be divided into data collection and localisation, data analysis, management decisions on applications, evaluation of management decisions; and then a new cycle starts. Each year, data are stored in a database and are used as historical data for future

[1] mjevtic@atssb.edu.rs
[2] vstupar@atssb.edu.rs
[3] mblazic@atssb.edu.rs

decisionmaking [4]. Modern PA has a rather short history. Its application started over the last twenty-five years, when global positioning systems (GPS) and yield monitors were made available in field crops. Harvesting was mechanised and sensors were placed on harvesting machines to measure the spatial distribution of yield continuously. Applications started in cereals using impact or γ-ray grain flow sensors. When first yield monitors were developed and yield maps were created, it was shown that yield and soil properties varied highly within the field. This fact marked the development of modern PA [5]. However, applications in fruit and vegetables did not start until the 1990's and were published even later. This delay may be attributed, at least in part, to lack of appropriate technology [6]to record yield or quality data of the crop in an automated way. For this paper, will be describe the methods used in PA, as well as the benefits of this type of production in growing vegetables.

2. ELEMENTS OF PRECISION FARMING

2.1.The information

Information includes data on crop characteristics like stage of crop, crop health, nutrient requirement; detailed soil layer with physical and chemical properties, depth, texture, nutrient status, salinity and toxicity, soil temperature, productivity potential; microclimate data (season and daily) about the canopy temperature, wind direction and speed, humidity; surface and sub-surface drainage conditions; irrigation facilities, water availability and other planning inputs of interest [7].

2.2.The technological tools

Global Positioning System is one of the cutting edge technologies of this information- age for vegetable farming. Which asks the basic question "where is". It is computer based and the key components in this technology are satellites.

Geographical information system (GIS): A geographic information system (GIS) is a computer based system for storing very large amounts of data (collected based on spatial location), retrieving, manipulating, and displaying them for easy interpretation. The term "geographic" should be interpreted to mean "space" or "spatial". For crop production, some of the data of importance are soils, land use, vegetation, fertility, hydrology, and rainfall averages. Spatial analysis is concerned with analysing data involved with changes with space on location within an area. GIS has the capability of linking multiple sets of data (in layers) to study relationships among various attributes and creating new relationships.

Yield monitors: Yield monitors are crop yield measuring devices installed on harvesting equipment. The yield data from the monitor is recorded and stored at regular intervals along with positional data received from the GPS unit. GIS software takes the yield data and produces yield maps.

Variable Rate Technology: Consists of farm field equipment with the ability to precisely control the rate of application of crop inputs and tillage operations. Typical VRT system components include a computer controller, GPS receiver, and GIS map database. The computer controller will record the actual input being applied as the equipment crosses the field.

Remote Sensing: The art and science of obtaining information from a distance, i.e. obtaining information about objects or phenomena without being in physical contact with them. The science of remote sensing provides the instruments and theory to understand how objects and phenomena can be detected. The art of remote sensing is in the development and uses analysis techniques to generate useful information [8].Application of Remote Sensing in Precision Agriculture include:

Soil and drainage maps Soil maps. The grid sampling technique takes separate soil samples from uniform sized grids laid out over the field. Smaller grids are required which then requires many more soil samples to be taken for a larger number of grids. Drainage maps: colour infrared (CIR) aerial photographs have been shown to be an effective tool in locating unknown subsurface tile lines. The CIR photographs show different tones of grey depending on soil type and moisture. By filtering out spectral reflectance differences due to soil type, soil moisture content in dry soils that have a higher reflectance can be identified from lower reflectance wet soils. The resulting image shows where the tile lines are located and whether they are working properly [9].

Monitor crop health. Remote sensing data and images provide farmers with the ability to monitor the health and condition of crops. Multispectral remote sensing can detect reflected light that is not visible to the naked eye. The chlorophyll in the plant leaf reflects green light while absorbing most of the blue and red light waves emitted from the sun. Stressed plants reflect various wave lengths of light that are different from healthy plants. Healthy plants reflect more infrared energy from the spongy mesophyll plant leaf tissue than stressed plants. By being able to detect areas of plant stress before it becomes visible, farmers will have additional time to analyse the problem area and apply a treatment.

Water stress. The use of remote sensors to directly measure soil moisture has had very limited success. Synthetic Aperture Radar (SAR) sensors are sensitive to soil moisture and they have been used to directly measure soil moisture. SAR data requires extensive use of processing to remove surface induced noise such as soil surface roughness, vegetation and topography. A crop evapotranspiration rate decrease is an indicator of crop water stress or other crop problems such as plant disease or insect infestation. Remote sensing images have been combined with a crop water stress index (CWSI) model to measure field variations [10].

Weed management. Aerial remote sensing has not yet proved to be very useful in monitoring and locating dispersed weed populations. Some difficulties encountered are that weeds often will be dispersed throughout a crop that is spectrally similar, and very large scale high resolution images will be needed for detection and identification. The use of machine vision technology systems to detect and identify weeds places remote sensors directly on the sprayer equipment. Being close to the crop allows for very high spatial resolutions. Machine vision systems have the ability to be used in the field with the real time capabilities that are necessary to control sprayer equipment [11].

Insect detection. Aerial or satellite remote sensing has not been successfully used to identify and locate insects directly. Indirect detection of insects through the detection of plant stress has generally not been used in annual crops. The economic injury level for treatment is usually exceeded by the time plant stress is detected by remote sensing. Entomologists prefer to do direct in field scouting in order to detect insects in time for chemical treatments to be effective and economical.

Nutrient stress. Plant nitrogen stress areas can be located in the field using high resolution colour infrared aerial images. The reflectance of near infrared, visible red and visible green, wavelengths have a high correlation to the amount of applied nitrogen in the field. Canopy reflectance of red provides a good estimate of actual crop yields[12].

Yield forecasting. Plant tissue absorbs much of the red light and is very reflective of energy in near infrared (NIR) wavebands. The ratio of these two bands is referred to as the vegetation index (VI). The difference of red and NIR measurements divided by their sum is normalised difference VI (NDVI). For crops such as grain sorghum, production yields, leaf area index (LAI), crop height and biomass have been correlated with NDVI data obtained from multispectral images [13]. In order to get reasonably accurate yield predictions this data must be combined with input from weather models during the growing season [10].

2.3.Decision support (management)

Just having information about variability within the field does not solve any problems unless there is some kind of decision support system (DSS) in order to make VRT recommendations. Russo and Dantinne (1997) have suggested the following steps for a DSS:

1. Identify environmental and biological states and processes in the field that can be monitored and manipulated for the betterment of crop production.
2. Choose sensors and supporting equipment to record data on these states and processes.
3. Collect, store and communicate the field recorded data.
4. Process and manipulate the data into useful information and knowledge.
5. Present the information and knowledge in a form that can be interpreted to make decisions. Choose an action associated with a decision to change the identified state or process in a way that makes it more favourable to profitable crop production[14].

3. METHODS FOR IMPLEMENTING A PRECISION FARMING STRATEGY

1. **Map-based technologies**- This is currently the most widely used method. It may involve a GIS-based method of pre-sampling and mapping of the field. The computer generated maps are then converted into a form that can be used by the variable rate applicator. The applicator's controller then calculates the desired amount of an agronomic input to apply at each moment in time as the equipment traverses the field. The farmer knows how much of the agronomic input is needed before starting the application. A DGPS (Differential Global Positioning System) must be used to constantly evaluate the location in the field with a coordinate on the map and the desired application rate for that coordinate.

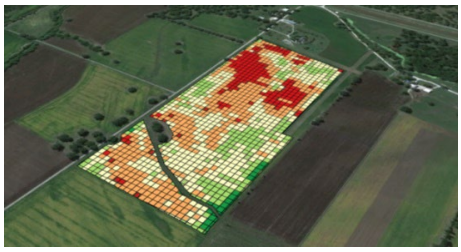

Figure 1. Mapping as a path to success in precision agriculture
Source: [15]

2. **Sensor-based technologies** – This method offers realtime sensing and variable rate control. The strategies provide on –the - go sensing of field characteristics, thereby eliminating the need for a positioning system. The sensors must be mounted strategically (e.g. at the front of the tractor) to allow the variable rate applicator's controller adequate time to adjust the rate of the agronomic input accordingly, before it passes the sensed location [7].

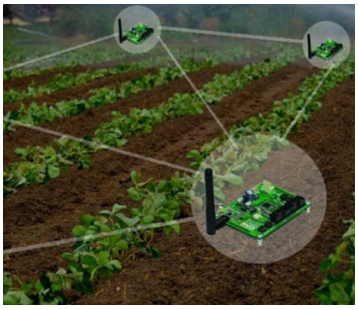

Figure 1. Examlple of the sensor based technology in agriculture
Source: [16]

4. CONCLUSION

Precision agriculture in vegetable farming has significant potential. Through technologies like sensors, GPS, and data analytics, farmers can optimize resource use, monitor crop health, and enhance overall efficency. PA enables targeted application of water, fertilizers, and pesticides, promoting sustainable practices and addressing specific needs of individualplants or areas within a field. Positive effect are increased efficency, enhanced yields, environmental sustainability, cost saving, this system can lead to reduced operational costs and increased profitability, data-driven decision making, because real-time data and analytics empower farmers to make informed decisions, allowing for proactive menagment of crops and addressing issues promptly. Negative sides are high initial costs, technological dependence, skill and knowledge gaps, data security concerns and environmental concerns. Balancing the positive and negative aspects of precision agriculture is crucial for its successful and susainable integration into vegetable farming practices. Addressing challenges and ensuring responsible use can maximize the benefits while minimizing potential drawbaks.

Abstract: *Precision agriculture has gained substantial attention due to the ever-growing world population demands for food and water. Due to the limited availability of both resources, farmers need a solution that changes the way they operate. The use of state-of-the-art technologies, such as the Internet of Things, transform traditional cultivation practices, like irrigation, to modern solutions of precision agriculture. Internet of Things (IoT)-based automation of agricultural events can change the agriculture sector from being static and manual to dynamic and smart, leading to enhanced production with reduced human efforts. Precision Agriculture (PA) along with Wireless Sensor Network (WSN) are the main drivers of automation in the agriculture domain. PA uses specific sensors and software to ensure that the crops receive exactly what they need to optimize productivity and sustainability. PA includes retrieving real data about the conditions of soil, crops and weather from the sensors deployed in the fields. High-resolution images of crops are obtained from satellite or air-borne platforms (manned or unmanned), which are further processed to extract information used to provide future decisions. In this paper will describe the basics of precision agriculture, as well as the systems that are applied.*
Keywords: smart agriculture, precision agriculture, IoT, PA, WSN

1. INTRODUCTION

Precision agriculture can be defined as a comprehensive system designed to optimise agricultural production through the application of crop information, advanced technology and management practices. To be a truly comprehensive system, it must begin during the planning stages of the crop and continue through the post harvest-processing phase of production. Information, technology and management are the keys to success in this production system [1]. The steps can be divided into data collection and localisation, data analysis, management decisions on applications, evaluation of management decisions; and then a new cycle starts. Each year, data are stored in a database and are used as historical data for future decisionmaking [2]. Modern PA has started over the last twenty-five years, when global positioning systems (GPS) and yield monitors were made available in field crops. Harvesting was mechanised and sensors were placed on harvesting machines to measure the spatial distribution of yield continuously.

[1] mjevtic@atssb.edu.rs
[2] gnestorovic@atssb.edu.rs
[3] mvasic@atssb.edu.rs
[4] dstojicevic@atssb.edu.rs

Applications started in cereals using impact or γ-ray grain flow sensors. When first yield monitors were developed and yield maps were created, it was shown that yield and soil properties varied highly within the field. This fact marked the development of modern PA [3]. However, applications in fruit and vegetables did not start until the 1990's and were published even later. This delay may be attributed, at least in part, to lack of appropriate technology [4] to record yield or quality data of the crop in an automated way. For this paper, will be describe the methods used in PA, as well as the benefits of this type of production in agriculture.

2. ELEMENTS OF PRECISION FARMING

Information, technology and management are the keys to success in precision farming system. Information includes data on crop characteristics like stage of crop, crop health, nutrient requirement; detailed soil layer with physical and chemical properties, depth, texture, nutrient status, salinity and toxicity, soil temperature, productivity potential; microclimate data (season and daily) about the canopy temperature, wind direction and speed, humidity; surface and sub-surface drainage conditions; irrigation facilities, water availability and other planning inputs of interest [5].
The technological tools often include:
Global positioning system (GPS). A global positioning system (GPS) is one of the cutting edge technologies of the information age. It asks the basic question "where is it"? It is a versatile navigational aid. It is computer based and the key components in this technology are satellites.
Geographical information system (GIS). A geographic information system (GIS) is a computer based system for storing very large amounts of data (collected based on spatial location), retrieving, manipulating, and displaying them for easy interpretation. GIS has the capability of linking multiple sets of data (in layers) to study relationships among various attributes and creating new relationships. It can be used to answer the location question "what is there"? It can also be used to study trends that is, answer the question "what has changed since a certain point in time"?
Yield monitors. Yield monitors are crop yield measuring devices installed on harvesting equipment. The yield data from the monitor is recorded and stored at regular intervals along with positional data received from the GPS unit. GIS software takes the yield data and produces yield maps.
Variable Rate Technology. Consists of farm field equipment with the ability to precisely control the rate of application of crop inputs and tillage operations. Typical VRT system components include a computer controller, GPS receiver, and GIS map database.
Remote Sensing. The science of remote sensing provides the instruments and theory to understand how objects and phenomena can be detected. The art of remote sensing is in the development and uses analysis techniques to generate useful information [6].

2.1. Application of Remote Sensing in Precision Agriculture

Soil and drainage maps Soil maps. The grid sampling technique takes separate soil samples from uniform sized grids laid out over the field. A problem with this type of sampling is the variability that can exist in soil types within each grid. To minimise this problem smaller grids are required which then requires many more soil samples to be taken for a larger number of grids. Drainage maps: colour infrared (CIR) aerial photographs have been shown to be an effective tool in locating unknown subsurface tile lines. The CIR photographs show different tones of grey depending on soil type and moisture. By filtering out spectral reflectance differences due to soil type, soil moisture content in dry soils that have a higher reflectance can

be identified from lower reflectance wet soils. The resulting image shows where the tile lines are located and whether they are working properly [7].

Monitor crop health. Remote sensing data and images provide farmers with the ability to monitor the health and condition of crops. Multispectral remote sensing can detect reflected light that is not visible to the naked eye. The chlorophyll in the plant leaf reflects green light while absorbing most of the blue and red light waves emitted from the sun. Stressed plants reflect various wave lengths of light that are different from healthy plants. Healthy plants reflect more infrared energy from the spongy mesophyll plant leaf tissue than stressed plants.

Water stress. The use of remote sensors to directly measure soil moisture has had very limited success. Synthetic Aperture Radar (SAR) sensors are sensitive to soil moisture and they have been used to directly measure soil moisture. SAR data requires extensive use of processing to remove surface induced noise such as soil surface roughness, vegetation and topography. A crop evapotranspiration rate decrease is an indicator of crop water stress or other crop problems such as plant disease or insect infestation. Remote sensing images have been combined with a crop water stress index (CWSI) model to measure field variations [8].

Weed management. The use of machine vision technology systems to detect and identify weeds places remote sensors directly on the sprayer equipment. Being close to the crop allows for very high spatial resolutions [9].

Insect detection. Aerial or satellite remote sensing has not been successfully used to identify and locate insects directly. Indirect detection of insects through the detection of plant stress has generally not been used in annual crops.

Nutrient stress. Plant nitrogen stress areas can be located in the field using high resolution colour infrared aerial images. The reflectance of near infrared, visible red and visible green, wavelengths have a high correlation to the amount of applied nitrogen in the field [10].

Yield forecasting. Plant tissue absorbs much of the red light and is very reflective of energy in near infrared (NIR) wavebands. The ratio of these two bands is referred to as the vegetation index (VI). The difference of red and NIR measurements divided by their sum is normalised difference VI (NDVI). For crops such as grain sorghum, production yields, leaf area index (LAI), crop height and biomass have been correlated with NDVI data obtained from multispectral images.

Decision support (management). Just having information about variability within the field does not solve any problems unless there is some kind of decision support system (DSS) in order to make VRT recommendations[11].

3. IoT BASED SMART AGRICULTURE

Every node is integration with different sensors and devices and they are interconnected to one central server via wireless communication modules. The server sends and receives information from user end using internet connectivity. There are two modes of operation of the system; auto mode and manual mode. In auto mode system takes its own decisions and controls the installed devices whereas in manual mode user can control the operations of system using android app or PC commands.

4. CONCLUSION

Smart agricultural technologies, such as precision farming and automation optimize resource use, leading to increased crop yields and overall productivity. This is a vital for meeting the growing global demand for food. Smart systems enable precise menagment of resources like wather, fertilizers, and pesticides. This not only maximizes efficiency but also reduces waste, contributing to sustainable agricultural practices. By minimizing environmental impact through target resource application, smart agricultural systems promote sustainable farming. This is crucial for preserving ecosystem, minimizing pollution, and mitigating climate change. The enhanced productivity and efficiency brought about by smart agriculture contribute to global food security by ensuring a more reliable and abundant food supply. In rural areas, this technologies can lead to improved livelihoods, economic growth, and overall development in agricultural aommunities. In sumary, the global benefits of smart agricultural systems extend beyond individual farms, positively impacting food security, sustainability, and the well-being of communities worldwide.

Abstract: *In order to reduce environmental pollution and negative impacts on human health, manufacturers of pesticide application machines started developing robotic systems which collect data on pests, harmful plants and diseases in order to provide information on the required amount of pesticides. One important design feature of a robot for controlled pesticide application is the robot locomotion system. Although unmanned aerial vehicles (drones) have been increasingly developed in recent years, wheeled robots have much higher payload capability. This paper analyses all the forces acting in the direction of the longitudinal axes of the wheels, as well as the main factors to be considered when selecting motors and reducers.*
Keywords: robots, controlled pesticide application, drive units

1. INTRODUCTION

The application of conventional pesticides is saddled with many problems such as negative effects on human health and the environment. Efforts to reduce these negative effects, enhanced by requirements of national and international regulations, have forced manufacturers to develop and promote more precise and more environmentally efficient machines. As a result, research and development activities have been intensified in the field of robotic systems related to controlled application of pesticides, which, according to available research data can detect and treat 85% to 100% of diseased areas, thus reducing the use of pesticides by 65% to 85% [1]. This results in substantial financial savings, which, for grain, amount to 12 EUR/ha for just one pesticide application [2].
Although robots for controlled application of pesticides consist of a large number of mechanical and electrical components [3,4,5,6], the drive unit of the locomotion system is one of the most important structural features. It makes it possible for a robot to overcome difficulties in complex terrains with longitudinal and transverse slopes and enables it to manoeuvre in small spaces, which is especially important for narrow rows in orchards and greenhouses. The aim of this paper is to analyze the forces acting in the direction of the longitudinal axes of the wheels, as well as the main factors to be taken into account when selecting motors and reducers.

2. DRIVE UNITS IN ROBOTS FOR CONTROLLED PESTICIDE APPLICATION

Generally, the drive units of robots for controlled pesticide application are mounted directly in the drive wheels (IWM). The main benefits of this design include an improved dynamic performance of the robot due to a more favourable mass distribution, the absence of need for complex transmission and a more flexible use of available space.

[1] mvasic@atssb.edu.rs
[2] zzivkovic@atssb.edu.rs
[3] gnestorovic@atssb.edu.rs
[4] dstojicevic@atssb.edu.rs

Basically, the drive unit of the in-wheel hub system consists of an electric motor, a reducer and a wheel hub [7]. Development of permanent magnet synchronous motors (PMSM) made it possible to have directly driven wheels without a reducer. These motors provide higher torque and higher efficiency compared to induction motors (IM); however, they are much more expensive [8].

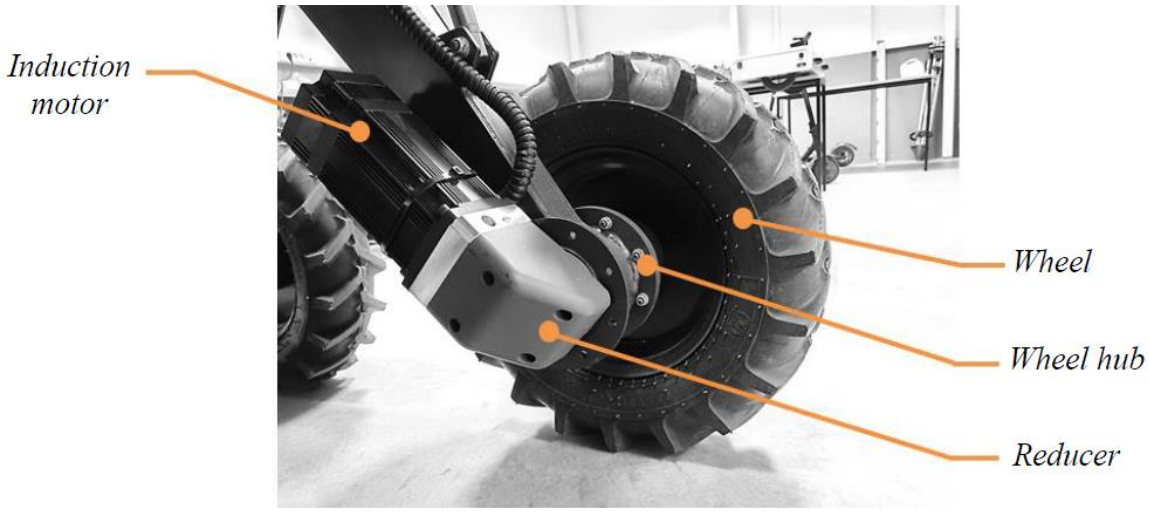

Figure 1. Drive units in an in-wheel-hub system
Source: own archives

3. TRACTION BALANCE, TORQUES AND MOMENTS OF INERTIA

The motion of the robot moving at a constant speed is opposed by: the rolling resistance (F_r), aerodynamic drag (F_{DF}), grading resistance (F_g), and, when moving at non-stationary speeds, by inertial forces (Figure 2). The values of these resistances are evenly distributed on the drive wheels. According to Newton's second law, the traction balance equation can be written as [7,9,10]:

$$m \cdot \frac{dv(t)}{dt} = F_T(\omega_{em}) - \left[F_r(t) + F_{DF}(t) + F_g(t)\right] \tag{1}$$

where: m – total mass, (Kg); $dv(t)/dt$ – change in speed per unit of time – acceleration, (m/s^2); $F_T(\omega_{em})$ – tractive effort as a function of the motor angular velocity, (N).

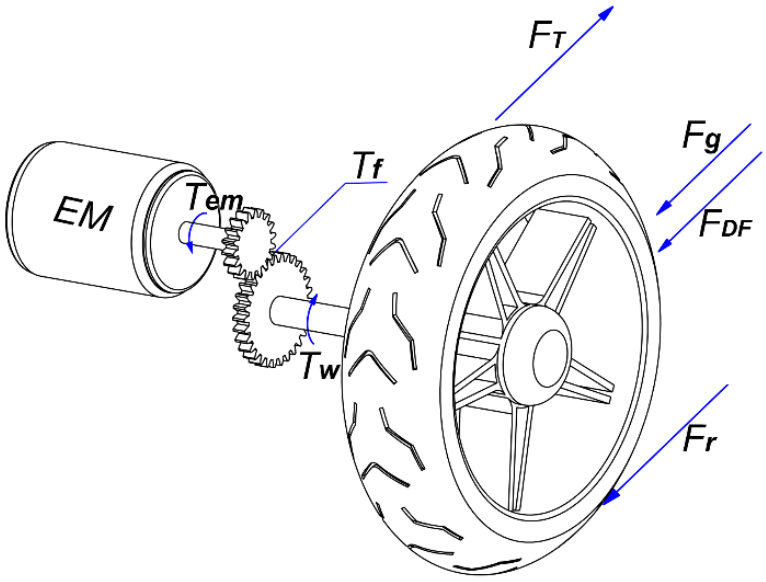

Figure 2. Drivetrain loading
Source: own archives

The total mass (m) is the sum of the actual mass of the robot for controlled pesticide application (m_v), the current volume of liquid in the tank expressed in mass (m_c), and the reduced electric motor mass (m_{em}), whereby the values of the other equivalent masses are neglected.

$$m = m_v + m_c + m_{em} \tag{2}$$

The reduced electric motor mass can be determined by the following expression [11]:

$$m_{em} = J_{em} \frac{4 \cdot {u_R}^2}{{d_w}^2} \tag{3}$$

where: J_{em} – moment of inertia of the electric motor, (kg/m^2); d_w – wheel diameter, (m).

The rolling resistance can be determined based on the expression [7,9,10]:

$$F_r(t) = m \cdot g \cdot \mu_r \cdot cos(\alpha) \tag{4}$$

where: μ_r – coefficient of the wheel rolling resistance; α – road grade angle, (°); g – acceleration of gravity, (m/s^2).

The rolling friction coefficient can be determined using the expression [10]:

$$\mu_r = \mu_0 \cdot \left(1 + \frac{v(t)}{161}\right) \tag{5}$$

where: μ_0 – basic friction coefficient; $v(t)$ – current velocity of the robot.

The aerodynamic drag can be defined as [7,9,10]:

$$F_{DF}(t) = \frac{1}{2} \cdot \rho_{air} \cdot C_d \cdot A_f \cdot \left(\frac{v(t)}{3{,}6}\right)^2 \tag{6}$$

where: ρ_{air} – air density, (kg/m^3); A_f – frontal area of the robot for controlled pesticide application, $A_f = 0{,}82 \cdot b_v \cdot h_v$, (m^2); b_v – maximum robot width, (m); h_v – maximum robot height, (m); C_d – aerodynamic drag coefficient which depends on the outer shape of the robot and the Reynolds number. The typical value of this coefficient ranges from 0.18 for a perfect aerodynamic body to 0.25÷0.30 when the tangential resistances and the surface discontinuity resistances are included [9].

The grading resistance can be determined based on the expression [7,9,10]:

$$F_g(t) = m \cdot g \cdot sin(\alpha) \tag{7}$$

The current value of the torque on the wheel can be defined as:

$$T_w(t) = \frac{\left[F_r(t) + F_{DF}(t) + F_g(t) + m \cdot \frac{dv(t)}{dt}\right] \cdot d_w}{2 \cdot N_w} \tag{8}$$

where: N_w – number of the drive wheels.

The current value of the torque that the motor needs to provide can be defined as follows:

$$T_{em}(t) = T_f + \frac{T_w(t)}{u_R} \tag{9}$$

where: T_f – total friction torque in the reducer.

The tractive effort that the motor can provide can be determined based on the motor characteristics:

$$F_T(\omega_{em}) = \left[T_{em}(\omega_{em}) - T_f\right] \cdot \frac{2 \cdot u_R}{d_w} \tag{10}$$

where: $T_{em}(\omega_{em})$ – the value of the torque which depends on the current speed of the motor (Figure 2).

4. CHARACTERISTICS OF THE INDUCTION MOTOR

Electric motors are mainly used in industrial machines which generally run at constant speeds, have little variability in load and have long running hours. However, in robots for controlled pesticide application, motors start and stop more frequently. Therefore, in addition to high reliability and efficiency, small size and low weight, electric motors used in robots must provide high torque for starting and climbing steep slopes and be able to withstand overload for a certain time period [11].
Figure 3 shows a typical characteristic of an induction motor. Here, three characteristic regions can be seen: the constant torque region, the constant power region and the reduced power region, which occurs at maximum speed [12].

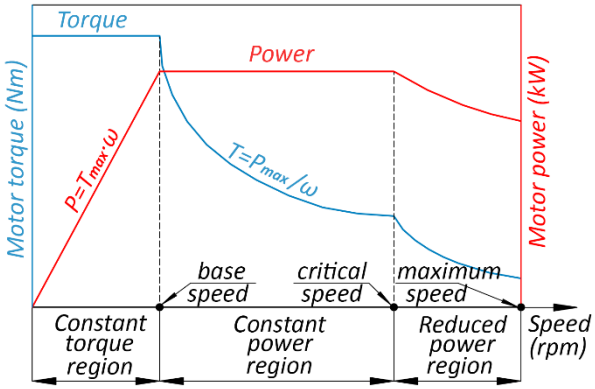

Figure 3. A typical characteristic of an induction motor

5. SELECTION OF A REDUCER

It is well known that a reducer significantly decreases the required torque, which affects not only the size and the weight of the motor but also the total weight of the robot for controlled pesticide application.
When designing the robot, special attention should be paid to the fact that the gear ratio of the reducer should enable the robot to achieve the maximum speed (v_{max}) and climb the maximum slope (usually α=16,7°, i.e. 30%). For that reason, it must be in the range defined as [13,14]:

$$u_{R\,min} = \frac{0{,}377 \cdot n_{max} \cdot r_{dyn}}{v_{max}} \tag{11}$$

$$u_{R_{max}} = \frac{r_{dyn} \cdot m \cdot g \cdot (f_r \cdot cos\alpha + sin\alpha)}{T_{em,max} \cdot \eta_{em} \cdot \eta_R} \tag{12}$$

where: n_{max} – maximum speed of the motor, (min^{-1}); v_{max} – maximum speed of the robot, (km/h); η_{em} – motor efficiency; η_R – reducer efficiency.

Depending on the mutual position of the input and output shafts, the reducers used to transmit the torque from the engine to the wheels can have either parallel axes or axes intersecting at a 90° angle. With reducers with parallel axes, the axes of the drive shaft and the wheel can be overlapping or the drive shaft axis can be above the wheel axis, which allows the motor to be be placed further up from the ground.

6. CONCLUSION

This paper describes the primary components of the drive units which enable robots for controlled application of pesticides to move around. The paper also analyses the forces acting in the direction of the longitudinal axes of the wheels (in the direction of the robot's motion) such as resistance to motion, required and available traction force. Some characteristics of induction motors and the most common designs of reducers which transmit torque to the drive wheels have also been analysed. Development of permanent magnet synchronous motors (PMSM) made it possible to have directly driven wheels without a reducer, however, these motors are much more expensive than the induction ones.
The methodology used in this paper can be applied to other robotic systems in agriculture as well as to electric vehicles, hence, it can be concluded that this paper makes a valuable contribution to engineering practice especially to the field of designing.

DEEP LEARNING IN FRUIT DETECTION

Dubravka Mandušić[1], Faculty of Agriculture, University of Zagreb, Republic of Croatia
Lucija Blašković[2] Faculty of Agriculture, University of Zagreb, Republic of Croatia

Abstract: *Over the past decade, there has been a marked surge in scholarly publications focusing on machine learning, the Internet of Things (IoT), and deep learning, particularly in the context of the fruit industry. Deep learning (DL) is a specialized approach within the broader field of machine learning (ML), which itself is a subset of artificial intelligence (AI). Deep neural networks serve as the backbone for constructing fast and reliable predictive systems that are increasingly vital in agricultural production. This paper aims to encapsulate the critical role that deep learning plays in shaping the future of the fruit industry.*
Keywords: artificial intelligence, fruit industry, Internet of Things

1. INTRODUCTION

The adoption of robotics in agriculture is on the rise, driven by the need to improve efficiency and enhance fruit production, especially in large-scale operations. Various technologies—from fruit detection and measurement to automated harvesting-are increasingly being integrated with robotic systems. While these advancements have brought transformative changes to the fruit industry, they also come with challenges that can impede their widespread adoption.
In this paper, we will explore the pivotal role of deep learning in fruit production. Deep learning is a specialized approach within the broader field of machine learning, which itself is a subset of artificial intelligence [1]. We aim to underscore the significance of deep learning technologies in shaping the future of modern agricultural practices.

2. WHAT IS DEEP LEARNING?

Deep learning, a specialized form of machine learning, represents a significant advancement in the field of computational science. In deep learning, neural networks comprise various interconnected layers that interact within an extended framework. This architecture allows artificial intelligence (AI) systems to tackle a wide range of complex, non-standard tasks. For instance, deep neural networks can process and recognize intricate images in real-time. The data fed into these networks is simultaneously analysed across multiple layers, each discerning unique input aspects. Without the foundational technologies of AI, machine learning, and deep learning, certain computational tasks—such as speech and image recognition or even playing board games like checkers—would be infeasible. The capability to process vast data sets and identify underlying patterns enables machines to execute tasks of varying complexity [2]
In simpler terms, machine learning is a methodology that empowers computers to perform specific tasks without the need for explicitly programmed algorithms [2]. The initial data sets often include the insights needed by experts across various domains. The ultimate goal is to leverage cutting-edge technologies to identify and implement effective solutions.

3. DEEP LEARNING IN FRUIT DETECTION-SHORT REVIEW

In recent years, there has been a surge in interest in applying artificial intelligence (AI) techniques and robotic systems to automate agricultural processes. This is particularly true for developing intelligent agriculture and automating fruit harvesting. Automatic fruit harvesting involves two key tasks: (1) the sensor-based detection and localization of fruit on trees, and (2) the robotic arm's precise movement towards the identified fruit for harvesting without causing damage to either the fruit or its tree [3].

Various studies have explored sensor-based detection and localization of fruit on trees, with many of these works summarized in the review by Gongal et al.[4]. Spectral and thermal cameras are commonly employed in these methods. Spectral cameras struggle to detect fruit that lies in the shadow of other objects, while thermal cameras identify fruit based on temperature differences between the fruit and its background, a method influenced by fruit size and exposure to sunlight.

Different attributes, such as colour and shape, are used for fruit detection. For instance, colour cameras in conjunction with a K-means clustering algorithm have been effective in locating apples on trees or soil [5]. Deep learning has proven to be a potent tool for detection and classification, often utilizing fruits' colour and shape characteristics for segmentation and recognition [6]. Spectral features and depth information are also used in fruit detection [7, 8, 9].

Thanks to deep learning's robust capacity for extracting high-dimensional features from fruit images, researchers have proposed a plethora of fruit detection and recognition methods. These methods are often based on deep learning architectures like Single Shot Multibox Detector (SSD), Alex Krizhevsky Networks (AlexNet), Visual Geometry Group Networks (VGGNet), Residual Networks (ResNet), Faster Region-Convolutional Neural Networks (Faster R-CNN), Fully Convolutional Networks (FCN), SegNet, and Mask Region-Convolutional Neural Networks (Mask R-CNN) for automatic harvesting [11].

4. ROBOTS IN FRUIT DETECTION

Robots employed in agriculture vary in form and size but generally share three distinct characteristics: they are designed for specific tasks, equipped with electrical components for power and control, and programmed with specialized software. These robots typically consist of five main components: sensors, controllers, actuators, robotic arms, and end-effectors. The types of sensors often integrated into these robots include microphones, ultrasound sensors, acoustic vector sensors, cameras, infrared sensors, and chemical detectors. The robotic arm, outfitted with end-effectors and sensors, executes pre-programmed tasks. In agricultural settings, common end-effectors include grasping and vacuum pumps [12].

Modern agriculture, also known as precision farming, increasingly relies on algorithms, satellites, drones, and robots. Innovations include carbon nanotube sensors embedded directly into plant leaves, which send alerts to farmers' smartphones when the plants show signs of infection, dehydration, or sun damage [13]. This kind of AI has even found applications in automated labelling and pricing in grocery stores, with colour and texture serving as crucial parameters for natural image recognition.

Agricultural productivity is influenced not only by the technology available to farmers but also by government policies. Deep learning has shown promise in fruit farming, streamlining tasks traditionally carried out by human experts, such as fruit classification and sorting. Thus, research in deep learning should not merely remain an academic exercise; it represents a key aspect of future management in an era where global fresh fruit production has reached 887 million metric tons (global production of fresh fruit from 1990 to 2021) [14].

5. CONCLUSION

Advancements in research and development are driving the automation of various sub-sectors in agriculture, aiming to boost economic growth, productivity, and environmental conservation through the use of deep learning, robotics, and artificial intelligence (AI).

Fruit detection typically employs two primary methods: traditional image processing techniques and deep learning-based approaches. Existing research indicates that while traditional methods can be highly efficient, they often struggle with colour similarities, complex backgrounds, and varying lighting conditions, leading to inaccurate results. One of the primary challenges in developing deep learning algorithms for this application is the lack of standardized datasets and high-performance computing resources. Furthermore, the use of large datasets can slow down the training process, even for pre-trained networks.

For effective fruit harvesting, pinpointing the exact location for detachment is crucial for maintaining quality and optimizing storage. Current limitations in sensing technology and fruit and picking point detection algorithms offer important avenues for future research. These gaps need to be addressed to develop a fully automated robotic system that can enhance processing speeds and overall productivity.

In this brief review, we have examined various deep-learning methods that have been explored for fruit detection and classification. While earlier reviews have largely focused on traditional computer vision techniques, deep learning models have not garnered as much attention, despite their proven effectiveness in numerous image classification tasks.

A comprehensive study is still needed—one that takes into account feature description, detection algorithms, classification algorithms, and the diversity of datasets used in fruit production. After critically analysing the reviewed methods, we identified open challenges, particularly concerning datasets. We hope this review serves as a foundational guide to the basics and applications of deep learning models in fruit detection and classification, particularly for those new to the field.

CHEMICAL PROPERTIES AND MICROBIOLOGICAL CONTROL OF FROZEN PLUM FRUIT

Dobrila Ranđelović[1], Toplica academy of Applied Studies
Svetlana Bogdanović, Toplica academy of Applied Studies
Ivana Zlatković, Toplica academy of Applied Studies
Dragana Stanisavljević, Toplica academy of Applied Studies

Abstract: *Plum (Prunus domestica) is one of the most commonly grown and most important fruit species in Serbia. The plum fruit is oblong in shape. The edible part of the fruit (skin and flesh) makes up to 94-96% of the mass, and the rest is the pit and seeds. The substances found in the edible part of the plum fruit are: water, sugars, organic acids, fatty, nitrogenous, as well as colored and aromatic substances, vitamins, enzymes and mineral substances (ash). The aim of this work was to examine the chemical properties and to perform microbiological quality control of the fresh and the frozen plum fruit. The following parametres were examined within this analysis: dry matter content, pH value, acid content (such as citric), total sugar content, vitamin C content, total phenol and anthocyanin content. The microbiological quality control of the fresh and the frozen plum fruit included testing for food spoilage bacteria, such as Salmonella spp, Listeria monocytogenes and Enterobacteriaceae. The test results indicated that both the fresh and the frozen fruit is a good source of vitamin C, anthocyanins and total phenols, which indicates that the plum fruit has a significant protective, dietary and therapeutic value. The microbiological methods performed to test the frequency of Salmonella spp., Listeria monocytogenes and Enterobacteriaceae, showed the absence of Salmonella spp. and Listeria monocytogenes and the presence of Enterobacteriaceae in less than 10cfu/ml.*
Key words: *plum fruit, chemical analysis, anthocyanins, microbiological control*

1. INTRODUCION

Plums are, directly next to peaches, one of the most important types of stone fruit, with a world production of more than 12 million tons per year [1,2,3]. They represent a relatively young species discovered by the Southern Slavs upon their migrations to the Balkan Peninsula. Their origin is considered to be Eastern Europe and Western Asia, namely the Caucasus Mountains near the Caspian Sea [1]. Along with China, Chile, Turkey and Romania, Serbia is one of the world's greatest producers of plums. Plum is the most commonly grown fruit species in Serbia. It is grown on the whole territory of Serbia, the most prominent growing areas being Western Serbia, Šumadija and parts of Southern Serbia near the town of Prokuplje [4]. Based on the data of the Republic Institute of Statistics, the total yield of plums in 2019 was 558,930 t on 72,316 ha of growing area [5]. The best known plum varieties include ″Čačanska lepotica″, ″Stanley″, ″Čačanska rana″, ″Čačanska rodna″ and others [6].

[1] dobrilarandjelovic74@gmail.com

The plum fruit is characterized by its oval shape and blue skin. The share of the stone in the fruit is about 6.2%. The edible part of the plum fruit consists of water, sugars, organic acids, fatty, nitrogenous, colored and aromatic substances, vitamins, enzymes and mineral substances (ash). As for its composition, the plum fruit is mostly composed of fibers and phenols. It is an excellent source of vitamins C, A and K, and it is rich in phytonutrients - potassium, magnesium, phosphorus and copper. Plums protect our health and prevent serious diseases because this fruit is rich in antioxidants. Depending on the variety, plums are harvested from the second half of August till the end of September [7]. The dark skin varieties are the most valued because they are extremely rich in antioxidants, phenols and catechins, and they also have a high content of neochlorogenic and chlorogenic acids [8]. Because of their low calorie content , they are recommended in the reduction diets [9]. Wang et al. (*2016*) [10] proved that the plums have several times higher antioxidant capacity than the apples. They can be consumed fresh, but they can also be processed into jam, compote, preserves and cloudy fruit juice, whereas considerable quantities are dried or frozen [7].

2. MATERIAL AND METHODS

Plums (*Prunus domestica L.*) of the Stanley variety were collected at a plantation in the vicinity of Prokuplje (Toplica district). The fruit for testing was selected at the beginning of September, based on acceptable appearance, lack of damage, acceptable size and color. Hand-picked fruit was transported in polyethylene containers to the laboratory for further analysis. The pitted samples of fruit intended for freezing were frozen in the Frigoscandia continuous tunnel. The process of freezing lasted 10 to 15 minutes at an air temperature of - 35°C to - 40°C within the tunnel , so that a temperature of - 18°C was reached and stabilized in the thermal center of the fruit.

The following parametres were analyzed for the purpose of this work: dry matter content, pH value, acid content (such as citric), total sugar content, vitamin C content, total phenol content and anthocyanin content . All the analyses were performed on fresh and frozen fruit. In addition, microbiological quality control of the fresh and the frozen plum fruit was performed. All the analyses were carried out in the laboratory of the Department of Agricultural and Technological Studies at the Toplica Academy of Applied Studies in Prokuplje. 10 repetitions of tests were carried out. The dry matter content was determined refractometrically from the chopped samples of fresh and frozen plum fruit, using an Abbe refractometer [11].

The mother solution was prepared in such manner that a homogenized sample of fresh or frozen fruit was covered with a certain volume of hot distilled water, heated and filtered after cooling. The filtrate was used to determine the pH value, total acidity and the total sugar content.

The pH value was determined using a pH meter, the sufficient volume of the mother solution being taken for the immersion of the electrode [11]. The total acid content was determined by acid titration using a standard sodium hydroxide solution in the concentration of 0.1 mol/dm3, in the presence of the phenolphthalein indicator. The result was expressed in % as citric acid [11].

The total sugar content was determined by the volumetric method according to Luff-Schoorl. This method is based on the principle that the reducing sugars convert copper (II)-sulfate from Luff's solution into copper (I)-oxide. The result was expressed in % [11].

The content of vitamin C was determined by a spectrophotometric method based on the reduction of vitamin C with 2,4-dinitrophenyl hydrazine. The absorbance was measured at a wavelength of 510 nm. The vitamin C content was expressed as mg/100 g [12].

As for the anthocyanin content, it was determined spectrophotometrically, using the pH differential method according to Fuleki and Francis. The homogenized sample was extracted with 0.1% HCl in methanol. The resulting filtrate was used for analysis. The absorbances of plum extracts were measured at 510 and 700 nm in 0.025 M potassium chloride buffer (pH 1.0) and 0.4 M sodium acetate buffer (pH 4.5). The content of anthocyanin was expressed as mg equivalent of cyanidin 3-glucoside per 100 g [13].
Determining the content of polyphenolic compounds was performed according to the Singleton method [14] using the Folin-Ciocalteu reagent. The homogenized sample was extracted for one hour with 80% ethanol. After 5 minutes, distilled water, Folin-Ciocalteu reagent and 20% Na2CO3 were added to the filtrate . The absorbance was measured at a wavelength of 765 nm. A calibration curve of standard solutions of gallic acid was used for the determination of total polyphenols (mg of gallic acid/100 g of sample). All the measurements were carried out in triplicate, and presented as mean ± SD.
The microbiological quality control included testing for food spoilage bacteria *Salmonella spp., Listeria monocytogenes, Enteriobacteriaceae*. All the methods were performed on the basis of ISO standards, namely ISO 6579-1:2017 for *Salmonella spp*. , ISO 11290-1:2017 for *Listeria monocytogenes* , ISO 21528-2:2017 for *Enterobacteriaceae* , ISO 16649-1:2018 for *E. coli*.

3. RESULTS AND DISCUSSION

The results of the chemical analysis of fresh and frozen plum fruit of the Stanley variety are presented in Table 1.

Table 1. Chemical analysis of fresh and frozen plum fruit of the Stanley variety

Fruit	pH	Acidity (total acidity as citric %)	Dry matter (%)	Total sugars (%)
fresh	2.98 ± 0.130	1.58 ± 0.07	18.4 ± 0.527	16.5 ± 0.726
frozen	2.52 ± 0.07	1.95 ± 0.07	17.0 ± 0.701	16.0 ± 0.866

The concentration of anthocyanins (mg/100g), vitamin C (mg/100g) and total polyphenols (mg of gallic acid/100g) in fresh and frozen plum fruit are presented in Table 2.

Table 2. The concentration of anthocyanins, vitamin C and total polyphenols in fresh and frozen plum fruit

Fruit	Anthocyanins mg/100g	Vitamin C mg/100g	Total polyphenols mg of gallic acid/100g
fresh	70.24 ± 0.633	5.84 ± 0.09	175.2 ± 0.667
frozen	65.42 ± 0.386	4.2 ± 0.02	124.5 ± 0.882

A comparative analysis of the Stanley plum variety was performed in this paper, both in the fresh and the frozen state. The results showed that the pH value of the fruit is expectedly lower in the frozen state. In the fresh fruit of the tested variety, the acidity is lower compared to the frozen fruit, which is consistent with the change in pH value. The obtained values of acidity (as citric acid) of the fresh fruit are in accordance with literature data [15]. There is no significant difference in the proportion of dry matter when comparing the fresh (18.4 ± 0.527 %) and the frozen fruit (17.0 ± 0.701). The share of dry matter of the fresh fruit is lower

compared to literature data [16], while the research by Pashova *(2016)* [17] showed the same content of dry matter. The content of total sugars in the fresh fruit showed no significant deviations in relation to the frozen fruit, while Bozhkova *(2014)* [15] and Pashova *(2016)* [17] determined a lower sugar content in the fresh fruit.
The difference in chemical composition can be significant depending on the production-related factors, but also on the conditions that occurred after the harvest [18]. The results of the anthocyanin content testing in the fresh and the frozen state showed significant deviations. The fresh fruit had a higher concentration of anthocyanins (70.24 ± 0.633 mg/100g) than the frozen fruit (65.42 ± 0.386 mg/100g). The lower concentration of total anthocyanins in the frozen state was due to the change in the pH value and the temperature of the fruit processing [19]. The research of Miletić et al. (*2012*) [20] found a much lower concentration of anthocyanin content in the fresh fruit of the Stanley variety. The difference in the anthocyanin content can be explained by the differences related to the geographical area, agro-ecological conditions and the year of cultivation.
The comparative analysis of the vitamin C content (5.84 ± 0.09 mg/100 g) was in accordance with the research of Pashkov*(2016)* [17], while there were deviations in relation to the research of Bozhkov *(2014)* [15] , which determined a higher content of vitamin C (11.92 mg/100 g). The amount of vitamin C in the frozen fruit decreased. The content of total polyphenols in our research (175.2±0.667mg GAE/ 100g) was in accordance with the results of research by Kim et al. (2003) [8]. A lower content of polyphenols was also observed in the frozen fruit compared to the fresh.
The classic microbiological test according to ISO standards, which is used for the detection and enumeration of food spoilage agents and potential opportunistic pathogens in humans, showed a lower frequency of microorganisms of the *Enterobacteriaceae* family and the absence of *Salmonella* spp., *Listeria monocytogenes*.

Table 3. The results of the microbiological testing of the frozen plum fruit

Microorganisms	Method designation	Determined value
Salmonella spp.	SRPS EN ISO 6579-1:2017	no presence determined
Enterobacteriaceae	SRPS EN ISO 21528-2:2017	< 10 cfu/g
L. monocytogenes	SRPS EN ISO 11290-1:2017	no presence determined

4. CONCLUSION

Considering that plums are one of the most important fruit species grown in our country and that they are used extensively in nutrition, every research of the chemical composition and the microbiological control of this fruit is extremely important. Each year, large quantities of plum yields are frozen, so it is important to examine the chemical composition and the microbiological properties of the fruit in frozen state. The results of our research of the Stanley variety showed that the fresh plum fruit is rich in anthocyanins, vitamin C and polyphenols, whereas these values decrease in the frozen state. The microbiological control of the fruit quality in fresh and frozen state showed a lower presence of the microorganisms of the *Enterobacteriaceae* family and the absence of *Salmonella* spp. and *Listeria monocytogen*es. Future research should be focused on examining the concentration of individual anthocyanins in different varieties of plums from our region, in the fresh and the frozen state.

Abstract: *In recent decades there is a strong demand for limitation or completely elimination of synthetic food additives since it has been confirmed their harmful effect on human health. At the same time, application of medicinal herbs and spices for the same purposes is gaining more importance since certain plant species represent a rich source of bioactive compounds that can effectively prevent undesirable microbiological and chemical changes in food. However, the application of medicinal herbs and spices as food additive is often subject to numerous limitations. Optimizing the conditions for isolation of targeted bioactive compounds, purification of isolates, low yields and limited application due to the changed sensory characteristics of the food to which they are added, are just some of the challenges that researchers encounter. Therefore, in this paper will be represents the main challenges and limitations that researchers and food producers are most often faced in the application of medicinal herbs and spices as natural substitutes for synthetic ones.*
Keywords: Food additives, Challenges, Phytochemicals, Medicinal herbs, Spices

1. INTRODUCTION

The confirmed harmful effect of certain synthetic additives on human health places a strong demand on food producers to search for an alternative ways and equally effective substitutes. These expectations force the food industry in the use of antioxidant, anti-browning and antimicrobial ingreadiens with more natural origin, safely promoting the shelf-life and quality of foods [1]. Medicinal herbs and spices are recognised as one of valuable source of active compounds. These botanical row material have high contents of phytochemicals that could be used in food industry, pharmaceuticals, health supplements and cosmetics. Large amounts of phytochemicals (phenolics, flavonoids, carotenoids and volatile compounds) are responsible for wide range of biological activities including antioxidant, antibacterial, antihypertensive, antitrombotic i immunomodulatory [2,3]. The use of medicinal herbs and spices dates back to 5000 B.C. so they might be considered one of the first functional foods [4]. Although the use of medicinal herbs and spices for flavoring and extending the shelf life of food products is not recent, they are mostly used in tea formulations and row material for isolation of essential oils which could be partly attributed to the lack of knowledge on chemical profile and bioactive potential of underutilized plants [3]. However, there is the great interest of researchers and food producers for application of these valuable natural ingredients in food. So far, most common essential oils are approved by Food and Drug Administration of United States (FDA) as generally regarded as safe (GRAS) [4,5]. In Europe, European Food Safety Authority (EFSA) already registered many volatile consitutents of essential oils such as citral, *p*-cymene,

[1]astojicevic@atssb.edu.rs
[2]tmarinkovic@atssb.edu.rs
[3]astevanovic@atssb.edu.rs
[4]mpuric@atssb.edu.rs

limonene, carvone, cinnamaldehyde, menthol and thymol as safe food flavoring aromatizing agents. EFSA also ruled many essential oils for use in feed of animal husbandry, and it is a matter of time when their usage will be extended on food products as well [5].
Nowadays, the focus of researchers and food producers is on isolates of medicinal herbs and spices, their extraction in the most purified form, in an economical and environmentally friendly way. In this responsible work, they encounter numerous limitations and challenges related to the proper selection of the extraction technique and conditions. Also, full implementation of this supstitution is postponed by some challenges associated with bioactive ingredients, including their low chemical stability, off-flavor, low solubility and short-term effectiveness [1].
Therefore, in this paper will be represents the main challenges and limitations that researchers and food producers are most often faced in the application of medicinal herbs and spices as natural substitutes for synthetic ones.

2. CHALLENGES AND LIMITATIONS ASSOCIATED WITH CHEMICAL COMPOSITION AND MANUFACTURING OF THE MEDICINAL HERBS AND SPICES

The use of medicinal herbs and spices is associated with chemical composition of isolated extracts and essential oils. Many factors such as season of harvest, environmental conditions, region of cultivation, plant parts used, and type of processing can affect the levels and mechanisms of various compounds in extracts. All above factors are limiting for the reproducibility of the composition of herb extracts and essential oils so characterization and authentication of active compounds are necessary to be established quality control procedures [6].
Also, application of medicinal herbs and spices essential oils demands safety assessment. Depending on the dose of exposure, the potential benefits of phytochemicals in medicinal herbs and spices might be changed and reversed to toxic effects including carcinogenic, neurotoxic, genotoxic, teratogenic, cytotoxic, nephrotoxic, hepatotoxic and gastrointestinal toxic effects [7].
In this respect, specific protocols for essential oils chemical and toxicological analyses were developed as well as approved guides for processing and the safety restrictions for the volatile components content in essential oils as the synergistic and antagonistic effect may arise for specific essential oil. In case of medicinal plant and spices extracts, studies concerning the toxicity of the most promising extracts are major challenge for their use. Most extracts have not been evaluated so, the lack of this information regarding the actual toxicity of many extracts in concerning, since the adverse effects caused by the misuse of medicinal herbs and spices are characterized as a public health problem [6]. The solution for this challenge lays in permanent control and setting up the production standards.
Besides that, there is a rising aspect of medicinal herbs and spices safety in their possible contamination by chemicals such as pesticides [2].

3. CHALLENGES AND LIMITATIONS ASSOCIATED WITH EXTRACTION TECHNIQUE AND CONDITIONS

Extraction is a first critical step since it is necessary to extract the desired phytochemicals from the plant materials [8]. Well standardized procedures are mandatory, but it is not simple to establish a standardized extraction method for each plant source [8,9]. Process optimization is usually on a case-by-case basis and should be thoroughly investigated for each plant species [3].
Selection of proper technique and optimal extraction conditions for the isolation of active compounds form medicinal herbs and spices is one of the key steps. The choice of an appropriate extraction method depends on the nature of the plant material, solvent used, pH of the solvent, temperature, solvent to sample ration as well as use of the final products [10]. Conventional isolation techniques of bioactive compounds (maceration, percolation, Soxhlet extraction) are characterized by a number of disadvantages: low yield, long extraction time, high solvent consumption, cost and negative enviromental impact and thermal decomposition of thermolabile compounds and additional costs in

the form of processing and purification of isolates [9,11,12]. Many of these limitations have been avoided by developing alternative, nonconventional extraction techniques, or by improving existing ones. Depending on the type and mechanism applied for modification of the process, nonconventional techniques could be accelerated by ultrasounds, microwaves, enzymes, high pressure (subcritical and supercritical solvents), electric fields (pulsed electric fileds and high voltage discharge) and others [3]. In case of extraction of volatiles, the combination of conventional techniques with new methodologies has increased yields, purity and quality of volatiles [5].For the solvent extraction, the selection of the solvent is crucial. Selectivity, solubility, cost, reactivity and safety should be considered in selection of the solvents [10,11]. The properties of a good solvent for herbal plant extraction also include low toxicity, easy evaporation, inability to cause the extract to form complexes, preservative action and promotion of rapid physiological absorption of the extract [8]. Traditional extraction techniques usually involved large quantities of organic solvents which caused additional costs in term of purification of isolate. Furthermore, these solvents have substantially high costs, as well as environmental and human toxicity, even if they are present in traces [3]. Novel extraction techniques support concept of „green“ solvent which is aimed to minimize the negative environmental impact from the utillization of large amounts of solvent [9].
Another important step is purification of the isolate. This step is neccesary in case non-selective extraction procedure is applied, so several undesirable components are also co-extracted and may interfere targeted active compounds [13]. Therefore, the usage of high selective techniques or some of techniques which comprise extraction and purification is required.

4. CHALLENGES AND LIMITATIONS ASSOCIATED WITH FOOD INGREDIENTS AND SENSORIAL PROPERTIES

Influence on the activity of bioactive compounds could also have the characteristics of the food to which medicinal herbs and spices are added. External factors (storage conditions, type of packaging, characteristic of microorganisms that cause spoilage) as well as internal (the presence of interfering compounds such as fat, proteins, water, antioxidants, other additives and pH reaction) can have different influence the effectiveness of the active compounds [4,14].
The main limitation of usage medicinal herbs and spices as food additive is their influence on sensory characteristics of food. The complex nature of food requires higher concentrations of active compounds to achieve the same efficacy as *in vitro* conditions. On the other hand, higher concentrations are limited by development of negative organoleptic characteristics in food. These limitations can be overcome with several strategies: the use of synergistic interaction with other additives or combined action with heat treatment or vacuum-packaging. On the other side, medicinal herbs and spices in form as essential oils may be used in active packaging by incorporating low essential oil concentration in food packaging films [2,4]. Encapsulation into micro- and nano emulsions is other confirmed strategy to overcome these limitations. This approach allows the use of higher concentrations without the undesirable effects on sensorial properties of food or interacting with the food components and, at the same time, enables preservation of thermolabile components [5,14].

5. CONCLUSION

Medicinal herbs and spices are recognized as valuable source of active compounds which can contribute to food preservation and shelf life extension. Isolates of these plants represent a promising substitute for synthetic additives. However, the use of these herbs as food additive encounters numerous challenges and limitations associated with plant material, food ingredients and extraction procedure of active compounds. So far, several strategies have been developed to overcome them, but it is up to competent institutions and researchers to set certain standards and protocols in order to ensure the safest possible application.

Abstract: *Polycyclic aromatic hydrocarbons (PAHs) are among the most toxic compounds known to man. Several PAHs are proven to be carcinogenic, mutagenic and teratogenic. Due to their wide distribution in the environment and their toxicity, it is considered important to monitor the levels of these compounds in foodstuff. PAHs have been detected in many foods including plant-based such as vegetable oils, cereal grains, herbs, spices, teas and supplements. As the awareness for the healthy lifestyle has increased globally, the intake of medicinal herbs as tea and spices has also grown immensely. Therefore, even stronger emphasis must be made to monitor the toxic levels of PAHs in herbs. The legislations of the maximum concentrations of certain contaminants in food of the Republic of Serbia included PAHs values in dry herbs only by the end of 2019 (Official Gazette RS, No. 81/2019) in comparison to European Commission Regulation dating from 2011. Therefore, herein we focused on analytical method development for PAHs determination in medicinal herbs.*
Keywords: PAHs, medicinal herbs, validation, processing, HPLC-FLD

1. INTRODUCTION

Polycyclic aromatic hydrocarbons (PAHs) are organic compounds consisting of two or more condensed aromatic rings, they are toxic and have carcinogenic properties, and they are widespread in the environment [1]. PAH compounds can be produced naturally or anthropogenically. Naturally, a certain amount of PAHs in our region reaches the biosphere as a result of forest fires and hydrothermal processes. In urban [2] and industrial locations [3], PAHs are almost entirely emitted by human activity and are the main by-products of incomplete combustion of organic matter, and therefore become the main source of atmospheric pollution. These compounds from the air reach the soil and water environment through sedimentation or precipitation, from where they further reach fruits, vegetables and herbs, and finally the human body. People are exposed to PAHs in different ways. For non-smokers, the main source of exposure is the consumption of food and drink, as well as supplements. The special danger of PAHs for human health is due to their ability to bioaccumulate in the human body [4].

[1]milica.sentic@ihtm.bg.ac.rs
[2]trajkovic@ihtm.bg.ac.rs
[3]ivana.dersek@sepa.gov.rs
[4]slobodan.cvetkovic@ihtm.bg.ac.rs
[5]zoran.stojanovic@sepa.gov.rs
[6]onjia@tmf.bg.ac.rs

The natural presence of wax on plant surfaces can concentrate low molecular weight PAHs, mainly through surface adsorption. The concentration of PAHs is generally higher on the surface of the plant (outer leaves, bark) than in the interior [5]. However, the origin of PAHs in fruits, vegetables and herbs is mainly of anthropogenic origin. Pollution of raw products (agricultural products) occurs during cultivation, growth, but also during transportation due to the deposition of aromatic hydrocarbons present in engine exhaust gases as well as during storage [6].
In order to put on the market products that are healthy and safe for human health, the criteria of standards and maximum allowed concentrations prescribed by the provisions of national and EU regulations must be met. There are a large number of different PAHs, however, for the research and monitoring of their concentrations in environmental samples (water, air, soil, treated waste, sludge) the European Union and the American Environmental Protection Agency (Eng. Environmental Protection Agency, EPA) defines only 16 of them as priority (European Commission, 2005). PAHs known for their carcinogenic, teratogenic and mutagenic properties are: benzo[a]anthracene and chrysene, benzo[b]fluoranene, benzo[j]fluoranene, benzo[k]fluoranene, benzo[a]pyrene, benzo[gy]perylene, coronene, dibenzo[a,h]anthracene, indeno[1,2,3-cd]pyrene and ovalene. Although these 16 PAHs are highly relevant for environmental monitoring programs, they have not entered food legislation. Historically, benzo[a]pyrene has been used as the sole marker of toxicity; however, data have shown that foods, herbs, and food supplements contain toxic PAHs without the presence of benzo[a]pyrene. A re-evaluation by the European Food Safety Authority (EFSA) suggests that at least a subset of four PAHs, designated as PAH4, should be monitored in food. PAH4 compounds are benzo[a]pyrene, chrysene, benz[a]anthracene and benzo[b]fluoranthene. In the Republic of Serbia, the maximum allowed concentration of PAHs is regulated by the Rulebook on Maximum Concentrations of Certain Contaminants in Food, Official Gazette RS, No. 81/2019, which entered into force in November 2019 [7]. The maximum permitted concentration of benzo[a]pyrene in dried herbs is 10 μg/kg, while the maximum permitted concentration for the sum of PAH4 compounds is 50 μg/kg.
The development of analytical methods for PAHs should now focus on this subgroup. In terms of analytical methods, EU legislation on food contaminants follows a "criteria approach". This means that the legislator does not prescribe specific analysis procedures, but allows laboratories to use different analysis methods, if they can be objectively shown to meet the analytical requirements prescribed by the relevant legislation. The analysis of PAHs in herbs is a challenging endeavour, as there are isobaric PAHs that interfere with the quantification of the PAHs of interest. Seeds and raw plants can be contaminated with PAHs through artificial drying and heating during processing if precautions are not taken.

2. MATERIAL AND METHODS

Preliminary tests based on a literature review and already existing standardized methods for determining the content of polycyclic aromatic hydrocarbons for other matrices such as water (SRPS EN ISO 17993:2008, ISO 28540:2011, SRPS EN 16691:2016) were performed on three different chromatography methods including measurements on a gas chromatograph, a gas chromatograph connected to a mass spectrophotometer and a high-performance liquid chromatograph (HPLC) with a fluorescence detector. After preliminary tests, HPLC with a fluorescence detector (HPLC-FLD) was chosen as a satisfactory chromatographic method according to the modified ERA 8310 standard. Determination of polycyclic aromatic hydrocarbons (PAHs) in medicinal and herbal plants was done by liquid chromatography with a fluorescence detector (LC-FLD) according to the modified ERA 8310 standard method.

2.1 Concentration range of the method

The concentration measurement range of the method for determining the content of PAHs, using the HPLC-FLD technique, is 4.0-200 μg/L.

2.2 Principle of the method

2.2.1. Polycyclic aromatic hydrocarbons from dried herb samples were extracted with methylene chloride in an ultrasonic bath. The extract was purified and evaporated to near dryness in the absence of light and the solvent exchanged with acetonitrile. Analytes were separated by liquid chromatography [8] and identified and quantified on a fluorescent detector (HPLC-FLD).

2.2.2. The methylene chloride extract is purified from the presence of plant pigments and fatty acids on a silica gel column.

2.3 Preparation of sample for testing

2.3.1. A 2.00 g sample of dried herbal tea was soaked in 20 ml of water and left to hydrate well for 2 hours. Then, by liquid-liquid extraction, the aqueous solution is extracted with 2x5 ml of methylene chloride. The collected organic extracts were purified over silica gel and evaporated almost to dryness in the dark and the residue was dissolved in 2 ml of acetonitrile in an autosampler vial.

2.4 Interferences

The cleanliness of laboratory glassware, solvents, and reagents was checked. For this purpose, extraction vials were taken and carried out the entire analytical procedure. The obtained value was the value of the blank sample, blank test. The value obtained by analysing the blank sample was not included in the calculation, but it did not exceed 10% of the sample value.

2.5 Reagents

2.5.1 Reagents: Solvent for extraction, pesticide grade, or organic pollutant residues, methylene chloride, CH_2Cl_2, Solvent for modification, quality for pesticides, or for residues of organic pollutants; Acetonitrile; Mobile phase solvent, pesticide grade, or organic pollutant residues; Acetonitrile; Water (deionized); Water in which the presence of interfering peaks at the lower limit of detection of the analytes examined by this method was not found. Solvents used for sample preparation (toluene/methylene chloride/cyclohexane/acetonitrile) were of chromatographic grade. Solvent chromatograms showed no PAH interfering peaks.
The stock standard solutions were prepared in the appropriate solvent and stored in vials with Teflon-lined stoppers in the refrigerator. Intermediate mix standard solutions were prepared by diluting the stock standard solutions with acetonitrile. Calibration standard solutions were prepared by diluting the intermediate standard solution with acetonitrile - concentration range for PAH 1.0-200 µg/L.

2.5.2 Instruments
HPLC-FLD (AgilentTechnologies 1260 FC-AS, Quaternary pump – AgilentTechnologies 1260 Infinity, Autosampler – AgilentTechnologies 1260 ALS, Tremostat for the column - AgilentTechnologies 1290 thermostat.); Agilent Technologies ZORBAX Extend C18 Reverse Phase Separation Column, Rapid Resolution HD, 1.8 µm (particle size), 150 mm (length) x 2.1 mm (inner diameter); Ultrasonic bath; Fridge.

3. RESULTS AND DISCUSSION

3.1 Method validation

The method for determination of the content of PAHs in dried herbs using the HPLC-FLD technique was applied and validated on the instrument Agilent 1260 FLD Spectra with a fluorescence detection according to the modified standard ERA 8310. The limit of detection (LOD) and limit of quantification (LOQ) of the analytical method and the standard method were determined using blank samples that were treated in the same way as real samples.

Table 1. Limit of quantification

Analyte	LOD*	LOQ*	LOQ (methods)
Benzo(a)anthracene	0.8	0.9	1.25
Chrysene	1.0	1.2	1.25
Benzo(b)fluoranthene	0.5	0.8	1.25
Benzo(a)pyrene	0.6	0.8	1.25

** data obtained on the basis of OpenLabCDS,* LOD= ≤1.0 µg/kg, LOQ=≤4.0 µg/kg

Linearity was tested in a range of different concentrations for each analyte individually on a series of standard solutions prepared according to a standard procedure. Linearity is confirmed because the correlation coefficient (R^2) is greater than 0.999.

Table 2. Linearity in the range 1.25-200 µg/L

Linearity		
Analyte	y= Ax+B	R^2
Benzo(a)anthracene	y=177.92x +2.3658	0.9997
Chrysene	y=21.175x -0.0144	0. 9993
Benzo(b)fluoranthene	y=233.87x +1.9446	0. 9999
Benzo(a)pyrene	y=453.54x +6.2165	0. 9997

Recovery - spiked samples of dried elderberry were prepared by added known concentrations of each analyte and their content was determined.

Table 3. Recovery SANTE/11312/2021 70-120%; repeatability SANTE/11312/2021 %RSD ≤ 20%

Analyte	Recovery 1.25 µg/L			Recovery 20.0 µg/L			Recovery 100.0 µg/L		
	%	stdev	%	%	stdev	%RSD	%	stdev	%RSD
Benzo(a)anthracene	83.7	0.59	82.2	82.2	0.74	0.94	79.6	0.64	0.85
Chrysene	79.8	0.17	77.7	77.7	0.32	0.43	74.5	0.47	0.66
Benzo(b)fluoranthene	89.6	0.23	88.5	88.5	0.34	0.34	88.0	0.53	0.53
Benzo(a)pyrene	80.3	0.35	80.7	80.7	1.49	1.51	74.4	1.22	1.24

3.2 Method application

The content of polycyclic aromatic hydrocarbons was determined for four forms: benzo[a]anthracene, benzo[a]pyrene, benzo[b]fluoranthene and chrysene, as their sum PAH4 in accordance with the regulations of the Republic of Serbia on maximum concentrations of certain contaminants published in the Official Gazette RS, No. 81/20191, Article 2 of Annex 2, Section 6, in force since November 2019. The maximum permitted concentration of benzo[a]pyrene in dried medicinal herbs is 10 µg/kg, while the maximum permitted concentration for the sum of PAH4 compounds is 50 µg/kg. Samples were collected after drying. From 25 analysed samples four different samples of medicinal herbs contained a higher concentration compared to the reference limit values of the corresponding regulation.

4. CONCLUSION

Determination of the content of benzo(a)anthracene, chrysene, benzo(b)fluoranthene and benzo(a)pyrene in dried medicinal herbal using the technique of liquid chromatography with a fluorescence detector (HPLC-FLD) according to the modified standard ERA 8310, can be considered validated and put into routine operation.

Abstract: *A phase inversion concentration method was used in the preparation of pumpkin seed oil nanoemulsions for the encapsulation of turmeric extract. pH, refractive index, texture properties, morphology and stability of the nanoemulsions were studied. The optimal formulation that composed of 0.14% pumpkin seed oil, 2.2% surfactant Tween 80, 98% water and 0.02% turmeric extract is transparent, stable with smaller particle sizes and values for pH 5.27, RI 1.331, firmness 36.09 g, consistency 521.32 g·s. cohesiveness – 22.10 N and index of viscosity -11.07 N·s.*
Keywords: nanoemulsions, pumpkin oil, turmeric extract, stability.

1. INTRODUCTION

Nanoemulsion is a colloidal dispersion of two immiscible liquids: water in oil (W/O) or oil in water (O/W), stabilized by surfactants. It comprises droplets with a diameter ranging from 10 to 500 nm, mainly droplets from 10 to 200 nm. Nanoemulsion with a droplet size from 50 to 200 nm is transparent, while milky appearance is characteristic for droplet size to 500 nm. In the preparation of nanoemulsions, high-energy methods (high-pressure homogenization, microfluidization, and ultrasonication) and low-energy methods (phase inversion emulsification and self-emulsification) can be applied [1]. Nanoemulsions developed as delivery systems of drugs and bioactive substances with high efficiency to prevent the occurrence of creaming, flocculation, coalescence, and sedimentation, also, to protect bioactivity and to improve bioavailability are characterized by various applications mainly in cosmetics, pharmaceutical and food industries [2]. A promising application of nanoemulsions results in improving the barrier and mechanical properties of the packaging, which ensures the quality, safety, and extended shelf life of food products [3].
Turmeric (*Curcuma longa* L., fam. Zingiberaceae) is one of the most cultivated plants with a long tradition of use in food as a spice, preservative, and agent for colour and flavour. The curcuminoids, namely curcumin are the main biologically active turmeric compounds that possess a wide range of biological activities such as antioxidant, antimicrobial, anti-inflammatory, anticancer, etc. Curcumin is a hydrophobic substance, low soluble in water, very sensitive to light, and low bioavailability. At the same time, curcumin related to its spicy taste, significantly changes the sensory properties of the products where it is added [4]. For those reasons, possibilities to encapsulate pure curcumin or turmeric extract in lipophilic formulations such as nanoemulsions are being explored. High- and low-energy methods, various types of surfactants and sources of lipid phase in the formulation and preparation of nanoemulsions of curcumin or turmeric extract are used [5]. Application of these nanoemulsions is directed to improve the organoleptic and chemical characteristics, and shelf life of food products such as canned ham, cheese or food beverages [6,7] or in the prevention and treatment

[4]vesna@tmf.ukim.edu.mk

of some health problems for example against tumour incidence and metastasis, or as an antimicrobial and wound healing agent in burn wound infection [8,9].
In this study, the phase inversion concentration method was used in the preparation of nanoemulsions of pumpkin seed oil with turmeric extract. The influence of the nanoemulsion composition on the pH, refractive index, texture properties, morphology and stability was studied.

2. MATERIALS AND METHODS

2.1 Materials

Cold press pumpkin seed oil (Super Group Doo, Skopje, Republic of North Macedonia), surfactant Tween 80 (polyoxyethylene sorbitan monooleate, Sigma–Aldrich, Germany) and turmeric powder (BioCosmos, Skopje, Republic of North Macedonia) were used.

2.2 Preparation of turmeric extract

Turmeric powder (10 g, 0.1 mm particle size) was extracted by using the Soxhlet method with ethanol (250 mL) for 300 min at ethanol boiling temperature. The solvent was removed from the extract by rotary vacuum evaporator (Devarot Elektromedicina, Slovenia) at 40°C and 200 mPa. The extract was dried at 40°C and 105 mPa in a vacuum drier (Heraeus Instrument Vacuterm, Germany), cooled in a desiccator and weighed. The steps of drying, cooling and weighing the turmeric extract were repeated until the difference between two consecutive weights was smaller than 2 mg.

2.3. Nanoemulsion preparation

Nanoemulsions were prepared using cold press pumpkin seed oil (PO), Tween 80 (T80), distilled water (DW), and turmeric extract (TEX) in proportions given in Table 1. Firstly, the oil phase composed of pumpkin oil (PO), surfactant Tween 80 (T80) and turmeric extract (TEX) was prepared by mixing on a magnetic stirrer (VWR IKA VMS-C7, Radnor, PA, USA) at 800 rpm and a temperature of 25°C for 30 min. The distilled water was titrated drop by drop into the oil phase with constant stirring on a magnetic stirrer (800 rpm). After the titration was completed, the resulting dispersion continued to be stirred for 30 min.

Table 1. Nanoemulsion formulations

Sample	Concentration in formulation (%)				Ratio (g/g)			
	PO	T80	DW	TEX	DW/PO	T80/PO	TEX/PO	DW/ T80
E1	1.00	9.0	90	0.05	90	9	0.05	10

PO-Pumpkin seed oil. DW-distilled water. T80-Tween 80. TEX-Turmeric extract

2.4. Nanoemulsion characterization

pH values. pH values of nanoemulsion were determined at room temperature using a pH meter Mettler Toledo SevenEasyTM S20 (Switzerland). A constant pH value in the samples for 15 min was achieved.
Refractive index (RI). Abbe refractometer (WAY 2W Solid, Kirkland, WA, USA) was used to measure the RI values by placing one drop of nanoemulsion on the slide at 25°C. The RI value of DW used in the nanoemulsion preparation was 1.330.
Texture profile analysis. TA-XTplus Stable Micro System (UK) with the penetration test was used. The gel sample (75 mL) was poured into a glass beaker (100 mL with 50 mm diameter) avoiding air introduction and assuring a smooth upper sample surface. The " Mayonnaise Back Extrusion" method at a 25 mm distance and 10 mm/s speed was applied to measure nanoemulsion properties: firmness (g), consistency (g·s), cohesiveness (N) and index of viscosity (N·s).
Stability test. All samples were stored at 20°C for 24 h before undergoing the stability test by applying the "heating-cooling cycle" and "centrifugation test". At the "heating-cooling cycle" stability test the samples were submitted to three cycles of 48 h at 40°C in the refrigerator and then 48 h at 4°C in the thermostatic chamber. "Centrifugation test" - 1.5 g sample measured in Eppendorf was centrifuged at 5000 rpm and room temperature for 30 min by using Heraeus Biofuge Fresco centrifuge (UK). The instability of the samples visually was evaluated.
Morphology: One drop of nanoemulsion samples placed on a glass slide was observed under the optical microscope (M–100–FL, Konus, Italy) equipped with a digital camera (Vario–Tessar 8x, Sony, China), at a magnification of 40x.

3. RESULTS AND DISCUSSION

The values of the pH, RI and texture parameters determined for nanoemulsion formulations composed of pumpkin seed oil and turmeric extract are presented in Table 2.

Table 2. Nanoemulsion formulations

Sample	pH	RI	Texture parameters			
			FI±SD (g)	CN±SD (g·s)	CH±SD (N)	VS±SD (N·s)
E1	4.33	1.329	36.03±0.08	519.23±0.73	-21.84±0.34	-10.52±0.60

E1–E13-composition refers to Table 1. RI-refractive index. FI-Firmness. CN-Consistency. CH-Cohesiveness. VS-Index of Viscosity. SD-standard deviation. Mean value (n = 5).

pH. pH values ranged from 4.24 to 4.67 for samples E1-E4 where the ratio of water (DW) to Tween 80 (T80) was 10:1 w/w. By increasing the water content in the formulations pH values increased. The highest pH values were determined for samples E11-E13 formulated at the highest ratios DW/T80

(67:1 and 78:1 w/w). Increasing the concentration of surfactant (T80) in the formulation positively influences pH values. At a 600:1 w/w ratio of water (DW) to pumpkin seed oil (PO), pH values increased from 5.41 to 5.89 by increasing the ratio of T80/PO from 9:1 to 12:1 w/w, respectively. The resulting pH values from 4.53 to 6.4 are within the pH tolerance range (4.5 to 6.5) which is still safe for the skin (Table 2). Increasing surfactant concentration causes an increase in the pH because the used surfactant has a pH between 6÷8.6 [10]. Curcumin nanoemulsion prepared by applying ultrasound using clove oil as lipid phase, surfactant Tween 80 and PEG-400 as co-surfactant were characterised with pH 7.4 [9].

RI values. In the samples prepared at the lowest DW/PO ratio, respectively, 60:1 w/w (E2) and 45:1 w/w (E1), the highest RI values, 1.456 and 1.454, were determined. At a constant DW/PO value (600:1 w/w) by increasing the T80/PO ratio to 10:1, 11:1 and 12:1 w/w, the RI increased from 1.357 to 1.367 (Table 2). RI values close to water determined in other prepared formulations (Table 2) indicate transparency and isotropic stability of nanoemulsions, and small-sized particles [11].

Texture properties. The firmness and consistency increased for the nanoemulsions formulated at a higher quantity of T80. Increasing the quantity of oil caused a decrease in the values of firmness and consistency. The nanoemulsions (E1 to E7) prepared with a surfactant and oil ratio (T80/PO) of 9:1 w/w were characterized by the constant values of firmness and consistency, around 36 g and 530 g·s, respectively. In the nanoemulsions E8-E10 with the highest values for T80/PO the firmness increased to 68.65 g, while in the nanoemulsions E11-E13 increased values of firmness to 96.32 g are significantly influenced by the increased quantity of water. The influence of the quantity of oil phase, surfactant and water does not affect the cohesiveness and viscosity index. The cohesiveness ranged from -21 to -22 N, while the viscosity index values were from -7.81 to -11.26 N·s (Table 2).

Stability. Figure 1 shows the visual appearance of nanoemulsions after stability testing with the "heating-cooling cycle" method. The samples E1-E3 were evaluated as unstable due to the visible destabilization that occurred. Separation of lipid and aqueous phase was visible for sample E3 which was prepared with the lowest values for DW/PO (45:1 w/w), T80/PO (4:1 w/w), and DW/T80 (11:1 w/w). The samples E4-E7 prepared with 9:1 w/w T80/PO by increasing DW/T80 from 33:1 w/w to 60 w/w were highly in transparency without visible phase separation. Increasing the T80/PO ratio and DW/T80 ratio, the nanoemulsion samples (E8-E13) were low in transparency and high instability, susceptible to creaming and visible separation of oil droplets on the surface. A negative influence of the increased surfactant quantity on the nanoemulsion stability was reported in the literature [12].

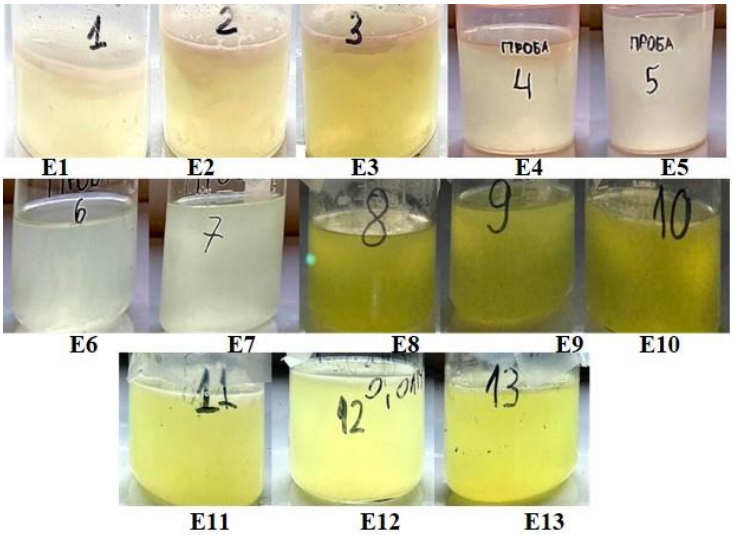

Figure 1. A visual appearance of the nanoemulsions after "heating-cooling cycle" stability testing (3 cycles, 48 hours at 40°C and 48 hours at 4°C)

After applying the centrifugation method, phase separation was observed in nanoemulsions E1-E4 and E8-E13. In contrast, formulations E5-E7 show high stability and homogeneity (Figure 2).

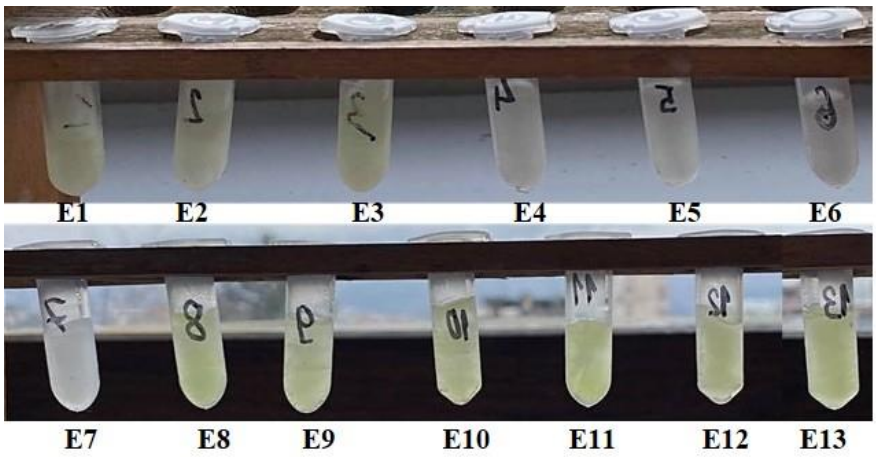

Figure 2. A visual appearance of the nanoemulsion formulations after stability testing by centrifugation method (5000 rpm, 30 min)

The microscopic appearance of the nanoemulsions is presented in Figure 3. The higher quantity of water and turmeric extract in E8-13 formulations increased the particle size. Small particles and narrow particle size distribution were determined in formulations E4-E7 that are characterized by RI values close to water, satisfactory transparency and stability without visible phase separation. The morphology, particle size and size distribution of the prepared pumpkin seed oil nanoemulsions with encapsulated turmeric extract are under high influence of the composition that corresponded with the literature findings [9,10].

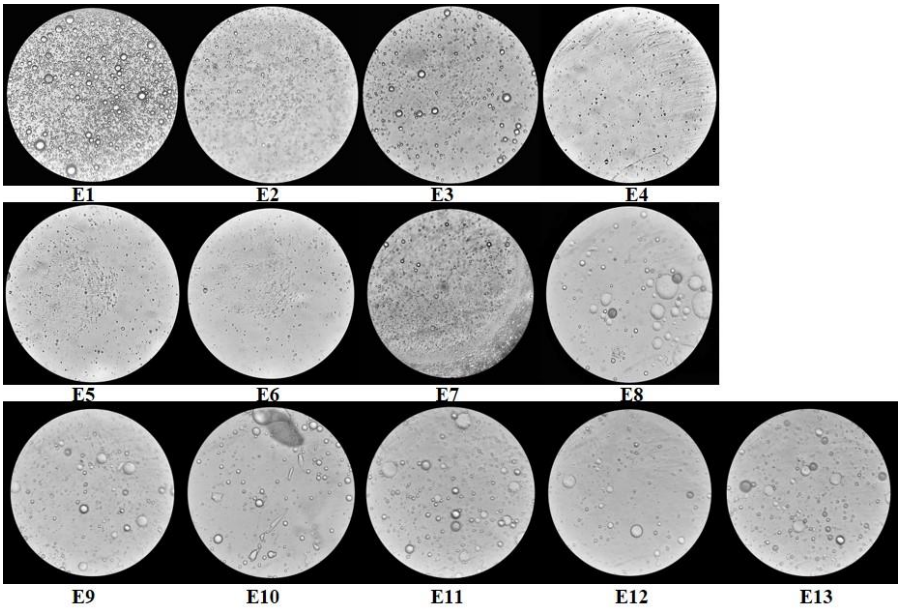

Figure 3. Microphotograph of nanoemulsion formulations, 40x (E1-E13 correspond to samples given in Table 1)

4. CONCLUSION

Based on the results, it can be concluded that increasing the ratio DW/PO and DW/T80, pH values and particle size increased, while RI values, transparency and stability decreased. Nanoemulsions prepared with a T80/PO ratio of 9:1 w/w, show a high degree of transparency and stability, small particle sizes and a larger distribution of smaller sizes. pH values, firmness and consistency of the nanoemulsion decreased by increasing the quantity of the pumpkin seed oil. The satisfied values of evaluated parameters were obtained for the nanoemulsion prepared with a ratio DW/PO of 500:1 w/w, 9:1 w/w T80/PO, 0.1:1 w/w TEX/PO and 58:1 w/w DW/T80.

FORMULATIONS OF CARBOXYMETHYL CELLULOSE-BASED EMULGELS WITH TURMERIC EXTRACT

Jana Klopcevska[1], Faculty of Technology and Metallurgy, University in Skopje
Zoran Kavrakovski[2], Faculty of Pharmacy, University in Skopje
Marija Srbinoska[3], Scientific Tobacco Institute-Prilep, University "St. Kliment Ohridski"-Bitola
Vesna Rafajlovska[4], Faculty of Technology and Metallurgy, University in Skopje

Abstract: *This study aimed to formulate a stable carboxymethyl cellulose based emulgel formulation loaded with turmeric extract and coconut oil. Emulgels were evaluated for their visual appearance, microstructure, pH, refractive index, texture, colour profile, and stability. The obtained results indicated that the characteristics of emulgels are highly influenced by the concentration of gelator carboxymethyl cellulose and oil phase coconut oil. The emulgel formulations were stable at 4℃, while at 48℃ the phase separation was observed. Particles were smaller in emulgels formulated at lower concentrations of carboxymethyl cellulose and coconut oil. Developed formulations have a potential for transdermal delivery of turmeric extract.*
Keywords: emulgel, carboxymethyl cellulose, turmeric extract, stability.

1. INTRODUCTION

Emulsion gels also known as emulgels or emulsion-filled gels are soft solid materials in which one phase in the emulsion, either continuous or dispersed phase, forms a 3D gel network structure with oil droplets incorporated. These emulgels as functional colloids show a great potential application in the food industry in improving the quality of food products related to the thermodynamic stability, texture modification, and incorporation of various functional lipophilic and hydrophilic compounds. The emulgels increase the bioaccessibility indicating the fast release and solubilisation of the encapsulated compounds in the aqueous phase in the gastrointestinal tract. According to the nature of the biopolymers included in the composition, the emulgels are classified as polysaccharide-based (alginate, starch, or pectin), protein-based (milk proteins, gelatine, soy proteins), and mixed-based emulgels formulated of proteins and polysaccharides, and different types of proteins or polysaccharides [1,2].
Curcumin is a biologically active compound of the turmeric plant (Curcuma longa L.), highly effective in the prevention of some health problems such as cancer, obesity, infections and cardiovascular diseases or in reducing the conditions of inflammation or metabolic syndrome. Due to the wide range of bioactive properties, there is increasing interest in incorporating curcumin into food products as a natural agent for flavouring, colouring, and increasing shelf life [3]. The limitations of applications in foods associated with poor solubility of curcumin in water, as well as its reduced bioavailability and high sensitivity to light, can be overcome by encapsulation within biological matrices that are based on lipids, proteins and polysaccharides such as liposomes, emulsions or gel structures [4,5]. This study aimed to incorporate curcumin in the form of turmeric extract into the oil phase of the gel-like structure based on carboxymethyl cellulose. The influence of the emulgel

composition on the pH, refractive index, texture properties, colour parameters, microstructure and stability was studied.

2. MATERIALS AND METHODS

2.1 Materials

Carboxymethyl cellulose sodium salt (Mw~90000, DS=0.7, Merck KGaA, Germany), organic coconut oil (Vitalia Healthy Food, Republic of North Macedonia), turmeric powder (BioCosmos, Republic of North Macedonia), and analytical grade ethanol (96%*v/v*, Alkaloid AD Skopje, Republic of North Macedonia) were used in this study.

2.2 Preparation of turmeric extract

Soxhlet extraction of turmeric powder (0.1 mm particle size) was carried out for 300 min with ethanol as a solvent with a ratio of solid to liquid phase of 1:25 w/v and extraction temperature corresponding to the boiling point of ethanol. The solvent released the extract by rotary vacuum evaporator at 40°C and 200 mPa (Devarot Elektromedicina, Slovenia). The solvent traces were removed by drying in a vacuum drier (Heraeus Instrument Vacuterm, Germany) at 40°C and 105 mPa, followed by cooling in a desiccator and weighed. The steps of drying, cooling and weighing the turmeric extract were repeated until the difference between two consecutive weights was smaller than 2 mg.

2.3. Preparation of emulgels

Emulsion gels were prepared using carboxymethyl cellulose (CMC), distilled water (DW), coconut oil (CO), and turmeric extract (TEX) in proportions as described in Table 1. The CMC was dispersed in DW and gelation was carried out on a magnetic stirrer (VWR IKA VMS-C7, Radnor, PA, USA) at 800 rpm and a temperature of 85°C for the time of 1 h. In the obtained homogeneous viscous CMC gel cooled to 30°C the oil phase was added continuing with stirring at 800 rpm, temperature of 30°C for 15 min until obtaining a homogeneous mixture. The oil phase for the samples with turmeric extract was prepared by mixing TEX in CO on a magnetic stirrer (800 rpm, 30°C, 15 min).

Table 1. Emulgel formulations

Sample	Ratio (g/g)			
	DW/CMC	DW/CO	CO/ CMC	TEX/CO
G1	100	100	1	/
G2	100	67	1.5	/
G3	50	25	2	/
G4	100	100	1	100
G5	100	67	1.5	75
G6	50	25	2	80

CMC-carboxymethyl cellulose. DW-Distilled water. CO-coconut oil. TEX-turmeric extract.

2.4. Emulgel characterization

pH value. The samples were homogenized with DW in a ratio of 1:10 before pH measuring using a digital pH meter Mettler Toledo SevenEasyTM S20 (Switzerland). A constant pH value in the samples for 15 min was achieved.

Refractive index (RI). RI was measured with an Abbe refractometer (WAY 2W Solid, Kirkland, WA, USA) with an accuracy of ±0.001 nD at a temperature of 25°C. The RI value of DW used in the sample preparation was 1.330.

Texture profile analysis. TA-XTplus Stable Micro System (UK) with the penetration test was used. The gel sample (75 mL) was poured into a glass beaker (100 mL with 50 mm diameter) avoiding air introduction and assuring a smooth upper sample surface. The "Shampoo Back Extrusion" method at a 15 mm distance and 10 mm/s speed was applied to measure gel properties: firmness (g), consistency (g·s), cohesiveness (N) and index of viscosity (N·s).
Colour parameters. L* lightness (100-white/0-black), a* (+red/-green) and b* (+yellow/-blue) were measured using a Dr. Lange spectra colorimeter (UK). The gel samples were placed in a 1 cm cell. L*, a*, and b* values were determined at a D65 light source and 10° observer angle. The standardized values for a white plate were L* = 95.93, a* = −0.19, and b* = 3.12. Chroma (C*), huge angle (h°), whitening index (WI) and yellowish index (YI) were calculated by using equations (1-4).

$$C^* = [(a^*)^2+(b^*2)]^{1/2} \quad (1)$$
$$h^o = \arctan(b^*/a^*) \quad (2)$$
$$WI = 100 – [(100 - L^*)^2 + (a^*)^2 + (b^*)^2]^{1/2} \quad (3)$$
$$YI = 142.86 \cdot b^*/L^* \quad (4)$$

Stability test. All samples were stored at 20°C for 24 h before undergoing the stability test by applying the “heating-cooling cycle” and “centrifugation test”. A “heating-cooling cycle” test was performed in three cycles, each cycle for 2 days. The temperature in the refrigerator was 4°C and 40°C in the thermostatic chamber. “Centrifugation test” - 1.5 g of gel sample measured in Eppendorf was centrifuged at 5000 rpm for 60 min at room temperature by using Heraeus Biofuge Fresco centrifuge (UK). The instability of the samples visually was evaluated.
Morphology: One drop of samples placed on a glass slide was observed under the optical microscope (M–100–FL, Konus, Italy) equipped with a digital camera (Vario–Tessar 8x, Sony, China) under 40x magnification. The drop was coloured with methylene blue.

3. RESULTS AND DISCUSSION

Table 2 presents the values of the pH, RI and texture parameters determined for carboxymethyl cellulose-based emulgels with turmeric extract and coconut oil.

Table 2. Characteristic of emulgel formulations

Sample	pH	RI	Texture parameters			
			FI±SD (g)	CN±SD (g·s)	CH±SD (N)	VS±SD (N·s)
G1	5.01	1.338	51.75±0.75	413.44±4.22	-10.29±1.15	-21.04±0.34
G2	4.94	1.340	76.17±1.03	504.46±2.64	-13.17±2.08	-48.94±1.25
G3	5.32	1.346	160.94±2.15	968.52±1.18	-57.50±0.73	-66.43±0.98
G4	5.15	1.339	49.77±1.05	383.35±1.25	-11.63±0.64	-23.83±1.82
G5	4.83	1.344	75.74±2.61	499.96±2.43	-12.16±0.83	-41.59±1.43
G6	4.95	1.348	116.54±3.15	724.67±3.09	-34.19±1.45	-56.85±1.04

G1–G6-composition refers to Table 1. RI-refractive index. FI-Firmness. CN-Consistency. CH-Cohesiveness. VS-Index of Viscosity. SD-standard deviation. Mean value (n = 5).

pH. pH. In the emulgels samples pH values ranged from 4.83 to 5.32. The influence of the emulgel composition on the pH was not significant (Table 2). The pH values of formulated CMC-based emulgels are in the range of pH tolerance values (4.5-6.5) that are required for topical products to ensure compatibility and skin safety [6]. Emugels with pH 4 could protect and control the release of curcumin by protecting some proteins from pepsin digestion and controlling the release of fatty acid. Related to the curcumin release rate and bioavailability at the intestinal stage, the emulgels with pH 6 showed the highest values, followed by the samples with pH 5 and pH 4 [7].

RI values. RI of all formulations were close to that of water as the external phase. The emulgel samples with turmeric extract (G4-G6) were characterised by higher RI values instead of the emulgels without turmeric extract (G1-G3). In the sample of emulgels formulated at the highest concentration of CMC and coconut oil, G3 and G6, the highest RI values were determined, 1.346 and 1.348, respectively (Table 2). The RI values determined in carboxymethyl cellulose-based emulgels with coconut oils and turmeric extract are comparable with RI data given in the literature [8], confirming their o/w structure and thermodynamical stability.

Texture properties. The quantity of gelator CMC and oil phase CO used affected the emulgel firmness. At higher CO concentrations in the formulations, softer emulgels were obtained. The CMC positively influenced the consistency of emulgels. The determined values for firmness and consistency were higher in emulgels without turmeric extract (G1-G3). Emulgel (G3) formulated at a ratio DW/CMC of 50:1 w/w and ratio CO/CMC of 2:1 w/w was characterized by the highest firmness (160.04 g) and consistency (968.52 g·s). At the lower concentration of CMC, the cohesiveness and viscosity index of the emulgels decreased. The CO quantity positively affected the cohesiveness and viscosity index, while turmeric extract decreased those parameters (Table 2). The CMC to 1.5% w/w provided the formation of a more uniform and compact gel network structure [9]. Increasing the virgin coconut oil to 10% w/w positively influences the emulgel texture profile [10].

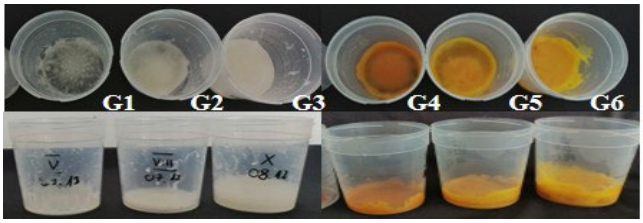
Table 3. Colour parameters of emulgel formulations

Parameter	Formulation					
	G1	G2	G3	G4	G5	G6
L*	35.48±0.92	34.59±0.61	33.48±0.97	50.47±1.34	51.90±0.82	52.19±1.34
a*	0.35±0.10	0.15±0.06	0.19±0.04	-17.55±0.85	-10.66±0.76	-10.88±0.85
b*	-6.70±0.51	-4.04±0.31	-4.33±0.31	44.49±0.24	46.68±0.48	47.18±0.14
C*	6.71±0.48	4.04±0.29	4.33±0.52	47.83±0.11	47.88±0.89	48.42±0.24
h°	92.99±2.08	92.13±0.84	92.51±0.36	111.53±1.13	102.86±0.78	102.99±1.37
WI	35.13±0.56	34.47±0.17	33.34±4.32	/	/	/
YI	/	/	/	125.93±1.64	128.49±0.69	129.15±1.04

G1–G6-composition refers to Table 1. L*-lightness (100-white/0-black). a* (+red/-green). b* (+yellow/-blue). C*-Chroma. Huge angle (h°). WI-Whitening index. YI- Yellowish index. SD-standard deviation. Mean value (n = 5).

Colour parameters. The values of the colour parameters determined in CMC emulgels are presented in Table 3. In terms of the L* parameter, emulgels without turmeric (G1-G3) are darker, than whiter emulgels with turmeric extract (G4-G6). The higher concentrations of CMC and CO insignificantly decreased the whitening index (WI). Turmeric extract increased the values of b, C, and h°. Increasing TEX quantity positively influenced the yellowish index (YI). Influence of the coconut oil on WI values is confirmed in the literature [10].

Stability. During stability testing in a thermostat at 40°C in the emulgel formulated with the lowest concentration of CMC (G1) visible small droplets of CO were observed, while no visible changes were detected in samples G2 and G3. In samples with turmeric extract, surface drying (G4) and insignificant phase separation (G5 and G6) were determined (Figure 1A). In samples, G1 and G3, formulated with a DM/CMC ratio of 100:1 w/w and CO/CMC of 1:1 w/w, the phase separation was observed. At a lower ratio of DM/CMC and a higher ratio of CO/CMC (sample G2, G3, and G5, G6), no changes in appearance were determined after testing at a temperature of 4°C (Figure 1B). In all formulated emulgel samples, phase separation appeared after applying the centrifugation method at 5000 rpm for 60 min (Figure 1C).



A.

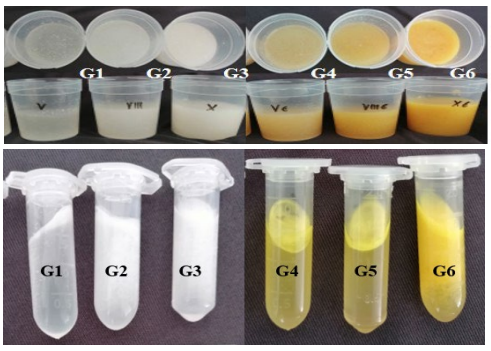


Figure 1. A visual appearance of the emulgels after stability testing with a "heating-cooling cycle" (3 cycles, 48 hours at 40°C-A and 48 hours at 4°C-B) and centrifugation method

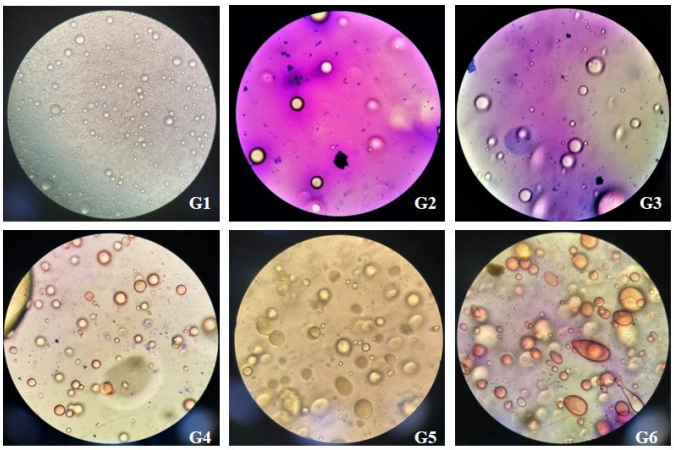

Figure 2. Microphotograph of emulgel formulations, 40x (G1-G4 correspond to samples given in Table 1)

Figure 2 shows the microstructure of the emulgels. The micrographs revealed that the emulgels studied consisted of a complex dispersion of turmeric extract in coconut oil droplets embedded in a matrix formed by a carboxymethyl cellulose gel. Small particles and narrow particle size distribution were determined in formulation G1. In the emulgel samples, G2 and G3, larger droplets were observed. The turmeric extract emulgels exhibited variations in particle size. The largest particles with visible deposition of turmeric extract in coconut oil were observed in sample G6 which is composed of the lowest ratio of water to carboxymethyl cellulose (50:1 w/w) and the highest ratio of coconut oil to carboxymethyl cellulose (2:1 w/w). The larger particles caused the instability of the emulgels which was confirmed by the stability testing at a temperature of 40°C presented in Figure 1. At elevated temperatures, the viscosity of the formulation reduces which may allow the globules to collide, subsequently resulting in increased globule size [11].

4. CONCLUSION

Based on the results, it can be concluded that the studied characteristics (pH, refractive index, texture, colour parameters, stability and microstructure were highly affected by the emulgel composition.

Abstract: *In this study, the potential of mullein leaf (Verbascum Thapsus) as a ground powder for the biosorption of Cu(II) ions from synthetic solutions was examined. Several factors affecting the biosorption efficiency of mullein leaf powder were investigated, including the initial Cu(II) concentration (25–400 mg L^{-1}), solution pH (3–7), contact time (10–120 min.), and biosorbent dosage (2–20 g L^{-1}). The concentration of Cu(II) ions before and after biosorption using inductively coupled plasma optical emission spectrometer was determined. The biosorption efficiency of 58.74% was observed at a biosorbent dosage of 20 g L^{-1} and an initial Cu(II) concentration of 100 mg L^{-1}. Also, the good biosorption efficiency of 50.74% Cu(II) was reached at a contact time of 90 min. The optimal solution pH was determined to be 4, but the highest removal efficiency of 64.27% for Cu(II) was determined at pH=7. Thus, mullein leaf shows the potential of a cost-effective biosorbent for wastewater treatment, but further investigation of modified mullein will be applied.*
Keywords: Biosorption, Non-toxic plant biomaterial, Copper(II)

1. INTRODUCTION

Heavy metals in polluted waters and industrial effluents are considered as a threat to living organisms and may cause many diseases. Among all existing metals, copper is included in the group of essential trace elements, but high concentrations of copper are toxic to most life forms [1, 2]. In recent years, detailed studies on the copper impacts to human health have been conducted and because of adverse effects, significant research has been performed for treatments of removing copper from contaminated water [3]. Some of the proposed treatment methods were: ion exchange, adsorption, membrane separation etc. These conventional methods require high investment, and that is why researchers focus on the use of low-cost and locally-available materials for cheaper and environmentally friendly methods for water treatment [4]. Such a method is biosorption, treatment that uses sorbent materials with high binding affinity and surface area [5]. Various biosorbents can be used for copper-containing wastewater treatment, such as agricultural waste, which includes walnut, pistachio, rice straw, corn, orange, pine cone, straw, tea waste, local seashells etc. [6]. Mullein (*Verbascum thapsus*) is a tea waste generated from local tea supplier after the expiration date. According to the [2] mullein surface has C–H, C–O, O–H, C=O and COO– groups that can be used for the binding of metals; it also contains phenol, alkaloids, tannins, saponins, flavonoids, and triterpenoids.
The purpose of this study was to investigate the use of mullein leaves powder as biosorbent for the removal of Cu(II) ions from synthetic solutions.

[1] mnujkic@tfbor.bg.ac.rs

2. MATERIALS AND METHODS

The stock solution of copper sulfate (1 g L^{-1} Cu(II)) was prepared using deionized water. Samples of washed, dried and grounded mullein were collected from a local supplier of tea, Adonis, Serbia. Additionly, waste mullein was previously grounded in a blender, and then sieved to get particle size below 1 mm. Prepared biosorbent was stored in the paper bags until biosorption experiments.

2.1 Biosorption experiments

The biosorption of Cu(II) ions using waste mullein was performed in copper synthetic solutions (50 mL of each solution), at room temperature. The effects of initial biosorbent dosage (2–20 g L^{-1}), contact time (10–120 min.), solution pH (3–7), and initial Cu(II) concentration (25–400 mg L^{-1}) on biosorption were investigated, at a speed of 600 rpm. After filtration, Cu(II) ions concentration in treated sample solutions, were determined using an inductively coupled plasma optical emission spectrometer (ICP-OES Optima 8300; Perkin Elmer, USA). Biosorption efficiency (E, %) and adsorption capacity (q, mg g^{-1}) of waste mullein were determined using equation (1) and (2), respectively [4]:

$$E\ (\%) = \frac{C_0 - C_e}{C_0} \times 100 \quad (1)$$

$$q = \frac{C_0 - C_e}{m} \times V \quad (2)$$

where *Co* and *Ce* are initial and equilibrium Cu(II) concentrations in the synthetic solution (mg L^{-1}), *m* is mass of waste mullein (g) and *V* is volume of Cu(II) solution (L).

3. RESULTS AND DISCUSSION

3.1 Effect of biosorbent dosage

The effect of the biosorbent dosage of mullein on the removal of Cu(II) ions from the synthetic solution was investigated with five different biosorbent dosages (2, 8, 12, 16, 20 g L^{-1}) under the following conditions: contact time 90 min, solution pH = 4, temperature at 25°C, and initial Cu(II) ion concentration 100 mg L^{-1} (Fig. 1). The results showed that increasing mullein dosage until an effective level of 20 g L^{-1} enhanced the adsorption efficiency of Cu (II) ions, resulting in a biosorption efficiency of 58.74% for Cu (II) ions. This may be a result of the initially available active sites and negative surface charge of the mullein which can favour electrostatic attraction between sorbent and solute [7]. As can be seen in Fig. 1., as the biosorbent dosage increases, the adsorption capacity considerably decreases. Consequently, increasing the amount of mullein biomass gradually increases the final removal of metal ions, but it also leads to reduction of active sites and adsorption capacity of mullein [8]. Therefore, the optimum mullein dosage was achieved at 20 g L^{-1} for further experiments analysis.

3.2 Effect of contact time

The effect of contact time (10, 40, 60, 90, 120 min.) for biosorption of Cu(II) ions at pH = 4 for initial metal concentration of 100 mg L^{-1} by using 20 g L^{-1} of mullein was investigated and shown in Fig. 2. The results indicated slower increase of biosorption efficiency and adsorption capacity of mullein till a good degree of adsorption was achieved at 90 min for Cu(II) ions. The maximum biosorption efficiency and adsorption capacity at contact time were 50.74% and 2.54 mg g^{-1} for Cu(II), respectively. After 90 min., the biosorption rate decreases because the equilibrium condition was

achieved due to repulsive forces on the mullein surface [4]. The optimal contact time of 90 min was used for further analysis.

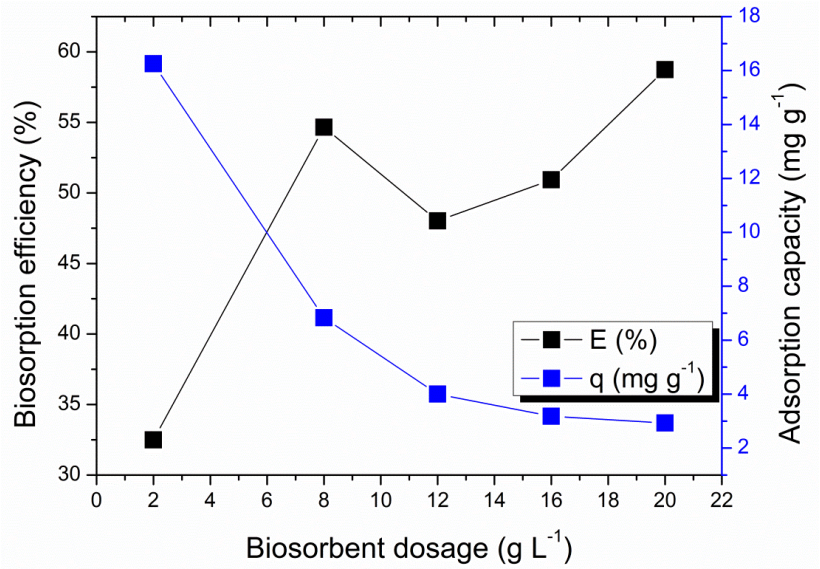

Figure 1. Effect of biosorbent dosage on adsorption capacity and efficiency of Cu(II) ions from synthetic solutions

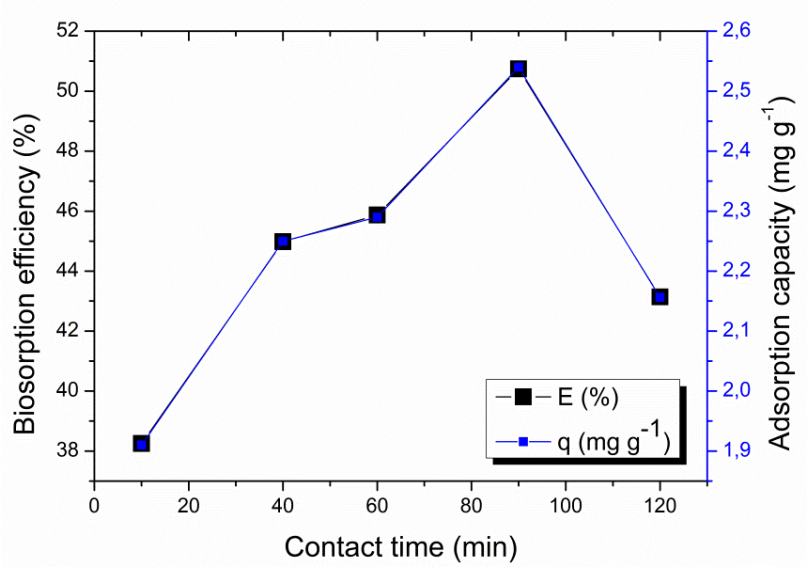

Figure 2. Effect of contact time on adsorption capacity and efficiency of Cu(II) ions from synthetic solutions

3.3 Effect of solution pH

Biosorption processes are highly pH dependent, because H^+ ion concentration may influence the charged biosorbent surface and the ionization degree of various contaminates. The effects of initial pH (3, 4, 5, 6, 7) on biosorption efficiency of Cu(II) ions were investigated by optimal contact time at 90 min and an initial Cu(II) concentration of 100 mg L^{-1} by using 20 g L^{-1} mullein. The biosorption efficiency of Cu (II) ions was raised by increasing the pH values, as shown in Figure 3.

Based on the results, it can be observed that the highest biosorption efficiency and adsorption capacity were observed at pH = 7. At higher pH, biosorption of Cu(II) ions can occur under the lower H^+ ion concentration, which further produces more negatively charged binding sites. This could free the functional groups on mullein surface, and in this way can be more suitable for Cu(II) ions adsorption

[5, 9]. The finding wasn't in agreement with the recently published result [2], where for the optimal pH value for Cu(II) biosorption using grounded mullein particle size below 2 mm, was 4.

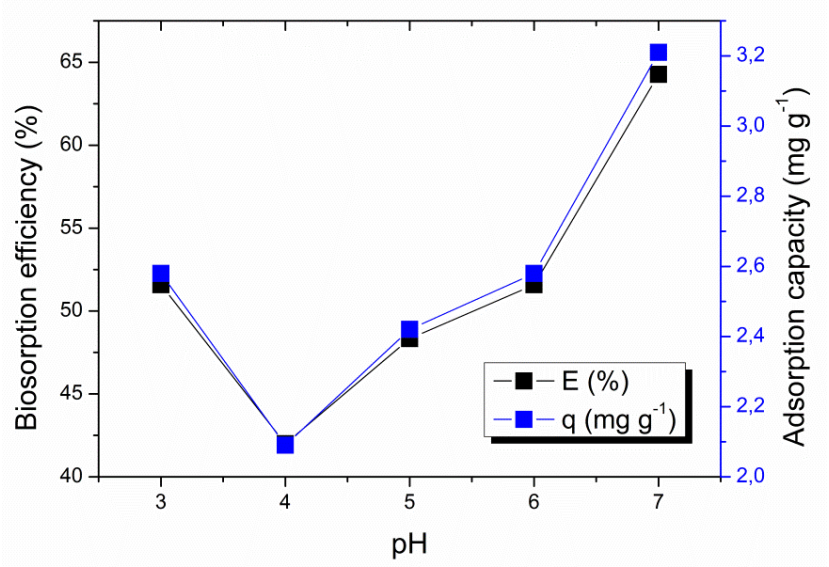

Figure 3. Effect of pH on adsorption capacity and efficiency of Cu(II) ions from synthetic solutions

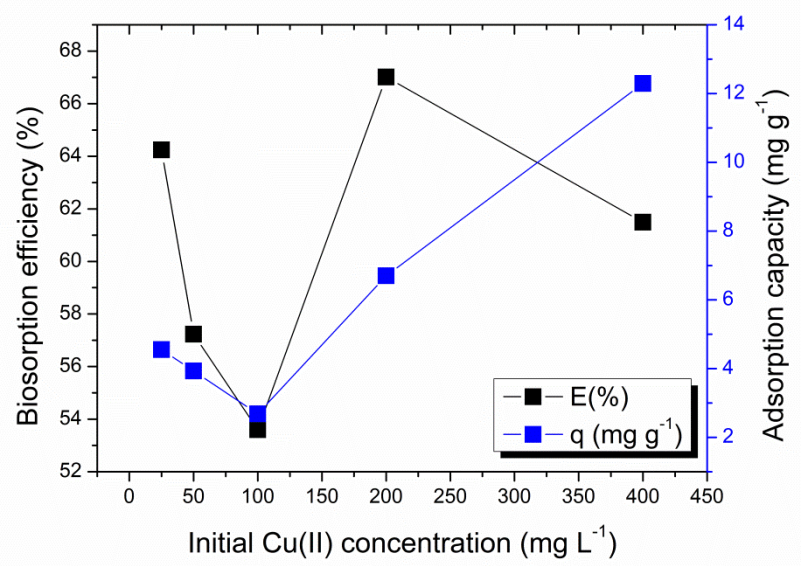

Figure 4. Effect of the initial Cu(II) concentration on adsorption capacity and efficiency of Cu(II) ions from synthetic solutions

3.4 Effect of the initial Cu(II) ions concentration

Initial Cu(II) ions concentration (25, 50, 100, 200, 400 mg L^{-1}) effect on biosorption efficiency of mullein was studied at previously optimized parameters (pH = 4, temperature of 25°C, contact time 90 min, and biosorbent dosage of 20 g L^{-1}). The results are presented in Fig. 4. It can be observed that an increase in the initial Cu(II) ion concentrations from 25 to 100 mg L^{-1}, leads to a decrease in biosorption efficiency and adsorption capacity. However, a further increase in the Cu (II) concentration resulted in an increase in Cu(II) removal. The highest removal efficiency (67.01%) of Cu(II) ions was observed with an initial Cu(II) ions concentrations of 200 mg L^{-1}. The results indicated that mullein gives maximum removal potential for Cu(II) ions at their higher initial concentrations. Higher initial concentrations lead to quick saturation of the mullein binding sites because the quantity of biosorbent stays constant [4]. However, a further increase in the Cu(II)

concentration resulted in a biosorption efficiency decrease. It can be seen that the highest removal efficiency (67.01%) using 20 g L^{-1} mullein was lower than results, given in our previously published paper [2], of copper removal (~79%) for 2 g L^{-1} mullein. Therefore, the initial Cu(II) ions concentrations of 100 mg L^{-1} was utilized for further experimental analysis.

4. CONCLUSION

This study presents the use of natural resource, a nontoxic edible plant and cost-effective biosorbent in wastewater treatment for biosorption of Cu(II) ions from synthetic solutions. Mullein with biosorbent dose of 20 g L^{-1} showed a good potential for biosorption of Cu(II) ions as compared to mullein with biosorbent dose of 2 g L^{-1}. Precisely, the maximum removal of Cu(II) ions was 67.01% at the initial Cu(II) ions concentration of 200 mg L^{-1}. Overall, it could be inferred that 2 g L^{-1} mullein was able to remove Cu(II) ions more effectively from Cu(II) solutions than the mullein of 20 g L^{-1} under the same conditions (pH=4, t=25°C, contact time of 90 min., and initial Cu(II) ions concentrations of 100 mg L^{-1}). For further investigations, the mullein could be examined under other various conditions or as new modified sorbent under the same conditions.

POSSIBILITIES OF PRODUCTION OF A NEW FUNCTIONAL PRODUCT – MAYONNAISE WITH REDUCED FAT CONENT

Višnja Sikimić[1], The Academy of Applied Technical Studies Belgrade
Slavica Čabrilo[2], The Academy of Applied Technical Studies Belgrade
Nada Jelić, Agricultural school with home of students "Sonja Marinkovic" Požarevac

Abstract: *Excessive consumption of fat leads to various health problems, and for this reason, food with a reduced proportion of fat, which in addition to its nutritional content also has health benefits (functional food), is increasingly sought after. A product with a high proportion of fat (60-80%) is mayonnaise, a semi-solid emulsion of oil and water, with the addition of vinegar and egg yolk, salt and spices (optional). The high total caloric value, the intake of cholesterol derived from eggs and the rapid autoxidation of unsaturated fatty acids of the lipid fraction are the reasons that encourage researchers to search for new mayonnaise formulations. Substitutes for fat in mayonnaise can be carbohydrate-based (cereals, legumes, chia seeds, pumpkin seeds) and protein-based or their combination. The possibility of replacing whole or partial egg yolk with soy, wheat, and milk proteins is also being investigated. By the way, low pH and high fat content make mayonnaise an emulsion stable for microbes, but mayonnaise with reduced fat content requires additional ingredients to maintain stability, and natural antioxidants, phytosterols, prebiotics and probiotics that give mayonnaise and added value are being researched as such additives. This paper presents the possibilities for the production of functional mayonnaise.*
Key words: *mayonnaise, reduced fat content, functional product*

1. INTRODUCTION

Mayonnaise is the oldest and most commonly used sauce in today's world, it is a semi-solid emulsion of oil in water, with a large proportion of fat (65-80%), with the addition of vinegar and egg yolk, salt and spices (most often mustard). Yolk is still mostly used as a supplement, due to its high emulsifying ability. A high proportion of fat, i.e. high energy value and cholesterol derived from eggs, makes mayonnaise a product that is undesirable from a health point of view. According to the recommendations of the World Health Organization for health, and in order to reduce chronic cardiovascular diseases and obesity, fat consumption should be reduced, and to this end, the food industry is researching suitable substitutes for fats, in formulating new functional products such as mayonnaise. The low pH and high fat content make mayonnaise an emulsion stable for microbes, but reduced-fat mayonnaise requires additional ingredients to maintain stability. There is an effort to produce mayonnaise with a lower fat content, i.e. a lower energy value, with the use of new emulsifiers, which will replace egg yolks and additional ingredients to maintain stability. Also today, there is an increasing demand for products, including mayonnaise with a clean label, i.e. so-called products "without additives", "minimum processing" and "short list of ingredients" [1,2,7,31]. In general, the production of a new product - functional mayonnaise implies the use of substitutes for fat and/or egg yolks and the addition of some functional ingredients to mayonnaise (prebiotics, antioxidants or phytosterols). This paper presents some possibilities for the production of mayonnaise with a reduced fat content, that is, the possibility of producing a new functional mayonnaise in which

[1] vsikimic@atssb.edu.rs
[2] scabrilo@atssb.edu.rs

part of the fat is replaced with carbohydrates or proteins and/or in which the egg yolk is partially or completely replaced, as well as the possibility of producing new mayonnaise formulations to which natural antioxidants, phytosterols, prebiotics and probiotics are added, which give mayonnaise and added value.

2. SUBSTITUTES FOR FATS IN MAYONNAISE

Oil-in-water emulsion is a very common form of food with many applications, especially in the fast food industry, which, like mayonnaise, has a certain texture, creaminess and taste thanks to fat, and for this reason fat substitutes must imitate the relevant properties in products with reduced by the proportion of fat. Rheological properties, such as viscoelasticity, thixotropy and stackability, which mayonnaise should possess, are also required from mayonnaise analogues with a low fat content. Fat substitutes in mayonnaise can be based on carbohydrates or proteins or their combination and are generally called fat mimics (mimetics), which cannot completely replace fat in food, but offer a similar mouthfeel and texture to fats. Carbohydrate-based fat substitutes are compounds derived from grains, legumes, and plants with digestible or indigestible carbohydrates. Studies have shown that corn dextrin, inulin, and polydextrose are the most acceptable fat substitutes in emulsion-based products. Modified rice starch, oat dextrin, inulin, pectin and konjac gel are also mentioned in the literature. Proteins with unique structure and functional properties, especially gelatin and whey protein, are often mentioned as fat substitutes. Whey proteins have a lower energy value (0-17. kJ/100g), but also the ability to coagulate a gel under different temperature and pH conditions. With microparticles, it covers the taste buds analogous to lipids, so this coating helps flavors to gradually reach the receptors and helps mask some astringent and bitter tastes in products with a low fat content. It is also very important that whey proteins have a generally recognized safe status (GRAS). which makes them suitable for use in food [4,6,9,21,27,33].

Starch-based fat substitutes are a type of fat mimetics that can be produced either chemically as modified starch or enzymatically as maltodextrins. Natural starch and modified starch are good fat substitutes because some starch granules have similar sizes and shapes to fat globules, which enables them to create a similar texture, i.e. they act like fat globules in modulating the structure and sensory characteristics of food. Modified starches increase water holding capacity and minimize starch syneresis, while maltodextrins can form thermoreversible gels [21,22]. Park J.J. et al (2020) examined the effect of using modified starch with 30% and 50% fat replacement on the physical stability of mayonnaise. Modified arrowroot starch (modified by octenyl succinic anhydride (OSA), annealing (ANN), citric acid hydrolysis (CA), acetylation (ACT), and heat moisture (HMT)) was used to replace fat in mayonnaise at 30% and 50% levels and different pastes with full-fat mayonnaise were compared. Mayonnaises with reduced fat content showed greater stability than full-fat emulsions. Those with starch obtained by annealing modification, OSA-starch and CA-starch were especially stable and are a suitable substitute for fat in mayonnaise [19]. In his research, Gaafar A. (2011) developed a light mayonnaise with the replacement of fat with mashed potato powder, at the level of 5, 10 and 15%, reducing the fat to 50% and the results showed a good potential for potato powder used as a substitute for fat in mayonnaise, i.e. all low-fat mayonnaise formulas have a significantly lower share of energy, a higher share of water, the color is better, the rheological characteristics are the same as those of commercial low-fat mayonnaise, and the microbiological picture was adequate during the entire storage period [13].

Although modified starch is used more in the food industry, because natural starch is not always suitable for all processing conditions, such as low pH, high temperatures and freezing, there is concern among consumers, even with some chemical modifications through which the ingredients of the status of safe are created (GRASS). Consumers are increasingly striving for natural ingredients and for this reason the demand for physical modifications of starch that will replace fat is growing. A study conducted by Werlang S. et al. (2021), confirmed the successful use of natural and heated oat starch as a natural fat replacement ingredient in mayonnaise. Annealing increased stability, smoothed texture, and reduced final viscosity, retrogradation, gel hardness, and gumminess. For both starches,

as the percentage of starch in the mayonnaise increased (0%, 50% and 75%), the stability of the mayonnaise increased [30].
In their research, Hosseinvand A. et al. (2019) used different levels of corn bran as a fat substitute for the production of low-fat mayonnaise. Four formulas were prepared including a control without corn bran, low-fat with 25% corn bran, low-fat with 50% corn bran and low-fat with 75% corn bran. Although the control formula without corn bran received the highest scores in some properties, such as texture, mouthfeel, viscosity and purchase intention, the low-fat mayonnaise samples had higher water activity and lower pH values during the storage period than the full-fat samples, the conclusion is that corn bran can be used in the formulation of low-fat mayonnaise as a fat substitute with acceptable physico-chemical and sensory properties [16]. Su H.P. et al. have developed a low-fat mayonnaise containing polysaccharide gums as functional ingredients. Xanthan gum ($15g/kg^{-1}$), citrus fibers ($100\ g/kg^{-1}$) and variable concentrations of guar gum were used to formulate optimal ratios of polysaccharide gums as a fat substitute. The proportion of fat in mayonnaise was reduced to 50% compared to full-fat mayonnaise, and the products still retained ideal rheological properties [26]. The complex of microparticles of whey protein and pectin proved to be a good gel-mimetic for the production of low-fat mayonnaise. A certain addition of fat mimetics (up to 60%) increased the stability of mayonnaise during storage, preventing coalescence and flocculation of droplets, and the application of fat mimetics (up to 40%) suppressed the reduced viscoelasticity of mayonnaise [27]. Research into functional foods with reduced fat content, such as is the addition of 6% pumpkin flour to mayonnaise with reduced fat, indicates a better physico-chemical quality of mayonnaise. Antioxidant compounds (carotenoids and polyphenols), as well as pectin in pumpkin flour, which serves as a stabilizer in the formulation of mayonnaise, and the composition of fatty acids (palmitic, oleic and linoleic), contribute to the functionality of this product [18]. One example of the production of mayonnaise with a low fat content is the formulation of an emulsion in which an emulsion gel made of alginate and konjac glucomannan is used, and which shows good thermal stability and stability during freezing and thawing [32].

3. SUBSTITUTES FOR YOLKS IN MAYONNAISE

The egg has excellent emulsifying properties, but there are some limitations such as the high cholesterol content and the possibility of contamination by *Salmonella sp.,* which is why in mayonnaise formulas it is tried to partially or completely replace the egg yolk. The use of vegetable proteins such as lupine proteins, soy proteins and pea proteins is the most common method for preparing emulsions, and one of the ways is also the use of egg yolk, which contains low cholesterol. Scientists have also investigated the use of animal proteins such as casein, protein whey and meat protein. A study done by Satriawan T.U. et al. (2022) showed that the use of whey protein concentrate as high as 15% gives the best low-fat mayonnaise [25].
One of the studies relates to the stability and rheological behavior (droplet size, microstructure, stacking ability, flow behavior and viscoelastic properties) of mayonnaise co-emulsified with konjac glucomannan at a concentration of 0.1-0.5% (w/w) and whey protein, at concentration of 1.0-3.0% (w/w) and the results showed that the mentioned mixture can be used as an efficient substitute for egg yolks in the production of cholesterol-free mayonnaise [20].The application of soybean oil as a substitute for egg yolks and as a raw material from which most of the mayonnaise is prepared also proved to be quite good, although the disadvantages were a low lecithin content and somewhat weaker stability and sensory properties. For this reason, Wang W. et al. (2022) conducted a study that showed that low-fat mayonnaise, where soybean oil was used as a substitute for egg yolk and in which xanthan gum, pectin and modified starch were added (ratio 2:1:1) as a stabilizer, it has good viscosity, stability, texture and microstructure. In addition, the storage stability was investigated and compared to whole yolk mayonnaise, this mayonnaise had better oxidative stability and bacteriostatic, which is important for mayonnaise storage [29].

The development of mayonnaise with the replacement of oil or egg yolk with the addition of chia mucilage (*Salvia Hispânica L.)* is something new when it comes to the production of a new functional mayonnaise. Chia mucilage is produced by the hydration of chia seeds and due to its properties such as the ability to emulsify and retain water, it can be used as a substitute for fat in various food products. In a study conducted by Fernandes S.S. et. al. (2018) mayonnaise was made with different levels of freeze-dried chia mucilage instead of oil or egg yolk. Replacing oil with chia mucilage in mayonnaise (45%) increased stability and improved texture, the proportion of lipids decreased by about 50% and sensory acceptability was good. When replacing the egg yolk, these properties were the same as with the control mayonnaise, i.e. it was not possible to significantly reduce the lipid content or maintain the stability of the emulsion [12]. The possibilities of using hydrocolloid emulsifiers, soy soluble polysaccharide, gum arabic and starch octenyl succinate were also examined, due to their ability to create oil-in-water emulsions such as mayonnaise. Xanthan gum was used as a stabilizer and/or thickener and the results showed a possible application [8].

4. ADDING SOME FUNCTIONAL INGREDIENTS TO MAYONNAISE

Milk protein, casein, which is a phosphoprotein, or a mixture of rice bran oil and casein powder or a mixture of rice bran oil and palm stearin are incorporated into some new mayonnaise formulations. Research has shown that mixtures of rice bran oil and palm stearin (7:3 and 6.5:3.5), as well as casein and rice bran oil (7:3 w/w) give a product that has a soft, creamy appearance, and in addition, due to the content of rice bran, it also contains antioxidants (oryzanol, squalene, tocopherols, tocotrienol) and polyunsaturated fatty acids such as linoleic [10]. According to the research of Vieira M.R. et. al. (2023), the use of fruit flour (apple, nectarine, pear and peach flour) in the production of mayonnaise as a substitute for sugar, preservatives and colors contributes to the incorporation of bioactive compounds (carotenoids and phenolic acids), which increases the antioxidant capacity, i.e. stability and the shelf life of mayonnaise, the color, viscosity and texture are better and the product becomes functional with a so-called "clean label" [28]. Another fruit has found its place in the formulation of mayonnaise, and that is watermelon, i.e. the addition of watermelon rind flour (6%) it can be used as a stabilizer because it has a significant effect on emulsion stability and moisture content, on ph, and does not affect the sensory evaluation of mayonnaise [11]. Beetroot powder (tested in conc.of 1.5, 3, 5 and 7%) can be used as a natural ingredient in the formulation of mayonnaise with added value because it is rich in antioxidants (betalain and polyphenols), and in addition, mayonnaise increases strength, adhesiveness and cohesiveness and improves viscosity [17].

A study conducted by Dipan Chatterjee and Paramita Bhattacharjee confirmed the possibility of formulating a 'new functional mayonnaise using the eugenol-lean fraction (a fraction low in eugenol) of clove buds as a flavor ingredient (replacing mustard in the classic formula) and as a source of natural antioxidants to improve shelf life and nutritional value of the product [5]. Mayonnaise has a sour, salty and slightly sweet taste that comes from sugar, and new research confirms the possibility of using stevia (stevia leaf flour - 0.5%), a natural sweetener that is used as a substitute for sugar in production new mayonnaise formulations (lower energy value, acceptable color, carbohydrate content strengthens emulsion droplets in mayonnaise) as a natural ingredient [14]. The addition of phenolic extracts to mayonnaise was investigated by Romeo R. et al. (2021) and all with the goal of producing enriched mayonnaise that will have better oxidative stability and antioxidant activity. Mayonnaise was enriched with different concentrations (50, 150 and 300 mg/kg) of commercial olive leaf phenolic extract and stored at 30°C for 30 days. Microbiological and sensory parameters, individual phenol content, oxidation stability, antioxidant parameters were monitored. Enriched mayonnaises showed good pH values and no microbial contamination was detected. The addition of 150 mg/kg of extract made it possible to obtain a mayonnaise more stable to oxidation, but it is better to use a lower concentration of phenolic extract (50 mg/kg) due to the taste of the final product, which must be acceptable to consumers[24]. Mayonnaises that contain microencapsulated oils can be a source of polyunsaturated fatty acids, and this has found application in the production of enriched mayonnaise with microencapsulated chia seed oil, pumpkin seed oil or palm oil (up to 5% by mass)

[23]. Microencapsulation has also found excellent application in encapsulating probiotics (*Lactobacillus casei* and *Bifidobacteria bifidum*) and adding them to mayonnaise, which makes mayonnaise bio-mayonnaise, and the probiotic flora embedded in mayonnaise has shown good results in improving the well-being of the intestinal microflora, and also reduces the possibility of mayonnaise poisoning [3]. A study done by Satriawan T.U. et al. (2022) showed that the use of whey protein concentrate of as much as 15% gives the best low-fat mayonnaise [25]. Not only is the goal of food technologists to produce a functional food product, but research is also being done where by-products are used, so it has been shown that the formulation of mayonnaise made with the addition of gum solution obtained from cold-pressed by-products of chia seed oil, flax seed and rocket seed can be use in low-fat vegan food [15]

5. CONCLUSION

Although fats provide good taste and texture and their replacement affects the properties of the final product, which limits consumer acceptance and the rate of commercial success, the association of fat in food products with increased cardiovascular disease and obesity has led to a great need for the development of new functional mayonnaise with a low fat content and/or replaced with egg yolk, and preferably enriched with antioxidants, phytosterols, prebiotics and probiotics, which will have rheological properties such as viscoelasticity, thixotropy and stackability that mayonnaise should have, with appropriate sensory properties. Today, mayonnaise as a product is increasingly demanded to have the so-called "clean label" and all that represents a big challenge for food technologists.

Abstract: *After the industrial processing of apple remains a large amount of low-cost agro-industrial apple pomace which is made up of the skin, pulp and seeds. Bearing in mind quantities generated annually, disposal of this by-product as waste in a soil and/or a water in addition to the economic one, creates a serious environmental problem. On the other hand, apple pomace represents a rich source of valuable phytochemicals such us phenolics, dietary fibres and fatty acids which benefits on health is well known. For this reason, apple pomace could be utilized as a functional ingredient in food industry, while at the same time avoiding the environmental problem. In this review paper, the application of apple pomace in bakery and confectionery products is presented. Added as substitute of wheat flour, apple pomace improves the textural characteristics and oxidative stability of them. Besides nutritional characteristics, this adding affects in techno-functional properties, such as water-holding capacity, oil-holding capacity and swelling capacity.*
Keywords: Utilization, Apple pomace, Bakery products, Confectionery products.

1. INTRODUCTION

The apple (*Malus* sp.) is one of the most popular fruits in the world, with an annual production of 87 million tons in 2019 [1]. About 18% of the world's apple production is processed, which creates significant amounts of apple by-products [2]. Apple pomace makes up 25-40% of the mass of processed apples, which depends on the processing technology [3]. Several million tons of apple pomace are generated annually as, mostly, the waste or used as animal feed. The disposal of apple pomace as waste is an ecological problem, due to its high water content and numerous nutrients [4]. It's necessary to find profitable ways to dispose of apple pomace waste or to discover value-added uses that are both economically and environmentally beneficial [5].

By recycling the by-products of the food industry, the amount of discarded materials dumped into the environment would be reduced, the economic efficiency related to the circular economy would be improved, and it would contribute to sustainable development [6,7]. In this regard, it's important to create new recipes for bakery and confectionery products that contain ingredients rich in natural antioxidants (polyphenols) and can be obtained in large quantities at a reasonable price. Dried apple pomace seems to meet all these requirements.

2. APPLE POMACE

2.1 Chemical composition and nutritive value of apple pomace

The largest part of apple pomace consists of skin and flesh (95%), followed by seeds (2-4%) and stems (1%) [8]. Due to its high water content, apple pomace is highly susceptible to microbial spoilage, so it's necessary to dry it immediately after processing to stop and slow down this deterioration [4]. Dried apple pomace is microbiologically stable and grounded into flour it can be used as an alternative to wheat flour [9]. It is considered a concentrate of various ingredients useful for health, mainly polyphenols, such as phenolic acids (especially chlorogenic acid), flavonoids (catechins, epicatechins) and phloridzin [10]. The content of polyphenols in apple pomace powder ranged from 17.83 - 38.83 mg gallic acid (GAE)/g [3]. After the juice extraction process during apple processing, it's estimated that 82-99% of polyphenols remain in the apple pomace [4]. These components show numerous properties that improve health, such as a hypoglycemic effect, hypocholesterolemic, anti-carcinogenic, anti-inflammatory, antiviral, antibacterial, anti-allergic, anticoagulant properties, and reduce the risk of diseases such as atherosclerosis and other cardiovascular diseases, cataracts, diabetes, genetic damage, degenerative bone changes, neurodegenerative diseases, including Alzheimer's and Parkinson's disease [11]. Apple pomace also contains simple sugars (glucose, fructose and sucrose), pectin, crude fiber, proteins, vitamins and minerals (Table 1).

Table 1. Quantity of nutritive compounds of dried apple pomace
Source: *[4]*

Compounds	Quantity (g/100g)	Compounds	Quantity (g/100g)
Moisture	3.97 – 9.75	Sodium	2 – 200
Fats	0.26 – 8.49	Potassium	449
Proteins	1.2 – 6.91	Calcium	50 – 150
Fructose	11.5 – 49.8	Phosphorus	50 – 950
Glucose	2.5 – 22.7	Magnesium	20 – 45
Total Dietary Fiber	26.8 – 82.0	Iron	2.4 – 23
Pectin	3.5 – 14.32	Zinc	0.22 – 1.5
Total polyphenols	0.17 – 0.99	Copper	0.11 – 0.22
Malic acid	0.05 – 3.28	Manganese	0.61 – 0.9
Ash	0.5 – 4.29		

Total dietary fibers (TDF) make the greatest contribution to the chemical composition of apple by-products (55.48±0.7g/100g of dry matter). Insoluble dietary fiber (IDF) makes up the largest proportion (43.58±0.6g/100g of dry matter), while soluble dietary fiber (SDF) makes up a smaller proportion (11.06±0.1g/100g of dry matter) [7]. Studies have shown that dietary fiber can also improve the functional properties of food such as increasing water-holding capacity, oil-holding capacity, emulsification and gel formation. Added to food products, dietary fiber can modify textural properties, prevent syneresis, stabilize high-fat foods and emulsions and extend shelf-life [12].
Dietary fiber and polyphenols are the two key ingredients in functional foods that are believed to provide health benefits. The combination of apple pectin and apple concentrate rich in polyphenols had a significant effect on the reduction of plasma cholesterol and triglyceride levels, as well as the absorption of cholesterol in the intestines [3,5].
In addition to the mentioned nutrients, apple pomace also contains triterpenoids and fatty acids. Apple terpenoids can be found either in the epidermal cells of the peel or in the epicuticular wax. Triterpene

acids show various pharmacological properties and health effects, such as antioxidant, anti-inflammatory or antimicrobial effects. Regarding fatty acids, recent studies have shown the presence of unsaturated fatty acids in apple seeds and peel [7]. Apple seeds contain significant amounts of oil. Oil content ranges roughly from 12 to 27.5%. Apple seed oil consists of unsaturated fatty acids (90%), mainly oleic and linoleic acids. In this way, apple seed oil belongs to the group of olein-linoleic type oils, which are considered to have positive effects on lowering LDL cholesterol and reducing the risk of heart disease [5]. Also, the antimicrobial and antiproliferative capacities of apple seed oil have been proven in studies [7].

2.2 Utilization of apple pomace in production of bakery and confectionery products

Based on literature data, various types of fruit and vegetable by-products, including apple pomace, were well incorporated into the composition of functional foods, such as bakery and confectionery products.

The influence of the addition of apple pomace in different proportions (10%, 20% and 30%) on the properties of cake was examined. With an increase in the percentage of added pomace, there is a decrease in volume and an increase in the density of the enriched cakes, due to the strong water binding properties of the apple fibers. Cakes prepared with a 25% of added apple pomace and wheat flour had 14.2% TDF with highly acceptable quality. Cakes prepared with apple pomace had a pleasant fruity taste [9].

The utilization of 20% apple pomace instead wheat flour significantly increased the total content of flavonoids, polyphenols and proanthocyanidins in baked scones by 4, 3.3 and 3.1 times, respectively [13].

Dried apple pomace was used as a substitute (15% and 20%) for wheat flour in the preparation of cookies and muffins. The resulting cookies and muffins had a higher amount of fiber, but significantly darker than the control ones, due to possible non-enzymatic browning. The enriched cookies and muffins were softer than the control ones, but there was no adverse effect on physico-chemical and textural characteristics of the final product [14].

In study [15] the utilization of apple pomace in proportions of 5%, 10% and 15%, instead of wheat flour in biscuits, showed that there was no significant difference in the overall acceptance between the control sample and samples with added 5% apple pomace. A further increase in the addition of apple pomace led to evidently lower sensory properties, due to a harder consistency. It was concluded that apple pomace powder can be used as an alternative source of dietary fiber with amount 51-52% of total dietary fiber.

The dough performance and bread quality, with the addition of 10% apple pomace, were examined. The addition of apple pomace significantly increased dough yields. The crumb and crust structure of enriched breads were very similar to control sample. There was a significant change in the color of the crumb and crust of the enriched products, compared to the control, and a smaller volume and thickness, which is similar to other studies described [12].

The total phenolic content and total flavonoid and antioxidant activity, as well as the quality and quantity of phenolic compounds in gluten-free breads with the addition of apple pomace in different proportions (5, 10 and 15%), compared to control sample with 100% wheat flour. Bread with 15% apple pomace had the highest content of phenolic compounds and the highest antioxidant potential, but the lowest organoleptic characteristics. The best results of the organoleptic analysis were obtained by bread with a 5% addition of apple pomace. Bread with this level of apple pomace has 2.5 times more polyphenols, 8 times more flavonoids, 4 times more chlorogenic acid and 21 times more phloridzin than the control sample, resulting in 6.5 times more antioxidant potential [10].

Examination of the chemical composition and physical properties of gluten-free cookies with 15%, 30%, 45% and 60% added apple pomace is described in [11]. It was found that the presence of apple pomace in gluten-free cookies caused an increase in the content of all polyphenols, a decrease in protein content, a slight increase in fat content and an increase in mineral content ranging from 14% to 58% compared to the control sample. Increasing the proportion of apple pomace caused a significant increase in fiber content, insoluble fraction 8–29 times, soluble fractions 1.5–5 times, and total fiber 3.5–13 times, compared to the control samples. As for the organoleptic characteristics, there was an increase in the hardness and darkening of the cookies, along with a decrease in their volume.

The study [16] describes the development of a sweet gluten-free bread with the addition of apple pomace flour. This addition leds to a denser dough structure and firmer breads, which was offset by a positive effect on taste.

The effect of the addition of apple pomace and rice flour on the physical and chemical characteristics of two enriched wheat breads was described. In the recipe for bread sample number 1, wheat flour was replaced with 25% rice flour and 10% frozen apple pomace, and in sample number 2, part of the wheat flour was replaced with 12.5% of rice flour and 10% of fresh frozen apple pomace. The results showed a superiority in the quality of enriched breads, compared to bread with 100% wheat flour. Sample number 2 had a more pleasant taste, texture, aroma, color and crumb. Sample number 1 had the holes in the structure. The use of rice flour and apple pomace in the production of enriched bread had an effect on increasing the content of iron and phosphorus in the finished product [17].

The addition of apple pomace to wheat flour in proportions of 5, 10, 15, 20 and 25% to prepare cookies resulted in a decrease in width (from 45.13 mm for 0% to 44.75 mm for 25% apple pomace) and cookie thickness (from 1.47 mm for 0%, to 1.21 mm for 25% apple pomace). The water absorption capacity of flour is increased by the addition of apple pomace (from 2.06% for 0%, to 2.83% for 25% apple pomace), because a higher fiber content increases water absorption. Sensory properties were also affected by the addition of apple pomace powder, but cookies with 10% apple pomace were found to have the best color and aroma, while crispness was similar to the control sample, which was rated best in taste, as well as mouthfeel, texture and overall acceptability [18].

The effect of replacing wheat flour with crude apple pomace flour (APF) in amounts of 25%, 50% and 75% on cookies showed that the crude APF gave better sensory properties, content and retention of dietary compounds and antioxidant activity. Cookies with an optimal proportion of coarse APF (50%) contained 21g/100g dietary fibers and several times higher amounts of polyphenols, flavonoids, as well as antioxidant activity, than control cookies, retaining health-promoting compounds and maintaining an intense fruity aroma and crunchy texture, which lasted throughout 12 months of storage. They were acceptable to consumers according to the hedonic test. Consumer evaluation using the hedonic test confirmed that replacing up to 50% of wheat flour with coarse APF is possible at the industrial level of cookie production, without compromising the acceptability of the product [19].

3. CONCLUSIONS

Enriched bakery and confectionery products with apple pomace have a significantly higher amount of dietary fiber and polyphenolic compounds compared to control samples, without apple pomace. This makes apple pomace an excellent alternative source of dietary fiber and antioxidants. On the other hand, the sensory characteristics of the enriched products are acceptable for consumers, at the share of 10% added apple pomace. It especially contributes to a very pleasant fruity taste and aroma. With a larger amount of apple pomace added, their density and hardness increase, while their volume and thickness decrease. They get a darker color of the crumb and the crsut, a denser structure, and the taste is more bitter. Dried apple pomace or APF can be considered an excellent functional ingredient for the production of new bakery and confectionery products with health-promoting compounds.

ALTERNATIVE PACKING IN WINE PACKING TECHNOLOGY

Slavica Čabrilo[1], The Academy of Applied Technical Studies Belgrade
Višnja Sikimić[2], The Academy of Applied Technical Studies Belgrade
Miloš Purić[3], The Academy of Applied Technical Studies Belgrade

Abstract: *In wine packaging technology, glass has been the dominant packaging material for many years. A glass bottle with a cap or stopper provides good protection against spoilage agents and contributes to the preservation of wine quality. For traditional wine lovers, the glass bottle is status symbol of the quality of this drink. New trends in the field of wine packaging are focused on the development and application of alternative packaging such as PET bottles, cans, Tetra Pak and BIB packaging. The use of the mentioned packaging depends primarily on its attributes in protecting the wine compared to glass packaging. For wine producers, the option of cheaper packaging and easier distribution while preserving product quality is acceptable, but the sustainability of this concept also depends on the habits of wine consumers. In the paper, we present an alternative packaging for wine packaging with an analysis of its impact on wine quality and consumer acceptability.*
Keywords: wino, quality, packaging, glass, alternative packaging.

1. INTRODUCTION

Packaging materials intended for food packaging differ from each other in terms of their permeability to gases, moisture, light and microorganisms. They also differ in physical and mechanical characteristics of shaping, printing and closing. The mentioned properties give greater or lesser advantages to the material when choosing packaging material for packing different foods.
Wine is a drink created by the complete or partial alcoholic fermentation of grapes of various varieties of *Vitis Vinifera.*Wine it has a complex chemical composition with participation of water 80 85%, ethanol as the primary alcohol of 9 -15% and a number of other compound such as organic acids, sugars, phenols, nitrogen and other compounds that contribute to the specific taste and aroma of wine.
The quality of wine depends on several factors, which include the assortment of grapes, growing conditions (soil type, climate), processing technique (yeast strain, fermentation conditions), wine oenology, storage and packaging conditions [5]. The choice of packaging material and packaging achieves several functions, of which the most important one is the protection of wine from external spoilage agents (oxygen, moisture, light and microorganism) and preserving the integrity of the packaging. The fulfillment of the protective function of the packaging depends on the properties of the packaging material because inertness is required, i.e. a barrier between the product and the external environment while avoiding the migration of molecules between the material and the product [17].
Glass is the dominant packaging in wine packaging technology, and other packaging materials such as plastic, metals and multilayer materials belong to alternative packaging for wine.

[3] mpuric@atssb.edu.rs

2. PET PACKAGING AS AN ALTERNATIVE TO GLASS FOR WINE PACKAGING

Polyethylene terephthalate (PET) is a polyester consisting of ethylene glycol and terephthalic acid. Injection and blow molding processes produce PET bottles used for packaging water, juices, soft drinks, beer and wine. During wine aging, its composition changes through a series of complex chemical reactions primarily on phenols (anthocyanin, flavon-3-ols, flavonol, hydroxycinnamic acid) and volatile organic compounds such as esters, fusel alcohols, aldehydes, ketones and acids. Oxidation is one of the factors that can negatively affect the color, taste and aroma of the product, which is why it is necessary to constantly monitor the amount of oxygen that comes into contact with the wine during production, storage and packaging. Oxygen can be considered the main gas present during the bottling of wine. The oxygen content of wine can change after bottling by diffusion from the surrounding atmosphere depending on the permeability of the packaging material. The presence of oxygen also facilitates the development of aerobic microflora, which can damage the quality of the product.

Permeability to oxygen and other gases is the dominant parameter that gives glass an advantage over PET packaging. Undesirable changes in the sensory profile of wine occur under the influence of oxygen, which reduces the shelf life of wine. During wine packaging, in order to slow down oxidative deterioration, about 20-40 mg/l of sulfur dioxide is added, and the first signs of undesirable oxidative changes in aroma and color become noticeable as soon as the level of free sulfur dioxide falls below 10 mg/l of the product. The advantage of glass compared to PET is that glass is practically impermeable to oxygen and other gases, i.e. the minimum permeability is related to the bottle cap.

Ghidossi R et al. (2012) analyzing the influence of the type of packaging (glass, single-layer and multi-layer PET and BIB) on the physical and chemical properties of red and white wine during 18 months of storage indicate that the highest degree of oxidation occurs with wine packed in single-layer PET with a thickness of 0,3mm. especialy with white wine. Concentrations of compounds such as phenyl acetaldehyde, methional and sotolone, which are associated with the oxidation of white wines, were registered above the level of perception. One of the solutions for reducing the permeability of PET material to oxygen and other gases is the application of multilayer PET by combining different films or adding oxygen scavengers.

For a better gas barrier, three-layer or five-layer PET/gas barrier/PET are suggested [22]. With the oxygen scavenger, one of the options is to incorporate it into the polymer coating on the inside of the closure or to integrate the scavenger directly into the structure of the polymer film. Mentana et al. (2009) in their study on the taste and aroma profile of red wines packed in PET and OkSC-PET packaging during a six-month storage period indicate a change in taste due to the loss of various organic compounds before all alcohol, acids and esters. The stated loss levels were lower for packaging than OkSC-PET.

Research on the development of the aromatic profile of rose wine packaged in glass bottles, PET and recycled PET, by Dombra et al. (2015) indicate the appearance of new compounds (derivatives of furfural, 5-hydroxymethyl furfural and ethyl pyruvate or dioxin) regardless of the type of packaging, as well as the appearance of specific compounds diethyl tartrate in glass, ethyl pyruvate in both PET and vanillin in pure PET in. Aroma changes that can negatively affect the shelf life of wine are related to sorption processes in the packaging material,as well as to the degradation process within the product [7].

Bottles of the same shape and volume as glass can be made from polyethylene terephthalate, bottles are closed with plastic caps, and plastic foil is used to unify the package. PET bottles are lighter than glass bottles, there is no breakage, lower transport costs.

3. BAG IN BOX PACKAGING AS AN ALTERNATIVE TO GLASS FOR WINE PACKAGING

Bag in box packaging unit is composed of two parts. The first outer part is a folding cardboard box, and the second part is a double flexible bag with a one-piece, flexible valve that opens and closes when a lever is activated. The outer layer of the bag is made of polyester, and the inner layer is made of low-

density polyethylene (LDPE) or ethylene vinyl acetate (EVA). The films used for this type of packaging have the property of absorbing non-polar compounds from the wine due to the hydrophobic nature of the polyolefin.
The wine is filled under vacuum, and nitrogen is added to the bags to remove residual oxygen. When the wine is poured, the bag collapses, protecting the wine from oxygen. The bag is exposed to constant bending pressures and it is necessary to be made of polymer films with high flexibility, because otherwise there will be perforations that can cause a reduction in the barrier properties of the material. The bag does not lose its integrity in terms of wine leakage, but oxygen enters, reduction of free sulfur dioxide and premature degradation of wine occurs. [9]. It is recommended to avoid contact of the wine with the outer film and to prevent the penetration of oxygen inside the films, which most often happens around the valve for pouring wine.
Analyzing the influence of the packaging material on some oenological parameters of dry white wine packed in BAG end BOX packaging leads to the sorption of flavor compounds into the polymer material. LDPE BIB packages have a higher potential for undesirable absorption of flavor compounds. Changes in titratable acidity, total and free sulfur dioxide and wine color were determined so that the product can be stored optimally for three months after packaging [18].
Moreira et al. (2016) reported similar results when looking at the effect of wine packaging and aging on the variable and sensory attributes of red wine. Due to the greater permeability of the bag-in-bax design, the wine should be consumed quickly and not aged.
Compared to a glass bottle, this type of packaging is practical for carrying, opening and closing the packaging unit. It is attractive to consumers because the freshness of the wine is maintained for three weeks after opening the bag, which relaxes the consumption of a certain volume of drink. In Australia, Sweden and Norway, more than 50% of purchased wine is packed in Bag and Box packaging. [10]

4. ALUMINUM CANS AS AN ALTERNATIVE TO GLASS FOR WINE PACKAGING

Aluminum cans as an alternative packaging for wine packaging is a fast-growing product category with great market forecasts and increasing consumer demand. Packaged wine has become available to wine lovers at sporting, cultural and themed events where access to glass packaging is limited. The global market for canned wine is valued at approximately USD 211.4 million in 2020., and is likely to grow at compound annual growth rate of 13.2% through 2028. [10]
Metals as packaging materials are impermeable to oxygen, light and microorganisms from the outside environment. With the use of cans for wine packaging, defects related to quality and shelf life appeared. The appearance of an unpleasant odor due to the reduction of sulfur dioxide to hydrogen sulfide and the transfer of aluminum to the wine related to the corrosion potential of cans are undesirable reactions in packaged wine. In theory, Al in food packaging is quite resistant to corrosion because it quickly forms a thin layer of aluminum oxide (Al_2O_3) on the surface in contact with oxygen. However, this metal is sensitive to salty, basic and acidic foods (including wine) that dissolve it, leading to its transfer into food. All canned food can interact with the metal inner surface of the package and cause metal corrosion, which is mainly due to a faulty coating.
According to Maslov-Bandic and Saks (2019), the high corrosivity of wine in cans can mainly be attributed to the following factors:

- low pH and high concentrations of bisulfite and Cl–, which can threaten the integrity of the internal Al coating;
- the expected low rH of canned wine, which hinders the regeneration of the Al coating; and
- the presence of Cu+, which can catalyze pitting corrosion inside the can

Recent studies by Allison et al. (2021) show that when SO_2 and Al come into contact, the reaction accelerates corrosion on the inner metal surface of the can and leads to the formation of hydrogen sulfide in the wine. Montgomery et al. (2023) found that wines stored in cans with epoxy coatings, with or without bisphenol A (BPA-NI), produced less H_2S compared to wines stored in acrylic-coated cans Although the coatings protect the metal surface, their constituents can migrate into food and beverages [19]. Moreover, they can reduce the amount of volatile compounds of the product by absorbing them[23]. The production of reductive aroma during the storage of canned wine is thought to occur through two main pathways: the reaction of metallic Al with SO_2 [6] and the decomposition of polysulfane, which does not imply a bond with Al [3; 12]. From a thermodynamic point of view, H_2S production is favored over other VSCs and is therefore most relevant in preserved wines [20].

5. TETRA PAK AS AN ALTERNATIVE TO GLASS FOR WINE PACKAGING

In the wine industry, the use of Tetra Pak for wine packaging began in 2006 and has a growing tendency. Tetra Pak is a multi-layer packaging made of: cardboard, polyethylene polymers and aluminum foil. The mentioned materials contribute to the integrity of the container, good printing and barrier properties of the packaging. The presence of Al foil protects the product from oxygen and light. To close the container, plastic closures are used, usually plastic lids with a screw with a protective film that is destroyed when the container is opened [17].

The impact of this packaging on the quality of the wine is related to the reactions between the ingredients of the wine and the polyethylene polymers, as well as the transfer of aluminum if the layers of the container wall are damaged. The manufacturers of Tetra Pak confirm that the shelf life of the wine is from three to six months after packaging. Cheap packaging is also suitable for wineries that tend to produce table wines and where wine aging and long-term storage are not required.

6. CONCLUSION

Production and consumption of wine is a growing category of world trade. The choice of packaging for packaging protects the quality of the wine and facilitates sales and distribution. Due to its inertness and good barrier properties, glass will be an irreplaceable packaging for wine for a long time. The attitude of traditional wine consumers and quality are looking for diminishes the possibility of greater participation of alternative packaging in the wine market. Nevertheless, cardboard, aluminum and polymer packaging is establishing is presence on the wine market because it provides lower production and sales costs, which is in the interest of wine producers with satisfactory product quality.

POTENTIAL MIGRATION OF PHTHALATES FROM DIFFERENT POLYMERS INTO FOOD

Jasmina Rajić[1], The Academy of Applied Technical Studies Belgrade
Tanja Petrović[2], Faculty of Agriculture, University of Belgrade
Dragana Mihajlović[3], Faculty of Agriculture, University of Belgrade

Abstract: *Plastic materials are commonly used for food packaging due to their excellent physical-mechanical, thermal, chemical, and barrier properties. They are also easy to process, can be combined with other materials, and are cost-effective. In order to improve flexibility, transparency, and durability, plasticizers such as phthalates can be added to the chemically stable polymers. The detection and determination of phthalates in articles of general use is crucial as they account for up to 50% of the mass and can easily migrate due to their physical and chemical properties. Exposure to phthalates can lead to various health problems, e.g. allergic diseases, asthma, thyroid dysfunction, fertility issues, endocrine disorders, and cardiovascular disease. There are several factors (temperature, ultraviolet radiation, ultrasound, mechanical forces, etc.) that influence the migration of phthalates. Thus, food products can be contaminated with phthalates by migration from plastic packaging. Therefore, it is important to investigate the migration of phthalates from plastic items and packaging into food. Packaging materials and packaging used in the food industry must be tested to ensure that they do not pose a health risk. The legal framework relating to these materials was created to ensure the safety of food that is consumed and sold.*
Keywords: Phthalates, migration, polymers, food

1. INTRODUCTION

Selecting the appropriate packaging material plays an important role in protecting the packaged product and ensuring its safety and quality. Polymers, which are commonly utilized as food packaging materials, are enhanced with a variety of additives including fillers, colors, plasticizers, softeners, and stabilizers. These additives are usually not chemically bonded to the structure of the basic macromolecular chain which may result in their potential migration into the package contents during transportation, handling, and storage.

Phthalates are a group of semi-volatile organic compounds and most commonly used plasticizers worldwide due to their wide range of industrial applications. [1]. Certain ortho-phthalates, including Di(2-ethylhexyl)phthalate (DEHP), dibutyl phthalate (DBP), benzyl butyl phthalate (BBP), and diisobutyl phthalate (DIBP), may interfere with our hormonal system and are on the candidate list of substances of concern.

These phthalates are extensively used as a plasticizer in many products, especially medical devices, furniture materials, cosmetics, and personal care products, building materials, household furnishings, clothing, cosmetics, pharmaceuticals, nutritional supplements, medical devices, children's toys, glows, modelling clay, food packaging, furnitures, automobiles, lubricants, waxes, cleaning materials and insecticides [2].

[2]tpetrovic@ agrif.bg.ac.rs
[3]draganap@agrif.bg.ac.rs

Polymeric (plastic) materials that come into contact with food products can be a potential source of phthalates in food. Therefore it is necessary to examine the health safety of packaging materials and packaging, which is carried out by specialized and authorized institutions and laboratories.

2. POLYMER FOOD PACKAGING

The role of packaging is to protect the product from physical and mechanical factors and external environmental conditions (light, gases, moisture and microorganisms), communicates with the consumer, and serves as a good marketing tool. Food packaging that comes into direct contact with food must be made of a material that does not impair the organoleptic, chemical, and physical properties of the food and must not contain or release any substances that are harmful to health over the quantities specified in the regulation [3]. Polymer packaging accounts for the largest proportion of food packaging, and generally is not harmful to human health. However, some additives found in polymer-based packaging can be harmful if they migrate into food causing adverse effects.
During the production of food packaging, plasticizers are added to serve as softeners and color carriers. Since they have a relatively low molecular weight and are not covalently bound to the polymer, they can potentially migrate from the packaging material into the food and thus become indirect "food additives" [4]. Many additives, solvents, and pigments used in the production of plastic packaging materials are also found in the food product [5], and many can be converted into toxic metabolites, most of which are difficult to identify.
Examples of potentially toxic substances (PoTS) that have been studied for their possible migration from various plastic packaging include phthalates, bisphenol A (BPA), bisphenol A dimethacrylate, lead, tin, and cadmium, as well as formaldehyde and acetaldehyde, 4-nonylphenol, MTBE (methyl tert-butyl ether), benzene, and many other volatile organic compounds [6,7,8,9,10].

3. PHTHALATES IN PLASTIC MATERIALS

Polymers can be transformed into polymer (plastic) materials by adding plasticizers such as phthalates, citrates, and phosphates. Diesters of 1,2-benzenedicarboxylic acid (phthalic acids), better known as phthalates, are widely used as plasticizers, solvents and additives in the manufacture of plastics [1]. They are commonly used to increase the flexibility, durability, elasticity, and transparency of plastics. For example, rigid polyvinyl chloride (PVC) can be transformed into a wide range of flexible materials and processed more easily by adding plasticizers such as phthalates (up to 40 % w/w), citrates, and phosphates. In addition, phthalates can be used in a variety of general-use products such as toys, personal care and household products, electronics, various solvents, adhesives, glues, pesticides, food packaging, medical devices, pipes, and building materials. Due to their non-polarity, phthalates have a low solubility in water, but dissolve well in a non-polar medium and have a high solubility in oil.
Although phthalates are usually used in the manufacturing of PVC, they are also used as part of the catalyst (Ziegler-Natta catalyst) during the polymerization process of polypropylene (PP), polyethylene (PE), and polystyrene (PS) [11]. Therefore, they have also been found in food packaging materials that are not made of PVC [12].

4. POTENTIAL MIGRATION OF PHTHALATE FROM POLYMERS INTO FOOD

Migration is the transfer of potentially harmful substances from the packaging material and packaging into the food. The legislation on plastic packaging materials that come into contact with food ("food-contact" legislation) has defined two types of migration: specific and general migration. Specific migration refers to the migration of substances that are present even in low concentrations can pose a risk to consumer health and therefore require strict control. General migration refers to the migration of components that do not pose a major risk to consumer health but are still undesirable. Since phthalate are not chemically bound to the macromolecular chain, but are merely attached to the polymer structure, they can leach, evaporate, or migrate from the plastic packaging into the

environment. Various factors influence the migration of phthalates, e.g. temperature, ultraviolet radiation, ultrasound, mechanical forces, or contact with a non-polar environment. It is very important to be aware of these factors and handle plastic products and packaging with care to prevent phthalate migration.

According to the European Union Directive [13], FCM suppliers are required to demonstrate that their materials comply with the relevant limits (EUROPEAN UNION, 2002), which are defined by the following values: Overall Migration Limit (OML), Specific Migration Limit (SML) and Maximum Permitted Quantity (QM). Several studies have shown that phthalates migrate from plastic packaging mainly into fatty foods such as oil, milk, butter, meat, fish, etc. [14]. Food in plastic packaging heated or cooked in a microwave oven is also a source of phthalates, and it was reported that phthalates easily migrate into fatty foods under high temperatures [15]. Monitoring of potential contamination of milk and dairy products with phthalates is important as milk is the main food source for children [16]. It has already been reported that cow's milk can be contaminated by the plastic utensils used in processing. In addition, human milk can also be contaminated with phthalates through the use of breast pumps [17].

The investigation of phthalates in alcoholic beverages revealed a negligible migration of phthalates from plastic packaging into alcoholic beverages. The detected phthalate concentrations were low, although most of the samples in this analysis were packaged in plastic bottles [18]. The study carried out by Del Carlo et al. also showed that the increased phthalate concentration in alcohols is not due to the interaction between plastic packaging and alcoholic beverages, but to the migration of phthalates during the technological process [19]. When comparing the results of phthalate concentration in plum brandy bottled in glass and plastic packaging, it was found that there is no migration of phthalates from plastic packaging into alcoholic beverages, as there is no significant difference in phthalate concentration between brandy in different packaging [20]. On the other hand study with showed extremely high migration of phthalates (350%) in olive oil, from the sealing material of closures [21].

Generally, it is recommended to avoid heating of food in plastic packaging in the microwave as well as washing the plastic material in the dishwasher. It is suggests to use glass packaging as far as possible, and to check the composition of the plastic on the product declaration.

Phthalates in food, beverages, and other products are analyzed using various analytical methods, including liquid and gas chromatography with mass spectrometers or UV spectrophotometers. The most important method for determining phthalates is gas chromatography-mass spectrometry (GC-MS) [16]. However, Fourier transform infrared spectroscopy (FTIR) is also used.

5. TOXIC EFFECT OF PHTHALATES

The annual production of phthalates in 2009 and 2010 was about 230,000 tons per year, of which 210,000 tons were DEHP [22]. Humans are frequently exposed to phthalates, which can enter the human body through the skin, by inhalation, or through food. Due to their lipophilic nature, fatty foods in particular are contaminated with phthalates. When phthalates enter the body, they are rapidly metabolized and excreted in urine and feces. Their half-life is short, and more than 60 % are excreted within 24 hours, the rest in less than 48 hours [23]. However, endocrine-disrupting chemicals (EDCs) which include phthalates can interfere with the synthesis, secretion, mechanism of action, metabolism, and excretion of hormones in humans and animals, with adverse health consequences, including the occurrence of obesity and diabetes mellitus [24, 25].

According to the World Health Organization, individuals can be exposed to phthalates through the daily use of common plastic items. A growing number of studies are investigating the health effects of exposure to phthalates, which have been linked to various conditions such as allergic diseases, asthma, cancer, thyroid dysfunction, fertility issues, endocrine disorders, and cardiovascular disease [26, 27]. Phthalate exposure is associated with cardiovascular risk factors including obesity, lipid metabolism, blood pressure, and atherosclerosis [28]. During the prenatal period, in newborns, and during puberty, human sensitivity is at its highest level. Due to this reason, the European Union has

imposed restrictions on the use of some phthalates in children's toys and products intended for children. The results of the exposure assessment indicate that children are exposed to higher levels of phthalates compared to adults. Based on the latest data from human biomonitoring, it has been established that the intake level considered safe is exceeded in children. In some cases, the excess is up to 20 times the safe level. Due to their chemical properties, exposure to phthalates does not lead to bioaccumulation. However, there are health concerns regarding the developmental and/or reproductive toxicity of phthalates, even at environmental concentrations [29].

6. LEGAL REGULATION

In order to protect public health, various legislative bodies have been established to prohibit or regulate the use of harmful substances. European Union legislation, better known as the REACH Directive [30] (Registration, Evaluation, Authorization and Restriction of Chemicals), created the European Chemicals Agency (ECHA). In 1963, the Food and Agriculture Organization of the United Nations (FAO) and the World Health Organization (WHO) jointly established the Codex Alimentarius Commission (CAC), which is commonly known as Codex and deals with international food standards. The RAPEX system (Rapid Alert System for Non-Food Products) was also established in the European Union to quickly alert authorities and consumers about dangerous non-food products. According to EU regulations, the maximum migration limit for all contaminants from plastics into food is 60 mg/kg of food or 10 mg/dm² of the surface of the food contact material [31]. The specific migration limit is determined individually for each phthalate. Commission Regulation (EU) No 10/2011 establishes specific migration limits (SMLs) for individual phthalates and a limit for a group of phthalates (SML(T)) . The SML values for DnBP, DEHP, and BBP are 0.3, 1.5, and 30 mg/kg of food respectively. Meanwhile, the SML(T) value for the group of phthalates is 60 mg/kg of food [32].

In the Republic of Serbia, there are the National Consumer Organisation of Serbia (NCOS), the Sanitary Border Inspection, and the Public Health Laboratories. The Institute for Standardization of Serbia is the leading authority for the Codex Alimentarius. It is responsible for harmonizing food safety standards and regulations between the EU and Serbia, taking into consideration the differences in tradition and culture. The regulation on health and safety conditions of items of general use that can be placed on the market [33] specifies that synthetic materials used for making tableware and accessories, which come in direct contact with drinking water, milk, milk products, waxed food, foods that contain essential oils, alcoholic beverages, fats, oils, or foods whose outer phase consists of fat, must not contain plasticizers, unless a special regulation expressly stipulates otherwise.

The list of restrictions and prohibitions includes regulations on the production, marketing, and usage of certain hazardous substances, mixtures, or products [34]. Specifically, the list restricts and prohibits the use of phthalates and imposes a limit of 0.1% by weight of the plasticized material in toys and childcare products. Bis(2-ethylhexyl) phthalate (DEHP), dibutyl phthalate (DBP), benzyl butyl phthalate (BBP), and diisobutyl phthalate (DIBP) can cause damage to growth hormones and development, and lead to heart disease and obesity.

7. CONCLUSION

Migration is the transfer of potentially harmful substances from the packaging into the food. One of the main sources of phthalates is food packaged in plastic material, especially fatty foods such as oil, milk, butter, meat, fish, etc. Food products can be contaminated with phthalates through migration from polymers and during food processing from production facilities, but also during food storage. Monitoring the contamination of milk and dairy products is of utmost interest as milk is the main food source for children.

According to the legislation, the overall limit for the migration of all contaminants from plastics into food is 60 mg kg^{-1} of food or 10 mg dm^{-2} of the surface of the food contact material. In the EU, the specific migration limit (SML) for the group of phthalates is 60 mg kg^{-1} of food.

Svetozar Sofijanić[4], The Academy of Applied Technical Studies Belgrade

Abstract: *Establishing general principles, requirements and responsibilities in relation to food information, and in particular in relation to food labeling, is the basis for achieving a high level of consumer protection. Due to today's fast lifestyles, bakeries are taking the place of preparing homemade baked goods for everyday meals, school functions, and special occasions. When foods are labeled incorrectly, or an allergen warning is not properly declared, this can make a food product dangerous to sell to certain sensitive individuals. Improperly labeled food can cause someone to become ill and/or trigger a costly recall of products. For the purpose of monitoring of allergen info in bakery retail stores located in Belgrade 120 bakery retail stores were visited. It was concluded that 105 of them label their products according to labelling regulation. Further trainings and dissemination of information is needed in order to raise awareness among small bakery retailers.*
Key words: labelling, bakery, allergens, monitoring.

1. INTRODUCTION

Due to today's fast lifestyles, bakeries are taking the place of preparing homemade baked goods for everyday meals, school functions, and special occasions. Baked goods may range from those prepared in manufacturing facilities and sold at retail stores to specialty baked items prepared and sold in the stores themselves. Among other factors labeling is also to be consider when evaluating food safety risks in retail bakery products.
The primary purpose of food labels is to inform the consumer regarding nutrition, ingredients, claims, or allergen information. When foods are labeled incorrectly, or an allergen warning is not properly declared, this can make a food product dangerous to sell to certain sensitive individuals. Improperly labeled food can cause someone to become ill and/or trigger a costly recall of products. Therefore, providing an accurate list of all ingredients is vital.

[2] tmarinkovic@atssb.edu.rs
[3] astevanovic@atssb.edu.rs
[4] ssofijanic@atssb.edu.rs

2. FOOD LABELLING

The free movement of safe food is an essential aspect of the internal market and contributes significantly to the health of citizens, and to their social and economic interests. In order to achieve a high level of health protection for consumers and to guarantee their right to information, it should be ensured that consumers are appropriately informed as regards the food they consume.
Knowing the basic principles of nutrition and having appropriate information about the nutritional value of food significantly contribute to better informed consumers when choosing. Therefore, establishing general principles, requirements and responsibilities in relation to food information, and in particular in relation to food labeling, is the basis for achieving a high level of consumer protection [1].
The right to the availability of information must be guaranteed when choosing food and is the main reason why this regulation applies to subjects in the food business at all stages of the food chain, to all food intended for final consumers, including food offered by public catering facilities and food intended for supply public catering establishments.
Food labelling should be done in a way that does not mislead the end consumer, especially in terms of:

- characteristic features of food, especially its nature, identity, properties, composition, quantity, durability, country of origin or country and place of origin and method of production;
- attributing properties and properties to food that it does not possess;
- indicating the special properties of food and if similar food has the same properties, especially by highlighting the presence or absence of certain ingredients and/or nutrients;
- indicating the presence of a certain food or ingredient by appearance, description or pictorial representation, when in reality the ingredient that is otherwise naturally present or used in that food has been replaced by another component or another ingredient.

Food information should be accurate, clear and easy to understand for the consumer. Food business operators are responsible for the information on both packed and unpacked food.

When labelling unpackaged food following information are necessary:

- the name under which the food is placed in the marketed;
- information on ingredients that can cause allergies and/or intolerances;
- data on the entity in the food business that packs the food at the point of sale to the final consumer [1].

3. ALLERGEN INFO

Food allergy is an adverse immune reaction to a food allergen that can trigger mild (*e.g.*, rash, itchy sensation) to severe (*e.g.*, anaphylaxis) reactions [2]. Almost any food can trigger an allergic reaction in a susceptible individual, but some foods are more common than others. Studies from medical research show that 74% of allergen related food incidents can be linked to foods sold loose (in shops and in restaurants) [3,4].
Even though this disease is chronic, people tend to overlook its severity due to limited knowledge about it [5]. Food avoidance is one of the many methods to prevent food allergies [6]. Despite various preventions consumers may take to avoid food allergens, some have encountered difficulties when eating out. Therefore, it is important that information on the presence of

substances or products with a scientifically proven allergenic or intolerance effect should be given to enable consumers, particularly those suffering from a food allergy or intolerance, to make informed choices which are safe for them.

4. MONITORING PLAN

A food safety monitoring system is a tool that helps food businesses operator to ensure that their food is safe for consumers. The food safety monitoring system provides food business operators data and insights that can help them to improve their food safety practices.
For the purpose of monitoring of allergen info in bakery retail stores located in Belgrade 4 major food retail chains, 4 large bakery retail chains (each chain consisted with more than 20 stores), 4 small bakery retail chains (each chain consisted with less than 5 stores) and 20 single bakery retail stores were visited. Monitoring of allergen info compliance was conducted by visual inspection of the labeled products.

5. RESULTS AND DISCUSSION

All bakeries placed in huge food retail chains were following the correct procedure of listing the allergens when labeling products. Large bakery retail chains with over 20 stores complied with the labeling regulation as well (Table 1). On the other hand every 75% of bakery stores from 4 visited small bakery retail chains was labeling allergens according to the labeling regulation and 50% of single bakery stores clearly labeled allergens (Figure 1). Centralized production and certified quality control systems, well trained and well informed staff are the reasons for absolute compliance of the large food retail and bakery chains. On the other hand, lack of employes and information could be the reasons for partially successful compliance when it comes to small bakery retail chains and single bakery stores.

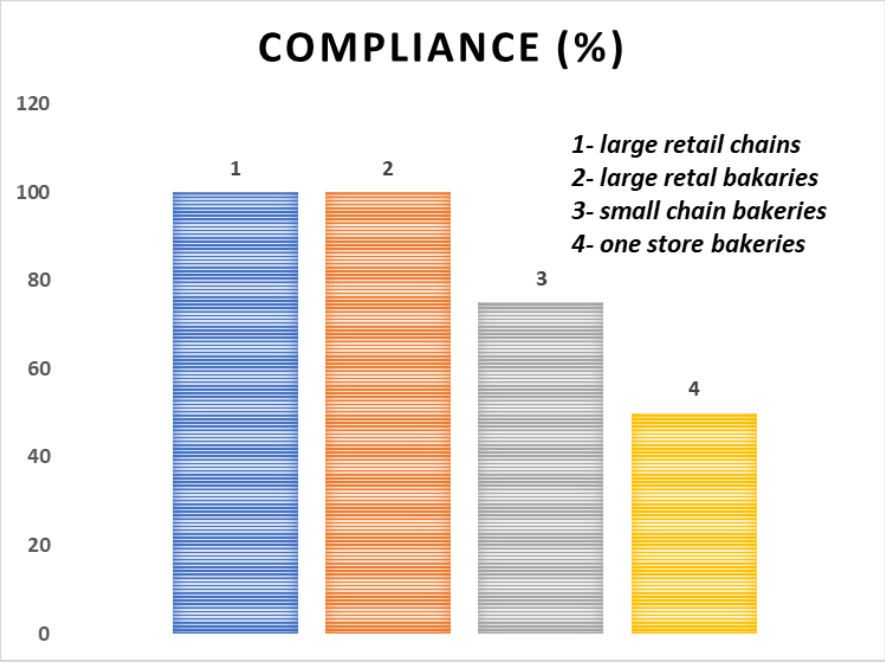

Figure 1. Compliance of monitored bakeries

Table 1. Monitored bakeries

FBOs	Total number of visited stores	Number of complied stores	Number of non complied stores
Food retail chains	40	40	0
Large bakery retail chains	40	40	0
Small bakery retail chains	20	15	5
Single bakery stores	20	10	10

6. CONCLUSION

Eating out at bakeries has become common over the years for almost all population. However, the risks of exposure to food allergens in bakeries have increased over the last few decades, prompting the bakery industry to be better prepared for such events. All major food retail and bakery retail stores in Belgrade proved to be compliant with the labelling regulation. On the other smaller bakery chains and single bakeries need further improvement when it comes to labelling their products.

Abstract: *Serbia is rich in vines. Serbian vineyards are fruitful and they are characterized by different varieties of grapes. The vines and the tradition of producing this divine drink are present in the south of Serbia, and the Čegar vineyards are also famous, located near the city of Niš. Wine has been produced in this area for centuries and, therefore, a lot of traditional methods have been retained in the production process, which were used in the process of obtaining the wine referred to in this paper. This paper examines the influence of raw materials, locality, and technological production process on the quality of produced rosé wine. The standard physical and chemical analyses were applied in the analysis of the wine, as well as the evaluation of the sensory characteristics of the wine (colour, clarity, smell, taste). The characterization of the produced rosé wine involved determining the content of the most important ingredients: relative density at 20/20°C 0.9936; alcohol 12.0% v/v; total extract 23.7 g/L; extract without sugar 17,4g/l; total acids 4.9 g/L; volatile acids 0.21 g/L; reducing sugars 7.3 g/L (semi-dry wine); total sulphur dioxide 85 mg/L; ash 1.51 g/L; pH 3.4. The wine is light red in colour, it is clear, and it has a distinctive aroma and a harmonious taste. The established chemical and sensory characteristics of the examined wine indicate that the grape varieties Prokupac can be considered good raw materials for the production of rosé wine.*
Keywords: grapevine, wine, production, quality, sensory characteristics

1. INTRODUCTION

Each grapevine variety possesses a unique combination of traits, which, along with applied agricultural and viticultural practices, geographical location, and ecological characteristics of the site, as well as winemaking techniques, impact the quality of grapes and the resulting wine [1]. With their distinctive characteristics, they play a crucial role in wine production, especially in the production of high-quality wines [2]. Behind each wine, there are one or more grape varieties, and each grapevine variety has a unique combination of properties, including the aroma, taste, and color of the wine. Knowledge of the spatial distribution of vineyard regions and conducting subsequent analyses is of essential importance for understanding the sustainability of wine production [3].

The locality of Sićevo is situated in the valley of the Nišava River, at an elevation of 365 meters above sea level. According to regional zoning, it is located within the 545 elevation level of the Čegar Vineyard, part of the Niš Region. The Vinkler index is 1736,7. The predominant soil types are colluvium and eutric cambisol. In this area, there are numerous vineyards on private properties. These are small areas primarily planted with wine and high-quality table grape varieties. The advantage of small vineyards is that they can receive full attention: manual pruning, coating each graft union with grafting wax, dedication to removing unwanted shoots, manual defoliation, and so on.

Aroma represents the most complex chemical component of grapes and wine. It consists of a large number of compounds whose concentration varies under the influence of the grape variety [4] and the terroir [5]. Several factors can influence the grape's aroma, including the application of specific viticultural techniques, the timing of harvest, and stressful growing conditions such as drought [6] . Additionally, the yeast strain used during fermentation, the type of wood from which the vessel is made, and the length of wine aging can also impact grape aroma [7,8].

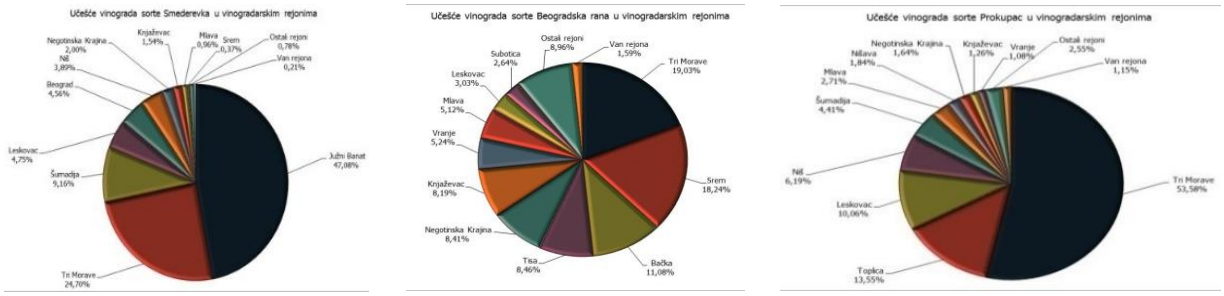

Figure 1. Participation of different varieties in wine-growing regions

2. MATERIALS AND METHODS

The grape harvest was conducted in sunny weather but not under high temperatures. The grapes were crushed during the harvest, with the removal of stems. The process took place in the shade. The prepared grape juice was stored in barrels located in a cellar room that had been previously treated with sulfur and had no direct sunlight, with a room temperature of 19°C. The entire process was carried out to avoid heating the juice. The grape juice had a sugar content of 21%, it settled for 48 hours, followed by racking, and then 10 grams of potassium metabisulfite per 100 liters of must be added, after which an S-shaped airlock was placed. Fermentation was completed in the middle of November, and the wine was racked in December.

The wine was produced in the Mladenović family vineyard. O.I.V. descriptors were used to determine the grape varieties. Phenological observations covered all phenophases to apply all necessary ampelotechnical measures adequately.

Variety Prokupac - the tip of the young shoot is very hairy, reddish-green in color. The developed leaf is of medium size, more or less entire with pronounced three sinuses. The upper side of the leaf is smooth and bare, while the underside is hairy. The berry is medium-sized, round, slightly flattened, with thick skin, bluish-black in color, and covered with numerous spots sprinkled with abundant bloom.

Beogradska rana - a vigorously growing vine. The developed leaf is of medium size, three-lobed, with deep closed sinuses. The cluster is large, conical in shape, and moderately compact. The berry is of medium size, slightly flattened, with moderately thick skin, yellow-green in color.

Afuz ali- a vine with very vigorous growth. The tip of the young shoot is green, without fuzz. Mature shoot thick, with long internodes. The developed leaf is of medium size, three-lobed, the upper side intensely green, without fuzz. The underside of the leaf is fuzz-free and pale green. The cluster is large, conical in shape, and loosely packed. The berry is large and elongated, amber-yellow in color, with specks and a dusting of grayish-white.
Smederevka - the vine is moderately vigorous. The tip of young shoots is green with a reddish shade, and it's hairy. Mature shoots are of medium thickness, with long internodes. The developed leaf is large, three-lobed, and heart-shaped. The upper side of the leaf is dark green and without fuzz, while the lower side is light green and hairy. The cluster is of medium size, cylindrical, and loosely packed. The berry is of medium size, oval, yellowish-green, and with amber spots on the sunny side.
Laboratory research was conducted in the laboratories of the Department of Agricultural and Food Studies in Prokuplje, which is part of the Toplica Academy of Vocational Studies. The physicochemical analysis of wine was carried out using methods prescribed by the International Organisation of Vine and Wine OIV (http://www.oiv.int/). The analysis included the following parameters: relative density at 20/20°C; actual alcohol %v/v; total extract g/l; extract without sugar g/l; total acids (as tartaric) g/l; volatile acids g/l; reducing sugars g/l; total sulfur dioxide mg/l; ash g/l; pH, with the addition of documented oenological methods [9].
In addition to the chemical analysis of the wine, a sensory evaluation of the wine was performed. The assessment of the sensory characteristics of the wine was conducted using the method of positive points from 0 to 100 [10]. For the obtained wine, visual, olfactory, gustatory, and gustatory-olfactory perceptions were scored.

3. RESULTS AND DISCUSSION

The vineyard was planted in the 1980s. Wine grape varieties Prokupac (40%) and Smederevka (15%) are represented, while table grapes include Beogradska Rana (15%) and Afuz Ali (30%). Afuz Ali is on a pergola, while the other varieties are trained using the Guyot double-cordon system. The rows are planted in cascades from east to west due to a slope of approximately 45 degrees, maximizing sun exposure and ventilation, which has a favorable impact on the vine microclimate. The support system is a trellis composed of concrete posts and three rows of wire. At the middle wire level, the wires are doubled, allowing shoots to be positioned in between, providing additional protection against damage from adverse weather conditions and crop load. In contrast to table grapes, short pruning is applied to wine grape varieties. In the case of Prokupac grapes, a significant presence of powdery mildew was observed, and the clusters were loosely compacted. The inter-row space is sown with medicinal herbs, horseradish, and other plants considered natural enemies of many diseases and pests. Thanks to the fact that Prokupac and Smederevka are indigenous varieties, Beogradska rana is a domestic variety, and Afuz ali showed loosely compacted clusters, there was no need for excessive use of chemical treatments. During pruning, which was done in a timely manner, each cut was coated with grafting wax, and two days after pruning, the vineyard was thoroughly sprayed with copper sulfate. The soil was enriched with potassium-based fertilizers. During the growing season, the shoot growth was monitored, and all green pruning measures were performed on time. During the flowering phenophase, there was no access to the vineyard. At the time of the veraison phenophase, shoots were trimmed to the level of the third wire, and leaf removal was carried out in the cluster zone. The territory of Serbia was divided into four homogeneous categories through cluster analysis. The most suitable region

includes cluster 3, which also covers the Sićevo area. This cluster abounds in warmth and light, with a favorable water regime and suitable temperature fluctuations, so according to Zirojević (1974) [11], the grapevine varieties of the examined vineyard can be successfully cultivated, which is equivalent to the data from the re-zoning extract (Table 1).

Table 1. Characteristics of grape varieties in the observed vineyard in the Čegar wine region

Variety	Origin	The use of	Characteristic
Prokupac	Autochthonous	Quality rosé wines	recommended/allowed
Smederevka	Autochthonous	Quality rosé wines	recommended/allowed
Beogradska rana	locally developed	Table grape	recommended/allowed
Afuz ali	International	Table grape	recommended/allowed

The physical-chemical analysis of the sample, which encompassed the examination of all relevant parameters for determining the properties, characteristics, and quality of the wine, is presented in Table 2.

Table 2. Results of the physical-chemical analysis of the examined sample.

Characteristic	Unit of measurement	Analysis method	Measured values	Values prescribed by the Regulations
Relative density at 20/20°C		VDM 14	0,9936	0,9850 - 0,9970
Actual alcohol content	% v/v	VDM 01	12,00	min. 8,5
Total extract	g/l	VDM 01	23,7	
Extract without sugar	g/l	VDM 01	17,4	min. 16,0 g/l
Total acids (as tartaric acid)	g/l	A10 (OIV-MA-E-AS313-01)	4,9	min. 4,5
Volatile acids	g/l	A11 (OIV-MA-E-AS313-02)	0,21	max.1,2g/l
Reducing sugars	g/l	VDM 02	7,3	4 g/l - 12 g/l
Total sulfur dioxide	mg/l	A17 (OIV-MA-E-AS323-04)	85	max. 250
Ash	g/l	A6 (OIV-MA-E-AS2-04)	1,51	min. 1,4

Table 2 shows that the alcohol content in the examined wine was 12.00% v/v, total extract 23.7 g/l, extract without sugar 17.4 g/l, total acids 4.9 g/l, volatile acids 0.21 g/l, reducing sugars 7.3 g/l (semi-dry wine), total sulfur dioxide 85 mg/l, ash 1.51 g/l, pH 3.4. The wine is light red in color, clear, with a characteristic aroma and a harmonious taste. In terms of quality, it is classified as table wine, in terms of color as rosé wine. Regarding the content of unfermented sugar, it falls into the semi-dry wine category. The alcohol content is within the range of ordinary vine. The extract without sugar in g/l is above the minimum of 16.0 g/l prescribed for rosé wines, and the total acids (as tartaric acid) are above the minimum of 4.5 g/l. The ash content expressed in g/l is above the minimum of 1.4 g/l prescribed for rosé wines. Sensory analysis of the sample is provided in Table 3."

Table 3. Sensory analysis of the tested sample

Serial number		Visual observations	Olfactory observations	Gustatory observations	Gustatory-olfactory observations	Total points
1.	Evaluator 1	13,33	18,00	18,00	12,00	61,33
2.	Evaluator 2	14,00	19,33	18,67	13,33	65,33
3.	Evaluator 3	14,67	20,33	21,00	14,00	70,00
4.	Evaluator 4	14,00	20,00	20,33	14,00	68,33
5.	Max. points	20,00	30,00	30,00	20,00	100,00

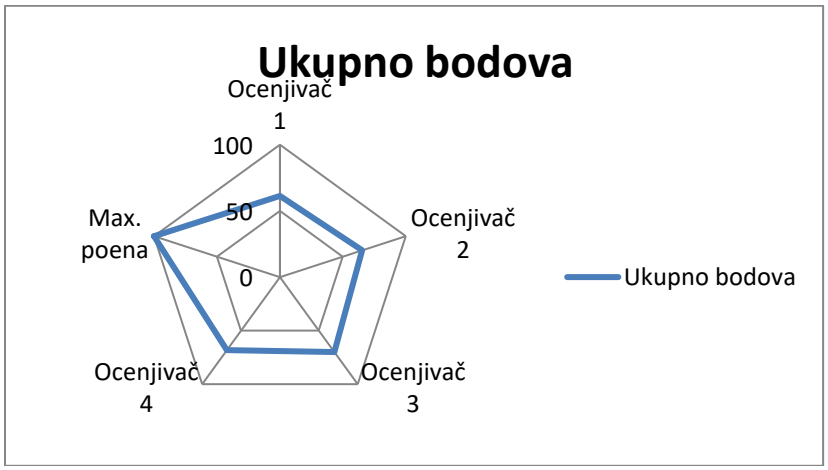

Figure 2. Graphic display of scoring

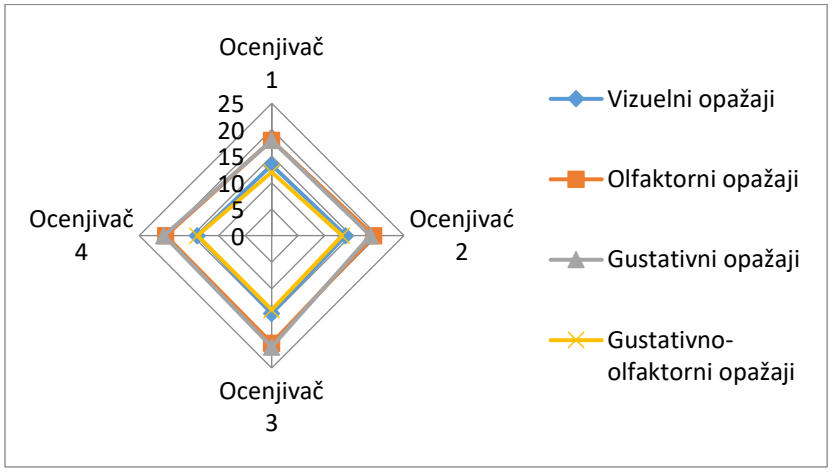

Figure 3. Graphic representation of sensory evaluation

4. CONCLUSION

Agroecological conditions in Serbia are extremely favorable for the cultivation of grapevines. The grapevine variety is the primary determinant of wine quality, both in terms of its chemical composition and sensory characteristics: color, aroma, and taste. The indigenous grape variety Prokupac is recommended for the production of rosé and red wines. The basic components of wine vary depending on the influence of various factors (raw materials, location, and production technology). The parameters of the chemical analysis of the examined wine corresponded to the values prescribed by the regulations. The wine is light red in color and clear. It has a fruity aroma, and the taste is fresh with a discreet bitterness and satisfactory aroma persistence. The established chemical and sensory characteristics of the examined wine indicate that Prokupac, which is the most dominant variety, along with Beogradska rana, Smederevka, and Afuz ali, can be considered good raw materials for the production of rosé wine.

OCCURRENCE OF OCHRATOXIN A IN WINE IN SERBIA IN 2022

Danka Mitrović[1], Faculty of Agriculture, University of Belgrade
Nikolina Živković[2], Faculty of Agriculture, University of Belgrade
Jelena Pavlović[3], The Academy of Applied Technical Studies Belgrade
Marko Jauković[4], The Academy of Applied Technical Studies Belgrade

Abstract: *Wine production in Serbia has a long tradition and represents one of the increasing branches of agricultural production in last decade. Wine produced in Serbia have for many years a reputation of good quality products. Health benefits of wine related mostly to cardiovascular diseases are well known. However, wine is also recognized as one of the main contributors to the dietary intake of ochratoxin A. Ochratoxin A is a widespread mycotoxin that is produced by several Aspergillus and Penicillium species and main mycotoxin occurring in wine. In this study, a total of 200 samples of red, white and rose wine were collected from Serbian market in 2022. The samples were analyzed for ochratoxin A (OTA) content by using an enzyme-linked immunosorbent assay Ridascreen® Ochratoxin A 30/15. The occurrence of OTA in tested red wine samples was 69%, with average concentration 0.71 µg/kg and maximum OTA content of 1.86 µg/kg. On the other hand, only two out of 136 analyzed white and rose wine samples were detected positive for OTA presence. These results suggest very high level of occurrence of OTA in tested red wine samples. The limit of 2.00 µg/kg imposed by Serbian legislation for OTA content in wine was not exceeded in any of the studied samples. It can be concluded that levels of OTA in wines from Serbia do not pose a risk for human health.*
Key words: wine, ochratoxin A, ELISA.

1. INTRODUCTION

The presence of ochratoxin A (OTA) in wine is mainly due to the contamination of grapes by *Aspergillus carbonarius* and *A. niger*, still in the vineyard or at stages prior to winemaking. Throughout winemaking process, although there is a reduction in OTA levels, modified mycotoxins may also be formed. Factors such as grape variety, damages in grape berries, vineyard, location, temperature, relative humidity, precipitation, microclimate, harvesting period, pesticide application and good agricultural practices in the vineyard, oenological steps and good manufacturing practices during winemaking will be decisive for OTA levels present in wine [1] Ochratoxin A (OTA) is a mycotoxin produced by some fungal species belonging to genera *Aspergillus* and *Penicillium* [2]. OTA can survive most food processes, such as baking, brewing, and heating because of their highly stable molecular structure and thermal stability. The

[1] danka.mitrovic@agrif.bg.ac.rs
[2] nikolina.zivkovic@agrif.bg.ac.rs
[3] jpavlovic@atssb.edu.rs
[4] mjaukovic@atssb.edu.rs

winemaking process strongly influences the OTA content, since higher concentrations have been reported in red wines than in rosé and white wines in general [3] due to differences in applied oenological practices: especially the maceration step [4]. During winemaking, crushing of grape berries and the maceration steps favor OTA release to must, suggesting grape skin is the main source of OTA [3]. After maceration for red wines and crushing for white and rosé wines, alcoholic fermentation occurs, a process by which the sugars present in the grapes, thanks to the metabolism of yeasts, are converted into alcohol. Although mycotoxigenic fungi can accompany the grapes from the time they are on the vine, the fermentation process inhibits their growth [5]. The reduction in OTA levels during winemaking has been justified by the partition of OTA between liquid and solid phases (due to the adsorption of OTA in the solid particles of the must) and subsequent natural sedimentation [6]. The second reason is adsorption or degradation by yeasts (composed of mannoproteins and-glucans) and/or lactic acid bacteria (LAB). It was shown that chitin,-glucan, and their hydrolysates could remove 64 to 74% of OTA from contaminated wine. However, this reduction is limited and, due to its partial stability, OTA is not completely eliminated throughout the oenological steps and residues of this mycotoxin are still detected in the final product [5]. Also, there is possibility of degradation or transformation into modified mycotoxins during fermentation processes [1].

2. MATERIALS AND METHODS

2.1.Collection of samples

Present study examined 200 samples of wine (red, rose and white), collected from markets from all over the Serbia in 2022. Before analysis, the samples were stored at refrigerator (4-6ºC), protected from light.

2.2.Sample preparation

All collected samples were prepared and analyzed in accredited laboratory for testing food and feed safety „Jugoinspekt Beograd“. Samples of red wine were prepared according manufacturer's instructions. Prior to analysis, 5 ml of each sample was pipetted into a 50ml PP-tube and mixed with 20 ml of diluted ECO extractor. The mixture was shaked vigorously (manually) for 5 minutes. The extract was centrifuged for 5 minutes at 3500g, RT and 1 ml of supernatant was diluted with 1ml of ready to use wash buffer. According to manual instructions 50 µl of diluted sample was used in the test.

2.3.Ochratoxin A analysis and instrumental conditions

Determination and quantitative analysis of ochratoxin A was done by Enzyme Linked ImmunoSorbent Assay (ELISA) method, using RIDASCREEN® Ochratoxin A 30/15 (RBiopharm) test kit. Multiskan FC microplate reader with absorbance range 0 - 6.000 A was used. Normal reading mode was used with reading speed t = 13 s Analysis were performed according to manufacturer's instructions (RIDASCREEN Ochratoxin A 30/15 Art.No.:1312). Limit of detection (LoD) was set on 0,1 µg/kg while limit of quantification (LoQ) was calculated at 0,3 µg/kg. Measuring range was confirmed from 0,3 to 25 µg/kg, while recovery rate was ranging from 94 to

116 %. The measurement is made photometrically at 450 nm. The absorbance is inversely proportional to the ochratoxin A concentration in the sample of red wine.

3. RESULTS AND DISCUSSION

Ochratoxin A has been detected in 44 out of 64 (68%) samples of red wine, at levels ranging from 0.37 μg/kg to 1.86 μg/kg. Average concentration was 0.71 μg/kg and maximum OTA content of 1.86 μg/kg (Table 1). In majority of the contaminated samples (39) OTA concentration ranged from 0.3 μg/kg to 1.00 μg/kg. Only in 5 samples of red wine concentration exceeded 1.00 μg/kg.
On the other hand in only 2 samples out of 136 analyzed samples of white and rose wine were quantified with ochratoxin A (Table 1). Overall, this suggests very high level of occurrence of OTA in tested samples of red wine. High level of occurrence could be explained by the red wine making process. Maceration, which occurs just in red wine making process allows the migration of OTA from the grape to the must [4]. Žurga et al. [7] have found that 92% of studied samples of red wine were contaminated with ochratoxin A which is in correlance with this study (89%). Furthermore, in United States more than 85% of the samples evaluated were found to contain OTA [8]. The limit of 2.00 μg/kg imposed by Serbian legislation for OTA content in wine was not exceeded in any of the studied samples, which is comparable to those performed in some other studies. Mariño-Repizo et al. [6] have found that wines produced in Argentina have OTA concentrations far below the proposed European limit (2.00 μg/kg). Furthermore, Remiro et al. [9] have reported that concentrations in all examined samples of red wine were even 10 times lower than the maximum limit of contamination (2.00 μg/kg). Although high level of occurrence was detected contamination levels were way below a provisional tolerable daily intake (PTWI) established for this toxin by JECFA (112 ng/kg bodyweight) [10], which proves that wine from Serbia, consuming in reasonable amounts, are safe for consumption.

Table 1. OTA levels in Serbian wine in 2022.

	Wine		
	Red	**White**	**Rose**
No. of contaminated/Total No.	**44(64)**	**1(118)**	**1(19)**
Range (μg/kg)	**0.37 – 1.86**	**≤0.60**	**≤0.61**
Average of contaminated (μg/kg)	**0.71**	/	/
Median of contaminated (μg/kg)	**0.62**	/	/

4. CONCLUSION

Ochratoxin A has been detected in majority of the analyzed samples. This leads to a conclusion that presence of fungi and its metabolites is natural and hardly can be avoided. Also, it was confirmed that the process of making red wine is more favorable to occurrence level of OTA. However, the levels of contamination did not exceed maximum limit imposed by the Serbian law which proves that with good agricultural practice the level of contamination can be managed. Furthermore, contamination levels were way below a provisional tolerable daily intake (PTWI) established for this toxin by JECFA which proves that wine from Serbia are safe for consumption.

AFLATOXIN M1 LEVELS IN MILK IN SERBIA IN 2022

Anja Vuksan[1], Laboratory Field Test, Belgrade
Jelena Pavlović[2], The Academy of Applied Technical Studies Belgrade
Marina Stamenović[3], The Academy of Applied Technical Studies Belgrade
Marko Jauković[4], The Academy of Applied Technical Studies Belgrade

Abstract: *Aflatoxins are secundary metabolites of toxigenic fungi from the genus Aspergillus such as A. flavus and A. Parasiticus. They are considered to be most spread mycotoxins, infecting grains during storage, spices, nuts, milk and animal feed. Major forms of aflatoxins include B1, B2, G1, G2 and M1. Mammals that ingest AFB1 contaminated food eliminate amounts of the main hepatic metabolite known as milk toxin or aflatoxin M1 (AFM1) via milk. The incidence of contamination of aflatoxin M1 (AFM1) in milk samples collected from the Serbian producers was investigated by using the competitive enzyme linked immunosorbent assay (ELISA) technique. In this study, a total of 68 samples of raw, pasteurised and UHT milk was examined in 2022. AFM1 was quantified in 39 samples (57.3%), at levels ranging from 0.02 to 0.19 µg/kg. In Republic of Serbia, maximum residue limit of AFM1 is 0.25 µg/kg. These results suggest that number of milk samples contaminated with AFM1 is not negligible. The occurrence of aflatoxins in milk is one of the most serious problems, as milk is a key source of nutrients for human. Therefore, continuous monitoring over milk is necessary.*
Key words: Aflatoxin M1, milk, ELISA.

1. INTRODUCTION

Aflatoxins are secundary metabolites of toxigenic fungi genus *Aspergillus* such as *A. flavus* and *A. Parasiticus*. Due to their toxicity, which can cause a multiple negative effects on both human and animal health they represent the most examined mycotoxins [1,2]. Even in low concentrations, they are highly toxic. Depending on the amount, frequency, age, gender and physical state of the human ingestion can cause a development of series of illnesses [3]. Its toxicity is proved in numerous studies, both *in vivo* and *in vitro* [4]. Major forms of aflatoxins include B1, B2, G1, G2 and M1. Mammals that ingest AFB1 contaminated food eliminate amounts of the main hepatic metabolite known as milk toxin or aflatoxin M1 (AFM1) via milk [5,6,7] and is classified in the 1st group of toxins by the *International Agency for Research on Cancer, IARC* [8,9].
Aflatoxins are mostly detected in agricultural products from tropical and subtropical climatic conditions like those existing in Latin American, Asian and African countries, southern regions of US and certain parts of Australia [10]. However, as a result of climate change in Balkans aflatoxins became a greater concern for food safety in Serbia [11].

Milk is a widely consumed beverage that is essential to the diet of several millions of people worldwide because it provides important macro- and micronutrients. However, contamination of milk with AFM1 is considered to be a great risk for human health. Even low level of contamination can cause concern due to a high level of exposure of consumers [12,13].
Continuous monitoring of AFM1 contamination in milk is necessary and the aim of this research is determination and evaluation of levels of AFM1 in milk in Serbia in 2022.

2. MATERIALS AND METHODS

2.1.Collection of samples

Present study examined 68 samples of raw, pasteurized and UHT milk. All samples were collected during 2022, as a part of the food safety control. Before analysis, the samples were stored at refrigerator (4-6ºC), protected from light.

2.2.Sample preparation

All collected samples were prepared and analyzed in accredited laboratory for testing food and feed safety „Jugoinspekt Beograd“. Milk samples were prepared according manufacturer's instructions. Prior to analysis, 20 mL of each milk sample was centrifuged for 10 min at 3000 × g. The upper creamy layer was removed by aspirating through a Pasteur pipette. Skimmed milk (defatted supernatant) was used in the test (100µl per well) plate.

2.3.Aflatoxin M1 analysis and instrumental conditions

Determination and quantitative analysis of aflatoxin M1 was done by Enzyme Linked ImmunoSorbent Assay (ELISA) method, using RIDASCREEN Aflatoxin M1 (R-Biopharm) test kit. Analysis were performed according to manufacturer's instructions (RIDASCREEN Aflatoxin M1 Art.No.:1121). The measurement is made photometrically at 450 nm. The absorbance is inversely proportional to the aflatoxin M1 concentration in the sample. Multiskan FC microplate reader with absorbance range 0 - 6.000 A was used. Normal reading mode was used with reading speed t = 13 s. Special software Rida® Soft Win (Art. No. Z9999, R-Biopharm, Germany) was used for the evaluation of enzyme immunoassays. Limit of detection (LoD) was 0,005 µg/kg.

3. RESULTS AND DISCUSSION

The results on occurrence of aflatoxin M1 in raw milk, pasteurized milk and UHT milk are represented in Table 1.

Table 1. Occurrence of aflatoxin M1 in milk (monthly)

	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**	**11**	**12**
Detected AM1/Total number of analyzed samples	3/8	11/13	1/6	3/6	1/4	4/7	2/4	1/4	3/4	3/4	4/5	3/4
Detected AM1/Total number of analyzed samples (%)	37.5	84.6	16.7	50	25	57.1	50	25	75	75	80	75
Range of concentration (µg/kg)	0.02 - 0.04	0.02 – 0.19	0.02 - 0.04	0.02 - 0.04	≤0.02	0.02 - 0.06	0.03 – 0.04	≤0.03	0.02 – 0.03	0.03 – 0.04	0.02 – 0.04	0.02 – 0.04

Aflatoxin M1 was detected in 51 out of 68 milk samples (75%), at levels ranging from 0.02 to 0.19 µg/l. In 4 % of samples, maximum EU level for AFM1 in milk (0.05 µg/kg) was exceeded which is significantly lower frequency of AFM1 contamination than reported by Jakšić et al. [14] for the period 2013-2015, where 73.3% of the samples exceeded concentration of AFM1 of 0.05 µg/kg in 2013, 39.4 % in 2015 and 28.6% in 2015.

4. CONCLUSION

The presence of AFM1 was detected in 51 out of 68 analyzed samples of raw milk, pasteurized milk and UHT milk. The highest percentage of contaminated samples was detected in February (84.6%). The maximum contamination level of AFM1 (0.19 µg/kg) and the highest range as well was detected in February. In 4 % of samples, maximum EU level for AFM1 in milk (0.05 µg/kg) was exceeded. Obtained results suggest still high contamination frequency of AFM1 in examined samples. Considering that aflatoxins are highly toxic and since milk represents one of the main foodstuffs in human diet in Serbia, there is a concern regarding human exposure to AFM1. Although, high contamination levels seldom occur in commercial milk, there is a need for permanent control and continuous monitoring over milk in order to avoid health risks related to presence of AFM1.

ADVERSE EFFECTS OF PESTICIDES ON PUBLIC HEALTH

Danijela Pecarski[1], The Academy of Applied Studies Belgrade
Dubravka Marinović[2], The Academy of Applied Studies Belgrade
Dragana Dragaš Milovanović,The Academy of Applied Studies Belgrade
Svetlana Karić, The Academy of Applied Studies Šabac

Abstract: *The use of pesticides, in agriculture for food safety and epidemiology-wise for vector control purposes, has a future growth potential due to the estimate of the Earth's population reaching 9.9 billion inhabitants by 2050, with the primary growth in the developing countries accompanied by the increase of food production in line with the population's needs. Global climate changes contribute to the pests' distribution change leading to their extensive use. Pesticides can persist for a long while in the environment and are imminently part of everyday life. Because of its toxicity, they present a detriment to humans and eco-systems. They are used not only in agriculture, food production through weed growth control and pest extermination, on animal farms, households, forestry and wood-processing, but also in urban areas such as public parks, gardens and playgrounds. Wide population using urban green areas is exposed to pesticide toxicity risk, especially the children and the elderly whose organisms tend to be more sensitive. The pesticide residue in food and the environment presents a public health problem since it is linked to a series of health problems demanding monitoring on a regular basis. This paper presents an overview of pesticides in the light of their division, environment distribution, exposure maps, different properties, toxicology effects and health risks*.
Keywords: pesticides, residue, environment, toxicity, public health

1. INTRODUCTION

Pesticides are a group of chemical compounds used control and extermination of all pests ranging from insects, weeds to microorganisms. Indisputably, the mankind has benefited a lot from its wide use in agriculture, economy and medicine, but their toxicity captures global attention regarding the frequency certain illnesses compared to different exposure maps. There is massive evidence of the role of pesticides in the incidence growth of many illnesses due to oncogenic and other toxic potential primarily affecting the nervous and endocrine systems. The direct exposure is professional, and it is indirectly executed through food and water residue intake, aerosol inhalation or skin absorption. It is estimated that 1.8 billion people worldwide work in the agriculture sector, while the rest of population gets in touch with pesticides though the commercial use or application of pesticides in parks, gardens and households. Also, they can be traced in groceries, the pesticides used the agricultural production processes or the protection of the agricultural products from vermin in warehouses and storerooms. Many of the pesticides decompose over time, so it is important to keep track of the pre/harvest interval for pesticides, that is, the minimal time needed from the final pesticide treatment of the plant to the harvest or picking period.

[2] drmarinovic@yahoo.com

2. PESTICIDE CLASSIFICATION

Pesticides (the name comes from the Latin words “pestis” = pestilence, plague or illness and “caedare” = to kill) are toxic substances or mixtures of substances used for selective extermination of macro- and micro-organisms which are found highly intrusive by the humans and the communities. According to FAO (Food and Agriculture Organisation of the United Nations) pesticides are “substances or mixtures of substances used for preventing attacks, exterminating or controlling any kind of vermin/pests (human/animal disease carriers, intrusive plants / weeds and animals which are accountable for losses during production, processing, storing, transporting or market-placing of food, agricultural products, wood, wood products or animal food) including the ones parasitising inside or outside an animal’s body”.
Pesticides include numerous substance groups used for vermin/pest protection: insecticides, herbicides, fungicides, rodenticides, wood preservatives, garden chemicals, household disinfectants and other compounds. The most common pesticides classification systems are:

A. Classification according to ways of entering the human organism
B. Classification according to the pesticide function and targeted organisms – vermin/pests exterminated
C. Classification according to the chemical composition of the pesticides

According to the organism entry ways, they are classified as systemic, contact, oral, fumigants and repellents.
According to the intended use, they are classified based on the type of vermin/pest they exterminate, thus the name (Table 1)
According to the chemical composition, they are classified based on the active substances, functional groups, effect and toxicity, which is the most common in use.

Table 1: Classification of pesticides according to intended use or effect mechanism

Pesticide Type	Pest/Vermin they exterminate/effect mechanism	Example
Insecticides	Insects	Malathion
Fungicides	Fungi (mildew, mold)	Carbamic acid derivatives
Herbicides	Weeds	Paraquat and Diquat
Acaricides	Mites and ticks	Permethrin
Rodenticides	Mice and rats	Warfarin
Algaecides	Algae	Copper sulphate
Larvicides	Insect larvae	Methoprene
Repellents	Repel vermin, primarily insects	N-diethyl-meta-toluamide
Weed pesticides	weeds	Boric acid
Ovicides	Inhibit egg growth, insects and mites	Clofentezine
Viricides	Herbal viruses	Beta-Caryophyllene
Nematicides	Nematodes	1, 3-Dichloropropane
Avicide	Birds	4-Aminopyridine

3. THE SIGNIFICANCE OF PESTICIDES

The UN Population Department estimates that the Earth will be populated by 9.7 billion inhabitants by 2050, which entails a necessary growth of food production by 80% according to FAO. There are some 9 000 types of insects/mites, 50 000 types of plant pathogens and 8 000 types of weeds, so, without the use of pesticides, the agricultural production losses would be huge.

4. POPULATION EXPOSURE TO PESTICIDES – FOOD RESIDUE

A contaminant is every substance detrimental to human health which is inadvertently added to food, obtained during the process of producing, processing, treating, packaging, transporting or storing food. Regardless of the food contamination origin – biological organisms, chemical substances or objects, the public eye has been predominantly focused on the presence of food additives and pesticides over the recent years. The food pesticide residue is detrimental to health because of its fat solubility, fat accumulation and long-lasting effects owing to high stability. For the sake of food safety and human healthcare, regulators dealing with this issue in all developed countries worldwide determine two key criteria aimed at limiting of the amount of permitted food contaminants: pre-harvest interval for pesticides and Maximum Residue Limit (MDK) found in groceries. The maximum residue limit refers to the amount or concentration of a pesticide which is still permitted. The health safety of a product is determined by comparing the measured pesticide level to maximum residue limit (mg/kg) which is legal in food. Higher level quantities are regarded as detrimental and such grocery must not be used in mass nutrition. It is determined for each substance respectively which is legal to be used in herb protection for every herb permitted to use the pesticide. Each developed country is obliged to legally regulate monitoring mechanisms of the pesticide amount in food products aimed at keeping a constant track of the pesticide value. Every increase in the MDK value is an alarm for the producer to correct the ways of pesticide application and adjust it with the instructions. It is vital to draw the inspection authorities' attention to strict and zealous control of the product samples coming from the producers/distributers whose products have been ascertained to contain MDK excess. Pre-harvest interval for pesticides is the minimum time needed for the pesticide decomposition or elimination between the final pesticide treatment and the harvest/picking period.

According to the toxicity level of a substance, types of human hazard have been ascertained. The first type of hazard includes substances whose borderline dosage is known or the concentration of a potentially detrimental substance followed by threshold effect if the exposure lasted long enough. The second type of hazard refers to the substances that exhibit non-threshold effect, because it emerges with the lowest concentration, like genotoxic effect substances, and the poisoning intensity depends on the poison dosage size that reach the human organism. The first-type hazard substances are permitted in food if below the borderline dosage, while the second-type hazard substances are banned, even in smallest quantities.

A special issue is health risk assessment after exposure to a certain toxic substance whose essence lies in the determination of the correlation of the poison dosage taken into organism and the type/intensity of the toxic effects on the human organism. International scientific committees, The Joint FAO/WHO Expert Committee on Food Additives (JRCFA) and Joint FAO/WHO Meeting on Pesticides Residues (JMPR) deal with the determination of the acceptable daily intake of the first-type hazard substances which exhibit the toxicity threshold. In this context. It is significant the differentiate the chronical exposure during a long period and the acute exposure during a short period of time. In both cases of exposure, the poison dosage taken into organism is compared to the Acceptable Daily Intake (ADI) and Acute Reference Dose (ArfD). Acute Reference Dose is the amount of the chemical substance which can be taken into the organism during one meal or during one without harmful effects. A certain type of food is regarded safe if the estimated intake of a harmful intake does not exceed the acceptable daily intake, or acute reference dose. The acceptable daily intake is calculated based on the dose obtained from animal experimentation. No-adverse-effects-level (NOAEL) is its highest dose which did not cause any harmful effect on the animals which took the dose during the experiment. Divided by the safety factor (which is 10 at least, usually 100) provides the acceptable daily intake.

Acceptable Operator Exposure Level (AOEL) is the dose which will not cause harmful effects in the people professionally exposed to pesticides within one-day, one-week, one-month period, and depending on the duration of exposure the short-term AOEL refers to the exposure during several weeks or during one season, and long-term AOEL on the repeated exposure for one year. The determination of AOEL and ADI value is aimed at preventing poisoning – bearing in mind that this refers to the professional exposure to potential poisonous substances. The primary exposure route in

the case of professional risk id through skin and because of that AOEL for many substances is determined in studies with experiment animals by skin tests.

5. TOXICOLOGICAL SIGNIFICANCE AND DETRIMENTAL EFFECTS OF PESTICIDES ON THE HUMA HEALTH

Depending on the toxicity level, World Health Organisation (WHO) has classified pesticides into four categories. Based on the experiments conducted on animals which yielded increasing pesticide doses, the medium lethal dose is determined for each pesticide (LLD 50 – the dose that leads to 50% mortality of the exposed animals), shown in Table 2.

Table 2: The Pesticide Classification according to the Toxicity Level

Classes according to toxicity level	**Toxicity level**	**LD 50 for rodents in mg/kg of the body weight**		**Examples**
		Oral	***Local***	
Class Ia	Extreme Toxicity	<5	<50	Parathion, Dieldrin
Class Ib	High Toxicity	5-50	50-200	Eldrin, Dichlorvos
Class II	Moderate Toxicity	50-2000	200-2000	DDT, Chlordane
Class III	Low Toxicity	>2000	>2000	Malathion
Class IV	Low probability of causing poisoning with normal use	>5000		Carbamate, Cycloprothrin

The uncontrolled application of pesticides and lack of pre-harvest interval for pesticides lead to adverse effects on the human health, useful insects and animals. Long-term use of the food containing pesticide residues can lead to serious disturbances due to the chronical organism poisoning. The estimated figures show that some 5 000 to 20 000 people die because of pesticides and some 500 000 to a million people get poisoned by pesticides. Bearing in mind these figures, 50% to 75% of all the people whose death cause can be traced in adverse pesticide effects are agriculture workers, while others get exposed by the contaminated food consumption. Half of the total number of the poisoned and two thirds of the deceased come from third-world countries, while at the same time as much as 80% of all pesticides is in the developed countries. WHO has issued the data that one person dies of pesticides each minute in the third-world countries due to mishandling pesticides. Even though the real consequences of chronical pesticide poisoning are not known, the literature features neurotoxicity, reproductive toxicity, immunosuppression, and cancerous effects and thus the involvement into the pathogenesis of many illnesses. The evidence brings to light the oncogenic potential of the chronical intake of arsenic which increases the possibility of lung cancer. The problem is becoming even more serious due to an increasing exposure to pesticides by humans. More than 98% of the used insecticides and 95% of the used herbicides gets on people through food, water or air, at least in small doses. After treating a plant/herb with a pesticide, the majority of the active substance is removed mechanically and gets into the ground or is decomposed, but a certain amount can be permanently stored in the plant tissue and reach the humans and animal through the food intake. The quantities of pesticides permanently kept on the treated plants are called pesticide residue. Pesticide metabolites can be more toxic than the initial active substance , such as paraoxon – parathion metabolite. The majority of pesticides get on food after the direct plant treatment, and the minority comes from rivers and subterranean water infected with pesticides. By raining down agricultural areas, pesticides reach surface water and groundwater. Pesticides that decompose slowly are evaporable liposoluble and can be transferred further away from the initial point of treatment. In the food chain, pesticides get to humans through animals, so a necessary and justified control of pesticide

residue is required for all the food, plant and animal origin. A part of the food pesticides can be removed while processing food. Most pesticides are kept on the fruit and vegetable skin, so washing and skin removing are efficient methods of pesticide removal. As for meat and fish, heat treatment is an efficient method.

6. CONCLUSION

Pesticide residues in water and air are the major concern because they pose a serious threat to biological communities, including humans. They are various ways that pesticides can enter water such as accidental spills, industrial waste, surface runoff from soil treated with pesticides, washing of spray equipment after spraying, and the like. The presence of pesticides in the air can also be caused by number of factors, including wind blowing and evaporation from cultivated areas. To what extent we will manage to limit the harmful effect of pesticides on the environment depends solely on our conscience and respect for the principles of their safe applicatiom.
Exposure to pesticides is imminent because their use is an integral part of the modern life in different walks of life including public health and modern agriculture. Given the widespread application, law-abiding approach is a must, coupled with strict contamination control and the effects on the environment and organisms which are not the target in order to reach the needed safety level of any biological system or people. Besides this, it is important to alert the public regarding the necessary hygiene measures and steps.

Abstract: *Potentially toxic elements (PTEs) are transferred to vegetables primarily through agricultural soil or irrigation water. PTEs in agricultural soil originate from pedogenic and anthropogenic sources. In most cases, soil contamination with these elements happens via river systems or air pollution. Furthermore, food is now imported from many regions and countries, where it is grown in various conditions and on various agricultural lands. Peppers (Capsicum annuum) are popular vegetables in Serbia and worldwide. They are consumed in numerous dishes as fresh fruits, spices, or ingredients. Peppers are reach source of carotenoids, vitamins, antioxidant compounds, and other nutritive compounds. This study aimed to estimate the human exposure to thirteen PTEs present in fresh, dried, and processed peppers obtained from the Serbian market. The exposure assessment was conducted for people in four regions of Serbia by calculating the target hazard quotient (THQ) and carcinogenic risk (CR). The comparison across areas was made due to significant disparities in pepper consumption between them.*
Keywords: Heavy metal(loid)s, Cancer Risk, Hazard Quotient, Non-carcinogenic risk, Vegetables

1. INTRODUCTION

Peppers (*Capsicum annuum*) are one of the most widely cultivated vegetables in the world. Pepper fruits are consumed fresh and processed (as a condiment, spice, and ingredient in numerous dishes) [1]. These vegetables represent an excellent source of vitamins, phenolic compounds, carotenoids, and other antioxidant compounds [2]. Fruits differ in shape, color, and whether they are pungent or non-pungent [3]. Capsicum is also a very popular vegetable species in Serbia, which is the most cultivated vegetable after potatoes. Serbia has many traditional processed pepper foods such as stuffed peppers, pickled peppers, peppers in sour cream, ajvar, pinđur, ljutenica, trljenica and many others [4].

Vegetables as well as other plants can accumulate potentially toxic elements (PTEs) in different parts. Food contamination with PTEs occurs through soil, water, air, dust, and the application of fertilizers and pesticides [4,5]. PTEs in soil originate from lithogenic or anthropogenic sources [6,7]. Anthropogenic activities include urbanization and industrialization, particularly mining activities. Additionally, contamination of agricultural soils happens due to wastewater irrigation, which causes aggregation of PTEs in the crops [8]. Vegetables are one of the main routes for PTEs exposure in humans. Therefore contaminated vegetables could cause human health risks [9]. Consumption of vegetables contaminated with PTEs can cause serious problems, such as damage to the kidney and

heart, nervous, cardiovascular, and gastrointestinal systems, development of cancers, and many other health issues [8,10]. Special concern has to be taken for toxic elements such as As, Pb and Cd which are classified as carcinogen of first category by the International Agency for Research on Cancer (IARC) [11]. The safety of vegetables is always a concern, so it is essential to monitor and evaluate human health risks arising from the accumulation of PTEs. Besides that, consumption of the same vegetables isn't the same in various regions. Therefore, exposure to PTEs for population from two regions can be different even if they eat the vegetables grown in the same agriculture field.
The aim of this study was to compare the health risk due to PTEs in pepper fruits between four regions in Serbia. The samples were purchased in local markets in Belgrade, and were imported from different countries in Europe.

2. MATERIALS AND METHODS

2.1 Samples and chemicals

The selected pepper fruits were obtained from local markets in Belgrade in February 2021. Selected samples (n=28) were fresh and processed pepper (pickle peppers, peppers in sour cream, stuffed pepper, and dried peppers). We assumed that peppers of the same or comparable origin are available on the markets in other parts of Serbia. Consumption of fresh and dried peppers in four regions in Serbia is given in Table 1. Nitric acid (65%), hydrogen peroxide and hydrochloric acid were supplied from Sigma Aldrich. Standard solutions were purchased from AccuStandard (New Haven, USA).

Table 1. Ingestion rates of peppers for adults and children in four regions of Serbia [12].

	Adults		Children	
	Dried	Raw or processed	Dried	Raw or processed
IR (g/day) Belgrade region	0.276	24.43	0.110	9.77
IR (g/day) The region Vojvodina	0.265	23.51	0.106	9.40
IR (g/day) The region of Šumadija and Western Serbia	0.443	39.23	0.177	15.70
IR (g/day) Region of Southern and Eastern Serbia	0.733	64.92	0.293	25.97

2.2 Sample preparation and analysis

The microwave digestion was carried out in PTFE containers, where 0.5 g of homogenized sample was mixed with 7 cm^3 65% HNO_3 and 2 cm^3 30% H_2O_2. A microwave oven system model CEM Mars 6 (Matthews, USA) was used to digest pepper samples.
The obtained supernatants were used for analysis of thirteen PTEs: As, Pb, Cd, Hg, Fe, Zn, Cu, Mn, Co, Cr, Li, Ni, and Al. The concentrations of elements were determined by ICP MS (iCAP Q, Thermo Scientific, UK). Good linearity was assumed since the correlation coefficients (R^2) were greater than 0.999. The detection limits ranged from 0.19 μg/kg to 12.5 μg/kg. The recovery ranged from 82.2% to 151%. Relative standard deviation (RSD) percentages vary from 5.12% to 42%. The value 42% represent RSD obtained for Hg (concentration level of 1 ppb). The accuracy of the results of the analysis was acceptable.

2.3 Health risk assessment

Health risks of PTEs ingested via food consumption can be estimated by calculating non-carcinogenic (NCR) and carcinogenic risk (CR). Those risks are calculated using the formulas introduced by the USEPA [13]. The NCR is determined by calculating target hazard quotient (THQ) (Eq. 1):

$$\mathrm{THQ} = \frac{\mathrm{C} \times \mathrm{IR} \times \mathrm{EEr} \times \mathrm{ED} \times 10^{-3}}{\mathrm{AT} \times \mathrm{BW} \times \mathrm{RfD}} \quad (1)$$

THQ is the ratio of chronic daily intake and oral reference dose (RfD) of pollutants. When THQ>1 risk is unacceptable and can cause adverse health effects. Table 2 shows parameters that were used for calculation of THQ. Data for ingestion rates for adults and children were calculated based on to the Household budget survey data in Serbia for 2019 [12]. Ingestion rate for children was assumed to be 40% of ingestion for adults. RfD for Hg, As, Cd, Cr (VI), Mn, Ni, Zn, Cu, Fe, Al, Co, Mo and Pb were 0.0001, 0.0003, 0.001, 0.003, 0.14, 0.02, 0.3, 0.04, 0.7, 1, 0.0003, 0.005 and 0.0035 mg/kg-day [14,15].
The CR is calculated using Eq. 2:

$$CR = \frac{C \times IR \times EEr \times ED \times 10^{-3} \times CSF}{AT \times BW} \quad (2)$$

Input parameters for calculation of CR are given in Table 2. Carcinogenic slope factors (CSF) for Cr, As, Pb, Cd and Ni were 0.5, 1.5, 0.0085, 0.38 and 1.7 mg/kg/day, respectively [1,15,16].

Table 2. Input parameters for calculation of THQ

Exposure parameter	Symbol	Unit	Value
mean concentration of element	C	mg/kg	-
daily ingestion rate	IR	g/day	0.411 of dried pepper for adults 36.39 of raw pepper for adults 0.164 of dried pepper for children 14.56 of raw pepper for children
exposure frequency	EEr	day/year	350
exposure duration	ED	years	20 for adults 6 for children
averaging time for non-carcinogenic	AT	days	365×20 for adults 365×6 for children
averaging time for carcinogenic	AT	days	25550
average body weight	BW	kg	70 for adults 15 for children

Total target hazard quotient (TTHQ) and incremental lifetime cancer risk (ILCR) were used to estimate non-carcinogenic and carcinogenic risk when the health risk of more than one PTE is considered. Those two cumulative risks are calculated as the sum of THQ, i.e. as the sum of the CR for individual elements (Eq. 3 and Eq. 4).

$$TTHQ = THQi + THQii \ldots + THQn \quad (3)$$

$$ILCR = CRi + CRii \ldots + CRn \quad (4)$$

3. RESULTS AND DISCUSSION

3.1 Descriptive statistics

The summary of PTEs concentrations in pepper samples is presented in Figure 1 using box-plots. This figure shows two groups of elements, the right that consists of elements with higher concentrations - mg/kg fresh weight (Fe, followed by Al, Zn, Mn, Cu, Ni, Cr, and Mo) and the left that represents elements found in lower concentrations - μg/kg fresh weight (Pb, Co, As, Cd and Hg). Mercury is the only element that wasn't detected in all samples (10 out of 28).

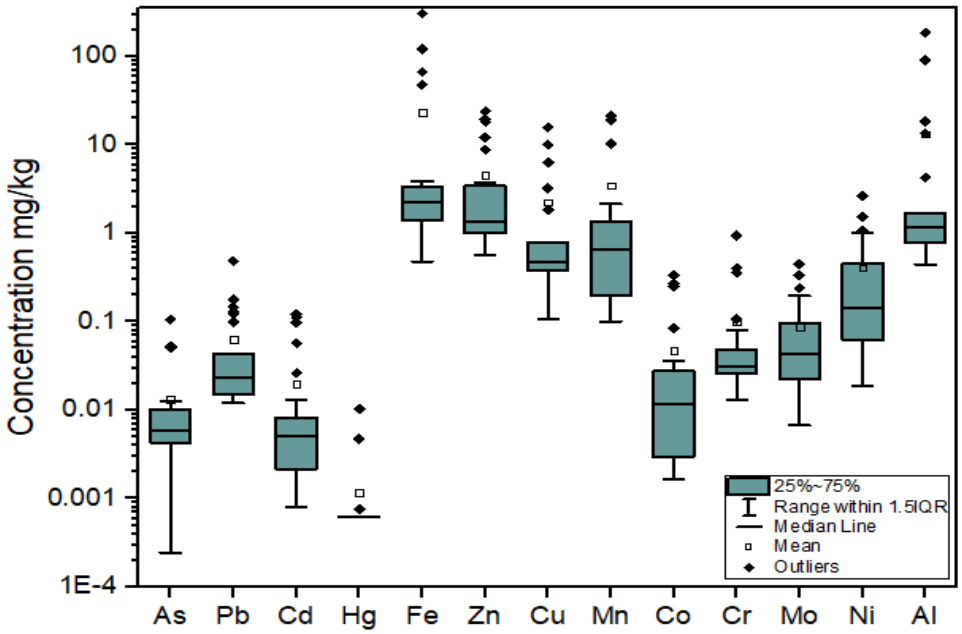

Figure 1. Boxplot of concentration of elements in pepper samples. Lognormal scale was used for element concentrations.

Dried pepper had higher concentrations of all analyzed elements due to lower water content. Generally, dried samples had higher Fe and Al content compared to fresh even when results are expressed on dried mass. For dried peppers concentrations of analyzed element were in following ranges: Fe from 48.0 to 306 mg/kg, Al from 13.4 to 184 mg/kg, Zn from 12.2 to 23.8 mg/kg, Mn from 10.3 to 21.4 mg/kg, Cu from 6.37 to 15.8 mg/kg, Ni from 0.447 to 2.73 mg/kg, Cr from 0.108 to 0.937 mg/kg, Mo from 0.188 to 0.449 mg/kg, Pb from 0.114 to 0.484 mg/kg, Co from 0.085 to 0.340 mg/kg, As from 0.013 to 0.106 mg/kg, Cd from 0.019 to 0.134 mg/kg and Hg from not detected to 0.011 mg/kg.

For fresh and processed peppers concentrations of analyzed element were in following ranges: Fe from 479 to 3880 µg/kg fresh weight, Al from 738 to 2636 µg/kg fresh weight, Zn from 559 to 8893 µg/kg fresh weight, Mn from 101 to 2146 µg/kg fresh weight, Cu from 108 to 3228 µg/kg fresh weight, Ni from 18.6 to 1011 µg/kg fresh weight, Cr from 13.1 to 79.6 µg/kg fresh weight, Mo from 6.69 to 196 µg/kg fresh weight, Pb from 11.9 to 125 µg/kg fresh weight, Co from 1.64 to 36.0 µg/kg fresh weight, As from 0.245 to 11.32 µg/kg fresh weight, Cd from 0.816 to 26.1 µg/kg fresh weight, and Hg from 0.62 to 0.759 µg/kg fresh weight.

3.2 Health risk assessment

3.2.1. Non-carcinogenic risk

The non-carcinogenic risk indicated that consumption of peppers and pepper products does not pose a risk to human health when considering four regions in Serbia (1 - Belgrade region, 2 - The region Vojvodina, 3 - The region of Šumadija and Western Serbia and 4 - Region of Southern and Eastern Serbia). THQ values for all elements were lower than 1, therefore it can be concluded that peppers and pepper products are safe for consumption.

Contribution of analysed PTEs to non-carcinogenic risk, based on average pepper consumption in four regions in Serbia is shown in Figure 2. The highest mean value of non-carcinogenic risk (THQ value) was found for Co, while the lowest mean value was found for Al. People from the region of Southern and Eastern Serbia are at the highest risk of non-carcinogenic risk due to highest consumption of peppers compared to other three regions.

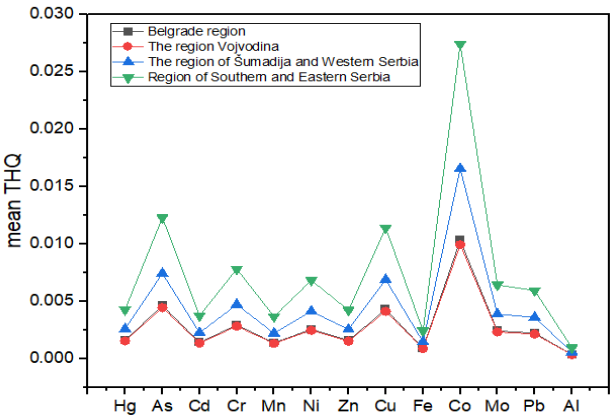

Figure 2. Contribution of analysed PTEs to non-carcinogenic risk due to pepper consumption in four regions in Serbia

Total target hazard quotient (TTHQ) that combine effect of all toxic elements showed that all samples had TTHQ<1 and were safe for consumption both for adults and children. Comparing results between regions, it was found that Southern and Eastern Serbia's people are at the highest risk.

3.2.2. Carcinogenic risk

The evaluation of carcinogenic risk indicated that consumption of peppers and pepper products do not pose a risk to children and adults when considering individual elements in one sample. However, consumption of some peppers does pose a risk when all five potentially carcinogenic elements are observed at the same time (As, Pb, Cd, Cr and Ni). Incremental life time cancer risk (ILCR) that combine effect of five toxic elements showed that same samples had ILCR value higher than 1×10^{-4}. For adults in Belgrade region and region of Vojvodina, ILCR>1×10^{-4} was found for one sample of yellow bell pepper. For adults in region of Šumadija and Western Serbia, ILCR>1×10^{-4} was found for three samples (one yellow bell pepper, and two green peppers), while for children ILCR higher than 1×10^{-4} was in one yellow bell pepper. As in the case of non-carcinogenic risk, the greatest carcinogenic risk exists for residents of Southern and Eastern Serbia where for adults ILCR>1×10^{-4} was found in six samples (one yellow bell pepper, one red pepper and four green peppers). For children ILCR higher than 1×10^{-4} was in three samples (one yellow bell pepper, and two green peppers).

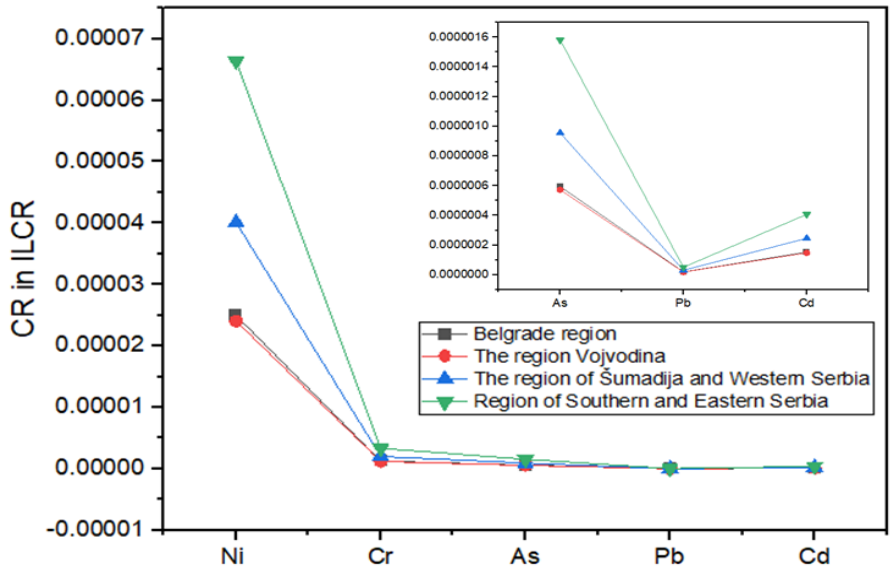

Figure 3. Contribution of analysed PTEs to carcinogenic risk due to pepper consumption in four regions in Serbia.

4. CONCLUSION

This study revealed that concentrations of potentially toxic elements (PTEs) varied significantly in peppers and pepper products. Estimation of non-carcinogenic risk indicated that peppers are safe for consumption by adults and children. On the other hand, the carcinogenic risk assessment showed that some samples of fresh peppers may pose a risk to adults and children due to the incremental lifetime risk (ILCR) values higher than 1×10^{-4}. People from the Southern and Eastern Serbia region are most at risk since in this region people consume greater quantities of these vegetables. In both cases (non-carcinogenic and carcinogenic risk) children are at the lowest risk because children consume smaller quantities of peppers than adults according to their body weight.

Abstract: *Composting is a biological aerobic process and the second most used treatment for organic waste (OW). The main observed component in this paper is the grape pomace (GP) which consists of Grape marc (GM) and grape stalks (GS) as a by-product of the wine production process. In addition to GM and GS, food waste (FW) and poultry manure (PM) were observed. The aim of this paper was to determine which co-substrate is better for composting with GM and GS using a previously developed mathematical model. By applying a mathematical model, it was obtained that the optimal mixture includes 65.00% GM, 15.00% GS and 20.00% co-substrate. The obtained results showed that the presence of FW in the optimal mixture contributes to increasing the content of C and N, while the presence of PM contributes to achive the higer pH value and a lower content of lignin. Also, the results showed that there are sufficient amounts of the observed OW fractions if the entire amount of GM was treated. From the aspect of nutrient content, the mixture when the co-substrate is PM has a higher content of* NH_4^+ *and* P_2O_5 *which makes this co-substrate more favourable.*
Keywords: grape marc, composting, optimization, nutrients

1. INTRODUCTION

The wine industry, viticulture, as the agricultural branch, have traditionally has been among the most represented economic activities in the world. It is estimated that the annual quantities of grape production are higher than 77.8 million tons [1]. The most significant cultivation of grapes is in Europe, namely, Italy, France and Spain, amounting to about 40.00% of the total production globally, followed by America and Asia [2]. A significant amount of grape pomace (GP) waste is released during the winemaking process, representing about 25.00% of the total processed grapes [3], which can amount to tens of millions of tons of GP annually. The main components of GP are skins, seeds, stalks and a small amount of pulp formed during the winemaking process. Some GP parts are used to obtain other products in the food and pharmaceutical industries, such as grape seed oil or phenolic compounds. After grape fermentation in wine production, GP is used to obtain alcohol or cellulose-based compounds. After that, it remains a solid residue with altered characteristics, which in most cases is rejected [4]. However, this type of organic waste (OW) should not be dismissed primarily because of the significant content of essential nutrients, especially P and K. Some negative properties of this OW, such as low pH value and the content of polyphenolic compounds, can be eliminated by using biological treatment. The problem of the presence of polyphenol compounds that have a phytotoxic and antimicrobial effect for use as an organic fertilizer is solved by treating the GP by composting [5]. The insufficiently good initial composition of GP can be solved by co-composting.

Composting is a biological treatment where mesophilic and thermophilic microorganisms are used to decompose complex compounds to obtain a stable end product that can be used as a organic fertilizer [6]. During the composting process, easily degradable components such as proteins and sugars are first broken down and provide the necessary energy for the reproduction and physiological activities of microorganisms and the transition to the next phase. The second phase of the composting process is accompanied by high temperatures at which more complex compounds from OW decompose. In the last stage, the decomposition of more difficult to decompose compounds is completed, and after that, the process of maturing the product begins and at the end a stable product is obitining [7].
Due to its favourable properties, many studies have focused on monitoring the process of co-composting GP with additional co-substrates. Research that has investigated the advantages and disadvantages of composting GP and organic fraction of municipal waste (OFMSW) has shown that the presence of OFMSW contributes to increasing the content of P and N and reducing the acidity of the mixture [8]. A study conducted in Brazil examining the use of compost obtained from GP showed that the final product contains a high content of nutrients. Due to the presence of metals, it is necessary to include an additional fraction of OW in composting [9]. A similar study was conducted in Chile, where the parameters of quality and stability of compost obtained from GP and animal manure were examined. The results showed that the obtained compost satisfies the quality criteria through phytotoxicity, and the absence of pathogens, and can be used as an organic fertilizer [10]. Research that has been conducted with composting certain parts of GP has shown that in the treatment of GS and sludge, GS contribute to achieving higher temperatures, and C/N ratio at the end and beginning of the process. These results were obtained for the case when the GS were chopped [11].
In this paper, a previously developed mathematical model was applied to obtain the optimal mixture for the composting process using multi-criteria optimization (MO) with the application of the global criterion method. Three different fractions of OW were taken into consideration: GP, which is divided into GM and GS, FW and PM. Two cases were observed, the first one when the composition of the mixture includes the GM, GS and FW as a co-substrate and the other when the composition of the mixture includes the GM, GS and PM as a co-substrate. The goal of this paper was to obtain an optimal mixture for composting and to select a favourable co-substrate that is necessary to included in the mixture with GM and GS, while meeting the boundary conditions and criteria set by the mathematical model.

2. EXPERIMENTAL RESEARCH

2.1 Mathematical model description and study area

In this research, a previously developed mathematical model was used to obtain the optimal mixture for the beginning of the co-composting process. During the formation of the model according to the rules of MO, boundary conditions were set and criteria were defined to obtain an optimal solution. The boundary conditions predicted by the model are that the C/N ratio should be between 25:1 - 35:1, the moisture content 40.00% - 60.00%, and the criteria is to achieve the maximum pH value and C content in the mixture, as well as minimum content of lignin and N [12]. The mathematical model was applied to the area that includes the territory of the Republic of Serbia (RS). According to the population census, RS has 7,041,599.00 inhabitants and the annual production of FW is 0.1045 [13, 14]. The average yield of grapes is 8t/ha, and assuming that GP represents 25.00% of the total amount of grapes and that GS are one-quarter of GP, the amount of waste generated during grape processing was calculated [15]. The average amount of excrement of poultry is 0.065 t/year [16]. Based on the number of inhabitants, the area under vineyards and the number of poultry, the amounts of OW that are generated on an annual level in the territory belonging to the RS were calculated, table 1.

Table 1. Amounts of organic mass on the territory of the Republic of Serbia
Source: (orig.)

Type of organic mass			
Vineyards	The area under vineyards [ha]	GP per area [t/area]	The total amount of GP [t/year]
Grape pomace	22,082.44	2.00	44,164.880
Animal excrements	Number of heads	Amount of excrement per head [t/head]	Total amount of excrement [t/year]
PM	26,710,921.00	0.065	1,736,209.865
Municipal waste	Number of inhabitants	Quantity of MW per capita [t/inh]	The total amount of MW [t/yrar]
FW	7,041,599.00	0.1045	736,055.90

2.2 Optimization of the co-somposting process

When optimizing the co-composting process, the main goal is to use the available OW fractions to obtain an optimal mixture, with which composition the necessary conditions for the begining and flow of the co-composting process is achiving. The mathematical model was formed with three fractions OW. The GP was taken as the main component, while the GM and GS were considered as separate fractions, and the other fractions of OW were changed during the experiment. In each part of the experiment, one fraction was taken, in the first case FW and in the second case PM.
For the modelling of the co-composting process, the basic characteristics of the substrates was used, table 2.

Table 2. Substrate characteristics
Source: [17-24]

Component Parameter	GM	GS	FW	PM
C [%][a]	52.49	46.42	56.57	33.31
N [%][a]	1.76	1.23	4.00	3.20
OM [%][a]	96.49	94.77	97.06	65.41
Moisture [%][b]	56.60	10.80	70.00	71.10
pH [%][b]	3.94	7.30	6.70	8.17
Lignin [%][b]	11.10	32.30	12.03	2.00
NO_3^-[mg/kg][a]	22.80	9.10	4.00	10.80
NH_4^+[mg/kg][a]	641.00	2,326.00	484.00	670.00
P_2O_5 [mg/kg][a]	1140.00	901.98	534.68	1,544.00
K_2O [mg/kg][a]	41,483.00	49,240.00	33,021.00	11,438.00

a - Determined by measurement, b - taken from the literature

3. RESULTS AND DISCUSSION

3.1 Physical-chemical characteristics of the mixture

After applying the developed mathematical model, the values of the share of individual components included in the composition of the optimal mixture were obtained for both observed cases, in the first case when the co-substrate is FW and in the second case when the co-substrate is PM. The obtained

results showed that by applying the mathematical model it is possible to satisfy the set boundary conditions and criteria.
In table 3 results are shown, the shares of individual components that enter in the optimal mixture as well as the obtained parameter values, namely: C, N content, C/N ratio, moisture, pH value and nutrient concentration.

Table 3. Composition of optimal mixtures after the mathematical model
Source: (orig.)

Mixture composition Mixture characteristic	Mixture 1 64.40 % GM 20.59 % FW 15.00 % GS	Mixture 2 64.61 % GM 20.38 % PM 15.00 % GS
Max C [%]	52.41	47.66
Max pH	5.01	5.30
Min N [%]	2.14	1.97
Min Lignin [%]	14.46	12.61
C/N	26.97	27.03
Moisture [%]	52.48	52.68
NO_3^- [mg/kg]	51.30	43.50
NH_4^+[[mg/kg]	49.00	177,00
P_2O_5 [mg/kg]	2018.00	2334,00
K_2O [mg/kg]	21268.00	18627.00

Based on the results shown in table 3, it can be seen that when the co-substrate is FW, the content of C, N and lignin is higher, and a lower value of pH value is achieved. On the other hand, in the second case when the co-substrate is PM, the obtained results showed that their presence in the optimal mixture contributes to the reduction of C, N and lignin content, while the pH value is higher compared to the first mixture. The values obtained in this way for the content of C, N, C/N ratio and lignin content can be related to the structure and properties of the observed OW fractions, i.e. FW contain more lignocellulosic components and have a lower pH, while PM has high pH and low lignocellulose content. Also, the obtained results show that in both cases the pH value is above 5, which is in the optimal range for the start of the process [25]. Based on the obtained results for the physical-chemical properties of the obtained mixtures, it can be concluded that the mixture has more favourable characteristics when the co-substrate is PM, namely a higher pH value and a lower lignin content.

3.2 Degree of utilization of fractions OW

If the developed mathematical model were applied to the available amounts of OW and assuming that the obtained share of the GM in the optimal mixture represents the available amounts in the territory of the RS, 33,123.66 t/year and if it were treated with the composting process, then it would be necessary to add 7,715.13 tons of GS and 10,580.31 tons of FW, in the first case. Since the proportions of the components included in the composition of the optimal mixture are the same in the second case when the co-substrate is PM, it is necessary to add the same amounts of observed fractions of OW. In this way, the problem of GM would be solved, and 69.88% of the available amount of GS, 1.44% of FW, would be used, while in the second case, the same share of GM and GS (100% and 69.88%) and a small part of PM, 0.60% of the total amount generated on the territory of RS would be used.
Based on the obtained results, it can be concluded that the utilization of larger available amounts occurs when the co-substrate is FW, and somewhat lower when the co-substrate is PM.

3.3 Amount of compost and nutrient content

Based on the obtained shares of individual OW fractions entering in the optimal mixture and their amounts, it was obtained that the mass of the optimal mixture would be 51,419.10 tons. Starting from the mass of the OW optimal mixture at the beginning of the process and assuming that after the composting process, the mass of the initial mixture is reduced by 75.00%, the amount of compost at the end of the process for both cases was obtained. The amount of compost if the process was carried out under controlled conditions would amount to 12,854.77t/year [26]. Based on the share of nutrients at the beginning of the process (table 2) and at the end of the process (table 3), the amounts of nutrients that would be obtained after the composting process for both mixtures were determined. Thus, in the first case when the co-substrate is FW, in the compost that would be obtained after applying the composting process, the amount of nutrients would be: 659.459 kg NO_3^-, 629.893 kg NH_4^+, 25,941.32 kg P_2O_5 and 273,399.50 kg K_2O. In the second case, when the co/substrate was PM, the amount of nutrient will be 559.191 kg NO_3^-, 2,275.32 kg NH_4^+, 28,718.00 kg P_2O_5 and 239,449.52 kg K_2O.
By comparing the mixtures, it can be seen that the content of NO_3^- and K_2O is higher when the co-substrate is FW, while the content of NH_4^+ and P_2O_5 is when the co-substrate is PM.
Based on the obtained results, it can be concluded that the presence of PM as a co-substrate contributes to an increase in the content of nutrients, especially NH_4^+ and P_2O_5which makes this mixture more favourable.

4. CONCLUSION

The development of the composting process is quite complex because it depends on many factors, such as the characteristics of the treated substrate and the physical parameters that are monitored. In this paper, a previously developed mathematical model was applied to obtain the optimal mixture for the composting process and the maximum proportion of GM in the mixture. It was shown that all criteria are satisfied when the proportion of GM in the optimal mixture is 65.00%, 15.00% and 20.00% of co-substrate. By applying the previously developed mathematical model for obtaining the optimal mixture, it was shown that it is possible to eliminate GM completely when observing both cases. If we look at the use of OW fractions, it was shown that in the first case, the GM is eliminated completely, i.e. 100%, the GS 69.88% and FW with 1.44%. In the second case, the utilization of the GM is 100%, the GS is 69.88%, and the PM is about 0.60%. Based on the obtained results, it can be seen that it is possible to eliminate the GM completely, and that there are also sufficient amounts of other fractions of OW, which would replace certain components. Also, the results showed that the content of nutrients in both cases is high, especially the content of phosphorus and potassium. A slightly higher content of NH_4^+ (72.38%) and P_2O_5 (9.66%) was achieved when the co-substrate was PM. It can be concluded that PM represents the optimal co-substrate that is necessary to be added to the GM and GS during co-composting.

PERSPECTIVES AND CHALLENGES IN COGNITIVE ENHANCEMENT BASED ON THE NEUROTECHNOLOGY APPROACH

Dragan Marinkovic[1], Faculty of Special Education and Rehabilitation, University of Belgrade
Tatjana Marinkovic[2], The Academy of Applied Technical Studies Belgrade
Aleksandra Jelic[2], The Academy of Applied Technical Studies Belgrade

Abstract: *Cognitive enhancement or neuroenhancement implies any action or intervention that improves performance related to cognitive abilities such as learning, memory, attention, or vigilance. The whole approach is based on an understanding of the underlying neurobiology of cognitive functions and interventions through conventional methods (environmental enrichment, adequate sleep, optimized diet, physical activity, etc.), pharmacological methods (nootropics and drugs used for treating patients with neurological disorders) and neurostimulation.*
Due to the latest developments in the field of technology, the possibility to enhance cognitive function using computer chip implants in the brain is opened. Such devices that interface with the neural system are presently in development and engaged only for those with a therapeutic requirement. On the other hand, as for all methods of cognitive enhancement, it is really hard to draw the line between their approved and non-approved usage. Therefore, the upcoming application of brain chip implants could expand brain performance for individuals even without therapeutic prerequisite, although both the public and scientists already anticipate some negative impacts.
This paper discusses perspectives and challenges in the latest development of the neurotechnology approach used to improve cognitive performance.
Keywords: Cognitive Enhancement, Neurotechnology, Brain Chip Implants.

1. INTRODUCTION

Cognition refers to mental processes that comprise attention, memory, making decisions, solving problems, producing and understanding language, reasoning, etc. Demand for memorising facts, learning new operations and skills, and performing complex analytics is on a constant rise in contemporary society. Modern humans are facing a huge amount of information on a daily basis, especially in certain technology-based professions. Keeping and improving mental capabilities might be crucial in daily life, but especially in some professions. For example, enhancing procedural memory may upgrade task competency in many job positions. Besides the high demand for improving cognitive skills of healthy population several disorders, for instance, attention deficit hyperactivity disorder (ADHD), Alzheimer's, Parkinson's and Huntington's diseases, schizophrenia, etc. are characterized by cognitive impairments. Such patients regularly fight with numerous everyday activities demanding focusing, memory, problem-solving and planning. The probable public health benefit of improving treatments for such patients is more than obvious. Cognitive skills are regularly and traditionally acquired through slow, step by step, effortful, and expensive procedures of education and training. Therefore, several approaches to augment brain function have been proposed. These different strategies of brain functioning improvement are usually termed cognitive enhancement or neuroenhancement (Table 1). Cognitive enhancement techniques are classified whether they are

[1]dragan.marinkovic@hotmail.com
[2]tatjana.marinkovic@hotmail.com

conventional or unconventional, but also if they are external or internal to the user, and whether they are hardware/software based [1]. Unconventional techniques of direct nervous system stimulation are here presented as a special category known as neurostimulation.

Table 1. Different approaches to cognitive enhancement
Source: presented data are acquired through literature review and appropriate references cited in the table

COGNITIVE ENHANCEMENT	**Conventional methods**	**Education**: formal, informal and non-formal types [1]; **Enriched Environment**: physical stimulation (nutrition, sleep, exercise…), social stimulation and cognitive challenges [2]; **Mental Training**: learning strategies, general mental activity, rhyming, recalling colourful or emotional scenes, recalling number series or letters, yoga, martial arts, meditation, video gaming [2]; **Use of external information processing devices**: cognitive training, neurofeedback [3].
	Pharmacological methods	**Nootropics**: classical nootropic compounds, substances increasing brain metabolism, cholinergic drugs, plants and their extracts with nootropic effects [4]; **Drugs for treating neurological disorders** [5].
	Neurostimulation	**Transcranial electric stimulation** (i.e., tDCS, tACS, tRNS) [6]; **Transcranial magnetic stimulation** (i.e., single, dual pulse, and rTMS) [6]; **Focused ultrasound** [7]; **Electrical vestibular stimulation (EVS)** [6]; **Vagus nerve stimulation (VNS)** [6].

Cognitive enhancement embraces three steps [1]. Assessment of cognitive abilities is the first step. It is followed by intervention aimed at cognitive abilities improvement. Final step is the validation of improvement that takes place by evaluating the cognitive abilities upon intervention. If the intervention is used to correct a certain pathological conditions or impairments of cognition, then it is stated as a therapy. However, drawing the line between intervention and therapy is not that easy in certain cases.

Conventional means of enhancing cognition embrace education, enriched environment, mental training, and the use of external information processing devices (Table 1). Education could be defined as any experience that has effects on the way one thinks, feels, or acts. Clearly, education is approached through formal and unformal programs and forms and affects how our "biological software" in the brain collects, preserves, and analyse information. Enriched environment is the stimulus for the brain by its social and physical surroundings, or by cognitive challenges [2]. Any stimulus which represents positive experience enhance cognitive flexibility through the process of neuroplasticity. Neuroplasticity is biological capability of the brain to constantly modifies in concordant to stimuli from the environment. In addition, there is a huge number of different forms of mental trainings through which cognitive enhancement is possible to achieve. Usually, these are learning strategies to memorize information, methods for general mental activity, use of rhyming, recalling colourful or emotional scenes, recalling number series or letters, yoga, martial arts, meditation, video gaming, etc. The list of mental trainings is constantly expanding. External information processing devices are applied in modern versions of "mental gym programs". They are often used in conjunction, such as neurofeedback and cognitive training. Cognitive training is a conventional method transformed into modern virtual game-like format of mental exercises. Neurofeedback is a technique to monitor brain signals with either visual or auditory feedback [3].

The use of pharmacological methods in cognitive enhancement is associated with the treatment of medical disorders such as dementia and ADHD, but there are considerations that certain medicines are also taken in non-clinically prescribed circumstances. Nootropics, also known as "smart drugs" are an assorted collection of medicinal substances whose action advances human mental activities, particularly in cases where these functions are impaired [4]. A heterogeneous group of nootropics has been divided into four subgroups according to their nature and effects: classical nootropic compounds, substances increasing brain metabolism, cholinergic drugs, and plants and their extracts

with nootropic effects. Nootropics are used in acute or subacute conditions for treating memory, consciousness, and learning disorders.
Neurostimulation embraces group of non-invasive technologies such as; transcranial electric stimulation (tES), transcranial magnetic stimulation (tMS), electrical vestibular stimulation, vagus nerve stimulation (VNS), and focused ultrasound; as well as invasive technologies as deep brain stimulation. All neurostimulation technologies are all grounded on the usage of electrical or magnetic stimuli to alter the electrophysiology of the central and peripheral nervous systems. Transcranial direct-current stimulation (tDCS) is a movable, wearable electric brain stimulation technique that delivers a low electric current to the scalp. In transcranial alternating current stimulation (tACS) a low-intensity sinusoidal electrical current is applied to the brain through electrodes on the scalp. Transcranial random noise stimulation (tRNS) is a method that involves the application of a low-intensity alternating current whose intensity and frequency change in a randomised way. Deep brain stimulation involves inserting neuro-stimulators in precise fragments of the brain, which direct electrical pulses that interfere with neural activity at the target sites. This technology is mainly used for the treatment of movement and memory disorders [7].

2. NEUROTECHNOLOGY IN COGNITIVE ENHANCEMENT

Until recently, deep brain stimulation and other invasive technologies based on the insertion of electrodes and devices were used in humans only due to medical interventions (e.g. epilepsy and Parkinson's disease). Research on cognitive augmentation in humans was limited to medically approved cases as learning enhancement and visual prosthesis. The development of brain-computer interfaces (BCIs) opened a new era for the implementation of technologies for brain recording and brain stimulation. Brain-computer interfaces obtain brain signals, analyse them, and decode them into instructions that are transmitted to output devices that perform wanted actions. The BCI includes hardware that records brain signals (electrical or magnetic signals made by brain neurons) and software that analyses and converts them into specific commands. The brain comprises of almost 100 billion neurons, each making thousands of synapses (connections) with other neurons. Therefore, interpreting the collected signals is quite a complex problem. Hopefully, it is expected that machine-learning algorithms will increase the capacity of BCIs to interpret brain activity in real time.
The main goal of BCI in medicine is to replace or restore useful functions to disabled people. BCI technology may permit individuals unable to speak or use their limbs to once again communicate or operate devices for walking and object manipulation. In other words, brain-computer interfaces are systems that allow communication between the brain and various machines like a computer, smartphone, or robotic limb. Looking from more general view, BCI might be used as an approach to cognitive enhancement not only in patients with medical diagnosis but also in healthy populations.
The term brain-machine interface is commonly used as a synonym to the described term brain-computer interface. Anyway, brain-machine interface (BMI) refers to the definite interface between nervous system tissue and a device (usually an electrode); accordingly, BMI is invasive. Many researchers assume that BCI encompasses the entire BMI field since brain-machine interface is focused on refining the electrodes themselves for recording or stimulating brain activity. The term neurotechnology is another term often used as a synonym, but more precisely it includes any method or electronic device which interfaces with the nervous system to screen or control neural activity [8]. Neurotechnology incorporates the use of brain chips, neural implants, and BCI technology.

2.1 Brain Implants

In April 2021, Neuralink, the tech startup co-founded by Elon Musk, demonstrated how a chip-implanted monkey could play the video game Pong with its mind. This demonstration opened the possibility for human brain implants. Neuralink announced in May 2023 approval from the USA Food and Drug Administration to begin trials to implant brain chips into humans. Most probably, many years will pass before patients get the Neuralink treatment, but that isn't stopping investors from

boosting the company. Neuralink aims to ultimately enable a patient suffering from paralysis to use devices such as computers or phones with their brain activity alone. It is presumed that their implant contains multiple chips, a wireless battery, and other electronics that are hermetically closed inside a small device (the size of a large coin). Ultra-thin threads will protrude from the implant directly into the brain tissue, and signals will be sent via Bluetooth to, and decoded by, BCI. As a result, a patient will be able to, for example, control an onscreen cursor or move a robotic limb. Neuralink already created a surgical robot to embed the implant and its 64 ultra-thin flexible connected threads upon which are 1,024 electrodes that record neural activity. The robot uses optical coherence tomography for non-invasive imaging of the brain and the needle as thin as a human hair to insert the "threads.
Neuralnik is not the only company in the field of inserting brain implants into humans. Synchron is a company financially supported by Bill Gates and Jeff Bezos and they already tested brain-computer interface (BCI) in humans. The same company also reported the insertion of Stentrode through the blood vessels into the brain's motor cortex.
According to some sources, more than 150,000 people from the USA have a type of brain implant known as a deep brain stimulator to treat tremors caused by movement disorders such as Parkinson's. One forthcoming practice of brain chip implants could be to expand brain functioning for people even without therapeutic requirements. A brain implant might work by transferring pulses of electricity straight into neurons that help rule a particular skill of interest or to improve memorizing facts. The chip might also give the brain some extra memory and subsequently knowledge could be kept externally.

3. PERSPECTIVES

Practically, neurotechnology can be applied to permit mind-controlled prostheses, improve cognitive abilities, and cure neurological dysfunction. The use of BCIs to enhance motor and cognitive recovery within neurorehabilitation settings is more than expected and approved by scientists and by public. In research published in 2019 Widge and associates determined that electrical stimulation of the ventral internal capsule/ventral striatum brain areas enhances cognitive control. They also found that upon deep brain stimulation of this area, specific neural biomarkers that correspond with clinical improvements could be observed and followed [10]. The almost identical framework could also be applied to further cognitive or emotional difficulties, for example, monitoring and enhancement of learning or emotion dysregulation, thus opening the possibility for some type of “cosmetical cognitive enhancement” approach.
In both cases from the point of technology, there are several critical segments to be improved. Implanting electrodes into brain tissue comes with certain risks. Therefore, it would be ideal to attach them outside of the brain entirely and specifically outside of the dura mater, the brain’s protective membrane. Currently, chip arrays record data from maybe a couple of hundred neurons at a time. Expanding this feature to record electrical signals instead from hundreds to hundred thousand of neurons opens much bigger possibilities around the type of fidelity keeping in mind almost 100 billion brain neurons, each having a couple of thousand synapses. Furthermore, an open question is do we need chip technology that is limited concerning the size of the implant and invasive surgical approach? The next step in brain chip development could be the creation of nanomaterials that move through the body and specifically through the bran. Injecting nano-sensors that would be deployed throughout the brain could be followed by their control by magnets or radio signals. Additionally, the technology of nanoparticles could be combined with genetic and molecular engineering. Huge number of such nanoparticles would substitute one or a few implants. As a result, instead of sensing broad signal from multiple neurons nanoparticles would detect specific signals from single cells of various cell types finally allowing us to associate them with specific neurological diseases or specific cognitive domains and functions. Another additional step in improving the usage of neurotechnology

in cognitive enhancement could be refining the connection between brains and machines. This would beef up our senses and allow us to control robots from a distance.

Neurotechnology that is based on non-invasive neurostimulation is at certain preference compared to invasive technology that uses brain implants. For example, transcranial direct current stimulation works by sending electricity through the scalp. Some scientists believe that this method could be further improved thus helping in the enhancement of skills such as learning and memory. Similarly, the transfer of electrical signals through the vagus and other nerves may prompt the brain to release neurotransmitters and metabolites that alter connections between different neural cells. The natural process of memorizing and learning is based on the same neurobiological mechanism. Thus, further stimulation and direction of the same neurobiological process via electrical stimulation of the vagus may "tune" the brain to recognize important details with less practice which might be of interest to both, patients and healthy population. Moreover, recent studies have revealed the prospect of using neurotechnological methods to assess the cognitive processes associated with individual and group decision making, memory enhancement, attention enhancement, different aspects of perception and awareness, and social interaction [7].

Lately, scientists have started exploring the option of brain-to-brain communication. This would be possibility to physically and directly connect two or more brains permitting straight and shortest exchanges of information between people. In several studies combination of electroencephalography and transcranial magnetic stimulation was used in brain-to-brain communication to spread information between individuals in a collaborative task [7]. Although described brain-to brain communication is currently characterized with lot of limitations achievements in this field represent an important proof-of-concept, and further development might potentially lead to future upgraded and more functional systems of brain-to-brain communication.

4. CHALLANGES

The usage of neurotechnology raises concerns in first place about free will and privacy of individuals. The potential ability to "read" or "assess" someone's thoughts, emotions, states, or attitudes opens the possibility of its misuse. Nowadays, many neuroscientists are worried about the latest consent for insertion of brain chips into humans that Food and Drug Administration approved. A logical question is whether the private company Neuralink will have admission to the neuro data of the people that they implant devices in.

As expected, different investigations on public attitudes demonstrated negative views across the whole population about using brain chip implants for enhancement. Most the people recognize usage of brain chip implants to improve cognitive processing as interfering with nature and passing a line. In this line, they are mostly bothered about potential economic inequality in brain implants application and cybersecurity. Most people claim higher standard to guarantee the safety of brain chip implants, especially if they are used in the cosmetic cognitive enhancement practice. In contrast, most people support the use of brain chips for medically approved therapeutic purposes in patients [11].

Neuroscientists are afraid that the application of BCI technology in humans will cause mental changes that are unpredictable and little understood. Most probably some changes might entirely modify someone's identity and sense of self. In some particular cases, patients have stated back feelings of estrangement, or even that the implant makes them feel unlike themselves. Consequently, the main questions are what kinds of changes does BCI-based cognitive enhancement cause, and how much changes matter to individuals and whole human society? Clearly, notions of personality, individuality, independence, and self are quite compact, obscure, and opaque dimensions. Therefore, all criticisms are well based and reasonable.

5. CONCLUSION

At present time, methods of cognitive enhancement based on neurotechnology approach look quite promising, but at the same time frightening. That is the step that all new technology passes on their path to approval and usage. Helping other people in their fight against neurodegenerative diseases and other types of handicaps is beyond any doubt something we should persist. Opening the gates for cosmetic neurology that will allow anyone with enough money in the pocket to "expand mind" is something different. Both practices are based on the same neurotechnology approach. In both cases at the moment, we are not able to predict all side effects, particularly ones that may affect someone's personality. Consequently, our attitude towards cognitive enhancement must be carefully determined and balanced.

This research was supported by the Serbian Ministry of Science, Technological Research and Innovation (Grant nr. 175083).

PRESCRIBING WELLNESS IN PRIMARY CARE: INTEGRATING HEALTH AND HEALTHCARE

Snežana Knežević[1], The Academy of Applied Technical Studies Belgrade
Tamara Gajić[2], Geographical Institute "Jovan Cvijíc" SASA, Belgrade
Dragan Vukolić[3], Faculty of Tourism and Hotel Management, University of Business Studies
Miloš Zrnić[4], Academy of Applied Studies
Slavica Đorđević[5], Academy of Vocational Studies Belgrade

Abstract: *The integration of wellness promotion in primary healthcare settings, emphasizing the concept of prescribing wellness is needed. Recognizing the significant impact of lifestyle on health outcomes, healthcare providers are increasingly incorporating wellness interventions into their practice. By prescribing and encouraging healthy behaviors, such as exercise, nutrition, stress management, and sleep hygiene, primary healthcare providers can prevent and manage chronic diseases more effectively. This proactive approach improves individual health, reduces healthcare costs, and enhances overall well-being. Research indicates that patients respond positively to wellness prescriptions, leading to increased engagement and adherence to healthy behaviors. Integrating wellness into primary healthcare involves educating providers on evidence-based interventions, and utilizing community resources to support behavior change. Collaborative care models that involve multidisciplinary teams and shared decision-making further enhance the integration of wellness in healthcare settings. Prescribing wellness in primary healthcare has the potential to address the root causes of many chronic conditions and promote holistic approaches to healthcare. By focusing on prevention and lifestyle modifications, primary healthcare providers play a critical role in empowering patients to take control of their health. However, challenges such as limited time, reimbursement constraints, and patient readiness for change need to be addressed for effective implementation.*
Keywords: Wellness, Primary healthcare, Lifestyle, Holistic approaches

1. INTRODUCTION

The idea of well-being, a healthy lifestyle, and wellness have as their common denominator the preservation and promotion of health. Achieving well-being refers to how individuals meet emotional, social, and spiritual needs [1]. Integrating wellness promotion into primary healthcare settings and emphasizing the concept of prescribing wellness is a pivotal strategy that aims to elevate the overall state of public health [2,3]. This approach departs from the traditional healthcare model centered solely around treating illnesses and places substantial emphasis on holistic well-being [3]. At its core, this approach recognizes that health extends beyond the absence of disease. It encourages a proactive stance by prioritizing prevention through education, screenings, and interventions. Healthcare providers take on the role of educators, equipping patients with knowledge about healthy lifestyle choices, the significance of regular check-ups, and the benefits of early detection [2,3]. By

[1]lesta59@yahoo.com
[2]tamara.gajic.1977@gmail.com
[3]vukolicd@yahoo.com
[4]milos.zrnic85@gmail.com
[5]slavica.djordjevic30@gmail.com

doing so, they empower patients to make informed decisions that positively impact their long-term health outcomes.

One of the key principles of this approach is the idea of "prescribing wellness" [2,3,4]. This means that, just as a physician might prescribe medication, they also prescribe personalized wellness activities tailored to each patient's needs. These activities could encompass physical exercise routines, stress management techniques, dietary guidelines, mental health practices, and more [4,5]. By integrating these recommendations into patients' lives, healthcare professionals help individuals adopt healthier habits, potentially averting the development of chronic conditions and enhancing their overall quality of life. Furthermore, this approach promotes a shift in patient-provider dynamics. Patients are encouraged to actively engage in their healthcare journey, moving from a passive recipient of medical treatment to an empowered participant in their well-being [3,5]. The collaboration between healthcare experts from various fields, such as doctors, nurses, dietitians, psychologists, and fitness trainers, is crucial in devising comprehensive wellness plans that cater to individual needs.

2. LIFESTYLE BEHAVIORS, HABITS, AND CHOICES

The Mueller and Kaufmann wellness model serves as the foundation for the idea of wellness-related lifestyles, which emphasizes social interaction, diet, travel, fitness, a holistic approach to life, and environmental protection [1]. This model highlights a range of factors that collectively contribute to fostering holistic well-being and a high quality of life. Central to this model are elements such as social interaction, dietary choices, travel experiences, physical fitness, adopting a holistic life perspective, and prioritizing environmental preservation. Social interaction holds a key role in the wellness-related lifestyle [1]. It recognizes the inherent human need for social connections and relationships, as they contribute significantly to mental and emotional well-being [1]. Engaging in meaningful interactions, nurturing friendships, and fostering a sense of belonging all contribute to a balanced and fulfilling life. Recognizing the profound impact of nutrition on overall health, the model underscores the importance of making informed dietary choices [1]. Prioritizing balanced and nourishing diet rich in vitamins, minerals, and nutrients not only supports physical health but also contributes to mental clarity and vitality. Travel experiences are emphasized as an integral part of wellness-related lifestyles [1]. The model acknowledges the benefits of exploring new places, cultures, and environments for personal growth, relaxation, and rejuvenation. Travel provides opportunities to step out of daily routines, gain new perspectives, and engage in activities that enhance physical and mental well-being. Physical fitness is a central component, emphasizing the significance of regular exercise and physical activity [1]. The model advocates incorporating movement into daily routines to promote cardiovascular health, flexibility, strength, and overall vitality. Exercise contributes to stress reduction, improved mood, and enhanced overall quality of life. A holistic approach to life is an essential tenet of the wellness-related lifestyle model [1]. It encourages individuals to view their well-being as an interconnected whole, encompassing physical, mental, emotional, and spiritual dimensions. By recognizing the interplay of these elements, individuals can strive for a balanced and harmonious life. Lastly, environmental protection is a vital consideration within this model [1]. Recognizing the symbiotic relationship between human well-being and the health of the planet, the model promotes responsible and sustainable practices that contribute to environmental preservation. This includes reducing waste, conserving resources, and making choices that minimize negative impacts on the environment.

By embracing these factors, individuals can cultivate well-rounded and fulfilling lives that prioritize not only their health but also the well-being of their communities and the planet. Healthcare providers today are increasingly recognizing the profound influence that lifestyle factors have on health outcomes [5,6]. Lifestyle, encompassing behaviors, habits, and choices that individuals make in their daily lives, plays a pivotal role in determining one's health trajectory [6]. These choices can either contribute to the development of chronic diseases or act as protective factors that promote long-term well-being. To address this, healthcare providers are integrating wellness interventions into their

practices. Rather than solely focusing on treating illnesses after they have manifested, these providers are adopting a proactive approach that emphasizes prevention and lifestyle modifications. By "prescribing" and encouraging healthy behaviors, primary healthcare providers are equipping patients with tools to take control of their health and make informed choices that lead to better outcomes.

3. WELLNESS-RELATED LIFESTYLE

Wellness-related lifestyle encompasses a multifaceted approach to health, addressing not only physical well-being but also psychological, social, and spiritual dimensions [7]. This comprehensive perspective recognizes that true wellness goes beyond the absence of illness; it embraces happiness, personal growth, purposeful living, and meaningful connections with others. Within the framework of wellness, individuals strive to achieve a balanced and harmonious life across various domains. Happiness and contentment are fundamental components of well-being [8]. Wellness encourages individuals to pursue activities and make choices that bring joy and satisfaction [7,8]. This could range from engaging in hobbies and spending time with loved ones to exploring new experiences that foster a sense of happiness and fulfillment. Personal development is another integral facet [7,8]. Wellness-related lifestyle emphasizes continuous learning and self-improvement [7,8]. Individuals are encouraged to set goals, challenge themselves, and engage in activities that promote personal growth and skill enhancement. This contributes to a sense of accomplishment and overall well-being. Finding one's life purpose is deeply intertwined with wellness. Having a sense of purpose gives life meaning and direction. Individuals are motivated to identify their passions, values, and goals, aligning their actions with their inner sense of purpose. This connection fosters a strong sense of well-being and fulfillment. Relationships play a crucial role in wellness-related lifestyle [5,6]. Nurturing social connections and building a supportive network contribute significantly to overall well-being. Meaningful relationships provide emotional support, a sense of belonging, and opportunities for shared experiences, all of which are vital for psychological and emotional health.

Spa and wellness centers are pivotal in the pursuit of well-being [1,6]. Visitors to these centers seek experiences that cater to various dimensions of wellness. Their perceptions of well-being are influenced by the relaxation, rejuvenation, and self-care practices offered [1]. Such centers provide environments that promote mental and spiritual wellness, often through practices like meditation, mindfulness, and stress reduction techniques [1]. Travel motives are also linked to healthy lifestyles and well-being [7,8]. Many individuals choose travel experiences that align with their wellness goals, seeking destinations and activities that support physical, mental, and emotional well-being. Wellness-focused travel provides opportunities for individuals to explore new cultures, engage in physical activities, and indulge in relaxation practices that contribute to their overall sense of well-being. In wellness centers, the concept of well-being is deeply rooted in psychological, spiritual, and social effects [1,8]. These centers provide a holistic approach to wellness, offering services and activities that address mental clarity, inner peace, and a sense of connection with oneself and others. This approach recognizes that a state of well-being involves harmony between mind, body, and spirit.

3.1. Spas and wellness centers

Modern spas and wellness centers have evolved into havens where visitors are encouraged to prioritize their enjoyment, enhance relaxation skills, find solace, and equip themselves to manage the stressors of everyday life [8]. These establishments serve as settings for self-discovery and self-improvement, providing a retreat from the demands of modern life. Spas offer a sanctuary for individuals to focus on their health and well-being, positioning themselves as oases of rejuvenation and holistic wellness. The realm of wellness tourism has witnessed substantial global growth, driven by evolving healthcare trends that emphasize proactive, comprehensive, and preventive approaches to health. This shift entails fostering behaviors that fortify personal, physical, emotional, and spiritual well-being [7,8]. Notable examples include the surging popularity of training programs tailored to individual needs, as well as the widespread adoption of practices such as yoga, tai chi, and meditative

exercises [8]. These trends reflect a broader recognition of the benefits of nurturing one's overall well-being holistically. Numerous entities, including healthcare facilities and corporations, have recognized the profound advantages of promoting a healthy lifestyle. This realization stems from an understanding that well-being significantly impacts productivity and quality of life. As a result, wellness is not only considered from a medical perspective but also as a strategic investment that enhances performance and fosters a balanced, fulfilling existence [1,8]. The contemporary approach to wellness acknowledges the multifaceted nature of well-being, integrating physical health with mental, emotional, and spiritual dimensions. Spas and wellness centers align with this philosophy by offering diverse programs and activities that cater to the whole individual. Guests can engage in relaxation therapies, treatments, mindfulness sessions, and educational workshops that collectively contribute to their overall wellness journey [7,8]. Furthermore, these establishments recognize the importance of personalized experiences. Each individual's well-being journey is unique, and spas have responded by providing tailored services that address specific needs and goals. From stress reduction and rejuvenation to personal growth and self-care, spas serve as platforms for self-discovery, learning, and empowerment. Modern spas and wellness centers have evolved into spaces that encourage individuals to prioritize their well-being, offering environments conducive to relaxation, self-improvement, and stress management [7,8]. The growth of wellness tourism reflects a broader shift towards proactive health practices that encompass various dimensions of well-being. As society increasingly recognizes the interplay between well-being, productivity, and overall quality of life, the role of wellness establishments in promoting holistic health becomes even more vital.

3.2. The role of general practitioners in Wellness and health tourism

Wellness and health tourism have emerged as transformative approaches to nurturing holistic well-being. These forms of tourism encompass journeys that prioritize health enhancement and self-improvement through a range of activities tailored to promote physical, mental, and emotional vitality [2,4]. From immersive spa retreats and rejuvenating yoga getaways to fitness-focused vacations and mindfulness workshops, these experiences are designed to empower individuals on their wellness journeys. Central to the effectiveness of wellness and health tourism is the role of general practitioners (GPs) in shaping patient perspectives and decisions. GPs serve as trusted sources of medical guidance, offering patients valuable insights into how such travel experiences can contribute to their overall health [2,3,4]. GPs can elaborate on the potential advantages, including stress reduction, improved mental health, enhanced physical fitness, and opportunities for relaxation and self-discovery [2]. Crucially, GPs are equipped to provide personalized recommendations that consider patients' individual medical backgrounds and specific health goals. By tailoring advice, GPs help patients select activities and destinations that align with their well-being needs, ensuring safety and effectiveness. They can also educate patients about potential risks and considerations, helping them make informed choices that foster positive outcomes. GPs play a vital role in preventive care by discussing vaccinations, safety precautions, and health considerations before embarking on wellness and health tourism journeys [2,3,4]. Post-trip, GPs can engage in follow-up consultations to monitor patients' well-being, address any concerns, and assess the impact of the experience on their health. This holistic approach to post-travel care supports a seamless transition back to daily life while maintaining the benefits gained from the wellness journey [4]. Furthermore, collaboration between GPs and wellness tourism providers is essential to ensure comprehensive care. GPs can share medical insights with providers, ensuring that activities are adapted to accommodate any medical conditions or specific requirements. This collaboration fosters a seamless integration of medical expertise into the design and execution of wellness experiences, enhancing safety and patient satisfaction. GPs serve as informed advocates for wellness and health tourism, guiding patients toward experiences that align with their health objectives and cater to their overall well-being. By fostering an open dialogue, offering personalized advice, and ensuring safety, GPs empower patients to embark on wellness journeys that can lead to transformative improvements in their physical, mental, and emotional health.

3.3. The concept of "prescribing wellness" within primary healthcare

Integrating wellness into primary healthcare entails a multifaceted approach aimed at fostering comprehensive well-being [3,4]. This process begins with educating healthcare providers about evidence-based interventions that extend beyond traditional medical practices. By equipping providers with knowledge about nutrition, exercise, stress management, and other wellness-related strategies, they become better positioned to address the broader determinants of health [4]. This integration also hinges on leveraging community resources as catalysts for behavior change. Collaborating with local organizations, fitness centers, mental health professionals, and nutritionists allows healthcare providers to extend their reach beyond clinical settings. Patients are not only informed about healthy choices but also empowered with accessible resources that facilitate sustainable lifestyle changes [3,4]. Central to successful integration is the adoption of collaborative care models. These models emphasize the importance of multidisciplinary teams comprising healthcare professionals from diverse fields. This inclusive approach encourages shared decision-making, where patients actively participate in their care plans, making them more likely to adhere to wellness recommendations. Collaboration also ensures that healthcare interventions are holistic and tailored to each patient's unique needs.

The concept of "prescribing wellness" within primary healthcare represents a paradigm shift [3]. By treating lifestyle changes as prescriptions, healthcare providers underscore the significance of wellness in disease prevention and management. This approach acknowledges that many chronic conditions stem from modifiable behaviors and lifestyle choices [3,4]. As a result, addressing these root causes becomes a pivotal strategy in achieving improved health outcomes. Moreover, this approach promotes holistic healthcare by recognizing that physical health is intertwined with mental, emotional, and social well-being. Prescribing wellness encompasses personalized plans that incorporate exercise routines, stress reduction techniques, dietary adjustments, and other self-care practices. Patients are empowered to take charge of their health, not only addressing current health issues but also preventing future ones. Integrating wellness into primary healthcare involves educating providers, harnessing community resources, and embracing collaborative care models [5]. By prescribing wellness, healthcare professionals target the underlying factors contributing to chronic conditions and emphasize a holistic approach to well-being. This integration not only improves patient outcomes but also lays the foundation for a healthcare system that prioritizes prevention, education, and the empowerment of individuals to lead healthier lives.

3.4. Challenges for effective "prescribing wellness" within primary healthcare

Primary healthcare providers assume a pivotal role in empowering patients to proactively manage their health through prevention and lifestyle adjustments. This approach emphasizes addressing health concerns before they escalate, fostering a culture of well-being, and minimizing the burden of chronic diseases. Nonetheless, several challenges must be navigated to ensure the effective implementation of this approach. The significance of prevention and lifestyle modifications cannot be overstated. Primary healthcare providers offer patients the tools and guidance needed to make informed choices that impact their long-term health outcomes [3,5]. By imparting knowledge about healthy behaviors, risk factors, and the benefits of proactive measures, providers inspire individuals to assume an active role in safeguarding their well-being. Yet, these efforts encounter obstacles that necessitate attention. Time constraints pose a significant challenge, as primary care appointments are often limited in duration. Effectively discussing preventive strategies and facilitating behavior change within these time frames can be demanding. Providers must balance addressing immediate health concerns while allocating sufficient time to educate patients about wellness practices [5,6]. Reimbursement constraints further complicate matters. In many healthcare systems, financial incentives might be skewed toward reactive treatments rather than preventive services [3,5,6]. This can discourage primary healthcare providers from dedicating ample time to wellness education and behavior change discussions. Recognizing and rectifying these financial disparities is vital to

encourage a more proactive healthcare approach. Additionally, patient readiness for change is a complex factor [6]. While primary healthcare providers offer guidance, patients' willingness and capacity to adopt lifestyle modifications play a crucial role. Some individuals might already be motivated to make positive changes, while others might require more time and support to initiate shifts in their behaviors. Tailoring interventions to individual needs and preferences is essential for effective engagement.

3. CONCLUSION

By fostering an integrated and proactive healthcare model, primary care settings become hubs for addressing health concerns and cultivating enduring well-being. Emphasizing preventive measures, behavior change, patient education, and collaborative care reduces the burden of preventable diseases, improves public health outcomes, and enhances individuals' resilience against health challenges. The inclusion of wellness interventions underscores the vital role of lifestyle in health outcomes. Through prescribing and promoting healthy behaviors, healthcare providers nurture a culture of prevention, empowering patients to make positive choices and contributing to a healthier society with reduced disease burden and enhanced well-being. This wellness-related lifestyle encompasses elements like happiness, personal development, purposeful living, relationships, and experiences from wellness centers and travel. This holistic approach acknowledges health as encompassing physical vitality, fulfillment, belonging, and balance across various life dimensions. Primary healthcare providers empower patients through prevention and lifestyle adjustments, equipping them with knowledge and strategies to be active participants in their health journey. Overcoming challenges like time constraints and reimbursement structures is essential for successful implementation. This ensures that primary care catalyzes improved well-being and is a cornerstone of holistic health management.

Abstract: *Lifestyle medicine utilizes evidence-based behavior modifications in diet, exercise, sleep, stress management, positive social connections, and substance use to prevent, treat, and potentially reverse lifestyle-related chronic diseases. By adopting and maintaining healthy behaviors, individuals can improve their health and overall quality of life. Healthy lifestyle recommendations have the potential to prevent over 80% of chronic conditions. Lifestyle-related diseases, influenced by misinformation and poor choices, are the leading cause of death in the modern world. To address this challenge, lifestyle medicine provides essential recommendations to extend life, enhance health, and promote well-being. Key interventions include healthy eating, active living, maintaining a healthy weight, and building emotional resilience. Integrating lifestyle practices into medical care helps reduce risk factors for chronic diseases and complements traditional therapy. By utilizing scientific evidence from various health-related fields, lifestyle medicine supports clinicians in promoting disease treatment and overall health. Transforming medical culture to prioritize lifestyle education empowers individuals to take control of their health, leading to longer, healthier lives with improved quality and reduced disability. While not all healthcare practitioners may fully incorporate lifestyle goals into their practice, having access to information and tools is a significant step forward.*
Keywords: Lifestyle, Well-being, Evidence, Healthcare

1. LIFESTYLE MEDICINE

Lifestyle medicine is a multidisciplinary field focused on utilizing evidence-based lifestyle interventions to prevent, treat, and manage various chronic diseases and health conditions [1,2]. This emerging discipline involves a spectrum of researchers and experts delving into various aspects encompassed within its purview, including but not limited to nutrition, physical activity, weight management, and smoking cessation. While these individual elements hold significance on their own, their collective exploration converges under the umbrella of lifestyle medicine, where the synthesis of these modalities highlights the interplay between human behaviour and health outcomes. Through an integrative approach that considers the cumulative effects of lifestyle choices, lifestyle medicine strives to empower individuals with knowledge and tools to optimize their health and foster a higher quality of life [2].

2. THE EVOLUTION OF LIFESTYLE MEDICINE

The evolution of lifestyle medicine traces a progressive path marked by the growing understanding of how daily habits influence health outcomes. It began in the early 20th century with a shift towards preventive medicine, emphasizing underlying causes over symptoms. As chronic diseases like heart disease and obesity surged in the latter 20th century, the role of lifestyle choices gained prominence. The 1960s and 1970s linked risk factors like poor diet and sedentary behaviour to chronic diseases [1,2]. Organizations like the American College of Lifestyle Medicine (founded in 2004) advanced the field. Scientific research increasingly supported lifestyle's impact on health, leading to its integration into medical education. Lifestyle medicine views health holistically, spanning physical, mental, and emotional well-being [3]. Collaboration among experts in various fields furthered understanding. Public interest grew, promoting lifestyle's role in disease prevention. This approach is globally recognized for its potential to alleviate chronic diseases and enhance overall health. Lifestyle medicine evolves, advocating proactive, holistic well-being approaches in modern healthcare.

3. HEALTHY LIFESTYLE RECOMMENDATIONS

Lifestyle medicine encompasses a range of practices that individuals can adopt to promote good health and prevent the onset of various diseases [1,2]. These practices focus on optimizing key aspects of daily life to create a foundation for overall well-being. Some essential practices of lifestyle medicine to promote good health are given in the text. Lifestyle medicine represents a paradigm shift in healthcare, acknowledging the profound impact of daily habits and practices on disease prevention and treatment. This multidisciplinary field investigates the interactions between human behavior and health outcomes, emphasizing the role of lifestyle modifications as integral components of comprehensive healthcare strategies [3]. The following review synthesizes key practices within lifestyle medicine that have gained recognition for their potential to promote good health and enhance overall well-being.

3.1. Nutrition and Balanced Diet

A cornerstone of lifestyle medicine, nutrition plays a pivotal role in preventing chronic diseases. The research underscores the significance of a balanced diet rich in whole foods, emphasizing fruits, vegetables, whole grains, lean proteins, and healthy fats. The Mediterranean and Dietary Approaches to Stop Hypertension diets, characterized by high fiber content, moderate fat intake, and abundant antioxidants, have demonstrated favorable outcomes in reducing cardiovascular risk factors. Mounting evidence also highlights the impact of nutrition on gut microbiota composition, implicating dietary choices in immune regulation and metabolic health [1,2,4].

3.2. Physical Activity and Exercise

Regular physical activity is fundamental to maintaining cardiovascular health, metabolic balance, and mental well-being. Incorporating aerobic exercises, strength training, and flexibility routines contributes to improved muscle mass, bone density, and insulin sensitivity [1,2,4]. Moreover, exercise influences neuroplasticity, with cognitive benefits observed in individuals engaging in routine physical activity. The role of exercise in enhancing mitochondrial function, promoting anti-inflammatory responses, and modulating hormonal profiles underscores its significance within lifestyle medicine.

3.3. Stress Management and Psychological Health

Psychological well-being is intrinsically linked to physical health. Stress management techniques such as mindfulness, meditation, and relaxation exercises are recognized for their capacity to mitigate the detrimental effects of chronic stress on immune function, cardiovascular health, and neuroendocrine systems. Mind-body interventions have demonstrated measurable effects on stress

hormone levels, neurotransmitter balance, and autonomic nervous system regulation, affirming their relevance in lifestyle medicine interventions [2,4,5].

3.4. Weight Management and Metabolic Health

Addressing weight-related concerns is pivotal in preventing and managing metabolic disorders. Lifestyle medicine advocates for sustainable weight loss strategies grounded in caloric balance, nutrient-dense food choices, and increased physical activity. Evidence supports the efficacy of behaviour modification interventions in promoting lasting weight reduction, with emphasis on setting realistic goals, monitoring progress, and cultivating intrinsic motivation [2,4].

3.5. Social Connections and Community Engagement

A growing body of research underscores the health benefits of social connections and community engagement. Robust social networks contribute to emotional resilience, reduced risk of mental health disorders, and improved cardiovascular outcomes. Lifestyle medicine interventions leverage the potential of group-based programs, highlighting the synergistic effects of social support in fostering adherence to healthy behaviours and sustaining positive lifestyle changes [2,4].

3.6. Personalization and Holistic Approach

Central to lifestyle medicine is the recognition of individualized interventions tailored to unique needs, preferences, and cultural backgrounds. Personalized approaches acknowledge the intricate interplay between genetic predisposition and lifestyle factors, emphasizing the importance of patient-centered care. A holistic perspective acknowledges the interconnectedness of physical, mental, and emotional well-being, promoting a comprehensive understanding of health that extends beyond disease prevention to encompass overall vitality [2,4].

4. INTEGRATING LIFESTYLE PRACTICES INTO MEDICAL CARE

In recent years, the integration of lifestyle practices into medical care has gained prominence as a transformative approach to health management. This paradigm shift recognizes that addressing the complex interplay between individual behaviours, environmental factors, and disease risk can significantly impact patient outcomes. By bridging the gap between conventional medical interventions and proactive lifestyle modifications, this integration holds the potential to revolutionize healthcare delivery and improve overall population health [6,7].

4.1. Rationale for Integration

Traditional medical models often focus on reactive interventions targeting specific diseases or symptoms. However, an increasing body of evidence highlights the pivotal role that lifestyle factors play in disease prevention, progression, and even treatment response. Lifestyle practices encompass a spectrum of behaviours, including nutrition, physical activity, stress management, sleep hygiene, and substance use, that collectively influence physiological processes and health trajectories. Recognizing this intricate relationship, healthcare systems are embracing a more holistic approach that encompasses lifestyle medicine as an integral component of patient care [6].

4.2. Benefits and Impact

The integration of lifestyle practices into medical care offers a range of benefits that extend beyond disease management. By empowering patients to take an active role in their health journey, this approach fosters a sense of agency and autonomy, leading to higher adherence rates and sustainable behavioral changes. Moreover, comprehensive lifestyle interventions have been shown to address multiple risk factors simultaneously, yielding synergistic effects on health outcomes. For instance,

lifestyle modifications can enhance medication efficacy, reduce the need for pharmaceutical interventions, and minimize the occurrence of adverse events. Additionally, the incorporation of lifestyle medicine aligns with the principles of patient-centered care, emphasizing personalized strategies that resonate with individual preferences and cultural contexts [6,7,8].

4.3. Clinical Implementation and Challenges

Integrating lifestyle practices into medical care requires a multidisciplinary collaboration among healthcare providers, including physicians, dietitians, physical therapists, psychologists, and nurses. This collaborative approach enables the development of tailored interventions that encompass diverse aspects of a patient's life. However, challenges arise in terms of time constraints within clinical encounters and the need for comprehensive training for healthcare professionals to effectively guide patients through behavior change. Overcoming these obstacles necessitates innovative strategies such as telehealth platforms, wearable technology, and group-based interventions that extend patient-provider interactions beyond the clinic walls [8,9].

4.4. Shifting Healthcare Culture

The integration of lifestyle practices into medical care necessitates a cultural shift within healthcare systems. Education and training must emphasize the significance of lifestyle factors, equipping medical professionals with the knowledge and skills to engage patients in meaningful conversations about behavior change [1,2,9]. Additionally, reimbursement structures should evolve to incentivize preventive measures and lifestyle interventions, reflecting their potential to mitigate the long-term burden of chronic diseases. The integration of lifestyle practices into medical care heralds a new era of healthcare delivery characterized by proactive, holistic, and patient-centered approaches [10,11]. By recognizing the interconnectedness of lifestyle choices and health outcomes, this paradigm shift has the potential to enhance preventive strategies, optimize treatment efficacy, and ultimately elevate the overall well-being of individuals and communities. As healthcare systems navigate this transition, collaboration among healthcare providers, policymakers, and patients is crucial to realize the transformative impact of lifestyle medicine on the landscape of modern medicine.

5. TRANSFORMING MEDICAL CULTURE TO PRIORITIZE LIFESTYLE EDUCATION

To transform medical culture to prioritize lifestyle education, a multifaceted approach is essential. One key aspect involves incorporating comprehensive lifestyle medicine education into medical school curricula and continuing education programs for healthcare professionals. By ensuring that both current and future practitioners are well-versed in the significance of lifestyle factors in health outcomes, a solid foundation is laid for the integration of lifestyle education [8,9]. Equally important is the development of evidence-based clinical guidelines that underscore the importance of lifestyle interventions alongside traditional medical treatments [11]. These guidelines can serve as a point of reference for healthcare practitioners when addressing patient needs. Interdisciplinary collaboration is another critical element. Encouraging teamwork among healthcare providers, including physicians, nutritionists, psychologists, and physical therapists, ensures that patients receive holistic and well-rounded care that takes into account various aspects of their well-being. Adopting a patient-centered approach is vital [2]. This entails involving patients in decision-making and goal-setting regarding their lifestyle choices, empowering them to be active participants in their health journey. To effectively guide patients toward making sustainable lifestyle changes, healthcare providers should also receive training in behavior change techniques and motivational interviewing. Institutional support is equally crucial. Healthcare institutions must provide the necessary resources, tools, and time for healthcare providers to engage in meaningful discussions with patients about lifestyle choices. Public awareness campaigns play a role in educating individuals about the role of diet, exercise, stress management, and other lifestyle elements in preventing and managing chronic

diseases [2,11]. Modifying reimbursement structures can incentivize healthcare providers to incorporate lifestyle interventions into their practice, acknowledging the value of addressing lifestyle factors. Robust research that highlights the impact of lifestyle interventions on health outcomes is paramount, reinforcing the importance of lifestyle education within the medical culture [11]. Leadership and advocacy within the medical community are powerful drivers of change. Encouraging influential figures to champion the integration of lifestyle education can lead to policy shifts and cultural transformations within healthcare institutions. Regular assessment and refinement of strategies are necessary as new research emerges and best practices evolve. Through this concerted effort, the medical culture can undergo a transformative shift, placing lifestyle education at the forefront. This approach ultimately leads to improved patient outcomes, elevated quality of care, and a more comprehensive understanding of health that extends beyond conventional medical paradigms.

6. MULTIDISCIPLINARY COLLABORATIONS IN THE CONTEXT OF LIFESTYLE PRACTICES

Multidisciplinary collaborations in the context of lifestyle practices extend beyond healthcare and can encompass various sectors to create comprehensive and impactful approaches to well-being. Some examples include the following [1,2,7,11]. Collaborations between educators, psychologists, nutritionists, and physical activity experts can lead to the development of comprehensive wellness programs for schools and universities. These programs can address students' physical and mental well-being through educational initiatives, stress management techniques, physical activity promotion, and healthy eating campaigns. Bringing together professionals from human resources, nutrition, fitness, and mental health fields can result in workplace wellness programs [12]. These programs focus on creating healthier work environments through initiatives such as ergonomic improvements, stress reduction workshops, healthy cafeteria options, and physical activity incentives. Collaboration between technology developers, healthcare providers, and fitness experts can lead to the creation of wearable devices and health apps that provide personalized recommendations for nutrition, exercise, and stress management. These technologies can help individuals track their progress and make informed lifestyle choices. Urban planners, architects, public health experts, and policymakers can collaborate to design cities and communities that promote physical activity, access to healthy food, and green spaces. This approach aims to create environments that naturally encourage healthier lifestyle choices [13].

Collaboration between chefs, nutritionists, and culinary experts can result in the development of culinary programs that focus on preparing nutritious meals that are also delicious [14]. These programs can be integrated into schools, restaurants, and community centers to promote healthy eating habits. Collaboration between social workers, healthcare providers, and community organizations can lead to programs that address social determinants of health, such as access to housing, food, and transportation. These collaborations aim to improve overall well-being by addressing broader societal factors [12]. Partnerships between fitness professionals, entertainment venues, and media outlets can promote active lifestyles through events, TV shows, and interactive experiences that encourage physical activity while providing entertainment. Collaboration between museums, cultural centers, and health experts can result in initiatives that combine cultural experiences with health promotion. Exhibits, workshops, and events can highlight the connections between cultural engagement and overall well-being. Collaboration between environmental scientists, health experts, and policymakers can result in initiatives that promote sustainable practices for the benefit of both human health and the environment [15]. Encouraging activities like walking or biking instead of driving can have positive effects on both personal health and the planet. Collaboration between farmers, nutritionists, and policymakers can result in initiatives that promote locally sourced, fresh produce and educate communities about the benefits of seasonal eating and sustainable agriculture. These multidisciplinary collaborations acknowledge that health and well-being are influenced by a wide range of factors and environments, and by working together across sectors, we can create more holistic and effective approaches to promoting healthier lifestyles.

7. CONCLUSION

Lifestyle medicine embodies a holistic approach to health by incorporating evidence-based practices that enhance well-being through behavior modifications. Integrating lifestyle practices into healthcare aligns with patient-centered and preventive approaches, with the potential to improve treatment outcomes. While the adoption of lifestyle goals varies, progress through information and tools signifies a promising path forward. As this integration advances, patient outcomes will likely improve, expanding the definition of health beyond traditional medical confines.

COMPLICATIONS OF PERTUSSIS INFECTION IN NEONATE: A CASE REPORT

Aleksandra Vracaric[1], Department for Pediatrics, General Hospital Uzice
Zeljko Karganovic, Academy of Applied Sciences Western Serbia
Slavka Mitricevic, Academy of Applied Sciences Western Serbia
Ivanka Djuricic, Academy of Applied Sciences Western Serbia

***Abstract**: Pertussis can cause serious and sometimes deadly complications in babies and young children. Babies who have not had all recommended pertussis vaccines are more likely to get serious complications. About one third of babies younger than one year old who get whooping cough need care in the hospital. Of those babies about: 68% will have apnea (life-threating pauses in breathing), 22% get pneumonia, 2% will have convulsions, 0,6% encephalopathy, and 1% will die. Case presentation: Neonates and infants are more likely to develop severe pertussis. The authors report a malignant pertussis case in not vaccinated 23-days-old girl with respiratory failure, severe pneumonia and convulsions. Bordetella pertussis was detected from nasopharyngeal secretions by polymerase chain reaction. The child was treated for 6 weeks in the neonatal intensive care unit, either on mechanical ventilation, then depending on additional oxygen. The patients symptoms completely resolved after 8 weeks.*
Keywords: pertussis, complications, neonate, pneumonia

1. BACKGROUND

Pertussis, commonly known as whooping cough is highly contagious acute respiratory illness caused by Bordetella pertussis. Pertussis usually starts as an undifferentiated respiratory syndrome and, than, progresses to produce severe and paroxysmal attacks of “whooping” cough. Vomiting, cyanosis and apnea can occur as a result of these episodes of cough and, in infants and young children, complications have been described and may be life threatening, as impaired cerebral oxygenation may occur [1].
Therefore, effective vaccines against pertussis have been developed and have been included in national immunization programmes worldwide for several decades. The first dose of vaccine is at the age of 3 months, according to the Serbian immunisation schedule.
A precise estimate of the burden of pertussis is difficult, as under-recognition and/or under-reporting probably occur, as physicians, including pediatricians, have not been used to deal with such a disease in children for a long time [2]. Here, authors report the clinical case of a unvaccinated neonate diagnosed with pertussis.

2. CASE PRESENTATION

A 23-days-old girl was admitted to the Pediatric Department on the request of her general pediatrician, because of 5-6 days lasting cough, with cyanosis during of some episodes, fever (37.8C) and malaise on the day of admission. On admission the patients body temperature was

[1] vracaric.aleksandraa@gmail.com

37.3C, heart rate was 156 beats per minute, respiratory rate was 64 breaths per minute, the oxygen saturation was 92% on room air. She presented with puffy nose, pharynx was slightly injected. Pulmonary auscultation presented diffuse crakles. The rest of the physical examination was unremarkable. The blood analysis revealed an increased peripheral white blood cell count (24.8, than $46.5x10^9$) with lymphocitosis (67.3, than 48.6%) and a normal biochemistry, including normal C-reactive protein. The chest radiography showed a reinforcement of the perihilar bronchovascular reticulum and heterogeneus infiltrates on the inferior third of right lung. Echocardiography revealed no abnormalities. At this point, the differential diagnosis included viral respiratory infection and pertussis. The patient received azithromycin per os, inhalation of fenoterol/ipratropium-bromide and budesonide. On Day 3 of hospitalization, the patient worsened, developed more frequent paroxysms-rapid, violent and uncontrolled coughing fits, apnea and crises of cyanosis. Oxygen saturation dropped to 82% on room air. Patient developed a GTC convulsion that lasted about one minute and stopped spontaneosly. The patient was referred to a University clinic on the Day 3 for further diagnosis and treatment. On admission to the clinic patient was febrile (38.8C), tachypneic (50/min), with retraction of the intercostal spaces, tachycardic (150/min), the oxygen saturation was 92% on room air. The blood analysis revealed an increased peripheral white blood cell count ($65.14x10^9$) with lymphocitosis (45%), and a normal biochemistry, including normal C-reactive protein. The chest radiography showed homogeneosly reduced transparency of the upper right lobe; the left lung as a whole had reduced tranparency.
Bordetella pertussis was detected from nasopharyngeal secretions by polymerase chain reaction. Nasopharyngeal aspirate for RSV was negative. A bronchoscopy was performed, during which a large amount of secretion was aspirated. Fiber aspirate was sterile. Blood culture was sterile. Parenteral antibiotic therapy with ampicillin, amikacin and azithromycin was applied. On Day 3 of admission, during bronchoscopy, cyanosis and desaturation developed, for which the newborn was intubated and mechanical ventilation was started. In the further course, due to febrility and the increase in the laboratory parameters of the infection, the microbiological analyses were repeated and the antimicrobial therapy was corrected on two occasions. From 11^{th} day of admission, the child is afebrile, there is an improvement in the general condition and auscultatory findings over the lungs. On the eleventh day the patient was extubated, supplemental oxygen therapy via nasal cannula was continued. Application of inhaled bronchodilators and percussion drainage were continued. On the 35^{th} day of hospitalization the use of antimicrobial therapy and oxygen therapy was stopped. The child was discharged on the 40^{th} day after admission.

3. DISCUSSION

Such a short clinical report highlighted that the occurrence of pertussis must be suspected and investigated in infants presenting persistent cough, both in unvaccinated children in the first two months of life, and in children whose vaccination has not yet been completed. In addition to pointing the attention on a diagnosis of pertussis, this case report further raised the issue of modifying and/or implementing the immunisation strategy. Lowering the time points of the three vaccine doses during the first year of life could help to improve the coverage in infants, but it is nod enough, as evidenced by the model of disease prevalence provided by Bento et al in USA [3]. Indeed, an important window of susceptibility persists during the first year of life and, in particular, in the first two months, if the environmental circulation of the bacterium is not interrupted by minimizing also the number of susceptible adults, representing the weakest link in the “prevention chain”. However, pertussis can be mitigated and manifest through an atypical course of disease in infants, if the infection occurs when the immunisation schedule has started regularly, but not completed yet. [4,1]. It is well known that there is a lack

of long-term persistence of pertussis immunity after the completion of the scheduled immunisations in the pediatric age and, therefore, the protection against pertussis wanes if booster doses are not administrated every 10 years. Vaccination strategy which consists of immunising family members and close contacts of the neonate, and mothers prenatal vaccination should be proposed in order to reduce the risk of pertussis in neonates and younger infants [5].

4. CONCLUSIONS

Pertussis is a highly contagious disease that can have very serious complications, especially in unvaccinated newborns and incompletely vaccinated infants in the first year of life. Pediatricians should be aware of invasive B. pertussis infection and severe complications in children with pertussis. Also, it is necessary to consider a new vaccination strategy that would include mothers prenatal vaccination and immunising family members and persons who come into close contact with newborns.

SPORT RELATED INJURIES IN BRAZILIAN JIU JITSU

Vuk Aleksić[1], Department of neurosurgery, Clinical hospital Center Zemun
Radmila Aleksić, Department of head and neck surgery, Clinical hospital Center Zemun

Abstract: *Brazilian jiu-jitsu (BJJ) is a combat sport which relies mostly on ground combat, emphasizing grappling skill over strength and submission over striking. Given the main goal of the BJJ fight, which is to "tap out" or submit sparring partner by a vast spectrum of different levers on the joints of the arms, legs, and spine, as well as applying suffocation and strangulation without striking, many injuries can occur among BJJ fighters. We conducted a study on 162 BJJ fighters from the BJJ club ViN in Belgrade, Serbia regarding sports related injury-specific information. We found that most common injuries related to BJJ are minor in severity and predominantly located in the extremities, e.g. legs and arms. Loss of consciousness is common injury, but usually without any consequences. The results are discussed with small literature review.*
Keywords: Brazilian jiu jitsu, sport injuries.

1. ITRODUCTION

Brazilian jiu-jitsu (BJJ) is a martial art and combat sport which relies mostly on ground combat, emphasizing grappling skill over strength and submission over striking. BJJ is based on grappling, ground fighting and submission holds. It was developed in the early 19th century and instantly gained popularity all over the world with the creation of the Ultimate Fighting Championship (UFC) in 1993 when Royce Gracie, a famous BJJ practitioner won the first two UFC tournaments [1]. BJJ is still evolving and growing as one of the best combat sports for professional athletes as well as for amateur practitioners. BJJ fighters wear a belt that denotes their skill and rank. The belts for people older than 16 years of age in increasing order are white, blue, purple, brown, and black. Belts graduation is dependent on skill and duration of BJJ practice. Combining belts, weight class and age, competition groups are formed for BJJ tournaments [2]. The first BJJ team in Serbia was founded by master Jovan Žerjal in 1997. Since then, BJJ community in Serbia is constantly rising.

Given the substantial variability in ranking, skill and age of BJJ practitioners, as well as main goal of the BJJ fight, which is to "tap out" or submit sparring partner by a vast spectrum of different levers on the joints of the arms, legs, and spine, as well as applying suffocation and strangulation without striking, many injuries can occur in this population if the rules of the fight are not respected, which mostly depends on the coach.

While other combat sports such as mixed martial arts (MMA), judo and wrestling have been the focus of many studies regarding injuries, BJJ has not received many attention [3, 4]. According to our knowledge, there is little research on injuries in BJJ community, manly focusing on injuries

[1] aleksicvuk@hotmail.com

that occur during training sessions and no research regarding injuries sustained during BJJ-specific conditioning [5, 6]. Searching the internet and relevant medical databases, we did not find data on injuries among Serbian BJJ fighters and practitioners, even though it is now a relatively mass sport in this country with several thousand active practitioners. The main goal of this pilot study was to obtain and analyze basic data on sport related injuries among Serbian BJJ fighters, with the aim of better prevention of these injuries.

2. MATERIAL AND METHODS

The online survey was created to collect demographic and injury-specific information among Serbian BJJ fighters and practitioners. This survey was distributed to the 162 BJJ fighters from the BJJ club ViN in Belgrade. The study was approved by 5 coaches of the ViN team. The survey was anonymous in order to protect the health information and privacy of participants. Only athletes over the age of 18 were included, and regardless of a past injury history. Survey was conducted in January 2023. Basic demographic statistic was performed.
Basic demographic characteristics were collected about: age, gender, years of training, belt rang, weekly training schedule, weight class, and body mass index (BMI). Weight class was divided into standardized categories: feather, light, middle, heavy, medium heavy and super heavy. Injury-specific information were separated by "body parts" as follows: head, arm, leg, spine, other. Injury severity was self-assessed and classified as: no injury, minimal, moderate or severe injury. Explanation and example was given for each severity of injury (e.g. minimal – does not lead to an absence from training, like scratch; moderate – maximum of 2 weeks absence from training, like tendon stain; severe – over 2 weeks absence from training, like bone fracture). If the same BJJ fighter had several different injuries, he chosen only the most severe form of injury. Data on chronic diseases were also collected. As a dichotomous variable (yes/no), it was investigated whether a BJJ fighter ever lost consciousness after being choked or strangled. Similarly, the interviewed BJJ fighters answer the question whether they use protective equipment (yes/no) and what kind.

3. RESULTS

The results were obtained from 162 respondents in total. The majority of participants were male (n=146; 90,12%), while there was only 16 female BJJ fighters (9,88%). Regardless of gender, the average age was 28,58 years, ranging from 18 to 44. Since all fighters were from the same BJJ club, they all had same environment and training schedule with maximum of 10 training sessions per week. However, the majority of BJJ fighters (n=132; 81,48%) had 3 training sessions per week. About one third of BJJ fighters use protective equipment (n=61; 37,65%). The most common protective gear was a mouth guard which was worn by 45 BJJ fighters (27,7% of all fighters). Second most common protective equipment was crotch protector worn by 22 fighters (13,58%). Belt ranking is showed in the figure 1.

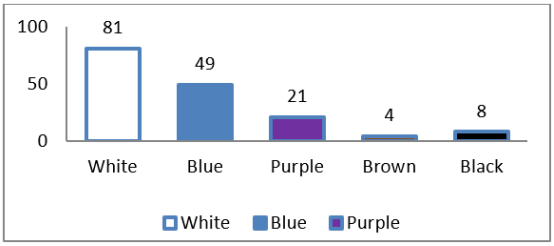

Figure 1. Belt ranking of all 162 BJJ fighters enrolled in the study.

Years of training are presented in the figure 2. This data are in linear connection with belt ranking.

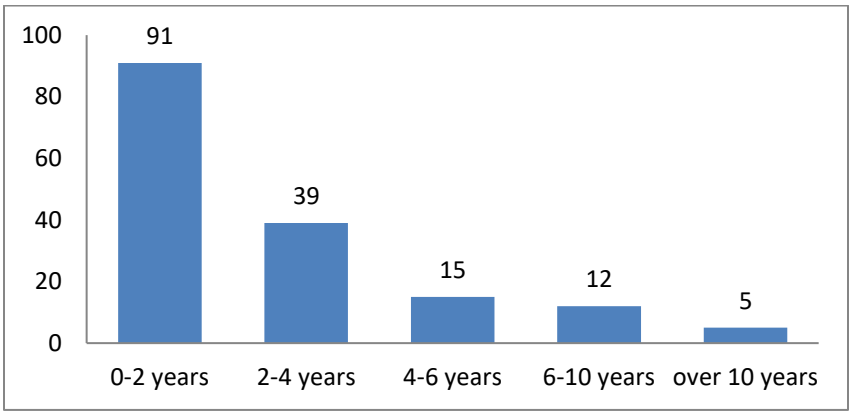

Figure 2. Years of training of all 162 BJJ fighters.

Body mass index as a measure of body fat indicated that majority of fighters had healthy weight with average body mass index (BMI) of 25,66. Weight class distribution of responders is showed in Table 1.

Table 1. Distribution of weight classes.

Weight class	Number	Percent (%)
Feather (≤62kg)	21	12,96
Light (62-69kg)	42	25,92
Middle (69-77kg)	36	22,22
Heavy (77-85kg)	22	13,58
Medium heavy (85-94kg)	28	17,28
Super heavy (≥94kg)	13	8,02

Data on which part of the body is injured are given in the figure 3.

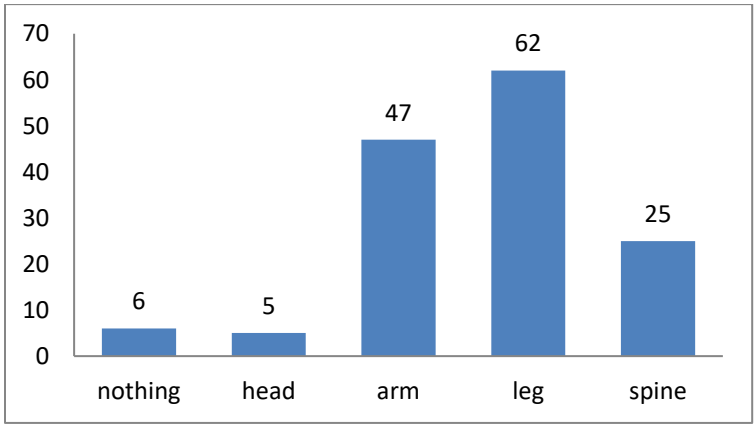

Figure 3. Injuries distribution concerning body parts.

The severity of injuries suffered by BJJ fighters during training or competition according to their own assessment, but after giving them above mentioned explanation and example of all types of injuries is shown in the figure 4.

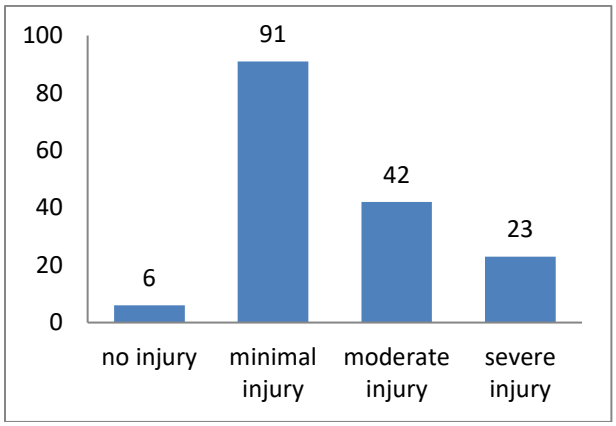

Figure 4. The severity of injuries in BJJ fighter from the study.

As a specific form of injury, lost of consciousness that can be consequence of applied choke or strangulation was also investigated, and results show that 35 BJJ fighters have lost consciousness (22%), and 127 BJJ fighters or 78% have not had a loss of consciousness.
Medical data on chronic diseases was collected for another pilot study, but since it can have influence on sport related injuries it was questioned whether BJJ fighters have or does not have chronic medical conditions. Results show that majority of BJJ fighters are chronic disease free, and only 7 out of 162 BJJ fighters have chronic medical conditions or 4,32%.

4. DISCUSSION

Brazilian jiu-jitsu (BJJ) is rapidly becoming a widely popular sport, with an estimation of nearly 3 million fighters worldwide [7]. Despite this, there is a paucity of literature investigating the injury profile of BJJ fighters during training or competition. Recently Hunker et al. and Petrisor et al. conducted studies about this topic [7, 8]. According to our knowledge, our study is first study of sports injuries in BJJ fighters in Serbia population, which now has several thousands practitioners. The average age of BJJ fighters in our study was 28,58 years, ranging from 18 to 44 years. This findings are in accordance with results of similar studies such as study of McDonald et al. in which an average age of BJJ practitioners was 30.3 years ranging from 18 to 55 years. This is the expected result considering that no minors were included in the study, as well as the fact that BJJ is a sport that is mostly practiced by young healthy people. This is supported by the fact that more than 95% of our fighters did not had any chronical medical condition. Our study showed male predominance of BJJ fighters, which is in accordance with similar studies [5]. Results obtained in our survey show that all demographic data, such as age, gender, years of training, belt rang, weekly training schedule, weight class, and body mass index (BMI) are similar to other studies with same goal of investigation [7-10].
However, since BJJ is a grappling-based martial art whose central goal is the skill of controlling a resisting opponent in ways that force him to submit or “tap-out” without using striking, but rather controlling opponents body or applying different techniques of strangulation, choking and using levers on the different body joints, a certain number of sports injuries is expected, but with the help of well-educated coaches it must be minimized. Examples of the most common techniques used in BJJ are given in the picture 1.

Picture 1. Most common techniques used in BJJ. (A) Choking that can lead to neck muscle injury or loss of consciousness if the opponent does not submit in time or the trainer/referee does not stop the fight. (B) A lever on the leg ("toe hold") that can lead to a sprained ankle if the fight is not stopped in time. (C) Suffocation ("rear naked choke – RNC") which may lead to loss of consciousness. (D) lever on the arm ("armbar") that can cause a elbow fracture if not stopped in time.

Recent studies show that more then 90% of BJJ practitioners suffered at least one injury during training or competition, but all studies show that injuries are much more common during training period then in competition, and this figure appears to be consistent with the studies available for other types of combat sports such as taekwondo, karate, and judo [5, 9]. In our study only 6 BJJ fighter out of 162 had no injury during training. Likely, most of the injuries were minimal, and did not require medical assistance or absence from training (91 BJJ fighter or 56,17%). On the other hand, 65 BJJ fighters from our study had moderate (n=42 or 25,92%) or severe (n=23 or 14,19%) injury which required medical assistance or intervention or absence from training due to recovery. In Hunker et al study, 91% of fighter had some kind of injury during training, and nearly two-thirds of those fighters required some form of medical intervention. In our study similar finding were obtained, with 40,15% of BJJ fighters having some sort of injury that required medical attention.
Literature review showed that most commonly affected locations of injury in BJJ practitioners included the hand and fingers (37% of injuries), and on the second place is led or knee. In a 2014 research by Scoggin et al. use of the leaver on the arm during competition was the most common mechanism of injury, leading to elbow injury [7]. Similarly, McDonald et al. found arm injuries to occur most frequently during competition [5]. Hunker at al also showed that injury type and location of injury vary in incidence by setting, e.g. out of the 11 reported neck injuries, all occurred in training whereas, of the 12 reported arm injuries, only 58.3% occurred in training with the remaining injuries occurring during competition [7]. The neck represents a particularly vulnerable area of injury and literature results show that 90% of injuries to the neck require a break in training and 70% of those disruptions in training lasted longer than two weeks [7]. In our study most frequent injuries were located in the leg and arm with a combined frequency of 67,28%, with slight predominance of leg injuries.
In the study about the safety of sportive chokes, conducted on 4307 BJJ fighters, 1443 (33.5%) reported being choked over 500 times during training, 3257 (75.7%) have been choked to near-syncope, and 1198 (27.8%) have been choked unconscious. Only 2 fighters of the 4307 (0.05%) reported ongoing symptoms from chokes 24 hours after training and which were likely not related to ischemia of the brain [11]. In our study lost of consciousness that can be consequence of applied

choke was positive in 35 BJJ fighters or 22% which is similarly to mentioned results of Stellpflug et al. Likely, no fighters had prolonged symptoms or complications due to applied choke leading to loos of consciousness.

Although injuries in BJJ are relatively common, most injuries are of minimal severity and do not require time off training or medical attention. The role of the coach in the club, i.e. the referee at the competition, is especially important in order to stop the fight in time. Also, the use of protective equipment significantly reduces the possibility of injuries.

ENERGY SAVINGS AND CO_2 EMISSION REDUCTION POTENTIAL THROUGH THE EXISTING BUILDING RENOVATION

Tamara Bajc[1], Faculty of Mechanical engineering, University of Belgrade

Abstract: *The Republic of Serbia has more than 2.2 millions of buildings built before 2011. when the Rulebook on energy efficiency of buildings was adopted. Which further implies that more than 289 millions of square meters of dwellings in Serbia have lower thermal envelop properties than it is recommended and thus much higher energy consumption for heating than it is the case in new buildings. This makes an opportunity for deep building renovation of Serbian building stock and potential energy savings. In this manner, it is possible to save up to 6.76·10^9 kWh/a of energy for heating yearly just by the renovation of the existing building stock built in a period from 1971-1980. If this calculation is extended to all Serbian dwellings, it is possible to save up to 2.68·10^10 kWh/a of final energy for heating yearly. Similarly, CO_2 emission reduction for the existing buildings can be accomplished up to 40% just by the refurbishment of the building envelope.*
Keywords: Deep Building Renovation, Energy Savings, CO_2 Emission Reduction, Existing Building Stock

1. INTRODUCTION

It is considered that building sector is the one of the biggest energy consumers in the European Union (EU), using about 40% of total energy consumption and 36% of global greenhouse gas emissions [1]. More, it is considered that about 75% of buildings in EU is energy inefficient, so the European Commission proposed a revision of Directive on Energy performance of buildings 2018/844 [2] in 2021. Further, new targets by 2050 include achieving zero-emission and full decarbonisation of building stock. Being at the road for accession to the EU, Serbia is following the European goals in building energy performances as well and prepares a long-term strategy for deep building stock renovation. Currently, there is no unique deep building renovation integrated strategy towards Directive's goals, but different single attempts such as: renovation of existing facades by adding internal or external insulation, windows replacement, roof renovation, replacement of heat sources etc [3]. Thus, the long term strategy for integrated and planed deep building renovation is mandatory in order to decrease building energy consumption and global greenhouse gas emissions.

1.1 Energy sources used in households in Serbia and worldwide

According to the data obtained through the research of the Statistical Office of the Republic of Serbia, the most commonly used fuel for heating in the Republic of Serbia is wood and wooden biomass, with a share of 48%, followed by district heating in a percentage of 20.7%, electrical energy 14.6%, natural gas 10%, coal 4.6% and the rest of the share goes on LPG, geothermal energy, fuel oil and other types of biomass [4]. On the other hand, in the EU, the biggest share of fuels in final energy consumption in households in 2021 goes on natural gas 33%, then electricity 25%, followed by renewables and biofuels with a share of 21% (Fig. 1) [5]. Looking at the USA energy consumption, it varies within the different countries due to the different climate conditions, but in overall, according

[1]tbajc@mas.bg.ac.rs

to the data from the year 2020, the most used fuel in new housing was natural gas with a share of 55%, followed by electricity with 45% and the rest of 1% goes on all other fuels [5].

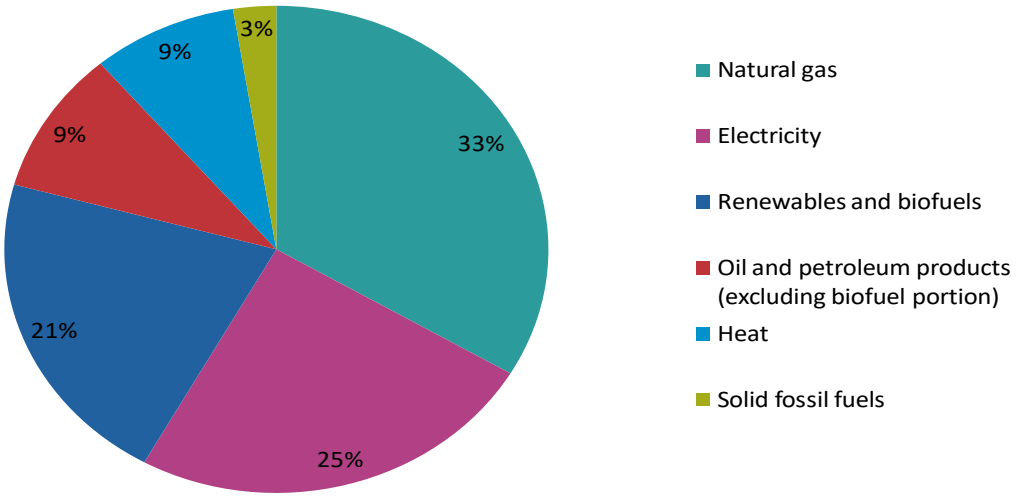

Figure 1. The share of fuels in final energy consumption in households in EU in 2021
Source: Eurostat [5]

The shares of fuels in the final energy consumption in the residential sector for space heating for 2020 for various countries are shown in Figure 2. It can be noted that the countries which are using the large quantities of wood for heating are considered to use a renewable energy sources, which could be discussed from the various points. For example, it is considered that the wood is a biomass, but on the other hand, it should be precisely defined by the legislation which type of wood can be used for heating purposes, since some of the developing countries do not have a defined strategies for planed timber harvests. More precisely, looking at the conversion factors for calculations of primary energy needs for heating in Rulebook of energy efficiency of buildings [6] for biomass for example for the Republic of Serbia, it can be seen that the all types of biomass has the same conversion factor 0.1. Obviously, it is necessary to reconsider this and introduce some weight factors which give a higher value to the biomass obtained as a waste from the wooden industry production, agriculture and fast growing seedlings. In this manner, it is possible to define a better strategy for future fuels usage for the heating purposes in households.

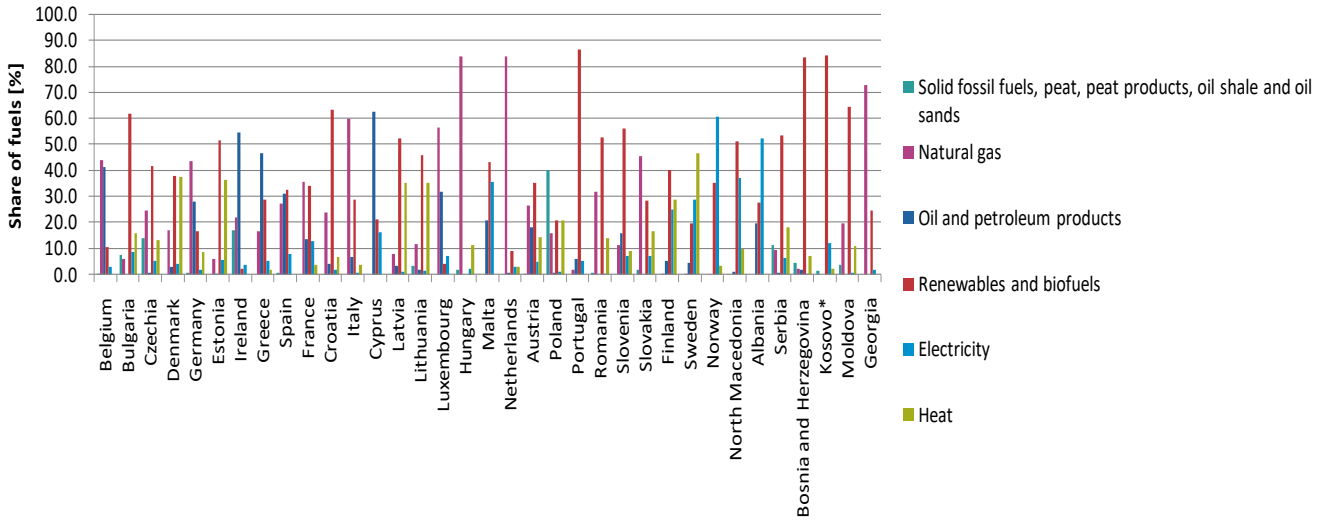

Figure 2. The share of fuels in the final energy consumption in the residential sector for space heating for 2020 ((*) This designation is without prejudice to positions on status, and is in line with UNSCR 1244.)
Source: Eurostat [5]

2. ANALYSIS OF EXISTING BUILIDNG STOCK IN THE REPUBLIC OF SERBIA.

According to the literature [7], there are more than 289 millions of square meters of dwellings in Serbia built before 2011, when the Rulebook on energy efficiency of buildings was adopted. A modest part of old building stock was under some type of the reconstruction, either the insulation was added or windows were replaced, but a large number of buildings still has the same thermal properties as when they were built. Looking at the period of last 20 years, 64% of Serbian inhabitants live in households which are not renovated. If the partial renovation was conducted, usually it was windows replacement with a share of 66,7% in existing buildings and adding the insulation in 47% [4].

If it is considered that more than 2.2 millions of buildings in Serbia are build before 2011, it is obvious that there is a large potential of building stock renovation. The share of number of buildings built before 2011 by the year of construction in Serbia is given in Figure 3. It can be noted that about 12% of buildings were built before the Second World War, while all the other buildings were built in a period after 1945, with the biggest share of buildings built in a period from 1971-1980.

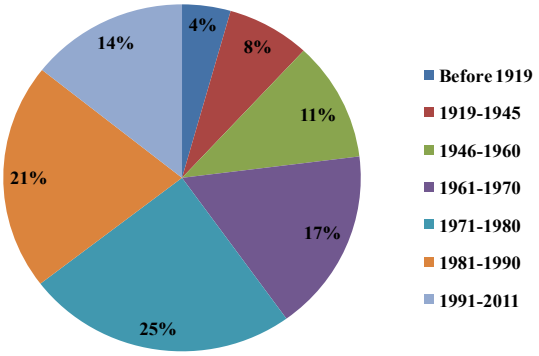

Figure 3. The share of buildings by the year of construction
Source: National Typology of Residential Buildings in Serbia [7]

The typical U-values for external walls and windows for existing building stock is given in Table 1.

Table 1. The typical U-values for external walls and windows for existing building stock
Source: [7]

Year of construction	Type of dwelling	Type of element	U-value
Before 1919	Free-standing residential building	External wall	1.12
		Windows	3.5
From 1919 to 1945	Free-standing residential building	External wall	1.67
		Windows	3.5
From 1946 to 1960	Free-standing residential, Residential buildings-lamella, Residential buildings in row	External wall	1.26
		Windows	3.5
From 1961 to 1970	Free-standing residential building	External wall	3.31
	Residential building – lamela	External wall	1.74
	Residential building in a row	External wall	1.26
		Windows	3.5
From 1971 to 1980	Free-standing residential building	External wall	1.68
		Windows	3.3

Comparing these U-values from the Table 1. to the maximum allowed values from the actual Rulebook on the energy efficiency of buildings [6], it is obvious that values for the existing buildings built before 2011 are far away from the prescribed ones.

3. POTENTIALS FOR THE ENERGY SAVINGS AND CO_2 EMISSIONS REDUCTION ON THE EXAMPLES OF THE EXISTING BUILDINGS.

3.1 Example of the energy consumption of buildings from 1980s and possible savings.

Since the biggest percentage of buildings in Serbia was built in a period of 1971-1980 (Fig. 3), the example of energy consumption of such a type of buildings will be presented on a building of total heating area about 2690 m^2 and climate conditions of Belgrade, the capital of Serbia. As a typical representative of these type of buildings, the thermal envelope layers are adopted according to the literature [7] and U-values are calculated and shown in Table 2.

Table 2. U-values for thermal envelop of the example building before the refurbishment
Source: [8]

Type of the envelope element	U-value [W/(m2K)
External wall	1.74
Ceiling	1.66
Internal wall	1.61
Windows and balcony doors	3.3
Floor construction	0.56

According to the U-values and methodology of calculation of building energy needs for heating prescribed in a Rulebook on energy efficiency of buildings [6], the final, delivered and primary energy needs are calculated and given in [8]. Using these data, the calculation was done per square meter of heated area before the reconstruction and with the various possibilities of energy efficiency improvement (Figure 4).

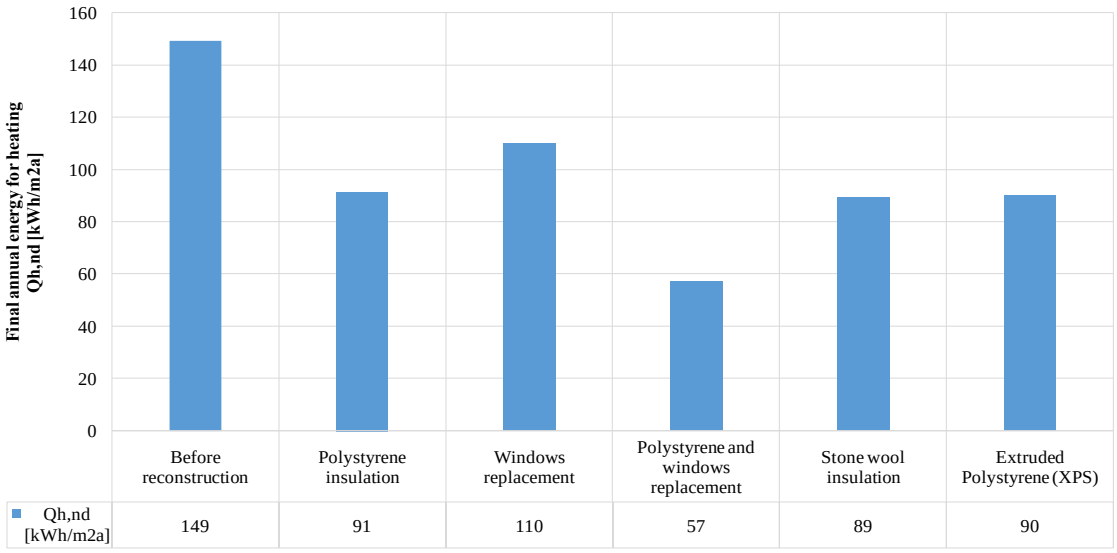

Figure 4. Final annual energy needs for heating per square meter for example building before and after renovation

Further, the analysed options from the energy point of view took into a consideration following measures: insulation of thermal envelope with polystyrene to fulfil the requirements from the Rulebook for existing buildings renovation, then windows replacement, combination of these two measures, insulation of thermal envelope with stone wool and insulation of thermal envelope with extruded polystyrene. The results are shown in Figure 4 for final energy needs for heating per square meter for these five options of building renovation. From the results, it can be seen that the building renovation with polystyrene insulation of thermal envelope and windows replacement provides energy savings of 62% of final energy needs for heating of the building.

3.2 Example of the CO_2 emission of buildings from 1980s and possible emission reductions.

Similarly, if it is assumed that the heating is provided using electrical boiler, using electrical energy as a source for heating and domestic hot water preparation (DHW), the CO_2 emission can be calculated as well, with a respect to the methodology given in [6]. The results of the comparison before and after the various possibilities of building envelope renovations are shown in Figure 5.

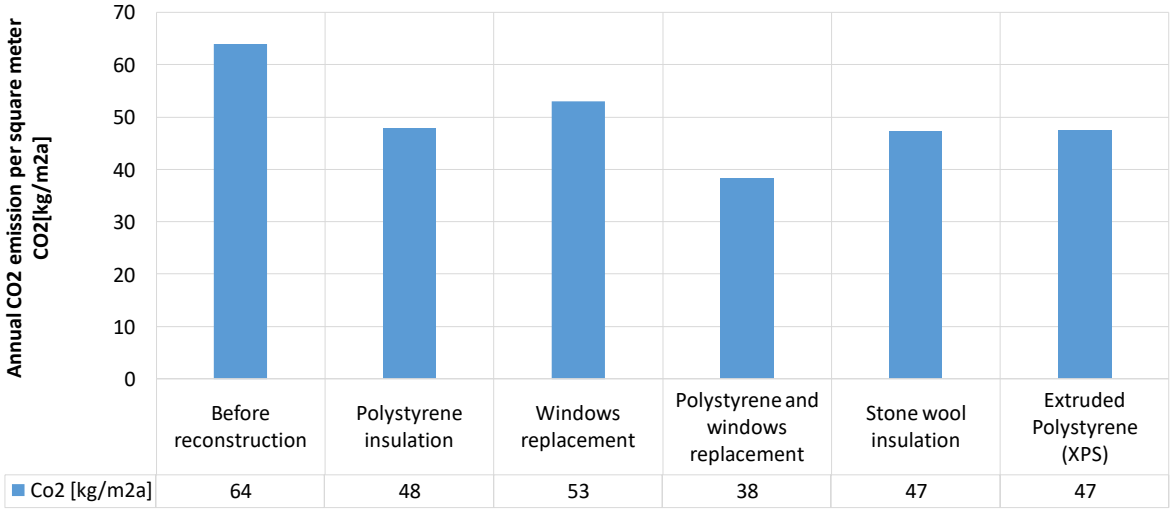

Figure 5. CO_2 emission per square meter for example building before and after renovation

If the deep renovation of thermal envelope is performed, it is possible to reduce up to 40% of CO_2 emission of the building for heating and DHW. This percentage can be even higher if the heating source is replaced as well. With other words, in the case of deep thermal envelope refurbishment and replacement of the electrical boiler with a boiler on biomass (conversion factor 0.1 is given in [6]), as well, it is possible to reduce up to 80% of CO_2 emission for heating needs of building.

3.3 Discussion on the potentials of energy savings and CO2 emission reduction.

Looking at the number of square meters of buildings 73173360 m^2 (25.26% of total square meters built before 2011) [7] built in a period from 1971-1980, and the results of final energy consumption per square meter showed in section 3.1., it is possible to calculate the overall final energy consumption of total building stock in Serbia built in this period. Further, if the overall final energy need for heating is 149 kWh/m^2a, the overall total final energy needs for heating of buildings in Serbia built in a period from 1971-1980 is 1.09·10^10 kWh/a yearly, which further implies with a possibility of 62% of the final energy savings for heating with renovation of thermal envelope (polystyrene insulation of thermal envelope and windows replacement), which is 6.76·10^9 kWh/a of saved energy yearly. Furthermore, looking at the characteristics of the thermal envelope of all buildings built before 2011 from the Table 1. it is notable that the overall values for windows are pretty much the same for all categories of buildings (U-value for windows is from 3.3. to 3.5 W/(m^2K)), while external wall values are in the range from 0.77-1.67 W/(m^2K). Moreover, if it is considered that all existing building stock needs before the refurbishment are about 149 kWh/m^2a of final energy for heating, multiplied by 289687720 m^2 of existing dwellings, gives 4.31·10^10 kWh/a yearly and if this dwellings are refurbishment as it is previously described, it is possible to save 2.68·10^10 kWh/a of final energy for heating yearly. Knowing that the prescribed maximum allowed amount of energy for new buildings heating by Rulebook on the conditions, content and manner of issuance of certificates of energy performance of buildings [9] is less than 65 kWh/m^2a, the saved amount of energy for heating is enough to fulfil the requirements of more than 4.12·10^8 square meters of new buildings in Serbia. Similarly, looking at the CO_2 emission from existing buildings obtained in Section 3.2. which is calculated based on assumption that the electricity is used for heating, and the share of used electricity

for heating in Serbia of 14.6%, it can be obtained that the 6.84·10^8 kg/a of CO_2 is emitted for buildings heating on electricity, built in a period from 1971-1980. This amount can be reduced to 2.73·10^8 kg/a of CO_2 just by the refurbishment of thermal envelope of this category of buildings.

CONCLUSION

This paper deals with a study of possibilities of refurbishment of the Serbian building stock and potential savings of energy and CO_2 reduction. The results are obtained based on the calculations for the example building, built in Belgrade in a period from 1971 to 1980, since the biggest share of existing buildings in Serbia (about 25%) was built in this period. Calculations showed that by reconstruction of all existing buildings built before 2011, adding the external insulation and replacing the external windows and doors could implies with 62% of final energy savings for heating in Serbia, which allows a more than 4.12·10^8 square meters of new buildings in Serbia to be heated on the same amount of energy that is currently wasted. Similar calculation showed potential in CO_2 emission reduction in between 40% to 80% depending on the type of refurbishment (only envelope or envelope and source). These figures implies with a huge potentials for energy savings and cleaner and more sustainable environment in the Republic of Serbia.

ANALYSIS OF REMEDIATION OF HORIZONTAL CYLINDRICAL TANK FOR OIL STORAGE

Marko Jarić[1], Innovation Centre of Faculty of Mechanical engineering in Belgrade

Abstract: *The paper deals with the problems related to the horizontal cylindrical tank with capacity 52m^3 for oil storage, which is in long time continual service. Before planned change of location necessary planned cleaning and inspection activities were performed. During inspection process cracks were observed in base metal and on internal side at reinforcement plates. Cracks were analysed and confirmed by detail visual and dye penetrant tests. Appropriate remediation documentation was prepared before starting of cracks excavation process. All cracks were fully removed which was confirmed by relevant NDT-tests. Repairing welding activities and appropriate NDE-examination tests after repairing welding process were performed. After successfully leak test, tank was transferred on the new location and put in service.*
Key words: Horizontal tank, Cracks, Suction, WPS

1. INTRODUCTION

Storage tanks are projected to operate with internal gas and vapour spaces at pressures close to atmospheric pressure and hence often they hold the name atmospheric tanks. Such tanks are usually made from carbon steel, alloy steel, aluminium or other metal depending on service. Also some tanks have been fabricated from non-metallic materials such as reinforced concrete, reinforced thermoset plastics and wood. Nowadays some wooden tanks, some riveted tanks and some bolted tanks can be found still in service.

Usually storage tanks in oil & gas (petroleum industry) are normally used for liquids having a true vapour pressure which is less than atmospheric pressure. Vapour pressure is the pressure on the surface of a confined liquid caused by the vapours of that liquid. Vapour pressure grows up with growing-up of temperature. Crude oil, heavy oils, gas oils furnace oils, naphtha, gasoline and non-volatile chemicals are usually stored in atmospheric storage tanks. Many of these tanks are protected by pressure-vacuum vents that limit the pressure difference between the tank vapour space and the outside atmosphere to a few ounces per square inch. Non-petroleum industry uses atmospheric tanks include storage of a variety of chemicals and other substances operated in closed-loop systems not vented to atmosphere and with pressure control and relief devices as required. These tanks may be designed and operated as low-pressure storage tanks. Additional uses for atmospheric storage tanks can include liquid (both hydrocarbon and non-hydrocarbon) storage in horizontal vessels, storage of process liquids or granular solids in skirt supported or column-supported tanks with elevated cone bottoms (non-flat bottom) and process water/liquids in open-top tanks.

In general exist many classifications of the storage tanks while the most common classification is classification according to their construction characteristics. According to this classification storage tanks can be classified into the following types: fixed cone roof tank, umbrella roof tank, geodesic dome roof tank, different constructions of storage tanks with floating roofs, tank with vapour dome

[1] mjaric81@gmail.com

roof, welded horizontal tank supported on saddles, figure 1, plan hemispheroids tanks, nodded hemispheroid tanks, plain spheroid tanks, plan hemispheroid tanks with knuckle radius and nodded spheroid tanks. Although welded horizontal tank supported on saddles are very often in long time service for oil storage critical places of cracks are not fully explored so the main goal of these paper will be analysis of the most critical places of formation and growth of cracks at these types of storage tanks [1,2]. Here should be mentioned that the horizontal tank, which was analysed in this paper, was made from carbon steel and it was capacity of $52m^3$ and that due planned plant modification its location was changed when was used opportunity for performing detail inspection on it.

Figure 1. Common construction of the horizontal tank which was supported on the saddles

2. DETERIORATION OF THE WELDED HORIZONTAL TANK SUPPORTED ON SADDLES DUE CORROSION

The prime cause of deterioration of the steel storage tanks and their accompanying equipment is corrosion. Locating and measuring the extent of corrosion is a major reason for storage tank examination. If left unchecked, tank deterioration can progressively lead to failure which may have adverse effects such as endangering personnel, environmental and property damage and business interruptions. Corrosion in general case can be divided on external corrosion and internal corrosion. On all external parts of a tank, atmospheric corrosion like a type of external corrosion can appear. The type of tank, construction details, and environmental conditions can all affect the location, extent and severity of external corrosion. For example a sulphurous, acidic or marine atmosphere can damage protective coatings and increase the rate of corrosion. External surfaces of the tank and auxiliary equipment if they are not protected with paint or other coatings where surfaces are in contact with moisture or the ground. Extended contact with water is likely to cause localized corrosion. Such susceptible areas should be protected with coatings designed to withstand long time immersion. Inspections should target areas where tank details cause water or sediment to accumulate. Beside external corrosion of tank shell, external corrosion of tank bottom can appear. The foundation material used for forming a pad that is directly in contact with the steel bottom plates may contain material that promote corrosion. For example, cinder may contain sulphur compounds that become very corrosive in the presence of moisture. The presence of clay, wood, gravel or crushed stone as contaminants in a sand pad may cause pitting corrosion at each point of contact. Faulty pad preparation or poor drainage may allow water to remain in contact with the tank bottom. If a tank previously leaked corrosive fluid through its bottom, accumulation of the fluid underneath the tank can cause external corrosion of the bottom plates. For tanks that are supported above grade, an improperly sealed ring wall may allow moisture to accumulate between the tank and the support, thereby accelerating corrosion. Asphalt-impregnated fibreboard is not a recommended sealant for tanks sitting on concrete ring wall foundations. The lower tank shell can become severely externally corroded near the grade line where soil movement has raised the grade level to cover the lower portion of the shell. External corrosion also occurs when insulation absorbs ground of surface water by wicking action, or when damaged or improperly sealed openings around nozzles and attachments allow water behind insulation.

Unlike of external corrosion internal corrosion in a storage tank depends on the contents of the tank and its materials of construction. Usually tanks which are using for storage crude oil and petroleum are made from carbon steel. Internal corrosion of these tanks in the vapour space can be caused by hydrogen sulphide vapour, water vapour, oxygen or any combination of these. In the areas in contact with the stored liquid, corrosion is commonly caused by acid salts, hydrogen sulphide or other sulphur compounds, dew point corrosion, or contaminated water that settles out and mixes with solids on the bottom of the tank, typically referred to as BS&W. Issues of SCC can be of particular concern when the product is known to be corrosive to welds and other heat-affected zones. Ethanol, di ethanolamine (DEA), and caustic products are just a few of the products that can be contribute to this condition when in contact with bare metal [1,3,4].

3. OTHER TYPE DETERIORATIONS OF THE WELDED HORIZONTAL TANKS

In the other types of deteriorations that most often appear at the tanks, include brittle fracture, leaks, cracks, mechanical deterioration and settlement of the equipment. The short explanations of these damage mechanisms will be show in the next lines.

Brittle fracture and sudden loses of the contents of a tank can result in injuries to personnel and extensive damage to equipment in surrounding areas. Pollution of streams or waterways can result when such a tank failure occurs near a waterway or is connected to one by a sewer or other flow channel. Probability of brittle fracture can be minimized by proper design, fabrication, operation and maintenance [5].

Leaks are primarily the result of corrosion but can occur at improperly welded or riveted joints, at pipe thread or gasket connections or cover plates, or at crack-like flaws (including arc strikes on plates) in welds or in plate material. Three-plate laps in lap-welded tank bottoms are particularly prone to defects that can lead to leaks. Cracks-like flaws can result from a number of causes including deficiencies in design, fabrication, and maintenance. The most likely points for crack-like flaws to occur are at the bottom-to-shell details, around nozzle connections, at manholes around river holes or around rivet heads, at welded brackets or supports and at weld seams. The lower shell-to-sketch plate or shell-to-bottom weld is especially critical because in relatively hot tanks there is a higher likelihood for this detail to develop a crack-like flaw due to high stresses. Potential for this occurrence can be minimized by the use of thicker, butt-welded annular bottom plates for higher design stress tanks and for larger elevated temperature tanks [1, 6, 7].

Many other type of mechanical deterioration can over the service life of a storage tank. If such deterioration is discovered, permit cost-effective maintenance and repair to be done on scheduled basis, the risk of failure. Examples of conditions that cause other types of mechanical deterioration can include severe service conditions like frequent fill/withdrawal cycling or elevated affecting the integrity of the shell-to-bottom weld, bulging, peaking, denting, overpressure, etc. [1,7].

Settlement of tank due to soil movement under the tank or tank foundation can also cause mechanical deterioration. Uniform settlement of the tank entire would not necessarily cause structural damage or be or be considered a serious issue. Large or uneven amounts of settlement can cause nozzles with attached piping to become overstressed and possibly deformed or cracked or interfere with nominal operation of a floating roof. Significant amounts of uneven settlement should be cause for concern and for further investigation. Edge settlement in tanks with cone-down bottom can trap BS&W, resulting in bottom and lower shell corrosion in this area. Soil and water can be retained against the external when such settlement is present [8,9].

4. ESTABLISHING OF INSPECTION PLANS

An inspection plan is often developed and implemented for tanks through the collaborative activities of the inspector, engineer, corrosion specialist, and operations personnel. An inspection plan should contain the inspection tasks, scope of inspection, and schedule required to monitor damage mechanisms and assure the mechanical integrity of the tank. Knowledge of the capabilities and

limitations of NDE techniques allow the proper choice of examination techniques(s) to identify particular damage mechanisms in specific locations. The plan should typically:

- define the type(s) of inspection needed, e.g. external, internal thickness measurements, NDE, associated piping, etc.;
- identify the regulatory intervals for seal or other component inspection needs, any applicable jurisdictional requirement, and the date for each inspection type;
- describe the inspection and NDE techniques, extent and locations;
- describe any surface cleaning requirements for needed for inspection and examinations;
- describe the requirements of any needed pressure of tightness test, e.g. type of test, test pressure and duration; and
- describe any required repairs.

Thus prepared inspection plans should consider information such as operating temperature ranges, process fluid corrosive contaminant levels, material of construction, tank design and configuration, service changes since the last inspection, and inspection/maintenance history. Ongoing communication with operating personnel when process changes or upsets occur that could affect damage mechanisms and rates are critical to keeping an inspection plan updated. Other common issues in an inspection plan include:

- describing the types damage mechanisms anticipated or experienced in the tank;
- defining the location of the damage;
- defining any special access requirements [10];

4. PLANNED CLEANING AND INSPECTION ACTIVITIES BEFORE TANK TRANSFERRING ON NEW LOCATION

Horizontal tank, which that presented in this paper, was long time in continual service in process plant and due planned modifications in the process after performed few surveys, and conducted discussions it was adopted new location and function of the previously mentioned tank. In addition, it was planned installation of the new ladders and new instrument equipment. Considering the previously facts before installation the tank on new location it was used opportunity for performing appropriate cleaning and inspection activities. On that occasion, it was conducted the following activities: preliminary visual inspection before cleaning process, full drainage of tank, venting, full inspection after cleaning process. Here should be mentioned that usually in all process plants preliminary inspection report and final inspection report should be prepared with that relevant department before put equipment in the service should approve final inspection report. In case of some repairing also repairing plans should be prepared and approved. Repairing plans should be mentioned in the final inspection report.

6. FINDINGS OBSERVED DURING FINAL INSPECTION

Full inspection was performed after finishing cleaning activities on the tank which was made from carbon steel and which capacity was $52m^3$. On that, occasion it were performed visual inspection of external and internal surfaces and ultrasonic thickness testing of metal elements such as penetrant tests of the suspected areas and weld joints. Here should be mentioned that focal points of the visual inspection were directed on the areas, which were considered as critically such as areas where tank was supported on the saddles, weld joints that connecting heads and shell welds around the nozzles [10]. On the other side ultrasonic thickness, testing was performed according to the relevant international standards in this area that are recommended measuring of thickness of metal elements in all four quadrants for the cylindrical part of the equipment while for the heads minimum one measuring point is recommended in the centre of the heads, figure 2. Penetrant tests were performed in the random basis and it was take into consideration of the connections between cylindrical shell and heads [11].

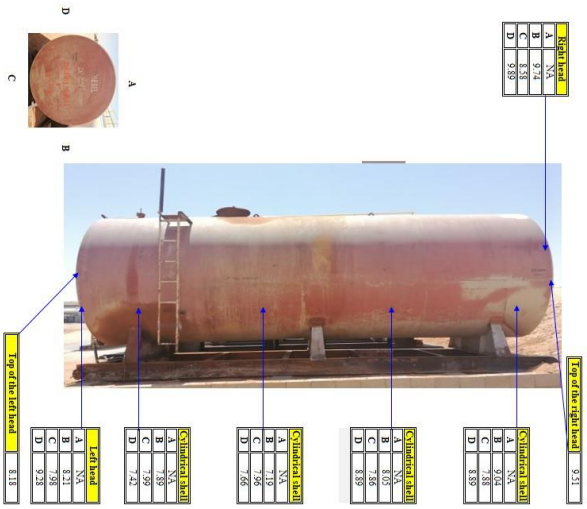

Figure 2. Scheme of performing ultrasonic thicknesses testing

During performed detail visual inspection of the interior of the tank, cracks observed at the area where tank has supported on the saddles, figure 3. Detected cracks also were confirmed by conducted additional penetrant test in these suspected areas.

Figure 3. Observed cracks in the suspected areas

Here should be mentioned that most of the cracks were individual while some cracks were found with branch.

7. PERFORMING OF REPAIR WELDING ACTIVITIES ON THE HORIZONTAL TANK

After detail examination of the tank and detecting defects (cracks) it was make a decision that before transferring the tank on new location and put in service its repairing should be detail performed. First step in repairing process is include removing of the all cracks from the tanks and performing adequate NDE examinations in sense of confirming that all cracks were fully removed, figure 4 and figure 5. Here should be mentioned that penetrant tests of affected areas in the tank were repeated up to the moment when it was established that cracks were fully removed. Also on assessable places together with penetrant tests, ultrasonic tests for defects were performed, [11].

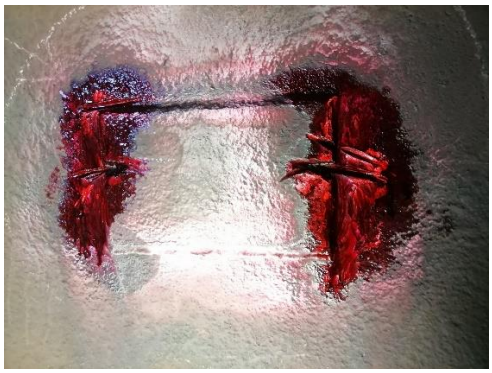

Figure 4. Penetrant tests for needs of confirmation of cracks removing-after spraying penetrant

Second phase is including of providing skilled welders for needs of performing repair-welding activities and creating and approving welding procedure specification for needs of this activity [12]. Creating of WPSs is of exceptional meaning for integrity of apparatus and safety of workers, which are doing maintenance of apparatus during its required working life. This phase is usually carried out in one of two possible ways, either a suitable WPSs are created which are checked and approved, or it is provided appropriate approved WPSs (or standardized WPS-SWPS) from renowned Welding houses.

Figure 5. Penetrant tests for needs of confirmation of cracks removing-after spraying developer

For some urgent welding operation often is cheaper and more reliable buying of appropriate WPSs than preparing and approving of their own especially when fabrication companies does not have experienced Welding engineers especially trained for preparation specific WPSs and also when are requiring to performing of destructive examinations of welding samples for needs of qualifying these WPSs, [13,14].

For needs of sanation of this tank, appropriate approved WPSs have provided with GTAW+SMAW welding processes with direct current, figure 6. After finishing of repair welding activities detail visual inspection, penetrant test of the new fabricated weld joints was performed as well as leak test of the tank [10]. Hence visual inspection has performed by using visual inspection tools. Generally visual inspection was performed before, during and after finishing sanation activities [12].

Review of the performed activities has presented on the figure 7 below. Since finishing all repairing activities and inspection activities, the tank was transferred on the new position where has also been performed one more additional visual inspection in sense of avoiding possible damages which could produce be transferring process. Since finishing all repairing activities and inspection activities, the tank was transferred on the new position, where has been also performed one more additional visual inspection in sense of avoiding possible damages which could happen during transferring process. This additional inspection was shown that transferred was performed in a proper way. After that, it was started painting of this tank and it has put in service on the new location.

8. CONCLUSION

The paper has shown one of the tanks classification in the process industry according their construction properties and also the problems, which can appear after made decision of transferring horizontal tank supported on the saddles (capacity-52 m^3) on new location which regular maintenance is non-clear followed. During preparation process before transferring on new location, which in generally case include detail cleaning and external and internal inspection of tank, was observed many individual and branched cracks in area of supporting the tank on the saddles. Taking into account the fact that during normal operation of the process equipment present of the cracks of any type is not allowed, it was make decision regarding of the fully horizontal tank remediation. At the first sanation phase cracks were removed by grinding and base metal around the cracks were continuously inspected for needs of checking possible residues of cracks. Confirmation in sense of fully clean metal was obtained by penetrant test and ultrasonic examination. Repair welding process was performed by procured approved welding process specification because it was cheaper and more reliable solution at that moment. After repairing relevant non-destructive examinations performed and on that basis, it has established that the equipment was repaired on a proper way. Since the horizontal tank was transferred on new location one additional visual inspection was performed in sense of checking possible damages during transportation process. After all mentioned equipment was put in service, properly painted and maintenance plan has been set according to the relevant standards from this area.

Abstract: *The results of studies of porosity and oil capacity of coatings formed by electric arc metallization with the use of aerosol fluxing and introduction of alloying elements from its composition into the combustion zone of electric arc are presented. Welding wire Cv-08G2C, flux components: Na_2CO_3, Na_3AlF_6, $Na_2B_4O_7$ and distilled water were used as materials. The characteristics of the coatings were investigated according to the generally accepted methods. The use of aerosol fluxing at electric arc metallization reduces porosity and oil capacity of formed coatings in 1.5-1.6 and 1.7-1.8 times, respectively, in comparison with coatings obtained without aerosol fluxing. When using aerosol fluxing, due to deoxidation of iron, the content of its oxide decreases, which contributes to an increase in the density and quality of the formed coatings.*
Keywords: electric arc metallization, coating, porosity, oil capacity, flux.

1. INTRODUCTION

Various methods of gas-thermal spraying of coatings are widely used in the restoration of worn machine parts: gas-flame, plasma, detonation, electric-arc metallization [1-5]. Electric arc metallization (EAM) is of particular interest for the repair industry. EAM is the process of melting two wires by burning an electric arc between them, dispersing the melt and transporting the particles with compressed air [3,5-7]. The scheme of realization of this process is shown in Figure 1. Electric arc metallization can restore machine parts of a wide range of nomenclature in various industries and agriculture, obtain coatings of pseudo-alloys, as well as decorative coatings of non-ferrous metals (copper, bronze, brass, aluminum) [4-6, 8-9].
The Electric Arc Metallization ("EAM") method is quite simple, productive and cheap [3-5, 9-11]. For example, coatings formed by the electric arc metallization ("EAM") are 3-10 times cheaper than coatings formed by plasma and detonation sputtering [7-10,12,13]. EAM allows to obtain coatings on machine parts from solid wire for metallization or cored wire with sufficient physical-mechanical and operational characteristics [7-12].

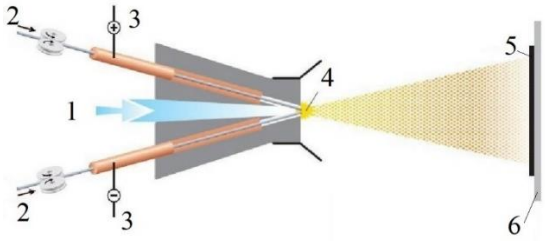

Figure 1. Schematic diagram of the process implementation at electric arc metallization:
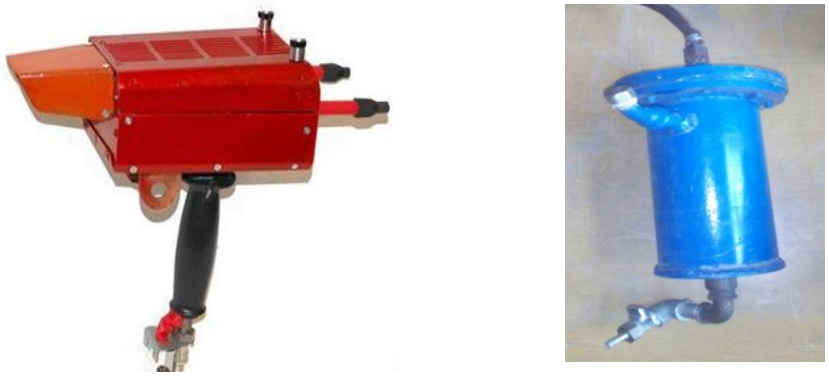
1 - compressed air flow, *2* – spraying wire, *3* – current supply,
4 – electric arc, *5* – coating to be formed, *6* – sprayed surface

To improve the physical and mechanical properties of formed electrometallization coatings, as well as to neutralize the negative effect of oxidation on the quality of the applied metal, it is possible through the use of aerosol fluxing (AF) and the introduction of alloying elements from its composition into the combustion zone of the electric arc [10-14].
The essence of the proposed method of AF, designed for deoxidizing and alloying of metal at electric arc metallization, is that in the flame of dispersed dispersed molten metal by electric arc is introduced together with compressed air aerosol, which is an aqueous solution of chemical inorganic materials, which when dissolved in water have passed the stage of electrolytic dissociation [14-16].
The essence of the proposed method of AF, designed for deoxidizing and alloying of metal at electric arc metallization, is that in the flame of dispersed dispersed molten metal by electric arc is introduced together with compressed air aerosol, which is an aqueous solution of chemical inorganic materials, which when dissolved in water have passed the stage of electrolytic dissociation Na_2CO_3, Na_3AlF_6, $Na_2B_4O_7$.

2. MATERIALS AND METHODS

Samples for research were made of steel 45. When forming the coatings, an electric arc metallizer "EAM-9ShD" (Russia) (figure 2a), a welding rectifier VDU-506 and a hydrodisperser (figure 2b) were used. Welding wire Cv-08G2C, flux components: Na_2CO_3, Na_3AlF_6, $Na_2B_4O_7$ and distilled water were used as materials.

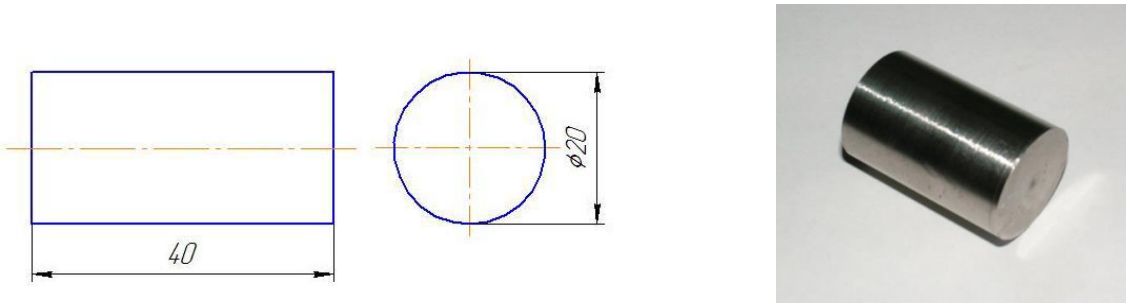


a) b)

Figure 2 Equipment for coating:
a – metallizer "EAM-9ShD", b – hydrodisperser

Coating formation modes: current intensity – 200 A, tension – 27V, wire feed rate – 13 m/min, air pressure – 0,60 MPa, metallization distance – 130 mm, part rotation frequency – 170 min^{-1}, solution flow rate for AF – 13 ml/min.
The porosity of the obtained coatings was determined by color defectoscopy. After grinding the coatings to Ra = 0.63-0.64 μm, the samples (Fig. 3) were washed in cold running water, then immersed for 30 s in a warm (35-40°C) solution of sodium hydroxide (20 g/l) and for 1 min in a

clarification solution (nitric and hydrofluoric acids in a ratio of 1:1). To stain the pores, the samples were placed for 5 min in a solution containing 20 g/L copper sulfoxide and 20 ml/L hydrochloric acid. Washed and dried samples with areas of pink spots of released copper on the coating were examined under a microscope (20x). The porosity of the coatings was determined as a percentage ratio of the areas of stained spots to the area of the considered area.



a) b)

Figure 3. Sample for the study of porosity and oil capacity of coatings:
a) scheme; b) general view

The oil capacity of the coatings was evaluated using a method based on determining the amount of oil penetrating into the pores of the coating. Samples were weighed, then immersed in Shell HF-E ISO 15 oil heated in an electric furnace SNOL-1,6.2,5.1/11 (СНОЛ-1,6.2,5.1/11) (*Russia*) to a temperature of 100-110°C and kept in it for at least 1.5-2.0 hours. Then the container with oil together with the immersed sample was cooled in air to temperature 20±5^{0}C. After extraction, the sample was washed in benzene for 10 min and dried in a SNOL-3.5 (СНОЛ-3.5) desiccator for 40 min at 40-50°C. After cooling in air, the sample was weighed. Oil capacity of coatings (M) in mg/mm^2 was calculated according to the formula (1):

$$O = \frac{m-m_1}{s}, \quad (1)$$

where m – sample mass after immersion in oil, *mg*;
m_1 – sample mass before immersion in oil, *mg*;
S – sample surface area, *mm*^{2}.

3. RESULTS AND DISCUSION

The results of studies of porosity of coatings obtained by electric arc metallization using aerosol fluxing depending on the content of flux components are presented in figure 4. Figure 5 shows a general view of the sample with colored pores marked on the coating. It is established that the use of aerosol fluxing at electric arc metallization allows reducing the porosity of the formed coatings by 1.5-1.6 times. This is due to the fact that due to deoxidation of iron the content of its oxide decreases, which contributes to an increase in the density and quality of the applied metal layer. Obviously, the high rate of the process also contributes to the increase of kinetic energy, which provides a more dense and low-porosity coating.
The oil capacity of coatings is related to the porosity formed during their application. For parts operating under conditions of changing lubrication from liquid to boundary lubrication, the oil capacity of coatings is one of the most important properties that can improve self-lubrication of interacting surfaces and reduce the coefficient of friction in a moving joint. This results in reduced wear rate and increased life of parts in the assembly unit.
The conducted studies have shown that the values of oil capacity of coatings applied without application of AF (65 mg/mm^2), are higher than with AF (36-39 mg/mm^2) by 1.7-1.8 times (Fig. 6). Obviously, the reduction in oil content of coatings is associated with a decrease in their porosity.

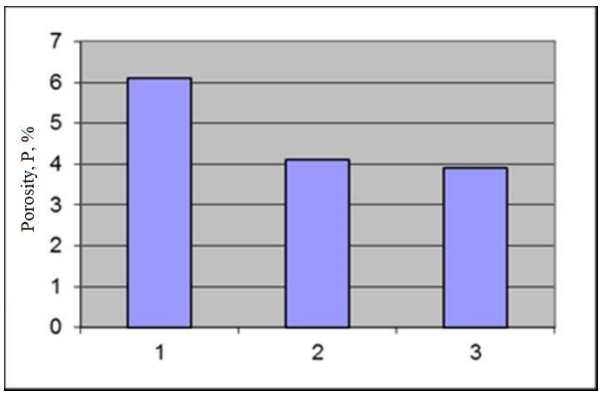


Figure 4. Change in porosity of formed coatings:
1 – Cv-08G2C (without AF); 2 – Cv-08G2C + AF (flux №1); №3 – Cv-08G2C + AF (flux №2)

Figure 5. General view with characteristic areas of released copper in pore locations, 20^x

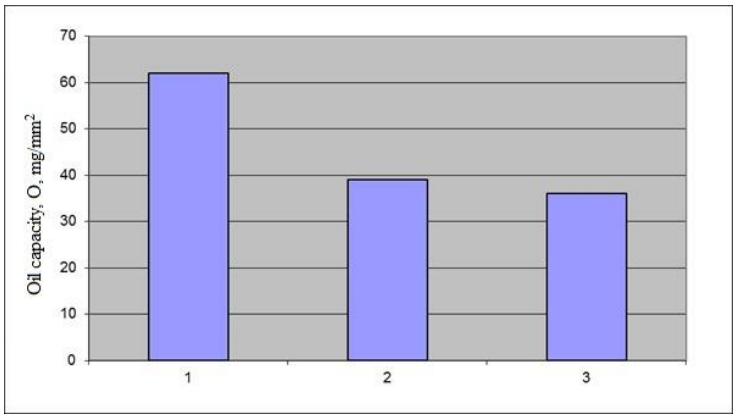

Figure 6. Results of studies on the oil capacity of coatings:
1 – Cv-08G2C (without AF); 2 – Cv-08G2C + AF (flux №1); №3 – Cv-08G2C + AF (flux №2)

4. CONCLUSIONS

The use of aerosol fluxing during electric arc metallization reduces porosity and oil capacity of the formed coatings by 1.5-1.6 and 1.7-1.8 times, respectively, compared to coatings obtained without aerosol fluxing. This should be taken into account when predicting the service life of moving joints, which will use parts with coatings obtained by electric arc metallization and using AF.

To achieve rational operational properties of the formed coatings it is recommended to use hydroflux of the following composition: $C_{Na_2CO_3} = 42$ g/l, $C_{Na_3AlF_6} = 6$ g/l, $C_{Na_2B_4O_7} = 12$ g/l.

Abstract*: Magnetohydrodynamics (MHD) is a field of study that takes into account the interaction of the magnetic field, the electric field represented by its current density and the characteristics of the medium involved. It was initiated by the Nobel Prize winner Hannes Alfven in the sixties. In this work, we conducted a three-dimensional and time dependent simulation of a magnetohydrodynamic (MHD) pump using COMSOLMULTIPHYSICS software. Additionally, a series of laboratory experiments were performed testing both the pumping mechanism and the MHD propulsion principle. The results obtained show that the performance of the proposed applications (MHD pump and MHD propulsion) is directly linked to the electrical conductivity of the liquids, to the electrical voltage applied and to the intensity of the magnetic field adopted. The simulation and the experimental results show that the flow velocity increases when the applied voltage is varied from 0V to 15V with a fixed magnetic field of 0.45T. The same conclusion is derived if the applied voltage is constant (V=2 V) and the magnetic field is varied from 0 T to 0.5T. The experimental observation of the performance of the prototypes shows bubble generation at the electrodes as well as thermal and electrochemical phenomena, which should be taken into consideration in future works.*

Keywords: MHD Pump, Voltage, Magnetic field, Velocity Field, Electrical Conductivity.

1. INTRODUCTION

With the energy crisis of the seventies and the new concern of the environmental issue of the beginning of the twenty first century, researchers are now looking for new clean solutions to the world's energy shortage. The interest in the MHD field is developing both as an energy source or as a propulsion method to compete with electrical vehicles [1-5]. New research results in desalination of seawater using portable apparatus shows a growing attention to the numerous applications of the MHD especially when combined with the solar energy [6-8]. In this paper, to test the performance of the proposed model, a series of experiments were conducted and a Comsol Multiphysics simulation was carried out to predict velocity field variations. The model for the MHD pump consists of a canal (8x3x1) cm placed in a magnetic field and subject to a current in the shown directions(figure 1). The fluid considered in the experiments and the simulation is a NaCl solution. When the ions present in the solution are subject to a magnetic field and an electric field, they are accelerated in the channel due to the Lorentz Force. This force either pumps the liquid or propels the channel. The analysis of such a model combines the electromagnetic model and the fluid flow model.

Characteristics of the solution used in the simulation:

- Density: 1020 kg/m3
- Dynamic Viscosity : 0.007 Pa.s
- Relative Permeability : 1
- Electric Conductivity : 1 S/m

2. MATHEMATICAL MODELS

The proposed system uses the coupling of two phenomenon: the magnetic field and the electric field as to produce the Lorentz Force. This force puts into movement the conducting fluid according to the Navier-Stokes Law [9-12].

2.1 The electromagnetic model

When electrical charges Q are present in an electric field $\vec{E}$ and a magnetic field $\vec{B}$, the Maxwell Equations show that they will be put into movement with a velocity $\vec{V}$ thanks to the electric force $\vec{F}_e$ and the magnetic force $\vec{F}_m$:

$$\vec{F}_e = Q.\vec{E} \text{ and } \vec{F}_m = Q.\left(\vec{J} \times \vec{B}\right) \quad (1)$$

With:

$$\vec{J} = \sigma.\vec{E} + \sigma.\left(\vec{J} \times \vec{B}\right) \quad (2)$$

Based on Maxwell's Equations, the reduced magnetic potential $\vec{A}$ verifies the following equation:

$$r\vec{o}t\left(\frac{1}{\mu} r\vec{o}t\vec{A}\right) + \sigma\left(\frac{\partial \vec{A}}{\partial t} - gr\vec{a}dU\right) - \sigma\left(\vec{V} \times \vec{B}\right) = 0 \quad (3)$$

Where σ , U , μ and J are respectively the electrical conductivity of the solution, the electrical potential, the permeability and the current density.

2.2 The Fluid Flow model

When a fluid of density ρ and viscosity υ is put into motion by a force $\vec{F}$ under a pressure p , the obtained velocity $\vec{V}$ is given by the Navier-Stokes equations which express the conservation of the momentum and mass according to:

$$\frac{\partial \vec{V}}{\partial t} + \left(\vec{V}.\vec{\nabla}\right)\vec{V} = -\frac{1}{\rho} gr\vec{a}dp + \left(\upsilon\vec{\nabla}.\vec{V}\right) + \vec{F} \quad (4)$$

$$\frac{\partial \rho}{\partial t} + div\left(\rho.\vec{V}\right) = 0 \tag{5}$$

The main driving force acting on the fluid is the Lorentz Force given by:

$$\vec{F} = \vec{J} \times \vec{B} \tag{6}$$

3. SIMULATION AND EXPERIMENTAL RESULTS

Considering all these parameters and applying the appropriate boundary conditions, a simulation is carried out to predict the flow velocity [13].A first simulation is carried out for a magnetic field of 0.15T and a potential of 2V. Figure 2 represents the velocity Field, The interaction between the magnetic flux density and induced current density applied on the channel yields the Lorentz force which puts the solution into motion.Figure 3 represents the variations of the fluid velocity at the exit of the channel (x=8cm) along the y-axis. The overall shape takes a parabolic form with a maximum value of 0.028 m/s at the middle and decreases progressively to reach its lowest value at the surface of the channel.

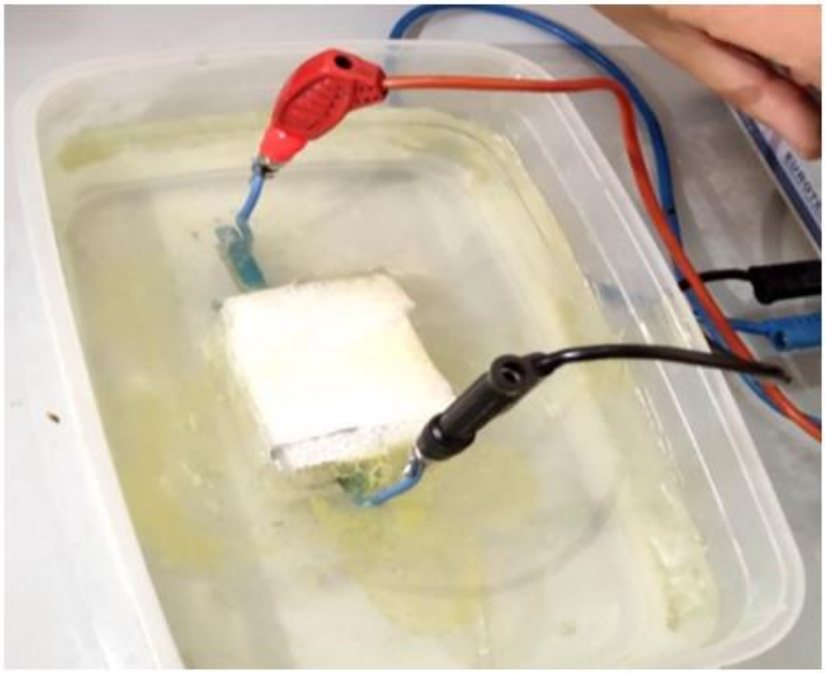

Figure 5. MHD pump exhibiting bubbles at electrodes
Source: original copyright

To analyze the effect of the magnetic field for a specific voltage and the effect of the applied voltage for a given magnetic field, few simulations and experimental tests are performed.The Matlab computer tool is used to plot the evolution of the velocity field using the numerical values obtained in both the simulation and the experimental data[15, 16]. The results are summarized in tables 1 & 2 and figures 6&7. According to the shown results, we notice that the flow velocity increases as either the voltage or the magnetic field is increased. When we compare between simulations analysis and experimental tests, we notice a larger increase in the velocity field in the experimental results as the voltage goes beyond 08 volts. The reason for this difference is the fact that, as the voltage is increased, the conductivity of the solution is also increased due to an increase in the temperature of the solution [17]. As voltages are increased, bubbles at the electrodes were observed due to the electrolysis phenomenon.

4. CONCLUSION

In this paper, we have presented a simulation of a MHD pump using Comsol Multiphysics and experimental tests to analyse the effect on the velocity field of the variations of the applied voltage and magnetic field. As the power supply or the magnetic field is increased, the fluid flow tends to increase. The comparison between the two methods show that the values obtained for the velocity field are relatively close and in the experimental tests, bubbles are observed for high voltages due to the increase in the temperature of the conducting solution.

THE EFFECTS OF TOOL WEAR ON CUTTING FORCES DURING THE TURNING OPERATION OF WORKPIECE WITH COATINGS

Milan Milutinović[1], The Academy of Applied Technical Studies Belgrade
Goran Vasilić[2], The Academy of Applied Technical Studies Belgrade

Abstract: *The development and application of cutting tools made of super hard materials as a precondition for increasing the productivity of machining requires higher costs of tools. Since tool life is closely related to tool wear, it can be influenced by the knowledge about the tool – workpiece interaction mechanism. Practical application of amorphous-crystalline coatings are limited by lack of scientific facts in terms of their mechanical machining. In engineering literature are not sufficiently represented papers related to cutting operations of the workpiece with coatings – coatings. Lack of information regarding the effects of the coatings with amorphous-crystalline structure on tool wear and tool life. This paper presents the influence of cutting conditions and structural composition of coatings on tool wear. Tools are based on hard metal P10, polycrystalline cubic boron nitride (PCBN)-kiborite and composite 10. On the other hand starting from the Merchant's model of orthogonal cutting and by introducing the effects of the tool flank wear height* B_L *and the concentrated force on the cutting edge, it is arrived at the novel concept of consideration of the forces acting in the chip formation process. The increase of the radial force developed as a consequence of tool flank wear is taken for the tool wear criterion.*
Keywords: Tool life, Tool wear, Merchant's model, Cutting forces

1. INTRODUCTION

Tool wear is an important factor that directly affects the productivity and surface quality. Traditionally, at the production environment, a tool change was based on experience or the quality of machined surface. In the early nineties of the last century there was a transition from traditional to automated tool change with the idea that implies possibility of monitoring the amount of wear on the cutting tool edges during the cutting process. With the development of computer this on-line monitoring of the tool wear is gaining more importance [4, 5]. Previous studies in the field of monitoring tool wear in a metal cutting process where based on measurement of the: cutting forces, stress/strain measurement, work piece dimensions, spindle motor torque and the surface finish quality. The paper shows the influence of the flank wear height at the clearance face on tool life and the forces that appear with a special review of the morphology of the flank wear. The starting point is basic Merchants model of chip formation in orthogonal cutting. As the cutting forces increase with increasing of the flank wear height it is necessary to complete Merchants model that would include: flank wear, forces caused by flank wear and force for chip formation. The presence of wearland has been found to have no effect on the basic model of chip formation and basic cutting quantities such as: shear angle, shear stress on the shear plane and friction angle. Existence of flank wear in the vicinity of the cutting edge resulting in an additional force of rubbing or ploughing at the clearance face results in increased radial force. Based on completed Merchant's model and predominant adhesion wear mechanism it is possible to define tool life using cutting speed, feed and

[1]mmilutinovic@atssb.edu.rs
[2]gvasilic@atssb.edu.rs

flank wear height, which is the efficient mathematical model that predicts tool life in production environment.

2. REGIONS OF THE TOOL WEAR OCCURRING DURING TURNING.

When mating surfaces of the tool and workpiece are brought together as the result of their contact the following forms of tool wear occur: adhesion, abrasion, diffusion and oxidant wear. Process of tool wear is related with adhesion and abrasion processes and depends of the cutting parameters: workpiece material, tool material, tool insert geometry etc. For a given workpiece and tool material, tool wear form may depend on the cutting parameters, cutting speed and un-deformed chip thickness. In the cutting process, as a result of chip formation, tool wear occurs on the rake and clearance face of the tool, Figure 1a. Tool wear on the clearance face is defined with flank wear height B_L, Figure 1b., while tool wear on the rake face is defined with crater depth B_{dk} and width B_{sk}, Figure 1b and 1c, where the length of the crater does not change significantly. During the cutting process tool wear, on rake and clearance face, is increased until the width of crater B_{sk} reaches the cutting edge and destroy it, Figure 1c. Tools that have cutting edge radius can wear on the clearance face in the area of the major cutting edge which represents nose wear or edge rounding, figure 1d. Flank wear arises due to both adhesive and abrasive wear mechanism from the intense rubbing action of the two surfaces in contact, i.e. the clearance face of the cutting tool and the newly formed surface of the workpiece. Increasing the height of the flank wear leads to deterioration of the surface finish and to increased heat generation, Figure 1a. In this paper are presented experimental results of turinig-tool wear with hard metal and cubic boron nitride inserts and their impact on cutting forces and Merchant's model of orthogonal cutting.

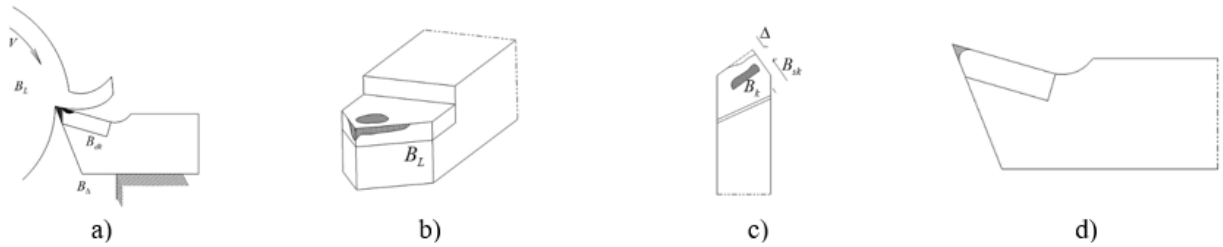

Figure 1. Regions of the lathe tool wear.

3. EXPERIMENTAL SETUP

The orthogonal machining tests were conducted on PH-42 CNC Lathe with variable spindle speed from 16 to 5200 rpm, spindle power 16 kw. Turning tools are used with hard metal P10, composite 10 and PCBN-kiborit inserts (Institute of superhard materials Kiev-Ukraine). Material of the workpiece with coatings are given in table 1. Cutting conditions: feed-rate $s = 0.05 - 0.38\ mm/rev$, depth of cut $a = 0.2 - 0.4\ mm$, rake angle $\gamma = -2^O - 18^O$ The cutting forces are measured using two-component piezoelectric dynamometer Kistler 9257B. Flank wear heights are measured using microscope (Carl Zeiss-LSM 510).

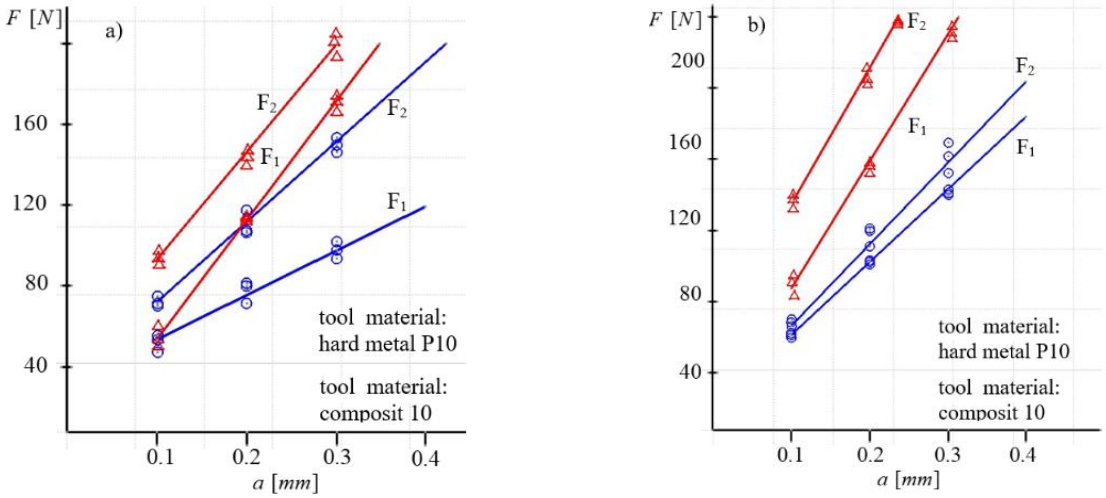
4. CUTTING FORCES AND TOOL WEAR-RESULTS AND DISCUSSIONS

Turning of the workpiece with amorphous-crystalline coatings with PCBN and P10 inserts are performing during the high cutting speed and small depth of cut (due to limitation of the coating thickness $a = 0.1 - 0.6\ mm$). Tools are working in the condition of fine turning characterized by small contact area between tool and chip but with very high specific load at the contact surface. Figure 2 shows the changes of components F_1 and F_2 as a function of the cutting depth during the turning operation of coatings 30HGSA and 65G with Composite10 and P10 inserts.

Table 1. Chemical composition of the workpiece with coatings

Source: original copyright

	Chemical composition %										
Workpiece material	C	Si	Mn	Cr	W	Mo	Ni	Cu	Fe	B	Hardness [HRC]
5H4V3MFS	0.9	0.7	0.7	5	3.5	1	-	-	basic	-	45-48
30HGSA	0.3	1.1	1	1	-	-	0.4	-	basic	-	20-30
65G	0.65	0.3	1.1	0.3	-	-	0.3	-	basic	-	45-48
SH15	1	0.27	0.3	1.45	-	-	0.3	0.25	basic	-	36-38
$Fe_{80}B_{20}$	-	-	-	-	-	-		-	80	20	56-58



a) b)

Figure 2. The effects of depth of cut on cutting forces F_1 and F_2 during the turning of: a) 30HGSA coating ($v = 30 m/s$, $s = 0.1 mm/rev$, $a = 0.25 mm$);b)65G coating ($v = 30 m/s$, $s = 0.1 mm/rev$, $a = 0.25 mm$)

Source: original copyright

From Figure 2 can be seen that cutting forces caused by turning of 65G coating are higher than cutting forces caused by turning of 30HGSA coating due to higher hardness. Force/resistance component in radial direction F_2 is higher than cutting force/resistance component F_1 which is characteristic of hard turning materials. Figures 3-6 shows the effects of flank wear height on cutting force components F_1 and F_2 during the turning operation of several coatings (30HGSA, 5H4V3MFS and Fe80B20) with hard metal P10, PCBN-kiborit and composite 10 inserts.

Source: original copyright

Tool wear is associated with content of amorphous component in the machined coating. During the turning of coatings with 70% of amorphous component, inflicted by $Fe_{80}B_{20}$ electrode, wear occurs on the rake and clearance face, creating strip chip caused by grater contact length with rake face of the tool. During the turning operation of the coating hard crystal fragments, in its structure, are abrasive particles causing tool wear. In this conditions abrasive tool wear occurs. Presence of large number of hard crystalline impurities in the structure of the coating with lower content of amorphous component causes more intense tool wear than coatings with high content of amorphous component particularly during the turning operation using less cutting speed $v < 1 m/s$. Increasing the cutting speed $v > 1.5 m/s$ comes to changes of the contact interaction between tool and workpiece-coating and increasing of the temperature in the cutting zone. On the rake and clearance face deposits can be observed whose structure includes elements of mating surfaces (Fe, Cr, Si, B, Ni) which indicates changes of the chemical composition of the surface layer of the tool. Deposits formed on the tool represents loose layer with significant thickness. It is well known that tool flank wear has great effect on machining accuracy and surface finish. Based on analysis of tool wear with hard metal insert all forms of wear on clearance face are given in Figure 7.

Figure 7. Morphology of flank wear: i) allowable regions of tool wear; ii) not allowable regions of tool wear.

Source: original copyright

During the turning of coatings with 50% of amorphous-crystalline structure, PCBN-kiborit primarily has flank wear, Figure 8. This is because, the structure of this coatings is formed form separated fragments as opposed to highly amorphous coatings are insufficiently deformed in the process of coating and poorly united primarily due to diffusion process.

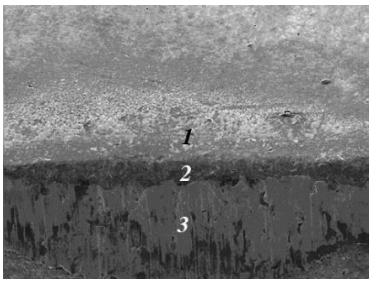

Figure 8. PCBN-Kiborit wear:1- clearance surface, 2-cutting edge, 3-flak wear ($v = 1.7\,m/s, s = 0.05\,mm/rev, a = 0.2\,mm, \gamma = -10°$)

5. ORTHOGONAL CUTTING ANALYSIS

Tool's cutting wedge penetrates in the workpiece under the influence of the resultant force F acting on the back of the chip and opposite to the resultant force F' acting on the shear plane (cutting resistance) [6]. In Figure 9 is shown orthogonal cutting-Merchants model. A single straight cutting edge with a plain face and flank is used to cut a workpiece of constant width at a constant cut thickness. Orthogonal cutting-Merchant's model assume the following: perfectly sharp tool with no concentrated edge force on the cutting edge, a continuous chip, plane strain, uniform shear stress distribution on the shear plane, and equilibrium of the under the action of equal and opposite resultant force acting at the shear zone and tool-chip interface. This has resulted in the well-known Merchant model [6]:

$$F_1 = \frac{\tau b a \cos(\rho - \gamma)}{\sin\phi \cos(\phi + \rho - \gamma)} \tag{1}$$

$$F_2 = \frac{\tau b a \sin(\rho - \gamma)}{\sin\phi \cos(\phi + \rho - \gamma)} \tag{2}$$

$$\rho = \arctan\mu = \gamma + \arctan\left(\frac{F_2}{F_1}\right) \tag{3}$$

$$\tau = \frac{(F_1\cos\phi - F_2\sin\phi)\sin\phi}{ba} \tag{4}$$

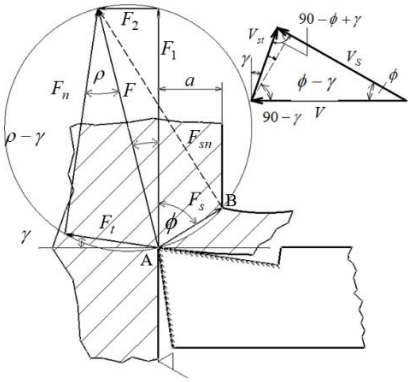

Figure 9. Forces during orthogonal cutting-Merchant's model
Source: Mechanics of the metal cutting process [6]

Experiments showed that that an increase of depth of cut a leads to increase of cutting forces F_1 and F_2, Figure 2. Increase of the rake angle γ leads to decrease of force components F_1 and F_2. Friction angle ρ, shear angle ϕ and shear stress τ are independent of cutting depth a[12]. During the cutting process flank wear height B_L occurs as one of predominant forms of tool wear. Introducing the flank wear height into Merchant's model means that in addition to force for chip formation R_S is the introduction of wearland force /resistance R_h, caused by existence of flank wear height B_L, Figure 10.

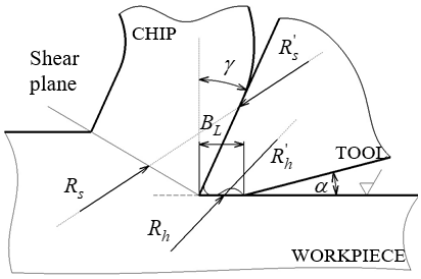

Figure 10. Introducing the flank wear force/resistance caused by the existence of the flank wear height into Merchant's model of orthogonal cutting
Source: Mechanics of the metal cutting process [6]

It has been suggested by many researchers that since the cutting edge is not perfectly sharp, a rubbing or ploughing process could occur in the vicinity of the cutting edge increasing total cutting force, in addition to the force for chip formation. The overall cutting force R, using tool with flank wear height, consists of the sum of the force for chip formation R_S and wearland force R_h:

$$R = R_s + R_h \tag{5}$$

where:
R_h – wearland force/resistance generated by the existence of the flank wear height B_L, R_s – force/resistance for chip formation during the orthogonal cutting for perfectly sharp tool $(B_L = 0)$. Wearland force R_h can be calculated by subtracting force for chip formation R_s (when the measured force is extrapolated for zero flank wear height) from the overall measured force R, equation (5). Wang's experimental results show that there is no effect of the flank wear height B_L and depth of cut a on the shear angle ϕ, friction angle ρ and shear stress τ which means that the force generated by increase of the flank wear can be treated in the same way as the force for chip formation. This means that Merchants model can be completed introducing wearland force, Figure 11. According to

the completed Merchant's model wearland force /resistance R_h, caused by existence of flank wear height B_L, can be decomposed into two components in primary cutting force and radial direction. Component F_{1h},of the wearland force R_h, generated between the clearance face of the cutting tool and the newly formed surface of the workpiece in the primary cutting force direction and component and F_{2h}, of the wearland force R_h, generated between the clearance face of the cutting tool and the newly formed surface of the workpiece in the radial force direction.

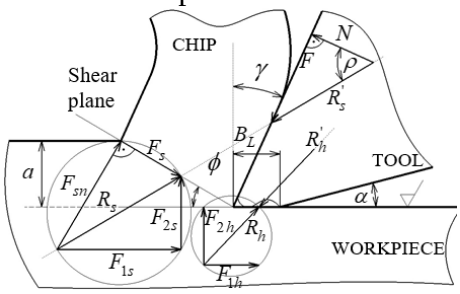

Figure 11. Completed Merchant's model of orthogonal cutting.
Source: original copyright

Based on the completed Merchant's model, the overall cutting force components F_1 and F_2 can be established based on equation (5):

$$F_1 = F_{1s} + F_{1h} = \frac{\tau b a \cos(\rho - \gamma)}{\sin\phi \cos(\phi + \rho - \gamma)} + F_{1h} \tag{6}$$

$$F_2 = F_{2s} + F_{2h} = \frac{\tau b a \sin(\rho - \gamma)}{\sin\phi \cos(\phi + \rho - \gamma)} + F_{2h} \tag{7}$$

Completed Merchant's model includes force analysis occurring in orthogonal cutting with special reference to wearland forces generated between the clearance face of the cutting tool and the newly formed surface of the workpiece which is typical for adhesion-abrasive wear model. According to the fundamental law of adhesion wear, adhesion flank wear volume, dV_A, per unit length is proportional to the rubbing force between the clearance face of the cutting tool and the newly formed surface of the workpiece in the radial force direction F_{2h}, which leads to the following equations:

$$\frac{dV_A}{dl} \propto F_{2h} \tag{8}$$

By changing cutting parameters (feed, cutting speed, depth of cut) leads to increase or decrease of wearland force components and wearland height:

$$F_{2h} = K v^{a'} s^{b'} B_L^{c'} \tag{9}$$

$$F_{1h} = K_1 v^a s^b B_L^c \tag{10}$$

$$B_L = C v^p s^q T^x \tag{11}$$

where: a', b', c', a, b, c, p, q, x, K, K_1 are constants to be evaluated by the experiment; v- cutting velocity; s- feed, B_L- flank wear height, T - tool life. Based on equation (5) wearland force R_h can be calculated by subtracting force for chip formation R_s (when the measured force is extrapolated for zero flank wear height) from the overall (measured) force R:

$$R_h = R - R_{s(B_L=0)} \tag{12}$$

$$F_{1h} = F_1 - F_{1s(B_L=0)} \tag{13}$$

$$F_{2h} = F_2 - F_{2h(B_L=0)} \tag{14}$$

Based on these facts tool life can be defined as:

$$T = \left(\frac{B_L}{C v^p s^q} \right)^{\frac{1}{x}} \tag{15}$$

According to ISO3685 tool is worn when flank wear height reaches threshold criterion $B_L=0.9mm$. Based on equation (14) tool life can be determined in production environment, [1, 3].

6. CONCLUSION

The paper shows the influence of the flank wear height at the clearance face on tool life and the forces that appear in two ways. The first one represents the completed Merchant's model of orthogonal cutting which, in addition to force for chip formation, comprises wearland force generated by increase of the flank wear or rubbing between clearance face of the cutting tool and the newly formed surface of the workpiece. The second way represents mathematical model that defines the correlation between tool life, cutting velocity, feed and flank wear height. Mathematical model is based on the fundamental law of adhesion wear. This leads to efficient prediction of tool life in production environment which is very important because it provides good machined part in manned factories so that a new tool may be introduced at the instant at which the existing tool has been worn out, thus preventing any hazards occurring to the machine or deterioration of the surface finish. Based on the above, mechanism of tool wear during the turning of workpiece with amorphous-crystalline coatings has complex character caused by abrasive, adhesion and chemical interaction in cutting zone. Tool wear characteristics are depending of the workpiece material, cutting conditions and tool geometry. Intensive adhesion wear of the hard metal insert P10 is consequence of the increasing plasticity of amorphous component in machined coating structure. In turning of the coating, surface layer of the tool is in contact with hard material, and temperature in cutting zone and cutting forces create good conditions for interaction between tool and workpiece material. During the turning of more heterogeneous coatings contact conditions with tool are unstable and changing rapidly which affects the reduction of deposits. In turning of crystalline coatings on contact surfaces of the PCBN tool adhesion wear is not present. Increasing the cutting speed influence of heterogeneity of the machined workpiece with coatings on tool wear intensity is significantly lower.

Abstract: *The aim of this paper is the dynamic calculation of the tool used in friction stir welding of aluminum alloy plates. The friction stir welding process ensures the joining of materials without melting them and using additional material. This procedure was created as a result of research carried out in order to find new solutions when welding aluminum alloys in order to avoid the problems that occur with conventional welding procedures. Using this procedure, welded joints with good mechanical properties are obtained. The paper presents the design and dynamic calculation of welding tools using the finite element method in Abaqus software.*
Keywords: Friction Stir Welding Tool, Dynamic Calculation, Equivalent Stress, Finite Element, Deformation

1. INTRODUCTION

Friction Stir Welding, i.e. FSW was created at the end of 1991 by Wayne M. Thomas from the Welding Institute TWI (Cambridge, UK), who successfully welded aluminum alloy sheets. The procedure was very quickly, already in 1994, received its commercial application and caused great attention of researchers in practice. The first application of the FSW procedure was related to the production of railway vehicles and the welding of aluminum and its alloys, but over time the scope of application has expanded. To join two or more working plates using the FSW process, you need: a machine, a cylindrical tool, two or more working plates that are made of the same or different materials, a backing plate and clamping tool [1,2,3]. The equipment for FSW is shown in Figure 1.

Figure 1. Equipment for friction stir welding

2. MATERIAL OF WORKING PLATES

The following materials can be successfully welded by friction stir welding: aluminum, titanium, lead, aluminum alloys, copper alloys, magnesium alloys, lead alloys, titanium alloys, nickel alloys, structural steel, low-alloy steel, mild still, stainless still, austenitic steel, duplex steel and polymers [4]. The working plates to be welded were 5xxx series of aluminum. The designation 5xxx refers to alloys of aluminum with magnesium (hydronaliums). These alloys are well polished and polished. Of all heat-resistant aluminum alloys, they are characterized by the highest strength. Working plates are made of aluminum alloy 5052-H32. The chemical composition of this alloy according to the EN 573-3:2009 standard is given in Table 1 [4].

3. WELDING TOOL

The special tool used for welding is cylindrical in shape and consists of the tool body and the working part of the tool, which consists of two concentric parts: the shoulder and the mandrel of tool pin. The shapes of the face and the tool pin can be different. The tool shoulder can have a concentric depression on its surface, while the pin is most often conical, profiled with a coil or grooves. The body of the tool serves to fix it in the chuck of the machine. The pin height is usually greater than half the thickness of the material of working plates, but it is always less than the total thickness of the material that is welded (the height of the pin is less than the thickness of the material by a few tenths of a millimeter). Figure 2 shows the geometry and part of the workshop drawing of the tool with the names of the basic dimensions [5].

Property	Tensile strenght, ultimate	Tensile strenght, yield	Reduction of area	Modulus of elasticity	Poisson's ratio
Value	1200-1590 MPa	1000-1380 MPa	50%	215 GPa	0.27-0.30

During welding, the tool undergoes dynamic loads. A dynamic load is a load that changes in intensity and direction over time. Tool loads during the welding process, directions of forces and directions of bending moment and torque are given in Figure 3.

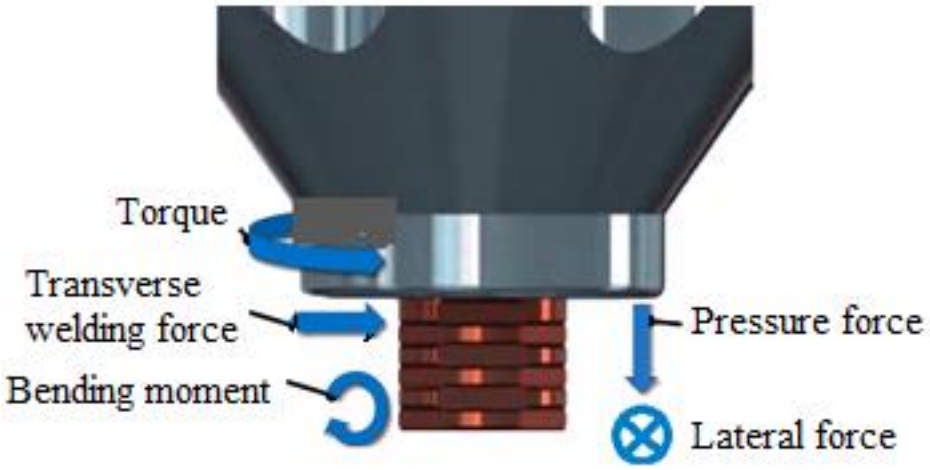

Figure 3. Tool loads during the welding process
Source: [7]

Tool torque depends on several parameters and influencing variables, such as vertical force, tool geometry, tool tilt angle, local shear stress on the tool due to contact with working plates, and coefficient of friction. By measuring the value of the torque, values can be assumed about the stress around the tool and the amount of slip between the tool and the working plates, but only when the other variables are constant.

4. NUMERICAL MODEL AND CALCULATION METHOD

The calculation was done according to the specified standards and using the finite element method in the ABAQUS software [8,9,10,11,12]. The tool model for friction stir welding is shown in Figure 4 a, while the computational model of the tool is shown in Figure 4 b. The finite element mesh is shown in Figure 4 c. Tetrahedron type finite elements were used.

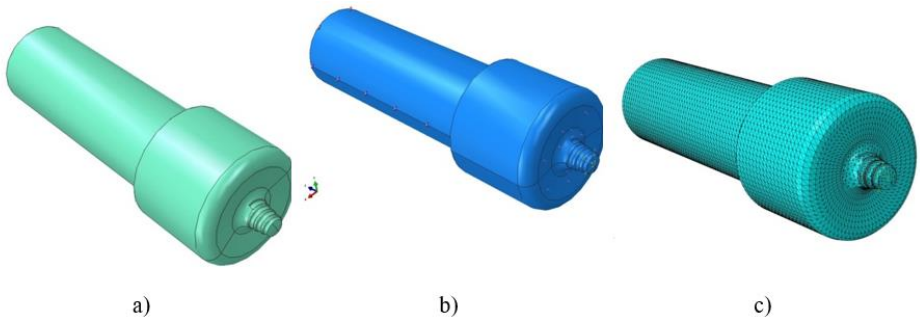

Figure 4. a) Welding tool model, b) Numerical tool model - boundary conditions and c) Numerical tool model - finite element mesh
Source: original copyright

The initial conditions, which were the input data for the numerical calculation, will be specified in this paragraph. The dimensions of the tool model are as follows: the total length is 750mm (of which the tool shank length is 50mm and the pin height is 5.5mm), the tool shank diameter is 18mm, the shoulder diameter is 25mm, and the pin tip diameter is 4mm, and the pin cone angle is 10°. From the mechanical characteristics, the Modulus of elasticity E=210GPa and Poisson's ratio ν =0.3 were used as input for the calculation. The mesh of finite elements consists of 140135 elements in the shape of a tetrahedron. Load value, i.e. torque is 60Nm.

5. DYNAMIC CALCULATION

The results of the calculation obtained using the ABAQUS software are given in the following figures. Equivalent stress distribution is given in Figure 5, and in Figure 6 is given the distribution of total displacement.

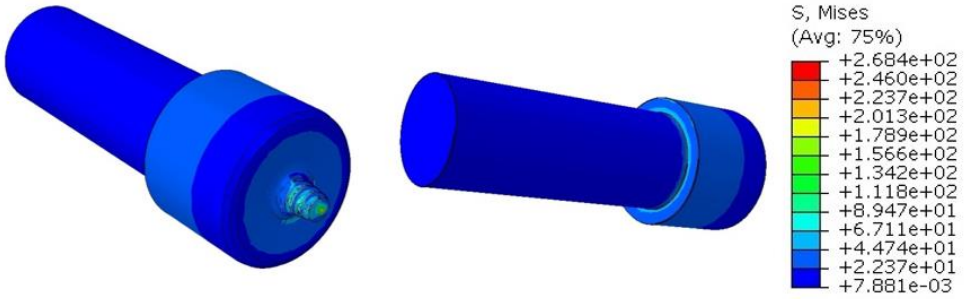

Figure 5. Equivalent stress distribution according to the Hencky-Mises hypothesis with the corresponding scale in MPa
Source: original copyright

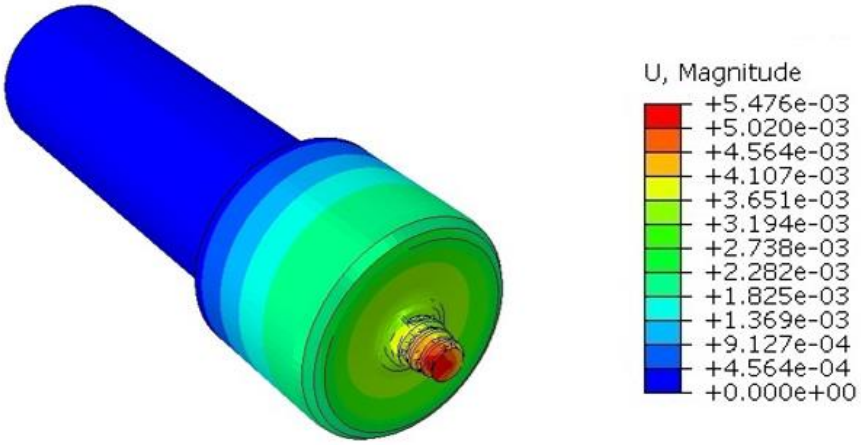

Figure 6. Total displacement with corresponding scale in mm
Source: original copyright

The results given in the figures show that the values of the obtained stress and displacements are within the recommended limits. On the scale, Figure 5, the maximum stress value of 268.4 MPa is observed. That value is much lower than the permissible stress, i.e. Tensile strength - yield stress (1000-1380 MPa, according to Table 4). Also, on the scale given in Figure 6, a maximum displacement value of 0.005mm is observed. This value is small, so that for the given initial conditions, there will be no impermissible deformations of the tool.

6. CONCLUSION

The work is the result of years of research into the deformation and stress state of structural elements. Initial considerations are given, which include an overview of previous research related to friction stir welding, as well as an overview of the available literature. As part of the work, calculation models of tools for FSW were made and dynamic calculation was carried out using the finite element method. The method of calculating the stress and deformation state of tools for FSW, which is presented in this paper, can be recommended for use in practice. The conclusions obtained from the calculation of this type of structures can be included in the process of designing new similar tools. The knowledge gained during the implementation of this work can be directly applied to identify the behavior of real structures in their working conditions.

CRITICAL REVIEW ON THE SAFETY BARRIERS FROM THE STRUCTURAL AND DEFORMATION PARAMETERS ASPECTS

Dragana Velimirović[1], The Academy of Applied Technical Studies Belgrade
Milan Marković[2], The Academy of Applied Technical Studies Belgrade
Milan Velimirović[3], OMR group

Abstract: *The paper gives an overview of the safety barriers from the aspect of the standards that establish the absorption of the part of the kinetic energy with which the vehicle collides with it. The role of the safety barriers is threefold: to prevent the vehicle from leaving the roadway but to enable the vehicle to continue moving, then to prevent the vehicle from leaving the roadway, while also foreseeing the possibility of the vehicle being unable to continue moving, as well as absorbing part of the kinetic energy at which foresees the possibility of the vehicle leaving the roadway. The work considers the standards related to the geometric and construction characteristics of barrieres that are present in Serbia, as well as updated contemporary bariers with rollers. Also, the influence of the environment on the choice of barrier is considered.*
Keywords: Safety Barriers, HIC, Safety Barriers with Rollers, Deformation Work, THIV

1. INTRODUCTION

The road as well as the road equipment, which includes, among others, the safety barriers, have a primary role in enabling road safety. This implies the prevention of a fatality and the minimization of material damage in extreme conditions of road exploitation. These conditions refer to situations where it is impossible to keep the vehicle on the road, which is especially evident in curves with a smaller radius when the vehicle moves at an inappropriate speed and when the angle of collision with the barrier exceeds 20^0. Vehicle speed overruns as well as the height of the vehicle's center of gravity are of particular importance. The paper deals with the principles of choosing a suitable barrier, both from the structural and geometrical aspects. In doing so, the standard applied in Serbia, SRPS EN 1317, is analyzed, where the choice of the type of barriers is established, both from the aspect of movement speed, and from the aspect of vehicle mass and height of the center of gravity.
Also, the dependence of the inertial force and the acceleration of the head and neck region at the moment of impact, on the acceleration severity index when the vehicle crashes into the safety barriers is analyzed, which is an indicator of risk from the aspect of the fatality of the accident. The size of this index is directly influenced by the level of absorption of part of the kinetic energy with which the vehicle hits the barrier and part of the kinetic energy that the vehicle retains after the collision. In accordance with that, safety barrierss with rollers are being considered, which allow a higher percentage of vehicles, that hit the barrier, to stay on the roadway and continue moving with a minimum of material damage. These barriers are widely present on the worldwide roads from 2017.

2. SAFETY BARRIERS, CONCEPT AND DEFORMATION WORK IN THE EVENT OF A VEHICLE COLLISION

Parameters of steel safety barrier, Fig. 1, as well as layered, New Jersey type, Fig. 2, are defined by the EN 1317 standard. The steel safety barrier is installed with or without curbs. Height of curbs is 200mm while on the highways such height must not exceed 70 mm, [1]. Barrier is located 500 mm from the edge of the road, [1] and is made of steel sheet which is elastically attached to steel vertical supports with screws. Stabilization of light vehicles after hitting a barrier is foreseen by bending and pushing up the side of the barrier that was struck while the posts bend in the direction of the force. In the case of heavier vehicles, it is assumed that the impacted elements will deform to a large extent and the posts will break, along with the removal of the cap and the elastic distance elements between the post and the sheet.

Figure 1. Steel safety barriers
Source: morava info, online portal, [12]

Figure 2. Concrete safety barrier New Jersey type
Source: MAPECURE SRA, MAPEI, [13]

In 90% cases when light vehicle weighing up to 1250 kg collids the barrier at a speed of 80 to 100 km/h and at gusting angle not greater then 30^0, concrete safety barriers New Jersey type ensures, even the continuaty of driving. In the case of heavy vehicle weighing up to 12.000 kg gusting at a speed of 70 km/h and at gusting angle not greater then 20^0, it allows to stay by the barrier without rejecting. The safety barriers belong to the road equipment, the main purpose of which is to prevent vehicles from running off the road. The road equipment consists of an indicator of the top of the separation surface, a linear reflector, a marker, a mounting curb, anti-dazzle equipment for the driver, a traffic mirror, a roadside traffic post and a shock absorber, [2]. The technical characteristics that the safety barriers should satisfy are prescribed by the SRPS EN 1317, standard [4], which is recognized and accepted by the legislation of the Republic of Serbia, [3], Table 1, and Table 2, [4]. Vehicle restraint system is shown in Figure 3, where W represents width of deflection, Table 1.

Depending on the size of the ability of absorption for the same size of deflection at impact, W, Table1, Figure 4, barriers are classified into type "N", corresponding to the low and normal level of retention, and "H", H1, H2, H3 and H4b for the level of strong and very strong retention, Table 2 [7]. The stress of the barrier is in the zone of plastic deformation. According to [8], and in accordance with the EN 1317 standard, it is established correlation between parameters: speed of movement, vehicle mass, as well as the height of the vehicle's center of gravity and the type of barrier, Figure 4. On the same figure it is presented the size of kinetic energy that could be absorbed by the corresponding barrier, as well as deformation work from barrier type and vehicle restraint levels for various types of vehicles and movement speed.

Table 1. Relation between barrier class and size of deflection

Class	Deflection size, Fig. 4
W1	W<0.6m

Presented amounts of kinetic energy are related to the retention level defined by the tests: TB 11 for light cars, TB 31 and TB 32 for heavier cars, while test TB 32 is to be integrated with TB 11 test. Corresponding safety barriers are N1 and N2. Tests applied for heavy vehicles movements in traffic are according to total weight, speed and gusting line angle. These are: TB 42, TB 61, TB 71 and TB81 together with TB 11.

Four types of barriers suitable for stronger and very strong retention are assumed. These barriers are: JDO/1.33, Super rail, Super rail reinforced and Super rail double side, Figure 5. Barriers classes W4 to W7 correspond to the deflection size, Table1.

Table 3. Safety barriers, types and characteristics
Source: SRPS EN 1317-2:2013, *Sistemi za zadržavanje na putevima — Deo 2*, [2]

Kind	Sign	Type	Class	Gusting intensity	Length on which testing is realizing
JDO/1.33	S 1.2-120	H1	W5	Low	80m
		H2	W7	Low	80m
Super rail	S 1.2-310	H2	W4	High	36m
Super rail double side	S 1.2-320	H2	W4	High	36m
Super rail	S 1.2-520	H2	W4	High	32m
Super rail double side	S 1.2-320	H4b	W7	High	40m
Super rail reinforced	S 1.2-340	H4b	W6	High	80m

Table 3 gives the relationship between the barrier types: H1 to H4, Table 2, class, Table1, gust strength: A and B and the length on which the test is performed during testing. Appropriate barrier types are: H1 to H4. Correlation between types of H safety barriers, impact intensity and length on which the test is performed on is, according to standard EN1317, given in Table 3.

3. GUSTING INTENSITY LEVEL AND WAYS FOR SAFETY BARRIER CHOICE

The seriousness of the accident in terms of the risk of a fatality when a vehicle gusts into a safety barrier is defined by the dependence of the inertial force of the head and neck region: HIC (Head Injury Criteria), Figure 6, as well as the speed that the head and neck region reach at the end of the impact: THIV (Theoretical Head Injury Impact Velocity), from accident severity expressed by Acceleration Severity Index: ASI, Table 4. ASI represents the dimensionless dependence of the intensity of the vehicle acceleration ratio in orthogonal directions on time, [9], as follows:

$$ASI = ASI(t) = \sqrt{\left(\frac{a_x}{x_l}\right)^2 + \left(\frac{a_y}{y_l}\right)^2 + \left(\frac{a_z}{z_l}\right)^2}$$, where: a_x, a_y and a_z represent acceleration of vehicle in x, y and z direction, while x_l, y_l, z_l are in the sum of $12 \cdot g$, where g corresponds to acceleration of gravity. Dependency diagram represents regression curve formed by applying the least squares method to pairs of values obtained by performing tests, [10]. On the same way it is obtained dependence of HIC from THIV, Figure 7.

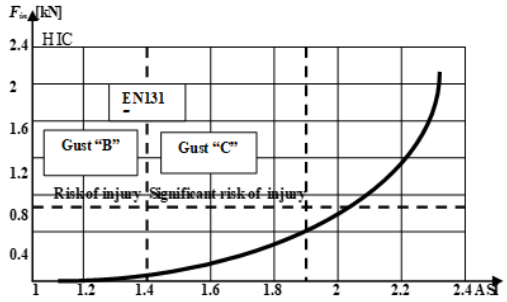

Figure 6. Head injury coefficient versus Acceleration severity index
Source: Authors and Shojaati M., ETH Zurich, https://ethz.ch/en/utils/contact.html [14]

It is characteristic that the critical speed reached by the head and neck region at the end of the collision, defined by the EN1317 standard, is 33 km/h, and from the point of view of the occurrence of fatality. That speed corresponds to inertial force of approximately 0.7kN, [9], as well as to acceleration of approximately 65.5 m/s2, which corresponds to 6.7·g. It is assumed that the mass of the head and neck region, in total, amounts to 15% of the mass of the entire body, that is, 10 to 12 kg. The head and neck injury criterion, HIC, Fig 7, represents the inertial force of the driver's or passenger's head at the moment of impact: F_{in} [N]. Gust time duration is expected to be between 140 and 160ms. The specified acceleration value corresponds to gust duration of 140 ms, which is less favorable. Necessity for safety barriers of specific type or no one depending of the risk for road surrounding and passengers in the car from traffic flow, mean allowable speed and heavy trucks.

Table 4. Dependence of injury severity level from ASI index and Head Injury Criteria

4. SAFETY ROLLER BARRIERS

For the difference safety barriers mentioned before, safety barriers with rollers, (Roller barrier system), Figure 8, are proposed, to prevent vehicle rolling out the road, assuming, at the same time, continuity of movement, Figure 9 and 10.

Figure 8. Safety roller barriers

Figure 9. Safety roller barriers enabling driving continuity
Source: Safe Direction, Crash Barrier Solutions, Australia, [18]

Safety Roller Barrier System provides greater kinetic energy with which vehicle is leaving the barrier, being able to continue movement. Collide energy is consisted of part transformed to deformation work and the part transformed to inertia moment of the rollers too. Namely, the difference in kinetic energies with which the vehicle hits and leaves the barrier is not only the deformation work, but also the roller's rotational energy, which is the product of the moment of the tangential force created by the vehicle's collision and the angle of rotation of the roller.

Figure 10. Safety barriers on low radius curves and for obstacles protection
Source: HE Shock Resistance Barriers for Highway Tunnel Corner [19]

This type of safety barriers was originally developed in South Korea, after which it was improved by Gregory Industries, based in Ohio, USA, under the designation: MASH TL-4. The installation permit was issued by the American Traffic Safety Services Association, and the presentation was at the 2017 Traffic Expo in Phoenix, Arizona. An improved model of this type was launched for impact loads of vehicles weighing over 36 tons, under the designation: MASH TL-5. The first installations of these barriers were realized not only in the USA, but also in South Korea, and in China, Malaysia and Australia. They are widely distributed for smaller radius curves, as well as for protection of obstacles on the road. Rotary roller, Fig. 14, is notable for its yellow-orange color and fluorescent strips.

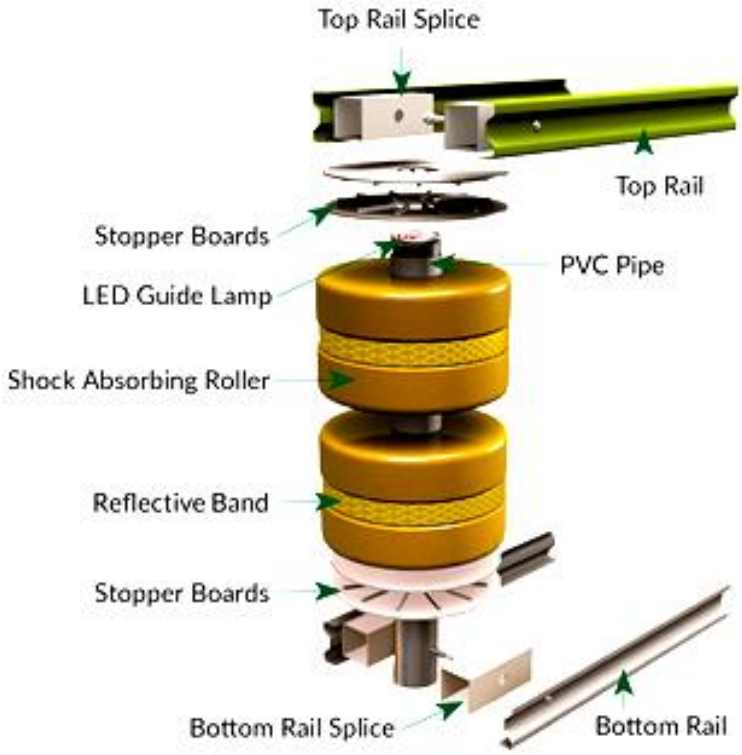

Figure 11. Safety roller barriers roller
Source: Gregory Industries Roller, World Highways Routes Du Monde, [20]

It is made of polyurethane or ethylene-vinyl acetate, which are polymer composite hydrocarbon materials of high strength and toughness. There is also the possibility of filling them with broken glass, plastic granulate or other fillings. Steel parts are made of galvanized sheet. One of the main advantages of such barriers is easier installation, lower weight, as well as simpler and partial replacement of damaged parts. The geometry of the roller with the support is given in *Gregory Industries Roller, World Highways Routes Du Monde,* [20].

5. CALCULATION OF THE ENERGY BALANCE IN THE CASE OF SAFETY ROLLER BARRIERS

The calculation of the energy balance is based on the laws of maintaining the amount of movement as well as the transformation of part of the kinetic energy into mechanical work and momentum of inertia in the form: $M = I_r \cdot \varepsilon = m \cdot r^2 \cdot \frac{d\omega}{dt} = F_{\tan} \cdot d\varphi,$ where *m* represents the mass of the roller, *r* - the radius of the roller's center of gravity from the point of contact with the vehicle, the angular acceleration of the roller, F_{tan} the tangential force, $d\varphi$ the angle of rotation of the roller and *dt* the duration of contact between the roller and the vehicle. The physical quantity that, in those terms, has the greatest influence on the fatality of the collision is the duration of the gust, which must be extended as much as possible. In the case of a plastic collision, deformation work occurs due to the deformation of the vehicle and the barrier. That work: A_{def} is the scalar product of the inertial force: F_i and the deflection *W,* in the form: $A_{def}[J] = \vec{F}_i[N] \cdot \vec{W}[m]$. Expression for the energy balance will be in view: in contrast to classic barriers, which is the main advantage of Safety roller barriers. Therefore, the expression for the energy balance will be in view: $E_{k_1} = E_{k_2} + A_{def} + M,$ in contrast to classic barriers: $E_{k_1} = E_{k_2} + A_{def}$. This statement represents the main advantage of Safety roller barriers.

6. CONCLUSION

The goal of the work is a critical review of the EN1317 standard, which is also applied to safety barriers in the Republic of Serbia. There is also a broader overview of the types of barriers in accordance with the Standard and from the aspect of the amount of deformation work that, depending on the type, is absorbed by the barrier, Fig. 5. There is also a review of the choice of safety barrier depending on the frequency and nature of the traffic, Fig. 6. Reviewing the criteria on the basis of which the Standard was formed, which refers to the dependence of HIC and THIV on ASI, was also the subject of this paper. A more comprehensive scope of consideration of these dependencies, on which the Standard is based, is, also, one of the contributions of the Work. The basic approach in Paper is to take into account the real traffic flow, which is permissible from the aspect of road parameters. The work is based on the premise of non-observance of the prescribed traffic conditions and, accordingly, the safety barrier is expected to prevent a fatal outcome and minimize material damage. The size of the deformation work needs to be as large as possible in order to reduce the ASI, Fig. 8 and Fig. 9. Also, it is necessary to take into account the road environment as much as possible, and in accordance with that, select a barrier, Fig. 10, from the aspect of the total volume of traffic, the maximum speed of the traffic flow that can be realized, as well as the participation of oversized vehicles. The key contribution of the work is a broader overview of Safety roller barriers, which are increasingly common in the world, and the main advantage is the energy of the rotation of the roller, which, along with the deformation work, absorbs most of the kinetic energy of the vehicle when it hits the barrier. These barriers are not foreseen by the EN1317 standard, and the author's intention is to expand the Standard by including this category of safety barriers.

Abstract: *Wire-arc additive manufacturing (WAAM) is a promising technology for producing medium and large components without traditional subtracting technologies. It is a hybrid of two manufacturing techniques: additive manufacturing and welding. The use of this technology has grown significantly due to advantages such as material and energy savings while achieving high deposition rates and low cost. However, there are some issues with microstructure homogeneity, and properties are affected due to the complexity of the arc-induced thermal cycles and metallurgical mechanisms, resulting in high residual stresses, distortion, porosity, cracks, and delamination. This article summarises the progress made in the field of wire additive manufacturing, with a focus on welding systems, tool path design software, material analysis, and control systems. It also highlights some critical aspects that must be addressed to ensure high-quality production, such as control and diagnosis mechanisms for defect monitoring, the effects of parameters and their optimisation possibilities for improving quality, ensuring process stability, and possible post-deposition heat treatments. The conclusions suggest further improvements to the wire-additive manufacturing process in terms of accuracy, reliability, and efficacy, as well as future applications of the technology and research activities.*
Keywords: Additive manufacturing, WAAM, Welding, Mechanical properties, Monitoring system

1. INTRODUCTION

Additive manufacturing (AM) uses the joining of materials to create three-dimensional structures, typically layer by layer [1]. In fact, it is one of the primary technologies in engineering that enables near-net-shape fabrication, which is thought to increase design freedom while achieving lower lead times and great potential for smart production [2]. It has mastered the production of high-end products while meeting sustainability standards by employing environmentally friendly manufacturing techniques, resulting in minimal waste and CO_2 emissions and a strong circular economy [2]. While there has been continuous progress in AM research over the years, there have also been some difficulties and problems encountered along the way, such as raw material incompatibilities, the lack of testing facilities, and the numerous defects in the AM parts [2]. Poor surface quality, flaws, and decreased corrosion resistance are some of the important problems that prevent the real-time application of AM products in some industries, but there are significant efforts to resolve these problems through research and there are also some post-processing techniques that can be used to overcome these difficulties [2]. AM technology has found great interest in applications in aerospace,

automotive, biomedicine, energy and chemical industry, micro-nano manufacturing, marine, and aeronautics.

A fundamental AM system is made up of a motion system, a heat source, and feedstock [3]. The process parameters and material used determine the quality of parts created using AM procedures. AM can use metals and alloys, polymers, ceramics, composites, and natural materials [2]. Metal additive manufacturing is one of the most difficult modern technologies. Powder bed fusion (PBF), direct energy deposition (DED), binder jetting (BJ), and sheet lamination (SL) are the four major categories of AM technologies for metal materials [4]. The primary distinctions between these technologies are the nature of the heat source and the form of metal used. Depending on the AM technology used, the metal can take the form of powder, wire, foil, or laminate. Powder-based fusion technologies involve spreading layers of powder on a metal building plate and melting this powder with a laser or electron beam heating source. PBF techniques include direct laser metal sintering (DLMS), electron beam melting (EBM), selective laser melting (SLM), and sintering (SLS) [4]. When using a laser beam, the part must be built in an inert atmosphere, whereas when using an electron beam, the part must be built in a vacuum [5]. These processes can produce products with high geometrical accuracy, but the equipment and overall process are very expensive, and the metal powder can be hazardous to people, necessitating additional precautions and control of the working environment [4]. When metal wire is used as feedstock instead of metal powder, not only is the powder protection and recycling system eliminated, but the raw material cost is reduced significantly [4]. These are referred to as wire-based (WB) technologies. The wire-shaped material is fed into the deposition zone and melted by a heat source (laser beam, electron beam, or electric arc). A controlled atmosphere is required when using a laser or electron beam as a heat source, whereas an electric arc is shielded by the gas that covers the melted pool of metal [5]. The technology that uses an electrical arc as a heating source and a wire to feedstock is known as wire-arc additive manufacturing (WAAM). WAAM has many advantages over other AM technologies, such as the ability to produce very large parts, higher deposition rates, less expensive welding equipment, less expensive hardware systems, a wide range of standard wires, efficient material utilization, and energy savings [5,6,7]. However, when compared to other metal additive technologies, WAAM has several disadvantages, including high heat input, which can result in residual stresses, distortion, poor accuracy, and roughness, which necessitates the use of additional finishing manufacturing operations. It also cannot produce very complex parts; the low accuracy makes geometry optimization algorithms ineffective [6].

WAMM is ideal for producing parts made of various metals and alloys, particularly highly reflective metal alloys such as aluminum, copper, magnesium, titanium and nickel alloys, and steel [4, 7, 8]. The WAAM hardware system is very simple; it employs a cartesian or robotic device for positioning the welding torch, welding equipment with a shielding gas source, a wire feeding unit, and power and control units, as illustrated in Figure 1.

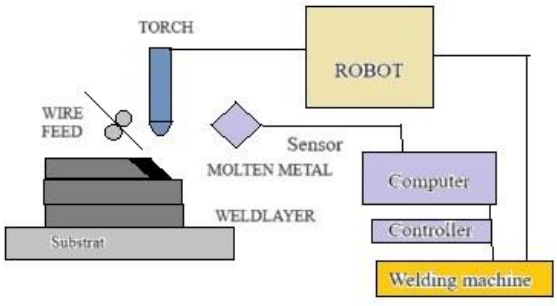

Figure 1. A schematic representation of WAAM system

When using reactive titanium alloys, an additional controlled chamber must be installed to control the production environment [5]. WAAM can be integrated into a hybrid machine that can also operate with other machine operations, making it suitable for in-between tasks [5]. The thermal cycles during the welding process have a significant impact on the microstructure and mechanical properties of

WAAM parts. Each layer is heated and cooled, resulting in multiple fusion, solidification, phase transformation, and highly non-linear dissipation. Another important factor influencing microstructure, defects, geometrical accuracy, and mechanical properties is heat accumulation [7].
The WAAM technology is very popular in research, and some of the findings in many articles suggest that the process can be used in production, owing to the favorable mechanical properties obtained. This review focuses on some aspects of welding processes and equipment, as well as material analysis and control systems. Additionally, potential optimization approaches for increasing product quality are discussed, and some ideas and recommendations for additional process enhancements are outlined.

2. WIRE-ARC ADDITIVE MANUFACTURING

Wire-arc additive manufacturing technology has been studied since the 1990s [3]. It employs standard welding equipment such as a power source, torch, and wire feeding system. Robotic or computer numerically controlled (CNC) systems can be used to control movement patterns [3]. It is critical to provide tools and guidelines for the process planning phase, particularly for the tool path, which must correspond to the shape and dimensions of the part [5]. The high deposition rate with minimal geometry constraints is ideal for the rapid production of large components as well as gradual manufacturing [5, 8]. The WAAM filler material is like the one for welding, therefore there is an available palette of materials that can be used for fabricating parts with this technology. The CNC machine or robot directs the torch along the deposition path, allowing metal layers to accumulate and form the desired shape. Using different arc welding machines and operating units, various hardware systems, each with its own set of characteristics and utility, have been developed [4]. Figure 2 depicts an example of a robotized WAAM setup [2].

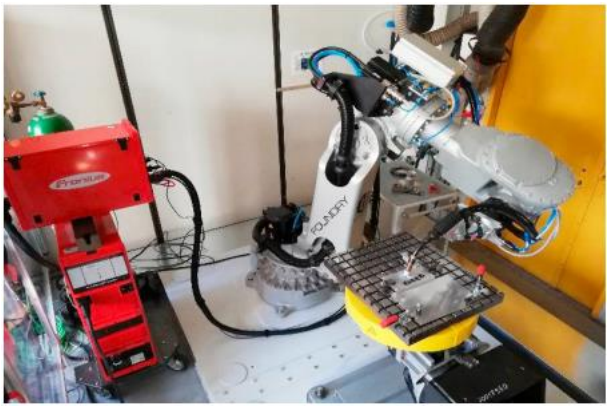

Figure 2. WAAM system with Fronius welding source
Source: Robot-Based Wire Arc Additive Manufacturing System with Context-Sensitive Multivariate Monitoring Framework. Procedia Manufacturing 2020

2.1 Welding processes

There are six types of arc welding-based AM: gas metal arc welding (GMAW), gas tungsten arc welding (GTAW), cold metal transfer (CMT), plasma arc welding (PAW), laser additive manufacturing (LAM) and electron beam welding (EBW) technology [4, 2]. The metal solidified during WAAM has a large column grain microstructure, which is useful for high-creep resistance applications [2].
In GMAW additive manufacturing (GMAW-AM) an electric arc forms between the continuous electrode and workpiece on the substrate surface. A robotic path that the torch follows is created from a CAD model at the beginning of the process [9]. A stable path generation and simple programming procedure are established due to the torch and wire being in a coaxial position with one another [4]. The electrode is a continuous wire that is supplied to the arc via a feeding mechanism. It melts and deposits in a defined pattern with relative movement of the torch and the worktable [10]. Inert gas is

used to shield the weld pool from the atmosphere, preventing any reactions or environmental contamination. The product is taking shape because of the overlapping weld layers creating bonds when they solidify. Shape, size, density, mechanical characteristics, and quality define each layer of welds that are deposited on the substrate. This process's high heat input causes the layers' geometry to become uneven, which negatively impacts the layers' shape and quality of the product [11]. Compared to the other three WAAM technologies, GMAW-AM has higher deposition rates, ranging from 3 to 4 kg/h [4]. However, the rates can be further increased by combining two GMAW processes or by using a pulse GMAW technique. In these situations, more external cooling atmosphere is required due to the higher heat. To increase the material utilization rate, GMAW and GTAW torches can also be combined [4]. There are process modifications with more potential because of the arc's poor stability in GMAW-AM. This applies to the modified GMAW process known as cold metal transfer additive manufacturing (CMT-AM), which depends on a regulated dip transfer mechanism [3]. Its superior arc stability, low heat input that results in less distortion, nearly zero spatters, and high process tolerance make it extremely promising [3]. CMT-AM is a high-resolution system for creating three-dimensional near-net-shaped objects that work with a robot system and simulation software [8]. Modeling software, material feeding via cord, data connection lines, soldering power, and activator operation make up this economical prototyping method [8]. The high-frequency alternation of forward wire and retraction sets apart the various CMT-based WAAM systems, some of which use CNC machines for the 3D path of the tool [8]. The advanced current dynamic creates the liquid droplet at the top of the wire, which is then unbundled at low pressure to produce a solid solder, stable arc, low heat input, and no spatter [8].

High-quality welds are produced by GTAW welding, also known as tungsten inert gas (TIG) welding, which forms an electric arc between the non-consumable tungsten electrode, the workpiece, and the filler metal. Because it is a splatter-free process that produces very little slag, it can be used for welding in all positions without the need for additional cleaning procedures. In GTAW-AM technology, GTAW is utilized as a heat source. The substrate surface is covered in melted metal as the filler wire is inserted into the arc from the torch's side. It is easier to control GTAW-AM because it has a lower heat input than GMAW-AM and because changes in heat input do not alter the arc length or the rate of deposition [11]. Numerous scholars have examined how control factors affect output metrics like deposition breadth and height [2, 11]. Their results indicate that the width and height of the deposition decrease with increasing tilt angle [2]. Anisotropy in terms of elongation at break is evident in tensile tests conducted on additively manufactured parts but yield and ultimate strength show uniformity in both directions [2]. Studies on the use of nanoparticle-enhanced aluminium wire in GTAW-AM have also been conducted; the findings indicate that the printed layers have larger metal grains [2].

While the GTAW and PAW processes are similar, the PAW process concentrates the arc more, improving stability, increasing heat transfer efficiency, and producing fast welding [6]. The majority of industrial metals, such as titanium and its alloys, nickel and its alloys, and stainless steel, can be welded using PAW. It requires less heat and is easier to control the feeding rate than the GTAW and GMAW-AM [2]. Although PAW-AM is more expensive than GMAW and GTAW-AM processes, it produces a final product with fewer defects and more consistent results. The wire fed in GTAW-AM and PAW-AM is not coaxial, which can cause variations when there is a direction change and cause the arc length to vary [6]. To make the process application possible, the robot system's rotary axis must be used to orient wire feeding and maintain it in the same direction as the welding [6]. Additionally, electron beam welding (EBW) and laser additive manufacturing (LAM) can be used to fabricate large individual components with reduced internal stress. These are additive manufacturing techniques based on high-energy-density (HED) welding [2]. Custom-built devices that use the EBW and LW processes with a separate wired procedure make up the majority of research employing these technologies [2]. Additional wire feeds and working chambers are included in the apparatus. A key component of Industry 4.0 is additive manufacturing based on laser beam welding, which makes extensive use of sensors for process control [2]. The most common issue that researchers are attempting to solve is geometry inaccuracy. Numerous factors have been taken into account, such as

trace height and width, breadth, depth, geometrical responses, and dilution. The findings of these studies indicate that there is an influence on the width but no relationship between the laser power and the trace height [2]. There are benefits and drawbacks to employing these methods. These methods have the advantage of having a narrow heat-affected zone, low heat input, high solidification rates, reduced distortion, deep penetration, excellent energy transfer efficiency, and lower consumable costs. The primary drawbacks are increased initial investment costs and the challenge of enhancing the fusion zone properties using filler metal. The use of additive manufacturing technologies based on fusion welding is restricted due to the production of extremely columnar grains with anisotropic characteristics [2]. Friction stir additive manufacturing (FSAM), ultrasonic additive manufacturing (UAM), and additive friction stir deposition (AFSD) are examples of solid-state welding-based additive manufacturing techniques that offer a metal a deformation processing path. Material addition and bonding are achieved through extreme temperatures and severe plastic deformation. One of the most innovative solid-state additive manufacturing (AM) technologies, FSAM is based on the FSW principle and has the potential to overcome limitations, especially in the case of light alloy additive manufacturing [2].

2.2 WAAM monitoring systems

WAAM technology has numerous potential applications in a variety of industries due to the many benefits it offers. This has led to a significant increase in interest in topics for the future development of WAAM in academic research and industry over the last decade. There are some challenges to fully implementing the technology, which can be attributed to a lack of process monitoring and closed-loop control over the entire process [10]. As a result, implementing process monitoring and feedback control is one of the most significant advancements that can be made [10]. Because the main challenges remain manufacturing precision, quality assurance, and automation level, various solutions for improving quality with the improvement of monitoring systems are proposed. Vision, spectral, acoustic, and thermal sensing are all used, and they all have different roles in the monitoring process. Visual sensors are used for surface monitoring, while spectral and acoustic sensors are used for internal changes in the metal [10].
A great deal of research has been done on feedback control systems in the last few years. Newly developed devices use feedback signal systems to measure the distance between the nozzle and the top of the surface to control the height of the layers. Additionally, neural self-learning PSD controllers for bead width measurement and adaptive controllers that maintain this distance constant through wire-speed adjustments are available [10]. If the wire feed is constant, the robotic movements in WAAM processes should decelerate at sharp corners, which leads to over-fill. The adaptive control system, which adjusts the wire feed based on the dynamic constraints of various sections, can be used to accomplish this. The bead can be observed using a thermal camera and laser scanner, and a closed-loop control can be put in place [4,10]. Most of the research on WAAM controlling systems indicates that this process is still in the early stages of development and that control systems and additional study are necessary to bring it closer to commercialization.

3. CONCLUSION

The manufacturing sector has changed as a result of additive manufacturing's (AM) use of layer-by-layer deposition to produce structures with nearly net shape and little material waste. However, by combining additive manufacturing (AM) with different welding techniques, it is possible to overcome the dimensional constraints of the parts produced through AM. This article aims to give a summary of the current state of welding-based additive manufacturing (AM) and the underlying principles of the WAAM technology. There is a great deal of research on arc-welding-based AM techniques in comparison to other techniques, like the beam welding AM technique, and a broad range of concepts used in AM with arc-welding filler metals. With fusion welding-based AM, only simple structures can be produced. The production of high-quality metal parts can be facilitated by the hybridization

of beam welding-based AM with arc to enhance process capabilities. This concept has many promising prospects, so it is expected that more research will be done in the future for the application of different welding techniques and materials in the additive manufacturing process. Research opportunities for the advancement of the WAAM process include the development of new materials, fabrication in different patterns, management of grain structure, and phase transformations for a wide range of alloys. Numerous benefits stems from the FSAM process, including efficient structural design, favorable microstructures and mechanical qualities, and environmentally friendly procedures. Further research on FSW-based AM is required to create innovative techniques that get around the drawbacks of fusion welding. Additional findings from this review include the following: GMAW-AM has a higher rate of deposition than the other basic welding technologies; CMT welding is a GMAW modification suitable for large stainless steel products; GTAW and PAW techniques are suitable for small to medium parts with medium to high mechanical properties; LBW-AM requires less energy and provides effective control over the weld pool and surface quality; FSW-AM has the potential to consume a small amount of material with low emissions, waste, and energy. This article's informational goal also includes providing details on the state of development and monitoring and control systems at this moment. The monitoring systems are designed to record process signals on the possible occurrence of a defect, while the control system controls the bead geometry and heat input. The monitoring and control system's goal is to improve process stability, accuracy, quality, and application of online defect diagnosis.

Abstract: *In recent years, friction stir welding (FSW) methods have been used to obtain joints with good mechanical properties. The development of FSW lap joint assembly will expand its use in ahigh number of industrial applications that can benefit from this technology. In this paper a study based on experimental methods were performed on FSW lap joints. The investigation includes experimental welding and measurement of microhardness using the Leeb method. The lap joint is welded by friction stir welding process. The welding process is implemented on a 3-axis milling machine. With Leeb's method, it was possible to measure only the microhardness on the face of the weld metal, and the microhardness was measured in three zones. This paper also represents an attempt to verify whether the Innova Test Time 5350 device can measure the microhardness of aluminum alloy series 5xxx.*
Keywords: Lap Joint, Friction Stir Welding, Microhardness, Leeb method

1. INTRODUCTION

Currently, riveting is the most used joining technology for manufacturing reinforced panels of aircraft structures. However, there are important disadvantages in the use of this technology that have to be solved. Among them, the low productivity and the significant contribution to weight increase are the most significant ones. By contrast with riveting, welded structures show remarkable benefits such as reductions in the number of parts to produce the structures, weight saving as well as significant reductions in manufacturing time and cost. Nowadays the most promising alternative joining technologies for the manufacturing of aircraft structures are laser beam welding (LBW) and friction stir welding (FSW) [1,2].
Friction stir welding is solid-state welding technology which provides joining of materials without melting and without the use of additional materials. Joining of material is performed by combined action of heat and mechanical work. Tool and base material stay in solid-state, while in the welding zone base material is in a slightly softened, i.e. plastic-state. Geometrical parameters and technological parameters are the main factors that affect the efficiency of the joint. Geometrical parameters include: dimension of the shoulder, dimensions of the pin, and the pin profile. Technological parameters include: tool rotating speed, tool feed rate, and the tool depth sinking into the sheets to be welded. These process parameters have to be properly chosen on the basis of the working material in order to maximize the joint strength, and to obtain a joint without defects. A schematic representation of the friction stir welding process during the joining of two working plates in order to produce a lapjoint is shown in Figure 1 [3,4].

[1] adjurdjevic@atssb.edu.rs

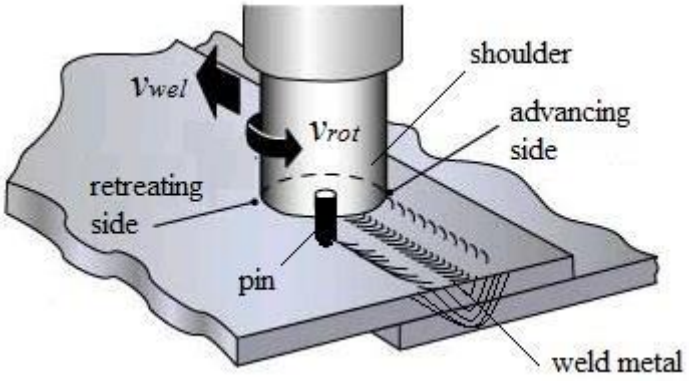

Figure 1. Friction stir welding of lap joint
Source: [5]

The shape of the weld metal is asymmetrical and the advancing side and retreating side are clearly visible. The advancing side is also called the direct side (the directions of the tool rotation speed vector and the welding speed vector coincide) [6]. The retreating side of the weld metal is the side where these two velocity vector directions are opposite.

The shape of the working part of the tool (Figure 1) is a combination of two concentric cylinders known as the tool shoulder (a cylinder with a larger diameter) and a tool pin (a cylinder with a smaller diameter). The transition between the shoulder and the pin is called the face of the tool, and it can be flat or embossed, with or without recesses.

2. EXPERIMENTAL PROCEDURE

Friction stir welding experiment were implemented on a 3-axis milling machine. Figure 2. a) shows the welding process. The tool is in direct contact with the working plates. Working plates are firmly clamped on the milling machine table using a clamping equipment. The tool is made of tool steel, the clamping equipment is made of stainless steel, and the working plates are made of aluminum alloy. The thickness of the working plates is 3mm.

a) b)

Figure 2. Experimental welding of lap joint: a) Welding process and b) Lap joint at the end of the welding process
Source: original copyright

The welding process begins with the immersion of the rotating pin into the material of the two working plates (working material). During this process, the temperature in direct contact between the surfaces of the rotating tool and the working materials is constantly increasing. The process continues

until the temperature in direct contact between the rotating tool and the working materials increases up to a temperature of softening of the working materials. The softened material is forced to move around the tool pin due to its rotation and due to penetration into the material. There is also direct contact between the shoulder of the rotating tool and the surface of the working plates. Heat is also generated due to the friction of the tool face and the upper surfaces of the working plates, causing the material of the plates in direct contact to lose all its strength, i.e. to soften. This is followed by the welding phase. The working temperature is reached and is about 0.8 of the melting temperature, the material is soft enough to be mixed and transported. The tool moves along the welding line with constant rotation. The softened material is forcibly transported around the pin of the tool, and along the axis of the tool, i.e. between the face of the tool and the solid walls of the material. A nugget is formed from the softened material that is located at the end edges of the tool pin in layers. With each translational movement of the rotating tool, the transport of the softened work material will be on the rear edge of the tool, and the front edge will capture and introduce new work material of a lower temperature. At the end, the rotating tool stops moving along the material joining line, pulls away from the work materials, leaving behind a cylindrical hole (Figure 2. b). A lap joint was obtained where the length of the weld metal is 170mm.

3. MEASUREMENT OF MICROHARDNESS

Microhardness was measured using Leeb's method. This method is usually used for measuring the hardness of field samples, which are massive. Leeb hardness measurement is regulated by the SRPS EN ISO 16859-1:2016 standard. The measurement was made on the face of the weld metal. The sample is first prepared, the surface is finely ground and leveled before hardness measurement. Measurements were made with the device Innova Test Time 5350. It is a portable device for measuring hardness. The device works on the principle of measuring the rebound speed of the ball, which is located in the probe. Measured values are in Leeb units HL, and conversion can be done in Vickers HV or Brinell HB units. Figure 3. shows its representation. The accuracy of measurement is quite satisfactory, but the accuracy of hitting a certain spot that can be seen under the eyepiece is not.

Figure 3. Innova Test Time 5350 - device for measuring microhardness
Source: original copyright

The sample was cut from the welded joint. The surface was prepared for measurement and three zones were marked. Zone 2 includes the weld metal surface. Figure 4. shows the marked zones and places of microhardness measurement (ball impressions).

Figure 4. Places of microhardness measurement on the sample
Source: original copyright

4. RESULTS AND DISCUSSION

The measurement points per zone were chosen randomly. Due to the construction of the measuring device, i.e. the probe, it is impossible to precisely choose the measuring point. Table 1. shows the measurement results.

Table 1. Measured microhardness values (HL)
Source: *original copyright*

Zone 1	186	193	213	176	189	260	202		
Zone 2	171	198	184						
Zone 3	189	229	222	282	214	268	304	285	249,1

In Zone 1, 12 measurements were made, and 6 were successful. In zone 2, 22 measurements were made, and only 2 were successful. In zone 3, 15 measurements were made, and 8 measurements were successful. Problems that can arise when measuring with the Leeb method are that field samples, which are large in size, are usually measured. This method also has limitations regarding the hardness of the material being measured. Due to the low hardness value of the aluminum alloy, the device could not display the values of individual measurements at all.

The lowest value of microhardness was observed in Zone 2. This is area of weld metal, and the material of the working plates was in direct contact with the tool. In case of thermally non-workable aluminum alloys that have been strain-strengthened, series 5xxx-H, a drop in microhardness is observed in the weld metal nugget. This happens as a result of the release of material, which occurs due to the heat generated by friction [7]. In Table 1, the mean values of microhardness in the respective zones are shaded.

After measuring the microhardness on the face of the weld metal, the measurement was also started on the surface normal to the face of the weld metal. It is actually the area that encompasses the entire cross-section of the joint. According to Leeb's method, it was not possible to measure the microhardness on that surface of the samples, because the joint is very thin (6mm) and a probe cannot be placed.

6. CONCLUSION

Two aluminum alloy plates were experimentally welded on a 3-axis milling machine and a lap joint was obtained using friction stir welding. The aim of this work, in addition to experimental welding, was to measure microhardness values according to Leeb's method. Until now, all measurements of the microhardness of welded joints weremade according to the Vickers method. This is actually an attempt to check if the device Innova TestTime 5350 can deliver results. In zone 2, only 2 measurements out of 22 attempts were successful. The reason for this is that the surface of the weld metal was slightly softer than the surface of the working plates, so more measurements failed. According to Leeb's method, microhardness measurements on the surface at an angle of 90° from the surface ofthe weld metal face failed, because the plates are very thin and the probe cannot be placed.
In this experimental measurement, the hardness was not measured by the typical zones of the welded joint (base metal, heat-affected zone, thermo-mechanically affected zone and the nugget), but as shownin Figure 4. In fact, the average microhardness values were obtained, which are given in Table 1. The disadvantage of the device is that the accuracy of hitting the specific place under the probe is low. And that's the reason why a typical microhardness measurement per weld zone could not be done. The microhardness measurement locations per zone were randomly selected and the measured values are given in Table 1. For this reason, average values were calculated which are shaded and are also given in Table 1.

COMPARATIVE ANALYSIS OF THE MANUFACTURING TIME OF A PART ON A CNC LATHE OBTAINED BY CALCULATION AND SIMULATION OF MACHINING USING THE CAD/CAM SOFTWARE SYSTEM

Danijela Živojinović [1], The Academy of Applied Technical Studies Belgrade
Aleksandra Božović [2], The Academy of Applied Technical Studies Belgrade

Abstract: *The manufacturing time is a factor that greatly affects the total cost of manufacturing a machine part. The manufacturing time and, therefore, the price of the manufactured part depend on the part's geometry, prescribed tolerances of measurements, shape and position etc. Depending on the machining method, according to generally accepted mathematical equations, the main machining time is calculated based on the machining regime obtained through machinability functions or recommended values. During the manufacturing of machine parts, CNC machines are often used. During the machining process, CNC machines execute movements based on a pre-prepared G-code program. Today's available CAD/CAM software systems, which generate G-code programs for CNC machines, also provide the main processing time for each of the defined sequences within the machining process. In this paper, a technological manufacturing process is defined for the selected machine part. The technological process includes defined operations, sequences, tools and machining regimes. Based on the manufacturing technology, the main machining times were first calculated for each sequences using mathematical equations. Subsequently, the main machining times were determined using a CAD/CAM software system. Determining the main machining times using two different methods aims to ascertain the reliability of the results provided by the CAD/CAM software system. For this purpose, a comparative analysis of the obtained results is presented, which leads to the corresponding conclusions.*
Keywords: CAD/CAM, CNC lathe, G-code, manufacturing, main time

1. INTRODUCTION

Market demands for the manufacturing of high-precision machine parts, within the shortest possible timeframe, have led to the development and implementation of software solutions, such as CAD/CAM systems. The use of CNC (Computer Numerical Control) machines has found broad application in the production of various machine parts. The accuracy of manufactured parts and reduced processing time are significant advantages of using CNC machines compared to traditional CNC machines. The machining process on a CNC machine is executed based on a pre-defined G-code instructions. Thanks to the application of CAD/CAM software, the generation of G-code programs for CNC machines has been significantly simplified. This greatly reduces both the preparation time and the main processing time for each of the defined operations within the overall machining process. The processing time represents a significant parameter from an economic perspective, and by calculating it in advance, the cost of the entire technological process can be determined. Through the analysis of the required processing time, it is possible to identify unnecessary time losses and, by rationalizing auxiliary processes, optimize the time.
The main processing time is influenced by the geometry of the machine part with specified tolerances for dimensions, shape, and position as defined on the workshop drawing.

[1]dzivojinovic@atssb.edu.rs
[2]abozovic@atssb.edu.rs

The main processing time for a machine part can be obtained in two ways:

- through classical calculation, which involves using traditional mathematical equations based on the machining conditions while taking into account workability functions or recommended values or
- by using appropriate CAD/CAM software.

In this paper, a comparative analysis of calculating the main processing time required for machining a machine part on a lathe using two different methods is presented. Determining the main processing times through two methods aims to assess the accuracy and reliability of the results obtained by the CAD/CAM software system being used.

2. CALCULATION OF THE MAIN PROCESSING TIME

2.1 Calculation of main processing time using traditional methods

In this paper, for the selected mechanical part provided with a workshop drawing (Figure 1.), a manufacturing process has been defined. The manufacturing process includes the following steps:

- definition of all operations,
- definition of sequnces (tools and manufacturing regimes for each sequences individually).

According to the manufacturing technology, the main processing times for each of the operations were first calculated using mathematical equations [1, 2].

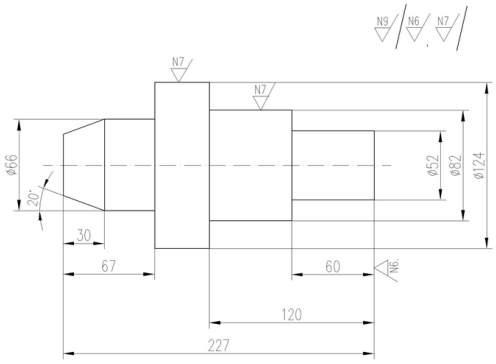

Figure 1. Sketch of mechanical part
Source: original copyright

The calculation of additive machining allowances for turning is a crucial step in the manufacturing process. These allowances are necessary to account for material removal during the machining operation and ensure that the final workpiece meets the desired dimensions and tolerances. Based on the selected additive machining allowances and the nominal dimensions of the finished part, calculated dimensions of the workpiece setup are obtained (Figure 2.):

$$D_P = 140\ mm\ ,\quad L_P = 240\ mm \tag{1}$$

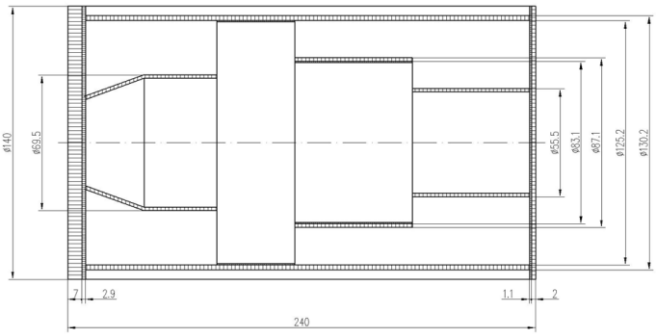

Figure 2. Workpiece definition with additive turning allowances
Source: original copyright

In manufacturing and machining, a technological process outlines the steps and procedures required to produce a specific product or component. It includes a sequence of operations, with a focus on ensuring that each operation is performed accurately and in the correct order to achieve the desired end result. Proper sequencing of operations, including tightening or fastening, is essential to ensure the quality and functionality of the final product.
The technological procedure defines appropriate operations with required sequences, as follows:

- Operation 10:
  - Sequence 01: rough radial facing of diameter Ø140 mm;
  - Sequence 02: fine radial facing (finishing) of diameter Ø140 mm;
- Operation 20:
  - Sequence 03: rough turning to diameter Ø52 mm;
  - Sequence 04: rough turning to diameter Ø83.1 mm (82 mm+1.1 mm);
  - Sequence 05: rough turning to diameter Ø125.2 mm (124 mm+1.2 mm);
  - Sequence 06: finish turning to diameter Ø82 mm;
  - Sequence 07: finish turning to diameter Ø124 mm;
- Operation 30:
  - Sequence 08: parting-off to Ø140 mm;
- Operation 40:
  - Sequence 09: rough radial facing of Ø140 mm;
  - Sequence 10: rough turning of cylinder with diameter Ø66 mm and cone from diameter Ø66 mm to diameter Ø44.162 mm.

Within each operation, processing parameters, tools, and toolpaths are defined.
Subsequently, the main processing time was calculated using traditional methods.

2.2 Calculation of main processing time through CNC machining simulation using CAD/CAM software

In the further work, a computer simulation of the machining of the required machine part on a CNC lathe is presented. The procedure for simulating the machining of the machine part on a CNC lathe is defined by an algorithm, which is provided in Figure 3.
The procedure for simulating the machining of a machine part using an appropriate CAD/CAM software system is based on the following steps [3, 4, 5]:

1. defining a 3D model within the 3D design module, based on a pre-defined workshop drawing;
2. defining a workpiece;
3. defining the coordinate system (workpiece zero point);
4. defining the machine center:
   a. definition of type of CNC machine (lathe)
   b. number of degrees of freedom
   c. fixtures
5. defining an operation:
   a. selection of type of CNC machine (lathe)
   b. define a retract surface
   c. define a coordinate system
6. defining each individual NC sequence (within the same operation):
   a. select or create a tool
   b. define NC parameters
   c. customize the tool path
7. machining process simulation, including visual monitoring of tool movement and material removal for each individual NC sequence;
8. calculating the main processing time;
9. generating CL-data;
10. postprocessing: generation of G-code for an operation.

Then, the main processing times for each sequence were determined using the CAD/CAM software system.

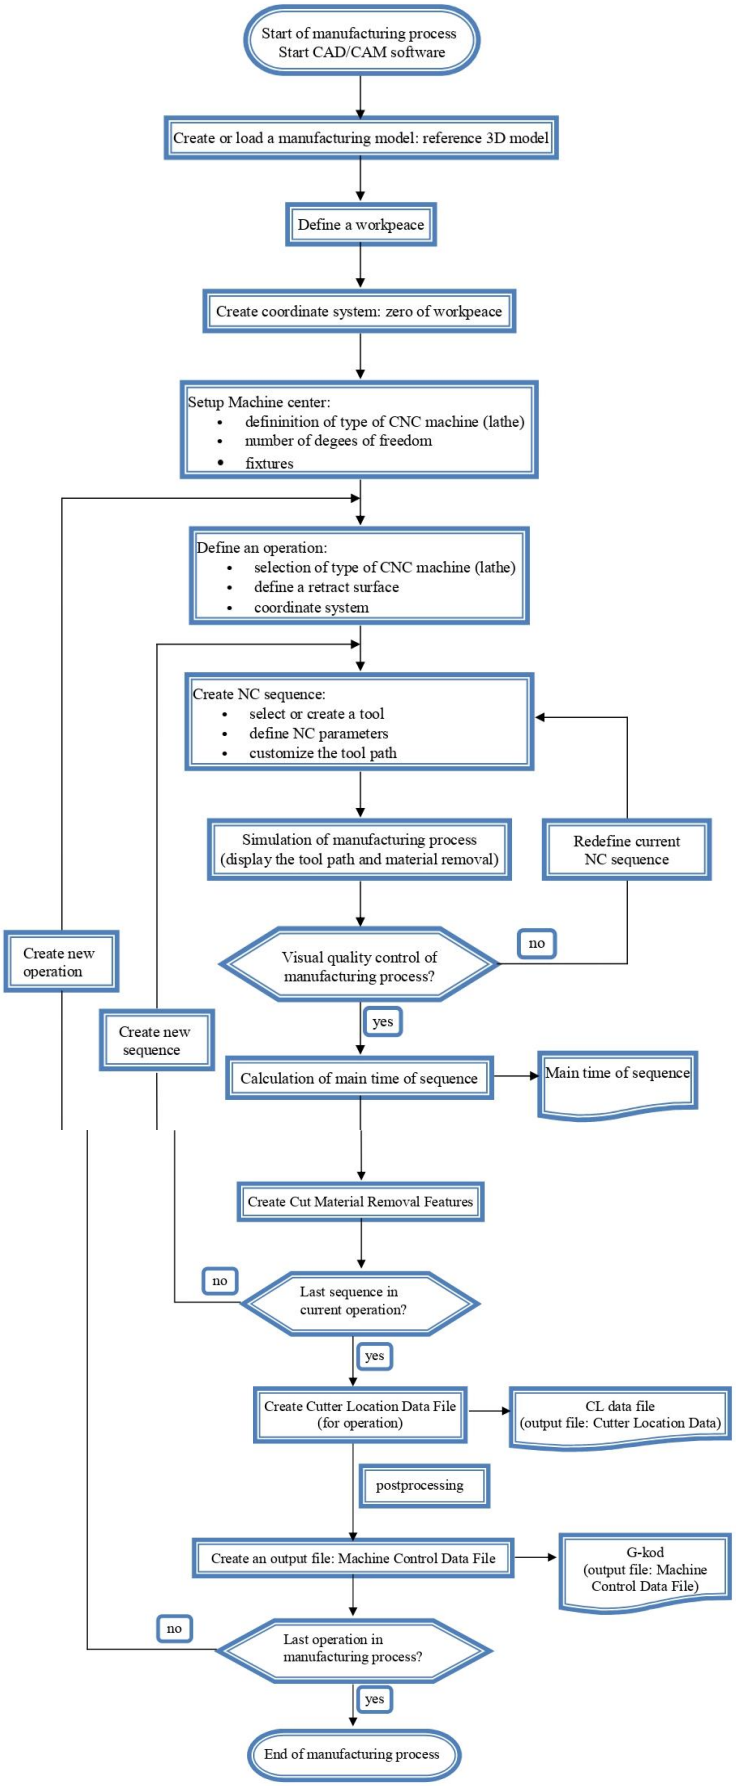

Figure 3. Algorithm
Source: original copyright

2.3 Comparative analysis of main processing times

In Table 1, a comparative overview of the main processing times is provided for traditional (conventional) machining calculations and the main processing time obtained through software simulation of machining a workpiece on a lathe.

Table 1. Operations and sequences with their respective main processing times
Source: *original copyright*

Operation	Sequence	Description	$Tm_{calculated}$ [min]	$Tm_{software}$ [min]
Operation 10	Sequence 01	rough radial facing of Ø140 mm	0.83	0.83
	Sequence 02	fine radial facing (finishing) of Ø140 mm	2.11	2.11
Operation 20	Sequence 03	rough turning to diameter Ø52 mm	*12.40	32.42
	Sequence 04	rough turning to diameter Ø83.1 mm	*9.30	24.05
	Sequence 05	rough turning to diameter Ø125.2 mm	*1.34	4.08
	Sequence 06	finish turning to diameter Ø82 mm	**0.89	0.92
	Sequence 07	finish turning to diameter Ø124 mm	**0.95	1.08
Operation 30	Sequence 08	parting-off to Ø 140 mm	32.00	32.00
Operation 40	Sequence 09	rough radial facing of Ø140 mm	0.83	0.83
	Sequence 10	rough turning of cylinder and cone	12.08	*33.26

3. CONCLUSION

Based on the data provided in Table 1, the following conclusions can be drawn:

- The main processing times for facing are identical.
- The main processing times for rough turning sequences significantly differ (marked with *). This difference is a result of taking into account the time required for the tool's back stroke, resulting in an almost double toolpath length in the software calculation compared to the classical calculation, which does not consider the time needed for the back stroke. The difference is more prominent in cases of turning sequences involving a greater number of passes (rough turning). The main processing times are approximately the same for finish turning, as they are completed in a single pass (marked with **).
- Through a detailed analysis, it has been observed that in these two types of calculations, the same measure of tool entry/exit is not included, resulting in slight deviations in the calculated main processing time.

This study has established a high level of accuracy and reliability in the results provided by the utilized CAD/CAM software system, in contrast to the classical (conventional) calculation approach.

OPTIMIZATION OF FGD PROCESS IN TPP KOSTOLAC 'B'

Aleksandra Mitrović[1], The Academy of Applied Technical Studies Belgrade
Ivan Banjac[2], Thermal Power Plant Kostolac "B"

Abstract: *This paper presents the first flue gas desulphurization system in the Republic of Serbia, which was built at the Kostolac "B" thermal power plant. The applied desulfurization technology using wet limestone with forced oxidation is described. Possible increases in energy efficiency, optimization of the desulfurization process and optimization of the absorber circulation pumps were presented. When the main operating parameters of the process were changed, the results of increasing energy efficiency were shown. By increasing the absorber slurry pH value above the regulation range, it is possible to save electricity from 718 kWh to 1115 kWh per FGD unit. The pH value was increased by adding more limestone slurry to the absorbers. A larger amount of limestone slurry in the absorbers did not compromise the obtained gypsum quality and absorbers' operating performances.*
Keywords: flue gas desulfurization, energy efficiency, optimization, circulation pump

1. INTRODUCTION

Thermal power plant (TPP) Kostolac "B" has two generating units, B1 and B2, of 348.5 MW capacity each. TPP Kostolac "B" uses coal (lignite) as the main fuel with a sulfur content of 1.3 %. The emission of sulfur dioxide (SO_2) ranges from 5000 mg/Nm^3 to 7000 mg/Nm^3 per generating unit. In order to comply with the legislation of the Republic of Serbia (RS), regulation on limit values of air pollutant emissions from combustion plants ("Official Gazette of RS", no. 6/2016) [1] and the legislation of the Energy Community, that is, the EU (Directive 2010/75 /EU) on industrial emissions [2], the first flue gas desulfurization (FGD) system in the Republic of Serbia was built in the TPP Kostolac "B" for units B1 and B2. The purpose of the FGD system is to reduce SO_2 emissions by 97.5 % (desulfurization efficiency), thereby achieving emissions lower than 200 mg/Nm^3 [3], which is the limit value of SO_2 emissions according to current RS and EU legislation. The goal of the analysis shown in this paper was to save electricity, optimize the process, and optimize the absorber's circulation pumps. The research was carried out over a period of one month.

2. WET LIMESTONE FGD WITH FORSED OXIDATION TECHNOLOGY

The desulfurization of flue gas is designed to use an alkaline reagent (sorbent) to remove acidic SO_2 in flue gas according to the gas absorption, gas adsorption, or catalytic conversion desulfurization mechanism. In general, FGD systems are classified as 'wet' or 'dry', with wet systems the most common. The desulfurization technology applied in the FGD system is the desulfurization of wet limestone flue gas with forced oxidation. In this process, a limestone slurry is used as a reagent, which reacts with SO_2 to perform its absorption and neutralization [3]. The desulphurization scheme in the TPP Kostolac "B" is shown in Figure 1.

[1]amitrovic@atssb.edu.rs
[2]ivan.banjac.83@icloud.com

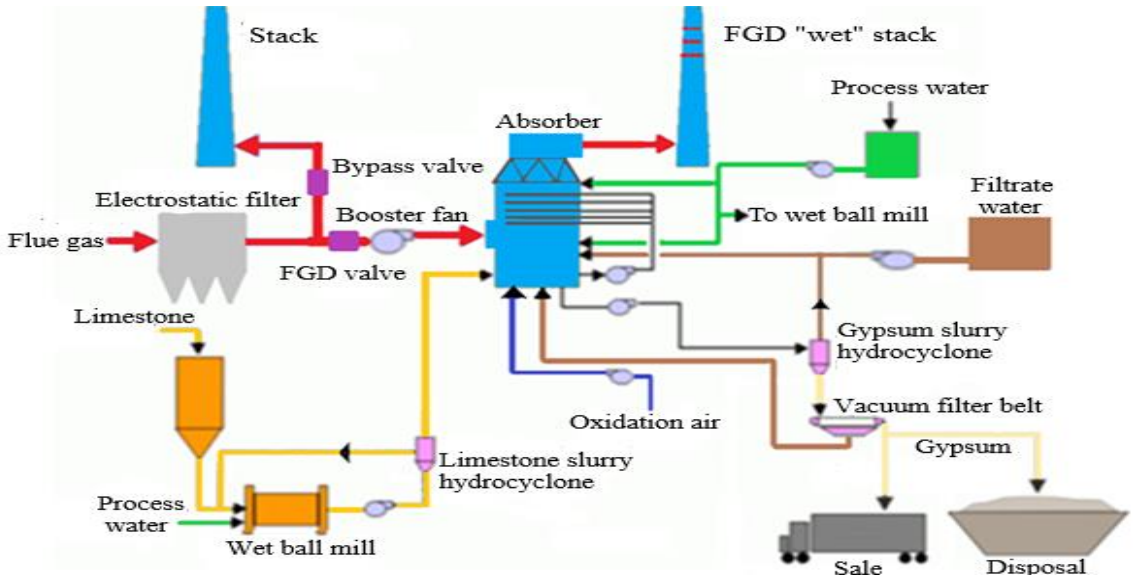

Figure 1. The desulphurization scheme in the TPP Kostolac "B"
Source: Original copyright

The flue gas, which is a product of the combustion of coal in a steam boiler, passes through an electrostatic filter. The bypass and FGD valve are used to direct the flue gas toward the FGD system or towards the stack in the case of a FGD system malfunction. The dedusted flue gas is directed towards the booster fan, in order to achieve the required flue gas velocity through the absorber. The absorber is the main component of the FGD system, a counterflow tower in which the desulfurization process takes place. The flue gas is introduced into the absorber just above the slurry level in the absorber tank and flows upward, coming into contact with the sprayed limestone slurry, which falls downward from the five spray levels. Each spraying level has its own circulation pump and distribution pipe for supplying nozzles (sprinklers) with slurry. The nozzles are arranged to ensure uniform spraying over the entire absorber cross section, ensuring uniform contact of liquid droplets and flue gas, and optimal absorption of sulfur dioxide. The ratio of slurry flow to flue gas flow is defined as the L/G ratio. The limestone slurry is prepared using a wet ball mill and a hydrocyclone to ensure the required grinding and density (solids content 30 %). The supply of the absorber with new limestone slurry is achieved through a pipeline in which the limestone slurry continuously circulates, replacing the previous one that was used for the absorption of SO_2. Dosing of the required amount of limestone slurry is done by regulating the main process parameter, the pH value of the circulating limestone slurry in the absorber slurry tank [3]. As the flue gas cools suddenly upon entering the absorber in contact with water, a certain amount of water evaporates, so the flue gas is saturated with moisture. The desulfurized flue gas is first directed through a mist eliminator to eliminate any water droplets. Following this, the gas enters the FGD "wet" stack, designed to handle wet flue gas from the absorber exit. The stack is optimized to disperse the flue gas effectively after it exits [4]. Following the reaction between the flue gas and the limestone slurry, calcium sulfite ($CaSO_3$) is generated. Then, this compound is directed by gravity into the absorber slurry tank, situated in the lower section of the absorber. Agitators in the absorber are used to prevent sedimentation of the slurry and to uniformly distribute oxidizing air in the absorber slurry tank. In the wet limestone process, an air oxidation system is used, which supplies an additional amount of oxygen in the absorber slurry tank, in order to oxidize calcium sulfite (12 hours residence time) into a more stable compound, calcium sulfate $CaSO_4$, i.e. gypsum, as a by-product of the desulphurization process with commercial use. Gypsum slurry settles at the bottom of the absorber slurry tank and when it reaches a certain density and quantity, it is transported by a gypsum bleed pump to the gypsum dehydration system. The removal of excess water from the gypsum slurry, with a solid content of approximately 25 %, was achieved using a hydrocyclone and a vacuum belt filter [3]. The outcome of the dewatering process yields gypsum as the end product, containing a moisture content of less than 10 %. The overflow (filtrate)

water from the hydrocyclone and the vacuum belt filter flows back to the absorber. Only a small amount of filtrate water is drained from the FGD system to the wastewater treatment plant. Gypsum is disposed of at the Drmno mine landfill, in case of irregular gypsum sale [3]. The construction industry is interested in this material, so almost the entire amount of gypsum is sold to wallboard and cement manufacturers. The FGD gypsum must comply with the quality criteria defined by Eurogypsum, presented in Table 1.

Table 1. Quality Criteria for FGD Gypsum
Source: https://fenix.tecnico.ulisboa.pt/downloadFile/1689244997256407/resumo.pdf

Quality Parameter	Unit	Quality Criteria
Moisture (H_2O)	mass %	<10
Calcium sulfate bihydrate ($CaSO_4.2H_2O$)	mass %	>95
Magnesium salts, water soluble	mass %	<0.10
Sodium salts, water soluble	mass %	<0.06
Chlorides (Cl^-)	mass %	<0.01
Calcium sulfite hemihydrate ($CaSO_3.^1/_2H_2O$)	mass %	<0.5
pH		5 - 9
Color		White
Odor		Neutral
Toxicity		Non-toxic

Eurogypsum, the European federation representing the gypsum product manufacturing industry, created a standard for FGD gypsum. Depending on the commercial use of gypsum, there may be different quality specifications [5]. Manufacturers of wallboard and cement sourcing gypsum from TPP Kostolac "B" demand adherence to the Eurogypsum standard. The most important criteria are gypsum purity (calcium sulfate bihydrate content), moisture, and chloride content.

3. OPTIMIZATION OF FGD PROCESS

The initial hypothesis of this research derives from the correlation of the FGD process parameters: limestone slurry density, limestone slurry flow rate added to the absorber, absorber slurry pH value, the gypsum quality criteria obtained, the operating order and number of absorber circulation pumps, the SO_2 inlet and outlet values SO_2. Through many years of research and experience with FGD systems, it is concluded that the pH value range of the absorber slurry should be regulated and used between 5 and 6. When the pH value of the absorber's slurry falls below the specified range, it leads to a decrease in the desulfurization efficiency. In contrast, if the pH exceeds the desired range, there is a higher removal of SO_2, but this results in a reduced gypsum purity [5]. The pH value of the absorber slurry is a crucial parameter of the FGD process that is constantly regulated and controlled during operation and has a direct impact on the efficiency of desulfurization, the amount of limestone used, and the quality of the gypsum [6]. In this research, the pH value was increased above 6 in both absorbers, to turn off one circulation pump of each absorber and thus save electricity. In addition, the goal was to maintain sulfur dioxide within the emission limit value and to maintain the obtained gypsum quality. According to the instructions of the Chinese company BOQI/NEPDI-Beijing, which built the FGD system in the TPP Kostolac "B", four absorber circulation pumps are continuously running, with an additional one serving as a backup. The circulation pumps are named A, B, C, D and E, from bottom to top, according to the spray levels of 20.4 m to 28.4 m [3]. Before the research, the pH value was maintained within the range of 5.2 to 5.8, following the same instructions provided. During operation, the A, C, D and E circulation pumps were in use. In order to make research results

as valid as possible, the density of the limestone slurry was kept constant at 1250 kg/m^3 (mean value of the regulation range). The gypsum obtained from both absorbers is stored in one depot. In order to make the obtained gypsum sample as valid as possible, research was done for both FGD units. To increase the pH value to 6.2, limestone slurry flow added to the absorbers has increased from the previous 30 m^3/h average to 35 m^3/h average per one absorber and the SO_2 output was 60 mg/Nm^3. At that moment, as the fourth operating pump, the circulation pump A of both absorbers was turned off. During the operation of circulation pumps C, D and E, the input SO_2 value ranged from 5100 mg/Nm^3 to 6100 mg/Nm^3, the outlet SO_2 value ranged from 160 mg/Nm^3 to 200 mg/Nm^3. Adding more limestone than required for the desulfurization process can consequently lead to residual (excess) limestone in the absorber slurry tank and thus in the gypsum [6]. Residual limestone in gypsum can compromise its purity. This was determined by daily FGD chemical analyzes, providing FGD system operators with insight into the FGD process and guidance on how to manage it further. The average values of limestone slurry, gypsum, and absorber slurry during the research period are shown in Table 2.

Table 2. Monthly FGD report
Source: TPP Kostolac „B"-Chemistry department

TPP Kostolac "B" Chemistry department	**MONTHLY FGD REPORT**	04.15.2023. 8:00 h	
LIMESTONE SLURRY ANALYSIS			
Parameter	**The limit values**	**Limestone slurry**	
Density (kg/m^3)	1250±50	1246.29	
$CaCO_3$ (%)	≥94.00	94.39	
Grinding (<44μm)	>85%	96.97	
GYPSUM ANALYSIS			
Parameter	**The limit values**	**Gypsum**	
Moisture (%)	<10.00	7.17	
$CaCO_3$ (%)	<1.50	1.17	
$CaSO_4 \cdot 2H_2O$	≥93.00	98.02	
ABSORBER SLURRY ANALYSIS			
Parameter	**The limit values**	**Absorber 1**	**Absorber 1**
pH	5.0-5.6	6.15	6.25
Density (kg/m^3)	1160±80	1176.12	1183.17
$CaCO_3$ (%)	<3.00	1.25	1.14
$CaSO_4 \cdot 2H_2O$	≥93.00	97.48	97.44

Gypsum analyses showed the limestone content in gypsum was 1.17 %, which did not exceed the limit value of 1.50 %, that is, obtained gypsum purity was not compromised. Before the research, with four operating circulation pumps, the value of $CaCO_3$ (%) in gypsum was 0.3 % in daily chemical analyses. The excess of limestone in the absorber is deposited and leads to the formation of deposits that can negatively affect the absorber performance. After three months of operation with three circulation pumps, the absorber inspection hatch was opened; larger limestone deposits than usual were not observed.

3.1 Saving electricity

The average electricity consumption before the investigation was 8.5 MW/h per FGD unit. The consumption per FGD unit is higher if the gypsum dewatering process is in progress. Devices that consume the most electricity are booster fans, wet ball mills, oxidation fans, vacuum pumps, and absorber circulation pumps. The electricity consumption of the absorber circulation pumps varies depending on the minimum and maximum density of the absorber slurry during FGD operation, as shown in Table 3.

Table 3. Circulation pumps electricity consumption depending on absorber slurry density for units 1 and 2.
Source: Original copyright

Slurry circulating pumps for units 1 and 2	Minimum slurry density 1080 kg/m^3	Maximum slurry density 1240 kg/m^3
Slurry circulating pump A	466 kWh	561 kWh
Slurry circulating pump B	523 kWh	617 kWh
Slurry circulating pump C	605 kWh	674 kWh
Slurry circulating pump D	636 kWh	750 kWh
Slurry circulating pump E	649 kWh	800 kWh

The shutdown of the circulation pump resulted in a decrease in the resistance to flue gases, thus reducing the spray level. Consequently, this led to a reduction in the load on the booster fan and, consequently, a decrease in its electricity consumption. The booster fan load fluctuates due to the regulation of flue gas under pressure. As a result of the circulation pump shutdown, the electricity consumption of the booster fan was reduced by approximately 252 kWh to 315 kWh. The smallest amount of electricity is saved when the 'A' pump is turned off at the lowest absorber slurry density and the booster fan's electricity consumption of 252 kWh. For one FGD unit, that is:

$$466\,kWh + 252\,kWh = 718\,kWh \tag{1}$$

The greatest amount of electricity is saved when the E pump is turned off at the highest slurry density and the booster fan electricity consumption of 315 kWh. For one FGD unit, that is:

$$800\,kWh + 315\,kWh = 1115\,kWh \tag{2}$$

Limestone slurry density in absorber reaches its minimum and maximum value during one day due to the formation of gypsum and its drainage from the absorber, so that the average saving during the day is 916.5 kWh. The working schedule of the circulation pumps is constantly changed in order to equalize their working time. The FGD system is in operation about 300 days a year. With three circulation pumps in operation, it is possible to save electricity of 6,598.8 MWh on an annual basis on average. Shutting down any circulation pump results in electricity savings, reduced pump run time, resulting in lower pump maintenance costs, and longer pump life [6]. The sequence in which the pumps operate influences the desulfurization efficiency by determining the duration of contact between the flue gas and the limestone slurry. A higher spray level provides more contact time between the flue gas and the limestone slurry and a higher desulfurization efficiency.

4. FURTHER FGD PROCESS OPTIMIZATION DIRECTIONS

Further optimization directions are software implementation, such as the CENTUM VP integrated process control system, i.e., the process optimization system of the Japanese company Yokogawa Electric Corporation. CENTUM VP regulates outlet SO_2 value. Based on the input SO_2 value and limestone density slurry value, it performs an optimized pH value calculation and limestone slurry flow, turns off one circulation pump and changes pumps operating order. After the pH value is adjusted to 6.3, gypsum is produced with a purity of over 95%. The advantages of CENTUM VP are: saving electricity, optimal limestone usage, monitoring operating times of each circulation pump and equalizing operating times of the pumps, shortened operating times of the pumps (lower pumps

maintenance costs) and extended pumps life. The FGD system of a 700 MW thermal power plant in Japan implemented the CENTUM VP. The FGD was in operation about 300 days a year. An optimization system was employed to reduce active circulation pumps from five to three, resulting in annual cost savings of 900,000 dollars, in accordance with market conditions in Japan. Furthermore, this modification successfully maintained the outlet SO_2 value below the specified regulatory threshold [7, 8, 9].

5. CONCLUSION

The FGD process often creates an unnecessarily large gap between the required and actual SO_2 output value. The optimization system solves this problem by turning off one circulation pump while keeping the SO_2 output below the emission limit value, so this operating mode is the most economical. When SO_2 inlet concentration reaches a critical value (>6500 mg/Nm^3) the operation of three pumps will exceed the SO_2 emission limit value. The additional circulation pump must be turned on at that time. The research findings suggest that it is achievable to optimize the FGD process while simultaneously staying within SO_2 emissions limits, upholding gypsum quality standards, and cutting down maintenance costs for the FGD system. Investment in optimizing the FGD process is profitable in several ways, as shown in this paper.

MATHEMATICAL MODEL OF CAR ROTATING DURING OVERTAKING IN A LEFT ROADWAY CURVE

Milan Marković[1], The Academy of Applied Technical Studies Belgrade
Dragana Velimirović[2], The Academy of Applied Technical Studies Belgrade
Andrijana Đurđević[3], The Academy of Applied Technical Studies Belgrade

Abstract: *The aim of the work is to establish the basic kinematic and dynamic parameters important for ensuring vehicle stability during the overtaking procedure in a critical situation. The movement of the vehicle during overtaking, which is considered by this paper, is realized in a curve to the left, which implies, first, a straight line movement, then entering the curve with the center of rotation on the opposite side from the center of the roadway curve, and then returning the vehicle to the roadway curve. This paper investigarte potential loss of stability occurs due to drifting and skidding of the vehicle during rotation, as well as due to the loss of contact of the rear wheels with the ground.*
Keywords: *Vehicle stability, Roadway curve, Kinetic energy*

1. INTRODUCTION

The work defines the procedure for overtaking a vehicle in a curve to the left, whereby the return of an overtaking vehicle to the lane in front of the vehicle being overtaken is realized by moving along a graded curve with damping to the right. After that, the overtaking vehicle enters the curve with the center of rotation on the opposite side of the previous one. The overtaking procedure is realized through three phases: straight-line movement, rotations in front of the vehicle being overtaken, as well as through the return to the the roadway curve line.
Previously, these are to be adopted:

- input parameters, the initial speed of the overtaking vehicle, the speed of the vehicle being overtaken and the amount of acceleration / deceleration on the straight section, as well as the angle of the corresponding curve of the vehicle returning to the lane in front of the vehicle being overtaken,
- roadway parameters: roadway curve angle of lateral and longitudinal slope and coefficient of rolling and sliding friction,
- boundary conditions that refer to the condition that the speed of the overtaking vehicle must not be less or equel to zero nor greater than the permissible speeds defined by the vehicle's stability conditions.

The paper describes the mathematical model on the basis of which the author of the paper created the program package: ACADPRET. The application of the software package to some variants of overtaking is given in the paper. The main contribution of the work is the definition of roadway parameters:

- the corresponding minimum required radius of the roadway curve,
- coefficient of sliding friction from the aspect of the roadway surface,
- the size of the appropriate longitudinal and lateral slope of the roadway,

[1] mmarkovic@atssb.edu.rs
[2] dvelimirovic@atssb.edu.rs
[3] adjurdjevic@atssb.edu.rs

in order to maintain the stability of the vehicle in case of imposed initial overtaking conditions. The variants refer to the driver's response in cases if he would accelerate on a straight section in order to avoid a conflict with an oncoming vehicle, or he would slow down in order not to enter the lane in front of an vehicle being overtaken too fast in order to avoid loss of stability. The program itself "corrects" the entered initial values, as the output being consisted of the maximum possible admissible initial values.

2. ANALYSIS OF THE VEHICLE ROTATING IN THE CURVE TO THE LEFT

As it is mentioned vehicle movement during overtaking is considered through three phases:

1. Overtaking along the rectilinear path; it is foreseen with variable initial speed, [5, 6], and with possibility for acceleration maximum absolute 4.5[m/s^2], as well as to be varied by program in order to control speed on the end of rectilinear path. Also, the value of the speed is not to be insufficient due to overtaking time being too long because it could cause conflict of the vehicles.
2. Vehicle rotates to right, in front of the vehicle being overtaken, [1] along the arc defined by the curve in the form: $f(x) = const \cdot \left(1 - e^{bx}\right)$,
3. Vehicle turns to right, rotating along the circle with the center on the opposite roadway side comparing the previous one. Speed which the vehicle exiting the previous curve line is equal to velocity vehicle entering this one.

3. MATHEMATICAL MODEL OF VEHICLE MOVEMENT

This analysis is important by the reason of critical situations have to be considered as to prevent skidding, [2] and [3], Figure 1 [4].

3.1. Rectilinear movement

Function which is taking in consideration the roadway parameters is in the form, [5]:

$$f_1 = -a_p \cdot m_v + G_v \cdot \left(\cos\alpha_p \cdot \mu_k + \sin\alpha_p\right).$$

Parameter which is taking into consideration the air resistance is in the form: $K = \frac{A_č \cdot c_x \cdot \rho_v}{2}$,

Where are:

- $A_č$ – Equivalent front vehicle area [m^2],
- c_x - Aerodynamic coefficient,
- ρ_v – Air density, [kg/m^3],
- m_v – Vehicle mass [kg],
- G_v – Vehicle gravity [N],
- μ_k – Sliding friction coefficient,
- a_p - Acceleration on rectilinear section, [m/s^2],
- α_p – Lateral slope angle.

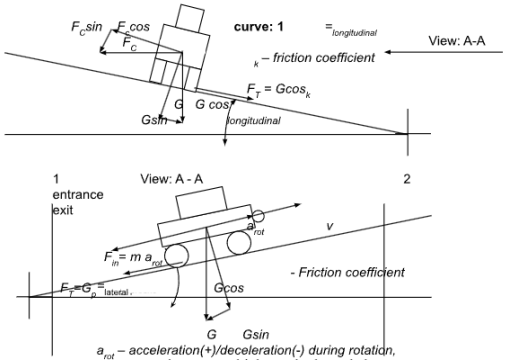

Figure 1. Vehicle on the lateral slope
Source: Authors

By the point of view of the initial speed, the velocity with which vehicle enters into the curve 1, (rotation in front of the vehicle being overtaken) is in the form:

$$v_{ul_1} = \sqrt{v_0^2 \cdot \left(1 - K \cdot \frac{l_p}{m_v}\right) - \frac{2 \cdot l_p \cdot f_1}{m_m} \cdot \frac{1}{1 + \frac{K \cdot l_p}{m_v}}}. \tag{3.1}$$

Acceleration on the rectilinear section could be found from the condition that expression (3.1) is to be ≥0:

$$\text{if } v_0^2 \cdot \left(1 - K \cdot \frac{l_p}{m_v}\right) - \frac{2 \cdot l_p \cdot f_1}{m_v} \cdot \frac{1}{1 + \frac{K \cdot l_p}{m_v}} < 0 \Rightarrow \text{if } a_p < 0 \Rightarrow a_p = a_p - \Delta a_p \rightarrow f_1,$$

$$\text{if } v_0^2 \cdot \left(1 - K \cdot \frac{l_p}{m_v}\right) - \frac{2 \cdot l_p \cdot f_1}{m_v} \cdot \frac{1}{1 + \frac{K \cdot l_p}{m_v}} < 0 \Rightarrow \text{if } a_p > 0 \Rightarrow a_p = a_p + \Delta a_p \rightarrow f_1.$$

On the other side, maximum permissible speed must not be exceeded. By that reason it follows:

$$\text{if } v_{ul_1} > v_{\max} \Rightarrow \text{if } a_p < 0 \Rightarrow a_p = a_p + \Delta a_p \rightarrow f_1,$$

$$\text{if } v_{ul_1} > v_{\max} \Rightarrow \text{if } a_p > 0 \Rightarrow a_p = a_p - \Delta a_p \rightarrow f_1.$$

In any case, the desired value of acceleration/deceleration: a_p on the straight section is the input data, so the speed with which the vehicle enters curve 1 is obtained as high as possible.

3.2. Curvilinear movement

Speed of the vehicle which is overtaking, on the lines along the curves 1 and 2, Figure 2, [5] and [6], could be found on the basis of boundary velocities established by the condition of skidding absence on the curve 1, (3.2) and on the curve 2, (3.3). The less value is critical and represents maximum speed which must not be exceeded.

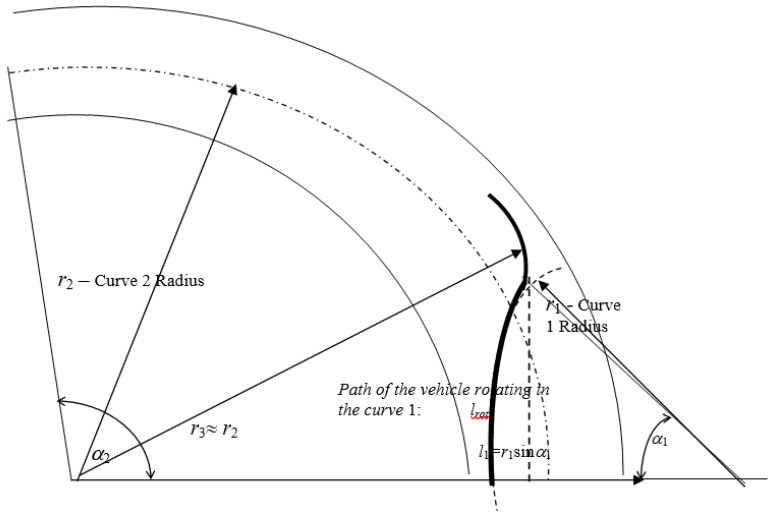

Figure 2. Curvilinear section of the roadway
Source: Authors

Boundary speed in curve 1 is in function of radius 1 and lateral slope of the roadway for the difference of the other one which is function of the radius 2 and longitudinal slope of the roadway, Figure 2 and Figure 3:

$$v_{iz_1 boundary} = \sqrt{\frac{r_1 \cdot G_v \cdot \left(\cos\alpha_p \cdot \mu_p - \sin\alpha_u\right)}{\left(\cos\alpha_p + \sin\alpha_p \cdot \mu_p\right) \cdot m_v}}, \tag{3.2}$$

$$v_{iz_2 boundary} = \sqrt{\frac{r_2 \cdot G_v \cdot \left(\cos\alpha_u \cdot \mu_p + \sin\alpha_u\right)}{\left(\cos\alpha_u - \sin\alpha_u \cdot \mu_p\right) \cdot m_v}} \tag{3.3}$$

Vehicle movement path in curve 1 is defined by:

$$f(x) = l_1 \cdot \left(1 - e^{-bx}\right), x \in (0, k), k = r_1 - r_1 \cdot \cos\alpha_1 \text{ , } b = 1 \text{ – attenuation rate,} \tag{3.2}$$

While: $l_1 = r_1 \sin\alpha_1$ and $r_1 = f(\alpha_1)$.

Path length is defined, [5,6,7], according to (3.2), by:

$$l_{rot} = \int_0^{r_1 - r_1\cos\alpha_1} \sqrt{1 + f'(x)^2}\, dx \text{ , } f'(x) = l_1 \cdot e^{-x} \Rightarrow l_{rot} = \int_0^{r_1 - r_1\cos\alpha_1} \sqrt{1 + \left(l_1 \cdot e^{-x}\right)^2}\, dx \text{ .} \tag{3.3}$$

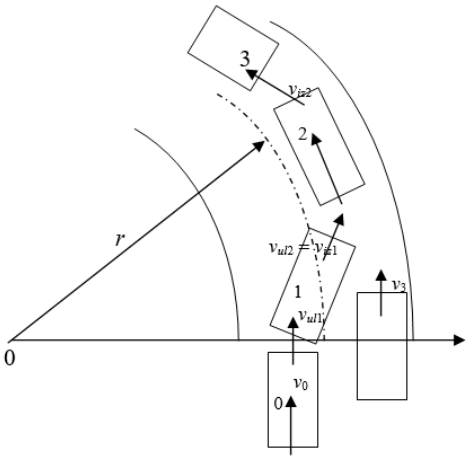

Figure 3. Vehicle positions during overtaking procedure
Source: Authors

Correlation between r_1 and α_1, Figure 2 is defined by regression curve has got by using least squares method, in the form: $r_1 = k_2 \cdot e^{\frac{1}{\alpha_1}}, k_2 \in (15,\ldots,30)$. In calculation, value for k_2 is adopted in the sum of 20. Circumstances that must be met are as follows:

$$\text{if } v_{iz_1} > v_{gran} \Rightarrow a_{rot} = a_{rot} - \Delta a_{rot}, v_{gran} = v_{iz1gran} \wedge v_{iz2gran}.$$

Acceleration and deceleration during rotation are regulation sizes by which it is possible to modify the velocity to be inside the limits. In the case as follows:

$$\left(\cos\alpha_p \cdot \mu_p - \sin\alpha_p\right) < 0 \Rightarrow \alpha_p = \alpha_p - \Delta\alpha_p, \alpha_p > 0, \alpha_p = \alpha_p + \Delta\alpha_p, \alpha_p < 0\,,$$

it is necessary to correct the lateral slope.

Value for the vehicle speed leaving the curve 1 that is vehicle speed entering the curve 2 is to be found by:

$$l_{rot} = \frac{m_v \cdot \left(v_{ul_1}^2 - v_{iz_1}^2\right)}{2 \cdot \left(a_{rot} \cdot m_v + G_v \cdot \left(\cos\alpha_u \cdot \mu_p + \sin\alpha_u\right) + const_4 \cdot \frac{\left(v_{ul_1}^2 + v_{iz_1}^{2\ldots}\right)}{2}\right)}, a_{rot} < 0, \tag{3.4}$$

$$l_{rot} = \frac{m_v \cdot \left(v_{ul_1}^2 - v_{iz_1}^2\right)}{2 \cdot \left(a_{rot} \cdot m_v + G_v \cdot \left(\cos\alpha_u \cdot \mu_k + \sin\alpha_u\right) + const_4 \cdot \frac{\left(v_{ul_1}^2 + v_{iz_1}^{2..}\right)}{2}\right)}, a_{rot} \geq 0, \quad (3.5)$$

where μ_p and μ_k represent sliding and rolling friction coefficients. Overtaking duration time could be found on the basis of expression (3.6) for the overtaking vehicle and according to (3.7):

$$t_{v_1} = \frac{2 \cdot l_p}{v_o + v_{ul_1}} + \frac{l_{rot}}{\left(v_{ul_1} + v_{iz_1}\right) \cdot \frac{1}{2}}, \quad (3.6)$$

$$t_{v_2} = \frac{l_p}{v_2} + \frac{r_2 \cdot \alpha_2[rad]}{v_2}. \quad (3.7)$$

Conflict of the vehicles will occur if $t_{v_{,1}} > t_{v_2}$. Loss of vehicle stability due to detaching rear wheels off the roadway line will appear in the cases when reactions on the rear wheels in curves 1 and 2:

$$F_{b_1} = \frac{F_{in_{rot}} \cdot h_c + G_v \cdot \left(\cos\alpha_p \cdot l_1 + \sin(\alpha_p) \cdot h_c\right)}{l_v}, \text{ and } F_{b_2} = \frac{F_{in_{rot}} \cdot h_c + G_v \cdot \left(\cos\alpha_u \cdot l_1 + \sin(\alpha_u) \cdot h_c\right)}{l_v},$$

where inertia force is in the form: $\vec{F}_{in\,rot} = m_v \cdot \vec{a}_{rot}$, respectively, become less then zero. In such cases program routines are to correct F_b by increasing roadway slope in the form:

$$\text{if } F_{b_1} < 0 \Rightarrow \alpha_u = \alpha_u + \Delta\alpha_u, \text{ and if } F_{b3} < 0 \Rightarrow \alpha_p = \alpha_p + \Delta\alpha_p.$$

4. SOFTWARE FOR OVERTAKING AND ANALYSIS OF RESULTS

Analysis of vehicle stability is realized using the program package: ACADPRET, implemented by the author of the paper at the Academy of Applied Technical Studies in Belgrade. The program package foresees the establishment of appropriate accelerations/decelerations on the straight section in order to enable overtaking and during the rotation so that there is no loss of stability and no conflict of the overtaking vehicle with the overtaken. Output files from calculation are as follows:

ANALYSES OF OVERTAKING IN THE CURVE TO THE LEFT
ROADWAY DATA

Roadway curve radius R_2: 250 [m], Longitudinal roadway slope: 4 [%], Lateral roadway slope:-.5 [%],
Rectilinear section lenth l= 300 [m], Sliding friction coefficient: .2, Rolling friction coefficient: .02,
Established radius of the curve corresponding to returning vehicle in front of the one being overtaken: 56.78 [m],
Angle of the arc corresponding vehicle to returning in front of the one being overtaken: 60 [step],
Length of the path corresponding vehicle to returning in front of the one being overtaken: lrot= 73.69 [m].

VEHICLE DATA

Overtaken vehicle speed: 25 [km/h], Duration of time spent by the vehicle being overtaken Tv2= 43.19 [sec.]
Front area of the overtaking vehicle: 2 [m^2] Mass of overtaking vehicle 1000 [kg]
Aerodinamic coefficient of the overtaking vehicle: .35 Center of gravity hight for overtaking vehicle: .5 [m]
Interaxial distance for overtaking vehicle : 3.2 [m] Horizontally distance from front axis to center of gravity for overtaking vehicle: 1.5 [m]

EXPLANATION OF THE SIGNS

au - acceleration / deceleration on rectilinear section
Venter1 – Speed with which vehicle enters in front of the vehicle being overtaken [km/h]
Vexit1 – Speed with which vehicle enters in the roadway curve [km/h]
Vexit1limit – Boundary speed with which vehicle could leave the curve in front of the vehicle being overtaken [km/h]
Venter2limit – Boundary speed with which vehicle could enter in the roadway curve [km/h]
Brot – Deceleration on the curvilinear section [m/s^2]
Fb1 – Reaction on the rear wheels in the curve: 1 [kN]
Fb3 - Reaction on the rear wheels in the curve: 2 [kN]
Tv1 – Duration of the overtaking time for overtaking vehicle [sec.]
Tv2 - Duration of the overtaking time for vehicle being overtaken [sec.]
Vmax – Maximum permissible speed [km/h]
alfau - Longitudinal roadway slope – established
alfap - Lateral roadway slope - established

Difference between that one and the speed with which vehicle enters the curve 1 is criteria for obtaining the value of deceleration. Figure 4 shows the diagrammatically dependence of acceleration along the rectilinear section and the acceptable total overtaking time from the speed at the beginning of overtaking for specific permissible maximum speed.

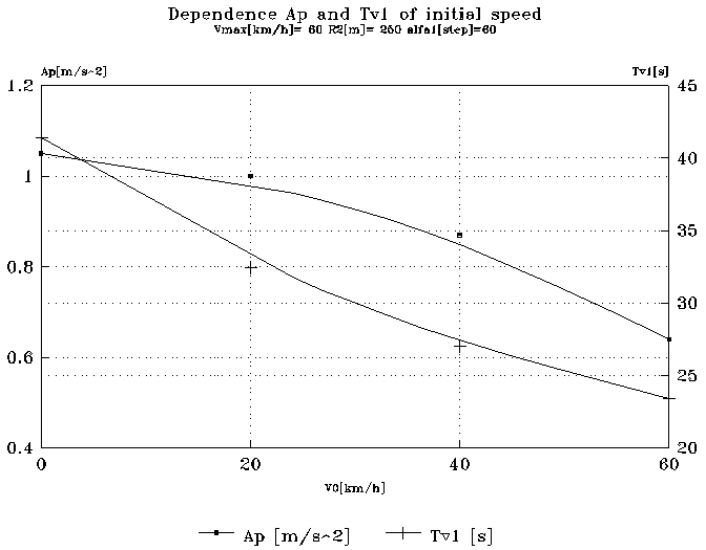

Figure 4. Dependence of acceleration along the rectilinear section and the acceptable total overtaking time from the speed at the beginning of overtaking
Source: ACADPRET, Harward Graphics and Authors

From calculation, it is clear that acceleration on the rectilinear section rises by growing the maximum of the permissible speed. On the other side that acceleration decreases by growing the speed on the beginning of overtaking. Deceleration along the curvilinear section rises with the growing the speed at the end of rectilinear section as well as with the lateral slope if it rises in minus direction. Also it is clear that speed with which vehicle exits the curve 1 is imposed with the lower of two boundary speeds.

5. CONCLUSION

The paper deals with the physics of vehicle behavior during overtaking in a left turn. In doing so, the critical case was chosen when the vehicle, during overtaking, enters a curve with the center on the opposite side from the center of the roadway curve, after which it enters the roadway curve. The work deals with cases of possible loss of stability due to vehicle skidding after returning in the roadway line, in front of an overtaken vehicle and when enter a roadway curve, afterwards. Drifting is caused by a discrepancy between vehicle speed at critical points, due to inappropriate acceleration / deceleration and roadway parameters. Loss of stability can also occur due to the redistribution of the load on the vehicle caused by sudden braking and in conjunction with specific boundary conditions from the roadway aspect. Based on that, the main contribution of the Paper is formation coupling of the roadway parameters with the imposed boundary conditions of vehicle movement.

THE LATEST STANDARDS OF ROLLING BEARING TESTING

Misković Žarko[1], Faculty of Mechanical Engineering, University of Belgrade
Zoran Stamenić[2], Faculty of Mechanical Engineering, University of Belgrade
Jovana Antić[3], Faculty of Mechanical Engineering, University of Belgrade
Radivoje Mitrović[4], Faculty of Mechanical Engineering, University of Belgrade

Abstract: *The wide use of rolling bearings requires a high level of control. Bearing damage can lead to serious consequences such as equipment failure, loss of control, human injury, increased maintenance costs, and issues with quality control. To reduce these risks, it is crucial to have bearings thoroughly tested and confirmed for their properties and accuracy before they are introduced to the market and put into use. In Serbia, this is achieved through the engagement of two accredited laboratories specializing in rolling bearing testing. These laboratories adhere to standards and regulations mandated by the state. By performing measurements and assessing permitted deviations for specific properties, they ascertain whether a bearing can effectively fulfill its intended function. The standards and methods for rolling bearing testing used in the LIMES laboratory (Laboratory for testing machine elements and systems) are presented in this paper.*
Keywords: standards, rolling bearings, measuring, tolerances, hardness, vibrations

1. INTRODUCTION

Standards have significant importance because they bring social, economic and technological benefits. For example, the whole planet benefits from standards that help protect the environment, such as standards for air and water quality, soil, gas emissions, and radiation. Also, standards related to traffic safety, machinery, tools, and similar areas contribute to the overall quality of life. In the field of economy and technology, standards enable a presence in global markets and a broader product offering, facilitate trade between countries, accelerate the penetration and application of innovations (particularly standards in terms of terminology, compliance, and safety), ensure product and service compliance with standards ensures their quality, safety, reliability etc.

1.1 History of standardization

Today's standardization is considered to be based on industrial standardization related to the middle of the 19th century and the development of the railway industry. The primary goal was to produce individual parts independently at different places and enable assembly at a third location without the need for subsequent processing or modification. The production of weaponry, firefighting equipment, machine tools, and later automobiles played a significant role in the development of industrial standardization.
In the beginning, standardization was developed within individual factories, and then it extended to related factories within the same industrial sector. Following that, standards were introduced that were valid at the state or regional level. These days, every developed nation has its own bodies where

[1]zmiskovic@mas.bg.ac.rs
[2]zstamenic@mas.bg.ac.rs
[3]jrantic@mas.bg.ac.rs
[4]rmitrovic@mas.bg.ac.rs

members are representatives from manufacturers, consumers, and scientific institutions. Finally, in order to harmonize standards at the global level, ISO was founded.

2. ISO (INTERNATIONAL ORGANIZATION FOR STANDARDIZATION)

ISO (International Organization for Standardization) is an independent, non-governmental international organization with a membership of 169 national standards bodies. ISO was founded on February 23, 1947. Up to date, it has published 24987 international standards, covering almost all aspects of technology, management, and manufacturing [1]. It has 824 technical committees (TCs) and subcommittees (SCs) to oversee standards development. The organization develops and publishes standardization in all technical and nontechnical fields, except for electrical and electronic engineering, which is handled by the IEC.

3. ISS

The Institute for Standardization of Serbia (ISS) is the sole national body for standardization in the Republic of Serbia. The founder of the Institute is the Government of the Republic of Serbia. ISS issues Serbian standards, which are indicated by a designation that begins with the abbreviation “SRPS”, followed by a sequence of numbers and letters that precisely identify the standard.
For example, in the case of the "SRPS ISO 1132-2:2017" standard, the meaning of the parts of the designation is as follows: "SRPS" indicates that it's a Serbian standard; "ISO" indicates that it's based on an international standard by the International Organization for Standardization; "1132-2" is the specific identifier for this standard within the ISO series; and "2017" represents the year when the standard was adopted or published.

4. BEARING

In a bearing, the connection between moving and stationary parts of a structure is achieved, namely, between parts rotating at different angular speeds. Relatively moving surfaces can exhibit either roll or slide against each other, leading to the classification into rolling bearings and plain bearings.
In the case of plain bearings, the moving surface slides along the stationary surface of the bearing's housing. To reduce friction, lubricant is introduced between the surfaces, and the bearing housing is typically made from materials with a low coefficient of friction.
Rolling bearings enable rolling friction to predominate during the relative motion of the working surfaces by inserting rolling elements, such as rollers or balls, between the stationary and moving surfaces.

4.1 The importance of bearing control

Depending on the nature of the damage and the intended function, bearing damage in mechanical systems can lead to a variety of dangerous consequences. Numerous machines and equipment depend significantly on their bearings, which might fail and cause a number of operational and safety issues. Potential dangers resulting from bearing damage include:

- Equipment failure: Damage to the bearings may result in total failure of the machinery (unexpected standstill, lost output, and expenses).
- Loss of control: In certain situations, such as in vehicles or airplanes, bearing damage can lead to unwanted vibrations and loss of control that can cause accidents and injuries.
- Fire and explosion: High friction resulting from damaged bearings can produce heat, which can lead to an explosion or fire, particularly in areas where flammable materials are present.
- Human injury: When bearing failure occurs, equipment may move unexpectedly and violently, injuring people around it.

- Increased maintenance costs: Frequent bearing damage can increase maintenance and repair costs, reducing the profitability and reliability of the machinery.
- Issues with quality control: Damage to bearings during precise manufacturing can compromise the accuracy and quality of the items produced, resulting in potential recalls and product issues.
- Etc.

This is why stringent bearing control is essential. In this paper, the focus will be on testing rolling bearings. In order to protect the country's economy, it is essential to pay attention to the quality of the bearings that are introduced to the market and put into use. For that purpose, the Republic of Serbia has adopted „Rulebook on technical and other requirements for rolling bearings" [8] and some standards that prescribe the conditions that the bearing must fulfill. Compliance with the conditions specified in those documents is determined in certified laboratories.
In the Republic of Serbia, there are two certified laboratories for rolling bearing testing. One of them is located within the rolling bearing factory FKL in Temerin. The other one is laboratory LIMES (Laboratory for testing machine elements and systems), located at the Faculty of Mechanical Engineering in Belgrade (Fig. 1).

Figure 1. Laboratory LIMES (Laboratory for testing machine elements and systems)
Source: Laboratory LIMES

This paper will present standards and methods used in certified laboratory LIMES.
The standards adopted by ISS that are used for rolling bearing control in LIMES are:

- Tolerances and radial clearance: SRPS ISO 1132-2:2017
- Hardness: SRPS ISO 6508-1:2017
- Vibrations:
  - SRPS ISO 15242-1:2018
  - SRPS ISO 15242-2:2018
  - SRPS ISO 15242-3:2018

5. TOLERANCE - SRPS ISO 1132-1:2016, SRPS ISO 1132-2:2017

The "SRPS ISO 1132-1:2016" standard was adopted on December 23, 2016, replacing the "SRPS ISO 1132-1:2015" standard. This standard is identical to ISO 1132-1:2000, Rolling bearings – Tolerances –Part 1: Terms and definitions.

The "SRPS ISO 1132-2:2017" standard was published on June 26, 2017. and replaced the "SRPS M.C3.800:1965". This standard is identical to ISO 1132-2:2000, Rolling bearings – Tolerances – Part 2: Measuring and gauging principles and methods.

The preparation for tolerance testing involves several steps. First, it is necessary to bring the measuring equipment, the reference standard (etalon), and the part being tested to room temperature (the recommended value is 20°C). Then, it is necessary to remove the anti-corrosion agent from the bearing surfaces to eliminate the possibility that the lubricant and a sealing or protective ring adversely affect the accuracy of the measurement, which is conducted on open bearings.
After the measurement, the bearing should be protected from corrosion.

5.1 Measurement principle of bore and outside diameter

Measuring devices for bore and outside diameter testing are different, but the principle of measurement is the same. This method can be applied to all types of rolling bearings. The first step is to zero the measuring indicator using an etalon. After the rolling bearing is positioned, the smallest and largest bore and outside diameter are measured in several radial planes. Based on these values, the average diameter, diameter deviation, and diameter variation are determined. Allowable tolerances are standardized, and based on them, it is determined that the diameters (bore or outside diameter) of the given rolling bearing are within allowed limits.

5.2 Measurement principle of radial clearance

The bearing is mounted on a mandrel. Then, the indicator is positioned toward the outer surface of the outer ring, in the direction of the centre of the rolling path. The mandrel rotates the inner ring. Radial load is applied, and it is possible to read the value of radial clearance on the scale.

6. HARDNES - SRPS EN ISO 6508-1:2017

The "SRPS EN ISO 6508-1:2017" standard was adopted on April 30, 2018, replacing the "SRPS EN ISO 6508-1:2016" standard. This standard is identical with EN ISO 6508-1:2016, Metallic materials – Rockwell hardness test –Part 1: Test method.

The measurement principle of the Rockwell method involves applying an initial (preload) force to indent the indenter. Then, an additional force is applied, and upon its termination, the force value returns to the initial value. Afterward, the depth of the indentation is measured. Many digital devices measure the depth, but they only display the hardness value.
To calculate hardness using the Rockwell method, in addition to the difference between the initial and final indentation depth (h), it is necessary to determine two more constants that depend on the scale (N and S) and apply the following formula:

$$\mathrm{HR} = N - \frac{h}{S} \tag{1}$$

The indenter can be in the form of a diamond cone or ball made of a tungsten carbide alloy. In LIMES, the HRC (Rockwell C) scale is used. In that case, the indenter type is diamond cone, the initial force (F_0) is 98.07 N, the total force (F) is 1.471 kN, the scale constant (S) is 0.002 mm, the full-scale constant (N) is 100, and the hardness range is from 20 HRC to 70 HRC, although the values below 35 HRC are unreliable. The formula for calculating HRC hardness is:

$$\mathrm{HRC} = 100 - \frac{h}{0.002} \tag{2}$$

Although there are many approximate conversion tables, there is no reliable way to accurately convert hardness measured on one scale to another (HB or HV) or to tensile strength.

7. VIBRATION

7.1 SRPS ISO 15242-1:2018

The "SRPS ISO 15242-1:2018" standard was adopted on March 26, 2018. and replaced the "SRPS ISO 15242-1:2016 " standard. This standard is identical to ISO 15242-1:2015, Rolling bearings – Measuring methods for vibration – Part 1: Fundamentals.

According to this standard, to determine the vibrations of a rotating rolling bearing, a measuring transducer is placed at a specific location on one of the bearing rings or on a device connected to one of the rings. The standard prescribes that the quantity to be measured is the speed of vibrations. The bearing under the determined load rotates at a constant frequency of rotation, and the signal from the measuring transducer is monitored. In the vast majority of cases, the outer ring is stationary and the inner ring is movable (although rare cases may have the opposite configuration).
The conditions required for vibration measurement depend on whether the bearings are pre-lubricated or not. If the bearings are previously lubricated, they are measured in the delivered condition. Previously unlubricated bearings should be thoroughly cleaned and lubricated with fine-filtered oil. Afterward, it is necessary to run-in the bearing in order to achieve a homogeneous distribution of the lubricant.
There are three scales on the vibration measuring device for three frequency ranges. Permitted values for each range can be found in the Rulebook on technical and other requirements for rolling bearings [8].

7.2 SRPS ISO 15242-2:2018

The "SRPS ISO 15242-2:2018" standard was adopted on March 26, 2018, replacing the "SRPS ISO 15242-2:2016" standard. This standard is identical to ISO 15242-2:2015, Rolling bearings – Measuring methods for vibration – Part 2: Radial ball bearings with cylindrical bore and outside surface.

As the title suggests, this part of the standard provides a detailed discussion of radial ball bearings. During the testing of these bearings, the rotation frequency should be 1800 min^{-1} (30 s^{-1}), with a specified tolerance range. Additionally, an axial load is applied to the bearing; first on one side of the stationary ring, and then the measurement is repeated with the load on the other side. Except in the case of single-row angular contact ball bearings. For their testing, the axial force acts in the direction of receiving the axial load of the bearing. Before measuring, it is necessary to position the measuring transducer on the outer surface of the stationary ring in the plane that is in the middle of the rolling contact path of the stationary ring.

7.3 SRPS ISO 15242-3:2018

The "SRPS ISO 15242-3:2018" standard was adopted on March 26, 2018, replacing the "SRPS ISO 15242-3:2016" standard. This standard is identical to ISO 15242-3:2017, Rolling bearings – Measuring methods for vibration – Part 3: Radial spherical and tapered roller bearings with cylindrical bore and outside surface.

This document refers to double-row radial cylindrical roller bearings and to single-row and double-row radial tapered roller bearings. The rotation frequency for measurements should be 900 min^{-1} (15 s^{-1}), and the measurement time should be at least 1 second.
Vibrations of double-row cylindrical roller bearings and tapered roller bearings are measured using a similar approach as that for radial ball bearings. However, for single-row radial tapered-rolled bearings, a specific loading force is applied in the direction of receiving the axial load.

When conducting measurements, it is necessary to position the measuring transducer on the outer surface of the stationary ring in the plane that is in the middle of the rolling contact path of the stationary ring.

8. CONCLUSION

In the Republic of Serbia, there are two accredited laboratories for testing rolling bearings. They use standards and regulations mandated by the State. On the basis of measurements and the permitted deviations of certain values, they determine whether the bearing corresponds to the customer order or prescribed technical documentation. The main contribution of this paper is to clarify the methods and standards used in the control of rolling bearings and to raise awareness about the importance of strict control measures for these bearings. By emphasising the role of thorough testing in accredited laboratories before market introduction, the paper aims to underscore that such measures not only protect end-users from potential hazards like equipment failure and human injury but also serve as a safeguard for manufacturers. A strict control system not only ensures the introduction of higher quality bearings but also contributes to establishing a competitive market environment. By raising the standard, it encourages innovation and quality production, ultimately benefiting manufacturers, customers, and the overall economic health of the country.

SOLAR-POWERED FARMING: EVALUATING THE VIABILITY OF PV WATER PUMPING IN TURKISH AGRICULTURE

Murat Ispir[1], Department of Mechanical Engineering, Konya Technical University, Konya, Türkiye
Ilker Goktepeli[2], Department of Mechanical Engineering, Konya Technical University, Konya, Türkiye
Muharrem H. Aksoy[3], Department of Mechanical Engineering, Konya Technical University, Konya, Türkiye

Abstract: *This study investigates the viability of solar photovoltaic (PV) water pumping systems in three Turkish cities, Antalya, Aydın, and Samsun, focusing on their efficacy in agricultural irrigation. The research uses PVsyst software to examine the interplay between solar irradiation, water demand, and pump efficiency. Results reveal varying effectiveness among the provinces due to disparities in solar irradiation. Antalya and Aydın meet 97.69% and 96.43% of their annual water needs, respectively, while Samsun achieves only 73.99%, emphasizing the critical role of irradiation intensity. Evaluation of unused energy demonstrates surplus of 263 kWh for Antalya, 39 kWh for Aydın, and optimal energy utilization for Samsun. The Performance Ratio (PR) analysis underscores higher efficiency for Samsun due to its lower irradiation levels. These findings contribute valuable insights for regional solar energy applications, emphasizing the significance of location-specific strategies in advancing renewable energy technologies.*
Keywords: Solar Photovoltaic Systems, Agricultural Irrigation, Solar Irradiation, Water Pumping Efficiency, Renewable Energy Applications

1. INTRODUCTION

Energy efficiency is crucial globally since energy sources tend to decrease with increasing population. Renewable energy resources are utilized as alternatives to traditional ones. For instance, solar energy is clean and environmentally friendly without requiring maintenance [1]. It is also related to the availability of solar energy and water demand [2]. However, the negative effects of local drought and global warming on water resources should be considered. Considering these issues, more efficient agricultural irrigation is an important factor that could reduce the risk of threatening water sources. It is well-known that a pump is one of the critical elements for agricultural irrigation. Electrical energy and fossil fuels are widely used for the operation of pumps.

Nonetheless, the electricity availability of rural areas is a matter of general debate [3]. The same situation could be valid for fossil fuels. Mainly, shortfalls in the water pumping system could be provided via rainwater [4]. However, it may not be possible for all climate conditions. For this reason, alternative energy resources are also considered for the power requirement of the pumps. Based on these deductions, solar photovoltaic (PV) water pumping systems are significant for protecting water resources and are effective for energy sources. Solar PV water pumping systems are observed for areas without grid connections [5].

Additionally, surplus energy generated by the solar pumping systems can be effectively utilized for various supplementary needs. The pumps operate exclusively on solar energy in regions with abundant solar radiation. However, in cases where solar radiation is insufficient, an alternative energy source is required to ensure the continuous operation of the pumps. Moreover, cleaner drinking water

[1]mispir@ktun.edu.tr
[2]igoktepeli@ktun.edu.tr
[3]mhaksoy@ktun.edu.tr

could be supplied via solar PV water pumping systems [6]. For livestock water supply, these systems are also used [7]. The previous studies examined overall efficiency, component efficiency, economical availability, and design optimization for these systems [2]. One of these deductions is that the pump flow rate depends on solar radiation and PV array size [8]. For this reason, these systems are very influential in regions where greenhouse cultivation is intense. Loxsom and Durongkaveroj [9] compared four locations in the USA by using a developed algorithm related to solar PV water pumping systems. The total volume of pumped water has been predicted monthly by considering solar insolation data. Similarly, Kou et al. [10] used weather data, including horizontal radiation and temperature, to estimate long-term system performance in the USA. Arab et al. [11] considered four different stations in Algeria to analyze the system performance based on meteorological year data. The system optimization has been presented as a result of various configurations. Pande et al. [12] considered a pump for drip irrigation in arid zones. Several parameters have been taken into account for their system. Benghanem et al. [13] proposed an optimum array design supplying ideal energy for a pump used in Saudi Arabia. Setiawan et al. [14] recommended two significant parameters of solar water pumping system for India. Ammar et al. [15] estimated PV power to balance generated energy and pump requirements. Miran et al. [16] presented the optimization result for the design of a PV drip irrigation system.

2. MATERIAL AND METHODS

In this study, simulations for solar PV water pumping systems have been made for three provinces of Türkiye consisting of Antalya, Aydın, and Samsun, using PVsyst software. It is known that plants grown in summer need more water than plants grown in winter. Therefore, water need varies according to months, as in the simulation. The monthly water needs for the simulation have been given in Table 1.

Table 1. The variations in daily average water requirements for different months

Months	Daily Average Water Need	Months	Daily Average Water Need
January	70 m³/day	July	110 m³/day
February	80 m³/day	August	105 m³/day
March	90 m³/day	September	100 m³/day
April	100 m³/day	October	90 m³/day
May	105 m³/day	November	80 m³/day
June	110 m³/day	December	70 m³/day

Table 2. Drilling, well, and tank characteristics

Characteristics	Value	Characteristics	Value
Static level depth	-40 m	Number of elbows	2
Specific drawdown	-3 m/m³/h	Friction losses	0.5 m
Well Diameter	15 cm	Tank volume	150 m³
Pump level	-90 m	Diameter of tank	5 m
Lower dynamic level	-85 m	Pipe type	DN65
Pipe length	95 m	Tank altitude	5 m

The head is an important parameter for pump applications. In order to start the simulation, drilling and the well characteristics must be determined. Drilling, well, and tank properties used in the simulations have been given in Table 2.
Hydraulic power is calculated with the expression presented in Eq. (1) using the properties given in Table 2.

$$P_H = \frac{\rho\ g\ H\ \dot{Q}}{3.6 \times 10^6} \tag{1}$$

In this equation, ρ is water density, g is gravitational acceleration, H is static level depth, and $\dot{Q}$ is water flow rate. A pump driver converts electrical energy into shaft energy. In this case, certain losses occur while converting hydraulic power into shaft power. The shaft power of the pump is obtained as the ratio of the hydraulic power to the hydraulic efficiency of the pump (η_H), as in Eq. (2).

$$P_S = \frac{P_H}{\eta_H} \tag{2}$$

The energy required for the pump shaft is obtained from PV systems. Energy attained from PV systems is also subjected to certain losses while being transmitted to the shaft. The PV power (P_{PV}) is provided by using the shaft power of the pump. PV power is the ratio of the pump shaft power to the derate factor (DF), as seen in Eq. (3).

$$P_{PV} = \frac{P_S}{DF} \tag{3}$$

The parameters of the system have been given in Table 2, and the expressions of Eq. (1), (2), and (3) have been indicated in Table 3.

Table 3. Power of the pump and PV system used in agricultural areas

Parameter	Value
ρ	1000 kg/m^3
g	9.81 m/s^2
H	40 m
$\dot{Q}$	15 m^3/h
P_H	1.635 kW
P_S	4.672 kW ~ 4.8 kW
DF	0.825
P_{PV}	6 kW

Pump power has been determined as 4.8 kW for the pump, with a daily average flow rate of 92.5 m³/day. Four PS-1800 HR-14H models from the Lorentz brand with 1.2 kW power have been chosen as pumps connected in series. The PV system providing the pump power has been determined as 6 kW. Twenty units of LG 300 N1C-B3 models with 300 W from LG Electronics have been used as the PV module. PV modules consist of five strings and four series. In all systems, a tilt angle of 35° and an azimuth angle of 0° have been used.

3. RESULT AND DISCUSSION

Effective global irradiation is one of the most important parameters affecting the efficiency of PV systems [17-20]. Monthly average practical global irradiation values of Antalya, Aydın, and Samsun provinces considered within the scope of the study have been given in Figure 1.

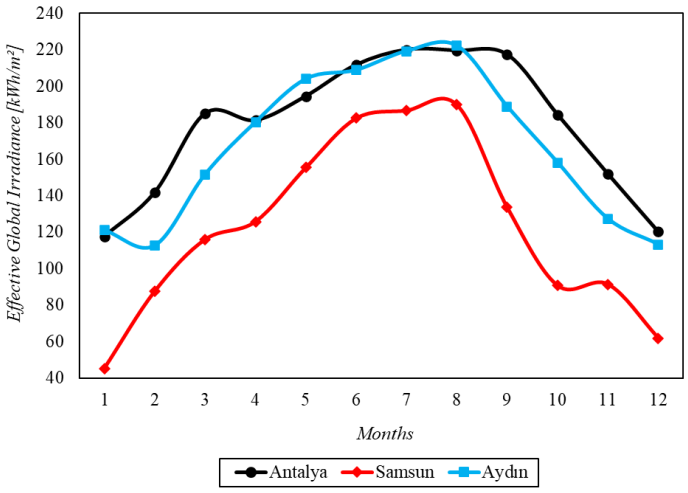

Figure 1. Monthly average effective global irradiation values of Antalya, Aydın, and Samsun

Table 4. Water needs of the system and water supply amounts of three cities

Months	Volume of water needs [m³]	Antalya		Aydın		Samsun	
		Volume of water used [m³]	Adequacy percentage [%]	Volume of water used [m³]	Adequacy percentage [%]	Volume of water used [m³]	Adequacy percentage [%]
January	2170	1921	88.53	2056	94.75	985	45.39
February	2240	2240	100.00	2005	89.51	1631	72.81

November	2400	2400	100.00	2174	90.58	1635	68.13
December	2170	2092	96.41	2034	93.73	1196	55.12
Overall	**33780**	**33001**	**97.69**	**32575**	**96.43**	**24994**	**73.99**

As expected, effective global irradiation increases towards the summer months and decreases towards the winter months in all cities. These irradiation values reaching the panel surface appear higher in Antalya and Aydın, located in the southern part of Türkiye, compared to Samsun, located in the north of Türkiye. Effective global irradiation values are 2145.7 kWh/m², 2007.5 kWh/m², and 1466.8 kWh/m² for Antalya, Aydın, and Samsun, respectively. Since the irradiation reaching the panel surface affects electricity production and system performance, the pump systems in Antalya and Aydın pump water. The water needs of the simulated system and the amounts of water pumped for the three cities have been shown in Table 4.

Water supply percentages are 97.69%, 96.43%, and 73.99% for Antalya, Aydın, and Samsun, respectively. For monthly examination, the entire water need is met in February, September, October, and November for Antalya, while it is only met in August and September for Aydın. On the other hand, the same situation is not valid for Samsun in any month. In addition to the amount of water pumped in these systems, many results could be obtained, such as unused energy in PV systems. The main results of these systems have been presented in Table 5.

Table 5. Main results the considered solar PV pumping systems

	Antalya	Aydın	Samsun
Water used	33001 m³	32575 m³	24994 m³
Specific volume	794 m³/kWp/bar	788 m³/kWp/bar	652 m³/kWp/bar
Water needs	33780 m³	33780 m³	33780 m³
Missing water	2.31 %	3.57 %	26.01 %
Energy at pump	10472 kWh	10126 kWh	7584 kWh
Specific energy	0.32 kWh/m³	0.31 kWh/m³	0.30 kWh/m³
Unused PV energy	263 kWh	39 kWh	0 kWh
Unused fraction	2.3 %	0.4 %	0 %
PV System efficiency	93.2 %	95.3 %	94.8 %
Pump efficiency	65.8 %	66.2 %	66.1 %

A critical significance metric is the surplus energy within PV systems. Specifically, the energy surplus in PV systems amounts to 263 kWh, 39 kWh, and 0 kWh for Antalya, Aydın, and Samsun, respectively. Within the PVsyst software framework, the Performance Ratio (PR) is an essential parameter utilized, a value computed according to Equation (4). This metric stands as a pivotal indicator, reflecting the efficiency and effectiveness of the PV systems under consideration.

$$PR = \frac{Energy\ at\ pump}{Incident\ global\ irradiation \times P_{PV}} \tag{4}$$

Annual incident global irradiation values are 2195.9 kWh/m², 2057.2 kWh/m², and 1502.1 kWh/² for Antalya, Aydın, and Samsun, respectively. Annual and monthly average PR values for Antalya, Aydın, and Samsun have been shown in Figure 2.

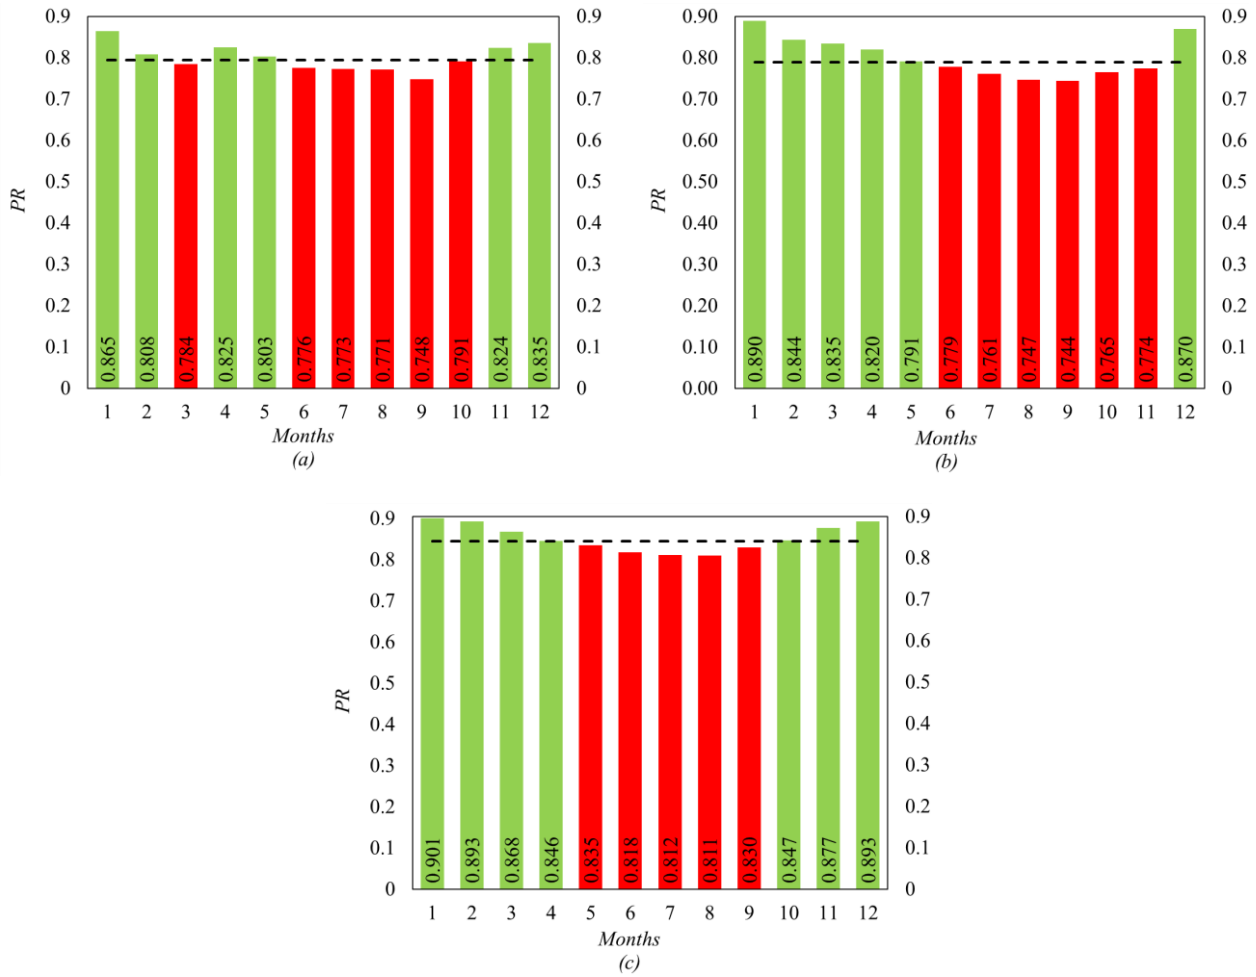

Figure 2. Annual and monthly average PR values of *(a)* Antalya, *(b)* Aydın, and *(c)* Samsun

The annual average PR values of Antalya, Aydın, and Samsun are 0.795, 0.820, and 0.841, respectively. Since PR is inversely proportional to the irradiation intensity reaching the panel surface, it is maximum in Samsun and minimum in Antalya.

4. CONCLUSIONS

The present study modeled the PV system-assisted pump system for three cities, including Antalya, Aydın, and Samsun, via PVsyst. The following statements have been listed as given below.

- Effective global irradiation values are 2145.7 kWh/m², 2007.5 kWh/m², and 1466.8 kWh/m² for Antalya, Aydın, and Samsun, respectively.
- Antalya and Aydın exhibited commendable performance, meeting 97.69% and 96.43% of their annual water needs, respectively. In contrast, Samsun achieved a modest 73.99%, underscoring the pivotal role of solar irradiation levels.
- Notably, Antalya demonstrated an unused energy surplus of 263 kWh, Aydın 39 kWh, and Samsun efficiently utilized all generated energy.
- Additionally, the PR analysis reinforced these findings, with Antalya, Aydın, and Samsun exhibiting annual average PR values of 0.795, 0.820, and 0.841, respectively.

While the system seems quite suitable for Antalya and Aydın, the 6 kWp PV system is insufficient for Samsun due to insufficient irradiation intensity. It is recommended to increase the installed capacity of the PV system for Samsun.

These findings underscore the critical importance of location-specific strategies in advancing renewable energy technologies. The study offers valuable insights into regional solar energy applications, emphasizing the need for tailored approaches in harnessing the potential of solar PV water pumping systems for sustainable agricultural practices.

Future studies could explore these systems' economic feasibility and scalability on a larger agricultural scale, considering varying crops and regional water demands, which would provide valuable insights for sustainable agricultural practices.

Abstract: *Considerable amount of power produced worldwide is obtained from hydropower plants (HPPs). This remains one of the cleanest available renewable power sources. Initial investment in construction of HPPs is often high and their life cycles span decades in almost continuous operation. This is the reason why revitalization of exhisting hydropower facility may be viable choice compared to building a new one. Revitalization of HPP consists of many tasks and has to take into account various phenomena. Unsteady regimes both in water supply systems or HPPs, precisely in their pipelines, could be very harmful and dangerous and might provoke damage of the critical infrastructure when they ocurre. Paper reviews various aspects of Kaplan turbine maintenance and causes of downtime. More than hundred years since its inception, Kaplan turbine remains in use worldwide in many of the hydropower facilities. In more detail the phenomena of rigid and reverse waterhammer are explored and examined in this paper. Both rigid and reverse waterhammer, if occure during exploitation of HPP, can result in many negative consequences on its operation. On site measurements are combined with numerical simulations to suggest values of parameters of influence in order to prevent both these harmfull phenomena to appear.*
Keywords: Kaplan Turbine, Measurements, Numerical Simulations, Reverse and Rigid Water-hammer

1. INTRODUCTION

Kaplan turbine has been designed more than 100 ago. Still this type of turbine is in use in many hidro-power plants throughout the world and remains in focus of reserchers, designers and builders [1-5]. When a hydropower plant (HPP) is planned and designed initial cost of investment is high. This is the reason why it is viable choice to revitalize existing HPP instead of building a new one in some cases (and in some places). Revitalization of a HPP consists of many tasks. One obvious task can be to make transition from legacy technologies to contemporary technologies that often provide new options in plant‘s operation. If it is possible, together with revitalization of the plant, assesment should be made if its capacity can be expanded. Various phenomena should be examined and taken into account. Among these of great importance are transient regimes. Revitalization of the HPP often tries to reach two concurrent goals. One is the increase of the aggregate power and another is the trend to simultaneously reduce the machine dimensions. However, these two aspirations in design make the probability higher for transient regimes to appear in the plant after it is built.

[1]bivljanin@atssb.edu.rs
[2]adjurdjevic@atssb.edu.rs
[3]djdjurdjevic@atssb.edu.rs
[4]nratkovickovacevic@atssb.edu.rs

Transient regimes in technical systems can be the cause of failure or loss. Transient regimes in HPPs can be either normal or emergency. If they appear/ occur in HPPs, water supply systems, in oil pipelines or in pipelines in general, these are very dangerous and may turn harmful to critical infrastructure. Technical diagnostics following issues with transient regimes usually finds visible evidence on a HPP itself. Some consequences of occurrence of transient regimes in a HPP can be visible not just on a plant, but in one country or even throughout the world.

2. REQUIREMENTS OF MATHEMATICAL MODELLING AND MEASUREMENTS

Models should be made as close as possible to the real world systems they tend to be modelling. Kaplan turbine is being modelled in order to optimize its performance [1-5]. Timely and detailed analysis of transient regimes in order to avoid their occurrence contributes to the improvement of operational safety, higher reliability and functional safety of a whole hydropower plant. At the same time the reduction of waste and losses is enabled as well as the number of unwanted issues or events and damages are decreased on minimum. During the analysis of transient regimes in hydropower plants it is necessary to take in consideration inertia and pressure force, friction force and gravitational force, water compressibility and influence of elasticity on tunnel or pipeline walls.
One of the transient regimes in hydropowerplants and pipelines is denoted as reverse waterhammer. Rigid waterhammer is also example of a transient regime in HPP. The theory of rigid waterhammer is the first and the simplest theory among the theories of unsteady streaming. If either of these transient regimes occur this could have many negative consequences on the exploitation of hydropower plant. In order to prevent these unwanted transient regimes (either reverse or rigid waterhammer) to occure and to aleviate their consequences three turbine models were tested in the laboratory conditions [1-3]. All three turbines were of the same runner diameter, namely 9.5 m. Variables of importance and parameters of the models were computed by the numerical software. The first is the model of the existing turbine with specific rotational speed $n_Q = 137$, while the other two models were derived for the two revitalized turbines that have $n_Q = 133$ and $n_Q = 135$ respectively [2, 4].
All three installed Kaplan turbines have the same runner diameter, and results obtained in modelling the reverse waterhammer were similar. However, any of the three turbines did not pass critical values of axial hydraulic force, pressure on the turbine cover, etc. It was difficult at all times to obtain the discharge measurements in huge cross sections, which were within a wide range from 100 m^3/s to 840 m^3/s. For all three cases the high measurement accuracy and repetition of measured results were obtained in measuring the turbine power output (assesed from the generator output), and the variation of the turbine net head due to electricity consumption limitations. Hydraulic and energy turbine characteristics were tested and unit efficiency determined at the net head close to the rated one. Maximal rotational speed for each of the three turbines was obtained and calculated in the relative form/ units based on rotational speed that they achieve each in its own optimum.

3. INFLUENCE ON KAPLAN TURBINES IN HPPS CAUSED BY RIGID WATERHAMMER

The mathematical model of the unsteady discharge is based on the theory of the rigid waterhammer. The model of rigid waterhammer occurrence consists of a system of differential equations describing case of air introduction into the intake behind the inlet wheel gate. This model is simplified by neglecting the fluid compressibility and the elasticity of pipeline walls therefore it assumes that the water in supply pipes behaves like a rigid body.
The model of the turbo machine behaviour during the normal transient regime is determined usually based on the data obtained from the monitoring of the turbine model and expressed in so-called propeller curves. Several positions of runner blades with different values of guide vans opening can be obtained from those propeller curves. The basic equation for studying water masses behaviour is the dynamic balance equation, which is expressed as [2, 3]:

$$\frac{\mathrm{d}h}{\mathrm{d}x}+\frac{1}{g}\frac{\mathrm{d}c}{\mathrm{d}t}+\lambda\frac{c|c|}{2D}=0\,, \tag{1}$$

where the fluid density, ρ, is assumed to be constant. The list of all symbols is given in notations. Mathematical model of rigid waterhammer is applicable on relatively slow change of boundary conditions because fluid is assumed to behave like a rigid body – its compressibility doesn't exist. However if boundary conditions change rapidly, pressure change is high, or even huge and this is significant because it is usually followed by changes in the fluid density. Mathematical model which is derived and applicable under those conditions is well known as the hydraulic waterhammer. This is the case in Kaplan turbines, where the time for a pressure change and discharge change is shorter than the pipeline reflection time. The scheme of a low-net head HPP is given in Figure 1.a) [3], [2].

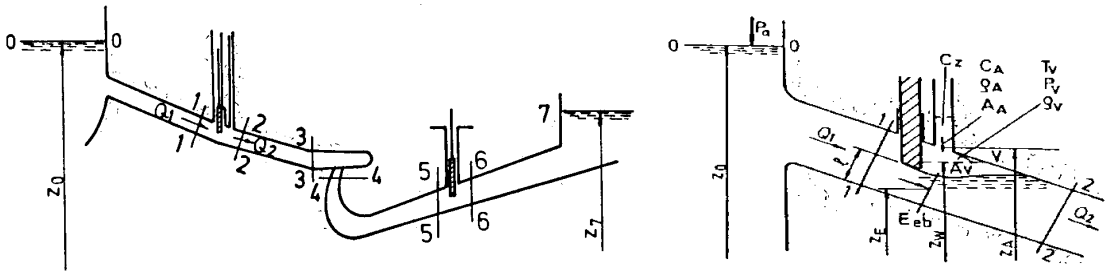

Figure 1. a) Scheme of mathematical model (on the left) [3], **b)** Intake structure (on the right) [3].

Unsteady discharge in the system is described by the following equations [2, 3]:

$$\frac{\mathrm{d}Q_1}{\mathrm{d}t}=\frac{\dfrac{p_a-p_v}{\rho}+g(z_0-z_v)-\sum_0^1\left(\dfrac{\lambda l}{4R_h}+\zeta\right)\dfrac{Q_1^2}{2A^2}}{\displaystyle\int_{l_0}^{l_1}\frac{dl}{A}} \tag{2}$$

$$\frac{\mathrm{d}Q_2}{\mathrm{d}t}=\frac{\dfrac{p_a-p_v}{\rho}+g(z_v-z_7-H)-\sum_2^7\left(\dfrac{\lambda l}{4R_h}+\zeta\right)\dfrac{Q_2^2}{2A^2}}{\displaystyle\int_{l_2}^{l_7}\frac{dl}{A}} \tag{3}$$

When discharges Q_1 and Q_2 are different ($Q_1 \neq Q_2$) and water elevation in the aeration pipe, z_v, is below z_a ($z_v < z_a$), then air discharge appears into the inlet structure (shown in Figure 1.b)). The corresponding equations describing this case are [3], [2]:

$$\frac{\mathrm{d}V_v}{\mathrm{d}t}=Q_1-Q_2\,,\qquad \frac{\mathrm{d}M_v}{\mathrm{d}t}=A_v\rho_v c_z\,,\qquad \frac{\mathrm{d}Z_v}{\mathrm{d}t}=\frac{Q_2-Q_1}{A_v} \tag{4}$$

where

$$\rho_v=\frac{M_v}{V_v}\,,\qquad p_v=\rho_v RT \tag{5}$$

$$c_z=\varphi\sqrt{\frac{2\kappa}{\kappa+1}\frac{p_a}{\rho_a}}\,,\qquad \rho_v=\rho_a\left(\frac{2}{\kappa+1}\right)^{\frac{1}{\kappa-1}},\quad \text{if}\quad p_v\le p_a\left(\frac{2}{\kappa+1}\right)^{\frac{1}{\kappa-1}} \tag{6}$$

$$c_z = \varphi \sqrt{\frac{2\kappa}{\kappa-1}\frac{p_a}{\rho_a}\left[1-\left(\frac{p_V}{p_a}\right)^{\frac{\kappa}{\kappa-1}}\right]}, \quad \rho_V = \rho_a\left(\frac{p_V}{p_a}\right)^{\frac{1}{\kappa}}, \quad \text{if} \quad p_v > p_a\left(\frac{2}{\kappa+1}\right)^{\frac{1}{\kappa-1}} \tag{7}$$

$$\rho_V = \lim_{V_V \to 0} \frac{M_V}{V_V} = \frac{0}{0} = \frac{p_V}{RT_V} \tag{8}$$

$$c_z = \frac{Q_2 - Q_1}{A_V}, \quad p_V = p_a, \quad \rho_V = \rho_a, \quad p_V = p_a - \frac{\rho_a c_z |c_z|}{2\varphi^2} \quad \text{if} \quad c < 40 \text{ m/s} \tag{9}$$

4. INFLUENCE ON KAPLAN TURBINES IN HPPS CAUSED BY REVERSE WATERHAMMER

To prevent reverse waterhammer, ranges for many physical values have to be determined appropriately. Among these neccesarry limit values, maximal and minimal pressure in the system and maximal rotational speed have to be assessed. Analyses of normal transient regimes on HPPs are focused on determination of the maximal net head cover pressure in the system and maximal rotational speed. It doesn't mean that low-pressure field, if appears, cannot endanger system safety especially if cavitation is present. Several different methods exist that can be used to estimate the risk of occurrence of reverse waterhammer; the two of these are: 1. the integral method or average pressure above turbine runner, and 2. the pressure distribution method.

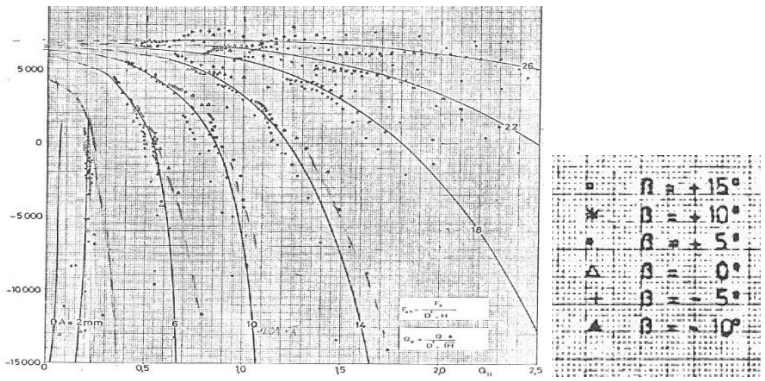

Figure 2. Axial hydraulic characteristics for range of angle β, where $-10^\circ \leq \beta \leq 15^\circ$ [2]

The first method is used in experiment which is described in [2] as well as in this paper. Values of average pressure above runner blade and below net head cover could be determined on the axial hydraulic force data. This force effects runner blades. For the first method it is necessary to obtain values of axial hydraulic force, F_a, by measurements in different stationary working points. It is more convenient to present this force as unit force F_{a11} in function of unit discharge Q_{11} for numerical presentation, see Figure 2. [2]. The curves in Figure 2. depend on values of relative angle of runner blade, β, as well as on the guide vane opening value, a_0. Characteristics shown in Figure 2. are applicable on the biggest Kaplan turbines in Republic of Serbia. Axial hydraulic force during any transient regime can be determined by using these data while neglecting the influence inertia makes on axial force. Unit axial force F_{a11} and unit discharge Q_{11} are given by equations as follows [2]:

$$F_{a11} = \frac{F_a}{D^2 H}, \quad Q_{11} = \frac{Q}{D^2 \cdot \sqrt{H}} \tag{10}$$

5. NUMERICAL SIMULATIONS AND HPP'S OPERATING REGIMES TESTED

Three turbine prototypes were tested with same shape of scroll case, guide vans and stator, except the shape of output edge stator's blades. Normal transient regimes were divided into two groups so that satisfactory and reliable results can be obtained [4], [2]:

- turbine quick closure and stoppage from 100% and 75% of maximal power output, and
- load rejection from 100% and 75% of maximal power output to the idle run.

Tests were based on using rigid waterhammer method and later on were calculated changes of axial hydraulic force (F_a), scroll case pressure (p_{sp}), net head cover pressure (p_{pok}), pressure below runner blades (p_{rk}) and guide vanes servomotor stroke (Y_a). Risk of appearing reverse waterhammer was also estimated during these tests. As a precondition to use numerical code it was necessary to obtain data about the parameters in optimal working point of each turbine (Q_0, H_0, M_0). These parameters are given in Table 1. [2, 4].

Table 1. Parameter values in optimal working point for each of tested turbines [4], [2]

Turbine	Q_0 [m^3/s]	H_0 [m]	P_0 [MW]	M_0 [Nm]	n_Q
A	539.5	27.8	194	19 000 000	137
B	550	28.7	205	19 500 000	135
C	568.62	30	210	20 000 000	133

Tests were performed for two net head values: H_n = 29.0 m and H_n = 26.5 m. Propeller curves refer only to turbine working area. Since the areas of low disharge are not included, all propeller curves have to be extrapolated not only to the areas of low discharge but also to areas with negative net head values. The same refers to $F_{a11} - Q_{11}$ characteristic that was mentioned in the previous chapter.

6. COMPARISON OF CHARACTERISTICS AND PARAMETERS OF INFLUENCE

Comparison of obtained relative values of axial hydraulic forces that refer to nominal working point of the turbine A or exciting turbine is presented in Figure 3. Equation that was used in order to obtain those relative values is described as [4], [2]:

$$F_{a11r} = \frac{F_{a11}}{F_{a11,0}}, \tag{11}$$

where F_{a11} refers to unit axial forces, $F_{a11,0}$ refers to unit axial force in optimal working point and F_{a11r} represents relative value of axial force. All measured axial hydraulic forces` values are achieved for different relative blade`s angles β at particular guide vanes opening values a_0 throughout model tests and test in laboratories.

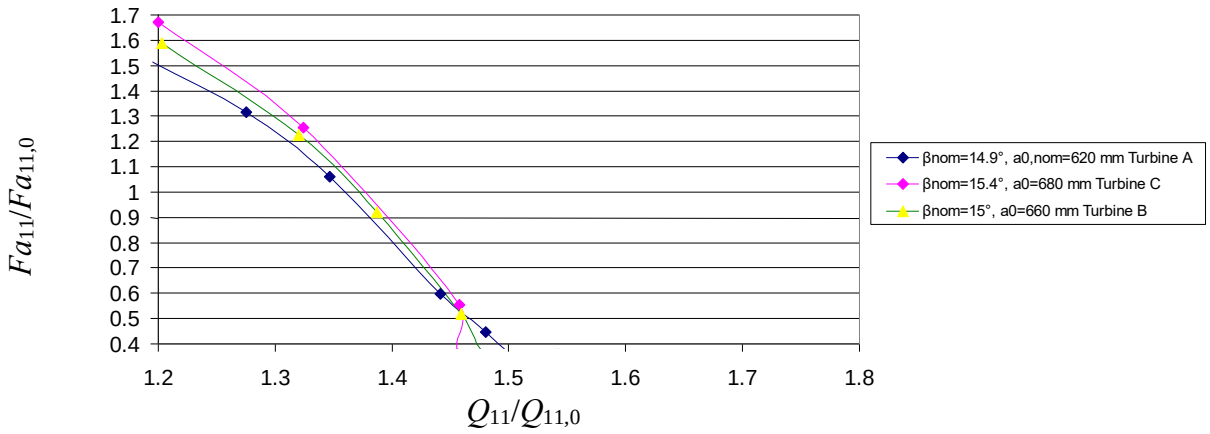

Figure 3. Comparative analysis $Fa_{11} - Q_{11}$ due to nominal point of turbine A [4]

7. CONCLUSION

Transient regimes and their analysis should give the answers about safety and functionality of a hydropower plant in order to obtain its efficient design, setup and exploitation. Here unsteady regimes were carried out and analysed on one hydropower plant. Analyses were fulfilled by using improved numerical programme which consist of extrapolated and interpolated methods that provide secure and reliable results in low discharge areas and especially in testing negative axial force and its influence on turbine rotor raising up. Guide vane opening curve have constant shape when the a_0 values are lower, but significantly differ when these values increase. Turbine quick closure and stoppage from 100% of maximal input as the most unpleasant regime is secure. Total axial force of approximately 1500 kN will perform its effect vertically down and turbine rotor will not be raised up. Vacuum on net head cover will not be present especially if air valves influences are taken in consideration. Reducing guide vane closing velocity is one of choices that can effect on range of $F_{a,\min}$ and $p_{pok,\min}$ critical values. Axial hydraulic force can be significantly reduced when guide vane closing velocity is nearly about 30% of nominal closing velocity. These are also recommendations gained from insights from good practice in order to avoid either rigid or reverse waterhammer to occurre.

Abstract: *Energy consumption is one of the most significant challenges in the modern world. Various types of buildings (commercial, residential, sports facilities, etc.) represent major consumers of energy. In households, energy is primarily used to achieve and maintain conditions of thermal comfort such as indoor temperature, relative humidity, and the required amount of fresh air. The aim of this paper is to explore various aspects related to insulation thickness and its impact on investment and operational costs. It will analyse how variations in insulation thickness can affect the energy efficiency of buildings, heating costs, and the maintenance of specified thermal parameters over time. In addition, economic factors such as investments in insulation and potential savings during the operation of the building will be analysed. Through a comprehensive analysis of relevant literature, energy consumption data, and economic analysis, this paper will contribute to a deeper understanding of the complex relationship between insulation thickness, construction costs, and operational costs throughout the lifespan of a building. The research results will enable investors, architects, and engineers to make optimized decisions during the design, construction, and maintenance of buildings, taking into account both short-term and long-term financial implications of energy performance and insulation thickness.*
Keywords: Optimal Insulation Thickness; Building Insulation; Energy Efficiency in Buildings.

1. INTRODUCTION

Many authors have already worked on a similar problems, analysing the optimal insulation thickness for residential buildings. In the paper [1], the authors conducted an analysis from the perspective of life cycle economic evaluation. Additionally, in [2], the authors performed a theoretical analysis, calculating the optimal insulation thickness for the climatic region in the territory of the People's Republic of China. The paper [3] involved numerical optimization of the thickness and layer arrangement of insulation for buildings in the climatic region of Riyadh, Saudi Arabia.

In this paper, a numerical analysis was conducted to determine the impact of insulation thickness on the walls of residential buildings, considering the climatic conditions prevailing at the territory of the city of Belgrade in Serbia. Furthermore, the analysis was conducted based on electricity prices and investment costs that are currently applicable in the territory of the Republic of Serbia.

Insulation materials have a crucial role in maintaining conditions of thermal comfort. The insulation layer increases resistance to heat conduction through the walls of the building, minimizing the loss of thermal energy through the building envelope in winter and gaining heat from the sun in summer.

[1]mmihailovic@atssb.edu.rs
[2]milosapx900@gmail.co
[3]tsimonovic@atssb.edu.rs

The most commonly used insulation materials for building envelopes are: Expanded Polystyrene (Styrofoam), Extruded Polystyrene (Styrodur), Glass Wool, Rock Wool, etc.
All of the above-mentioned insulation materials are characterized by similar values of thermal conductivity coefficients ranging from 0.035 to 0.045 W/mK. The difference in prices of insulation materials is mainly influenced by the production technology and the amount of energy consumed during their manufacturing process.

1.1 Parameters of the analysed house

For the purpose of this paper, a residential building with a total living area of 74 m^2 and approximately 135 m2 of external wall surface was considered. The building is located in the vicinity of Belgrade, in a windy area with an exposed position. For the purpose of analysis, heat losses of the building were calculated without external insulation, and subsequently, heat losses were calculated by adding 1 cm of Styrofoam on the external side, up to a total thickness of 15 cm. A recapitulation of heat losses for Styrofoam thicknesses of 0 cm, 5 cm, 10 cm, and 15 cm is shown in [4]. Where the values of heat losses are provided for individual rooms of the building and the total heat losses of the building are shown for the range of external temperatures from -15°C to 12°C. Based on the obtained data, it is possible to derive an equation representing the relationship between the building's heat losses and external temperature - a "sliding diagram". This relationship has a linear characteristic and can be represented by a general equation of the form:

$$P_b = a + b \cdot t_e \text{ [kW]} \quad (1)$$

Where:
- P_b [kW], is the heat loss for the residential building,
- t_e [℃], is the external (atmospheric) temperature.

Coefficients *a* and *b* can be determined based on regression analysis, and their values for different insulation thicknesses are shown in Table 1.

Table 1. Values of coefficients *a* and *b* for equation (1)

1.2 External Conditions

In order to perform a precise analysis, temperature data for every hour, during the representative winter season, were used in this study. The data were collected for every hour in the period from October 15, 2016, to April 15, 2017 at the meteorological station located in the Power Plant "Konjarnik" [4].

1.3 Heat source

In this study, an air-to-water heat pump was utilized as a simulated heat source for heating the building. Technical data from the manufacturer "DAIKIN," model "Altherma ERQL011CW1", were employed. Table (2) presents data (heat power) that the given heat pump can provide for the

selected discharge water temperature, depending on the external temperature, as well as, information about the COP (Coefficient of Performance) value that the selected heat pump can achieve for the chosen water temperature, depending on the external temperature.

2. METHODOLOGY

The analysis was conducted according to the following algorithm:

- Based on the external temperature at a specific hour, using equation (1), the heat energy losses for that hour were calculated. Depending on the hour in which the heat losses were calculated, the thermal energy needed to compensate for the heat losses is consumed either at the lower tariff (LT - from 00:00 to 08:00) or at the higher tariff (HT - from 08:00 to 00:00). The energy consumed in the lower and higher tariffs in the green, blue, and red zones was taken into account. Additionally, all other costs and discounts that the Electric Power Industry of Serbia (EPS) as the electricity distributor calculates (social discount, excise, discount, RTS fee, etc.) were considered.
- For the selected water temperature at the discharge, which in this analysis is 45°C, the available thermal power and COP of the heat pump were calculated. Since these values in the manufacturer's catalog are given for external temperatures with an approximate 5°C interval, the thermal power and COP were calculated using linear interpolation between two external temperature values.
- The engaged electrical energy (in kWh) is obtained from the ratio of heat losses in a given hour and the COP of the heat pump in the same hour. Depending on the hour in which the heat losses were calculated, the engaged electrical energy is consumed in either the lower or higher tariff.
- By summing up the consumed electrical energy in each hour for the entire month, the total consumption of electrical energy in the lower and higher tariffs for the entire month is obtained.

3. RESULTS

This described procedure is repeated for each month, first for the uninsulated building, and then for the building insulated with insulation thicknesses ranging from 1 cm to 15 cm of Styrofoam. To make the analysis more accurate, in addition to the electrical energy needed for heating the building, the electrical energy required for the operation of other appliances (hot water boiler, stove, washing machine, etc.) was added. This combined electrical energy was obtained based on electricity bills for the months when there was no need for heating or cooling (May and October).
Investment costs for all necessary materials and labour were adopted (for buildings without insulation, the costs of plastering were taken into account, and for insulated buildings, the costs of Styrofoam, mesh, adhesive, battens, and other necessary materials were included). When calculating seasonal electricity consumption, a seasonal electricity price increase of 3% was adopted, representing the average increase in electricity prices over the past 5 years.
Investment costs for the heat source (heat pump) and other heating system equipment were not taken into account. In Table 3, the second column displays the investment costs required for

plastering or insulating the building, while the other columns show the total heating costs for the building per season, for different insulation thicknesses.

The results of Table 3 are also presented in the form of a diagram (Figure 1). The x-axis represents the heating season, and the y-axis represents the costs for exploitation (electricity) coupled with investment for all insulation thicknesses in RSD. For better visibility of the data, Figure 1 shows the results only for the uninsulated building, as well as for the building insulated with 5 cm, 10 cm, and 15 cm of insulation.

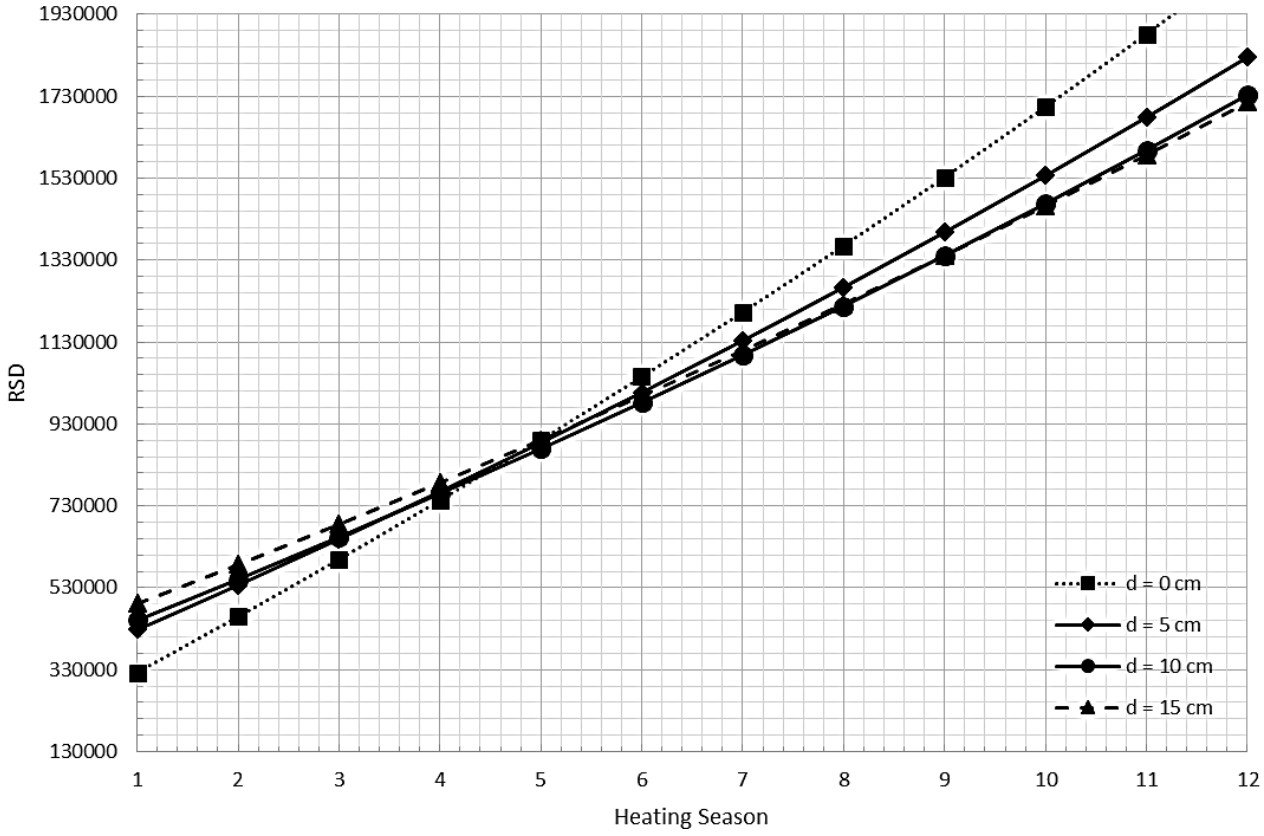

Figure 1. Total Costs by Heating Season
Source: BSc thesis [4]

4. CONCLUSION

During the construction of buildings in Serbia, the highest value of the heat transfer coefficient for external walls should not exceed 0.35 W/m^{2}K [6]. The most commonly used thickness of Styrofoam that meets these conditions is 10 cm. Based on the results of the conducted analysis, it can be concluded that by insulating the building with 10 cm thick Styrofoam, the investment will pay off within 4 heating seasons compared to an uninsulated building. By insulating the building with 15 cm thick Styrofoam, the investment would pay off within 5 heating seasons. By monitoring the trend of the curve shown in Figure 1, it is noticeable that the heating costs for a building insulated with 15 cm thick Styrofoam increase exponentially, but with a much lower slope compared to thinner Styrofoam, especially compared to an uninsulated building. Therefore, the recommendation, considering the relatively short period of investment payback, is to insulate the building with 15 cm thick Styrofoam.

The same model of heat pump was used as a heat source to compensate for heat losses for both the uninsulated building and the building insulated with Styrofoam of various thicknesses. This fact leaves room for additional investment savings, as the losses for the building insulated with thicker Styrofoam are proportionally smaller, allowing for the use of a smaller capacity heat pump and heating elements with a significantly lower investment cost.

HEADWATER LEVEL GOVERNING AT SMALL HYDROPOWER PLANTS WITH OPEN CHANNEL CONVEYING SYSTEM

Aleksandar Petkovic[1], The Academy of Applied Technical Studies Belgrade
Jovan Ilic[2], JSC Electric Power Authority of Serbia
Ivan Bozic[3], Faculty of Mechanical Engineering, University of Belgrade

Abstract: *From the ecological stand-point, the primary objective is to enable undisturbed release of ecologic flow downstream of the weir under any hydro-meteorological circumstances, whereas from the energetic stand-point, the tendency is to utilize available water flow through SHPP power-generating line as much as possible. In most circumstances, these objectives are confonted, because fulfillment of one binds restrictions onto the other one. Therefore, proper defining of hydro-technical functions of all the technological parts of SHPPs, especially weirs and water intakes, is of the utmost importance during the stages of SHPP design and exploitation. The entire variety of hydro-technical functions and ecological requirements is to be tailor-made defined for each particular SHPP, whereas their implementation is to be provided by state-of-the-art solutions of hydraulic waterways, hydro-mechanical equipment and automatic headwater level governing systems. Calibrated spillways, specifically embraced hydro-mechanical equipment and automatic control devices allow for proper consumption of water for the energy-generation purpose. The paper presents a case-study of SHPP, for which joint satisfaction of energy and ecological requirements is successfully achieved by implementation of appropriate headwater level governing system.*
Keywords: Small hydropower plants, headwater level governing

1. INTRODUCTION

In recent decades, small hydropower plants (SHPPs) are being constrained by ever more increase of rigorous exploitation conditions in regard of ecologic requirements (provision of adequately designed fish passes, release of ecologic/guaranteed flow downstream of the weir, adequate handling of floating debris, applying of oil-free bearings at turbine assemblies, fish-friendly types of turbine runners at run-of-river SHPPs, eco-friendly types of transformers, etc.).
Adequate and strict fulfillment of all of these requirements influences not only civil hydrotechnical engineering solutions, but electro-mechanical engineering solutions, as well.

2. HYDROTECHNICAL FUNCTIONS OF SHPPs AND TECHNICAL MEANS FOR THEIR FULFILLMENT

It is of utmost importance to clearly identify all necessary hydrotechnical functions which are to be fulfilled during exploitation of a SHPP, as well as appurtenant hydromechnical equipment. This task is to be done already within SHPP design stage.
Main hydrotechnical functions of SHPPs and their weirs comprise:

- undisturbed releasing of ecologic/guaranteed flow downstream of the weir,

[1]azpetkovicbgd@gmail.com
[2]ibozic@mas.bg.ac.rs
[3]Jovan.Ilic@eps.rs

- intaking of flow for energy generation (turbines operation), and
- undisturbed releasing of flood flows.

Additional hydrotechnical functions of SHPPs and their weirs, depending on specifics of particular plants, may comprise:

- flushing of sediments accumulated at the weir upstream side,
- prevention of floating debris intrusion towards power conduit,
- sedimenting (and flushing) of water before its delivery towards power conduit,
- water intaking for other, non-energetic facilities (agricultural irrigation, touristic facilities, etc.).

Each of the above listed functions (being of permanent or occasional nature) require implementation of adequate hydrotechnical structures and/or hydromechanical equipment (with auxiliary devices) of either shut-off (occasional engagement) or regulating (permanent engagement) type. It is of utmost importance to adequately intertwine the first two main functions, i.e. releasing of ecologic/guaranteed flow and intaking of flow for energy generation. Releasing of ecologic/guaranteed flow is usually performed at fish pass. The uppermost section of fish pass (at weir) hydraulically acts as a spillway, so there is unique relation between spilling water level and spilling discharge through the fish pass. If operating value of the weir/reservoir water elevation is higher than actually necessary, more water than truly necessary will be discharged through it and therefore less water will be used for energy generation, and vice versa.

Therefore, it is of utmost importance to provide adequate and precise maintaining of the weir/reservoir water level during exploitation of SHPP. Such goal can be adequately fulfilled only by means of automatized system for SHPP headwater level governing (AHLG). In addition, concept of the headwater level governing system should be adequate to the overall layout of the weir.

3. HEADWATER LEVEL GOVERNING SYSTEMS

Conception of AHLG should be adopted in line with overall layout of SHPP and all of its specific hydraulic and hydro-technic issues.

There are several possible generic types of bloc-diagram schemes of AHLG for SHPPs, depending on SHPP overall layout. They comprise:

- SHPPs with weir and penstock (pressurized conduit),
- SHPPs with weir, derivation tunnel (including surge tank) and penstock (pressurized conduits),
- SHPPs with weir and derivation channel of selfregulating type (open-surface conduits), and
- SHPPs with weir and derivation channel of non-selfregulating type (open-surface conduits).

Generic types of bloc-diagram schemes of AHLG for SHPPs are thoroughly investigated in the sources [1, 2]. In this paper, however, only the last generic type is considered, i.e. bloc-diagram schemes of AHLG for SHPPs with weir and derivation channel of non-selfregulating type (Fig. 1).

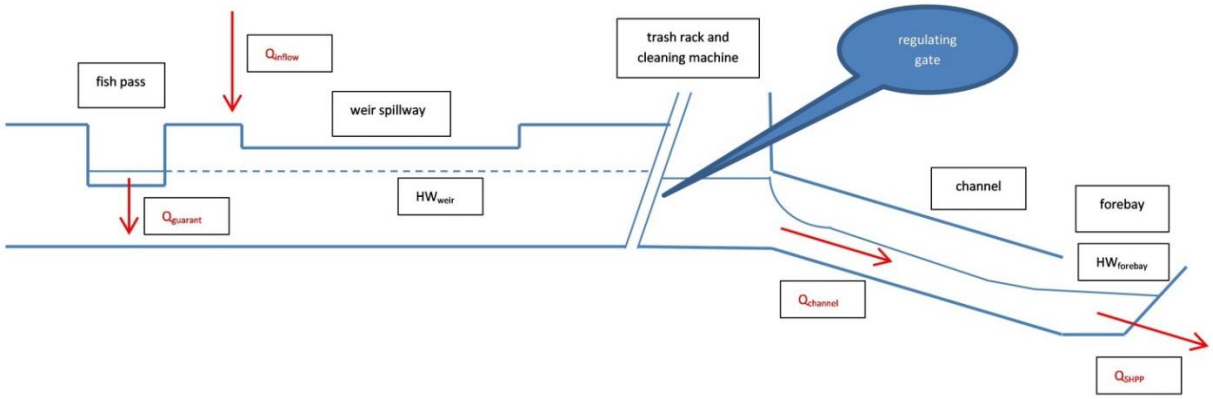

Figure 1. Schematic presentation of a SHPP which comprises weir and non-selfregulating headrace channel – two governing loops for headwater level governing (at the weir/reservoir and at the forebay)

Due to relatively huge length of non-selfregulating channels and significant difference in elevations of channel bottom at its upstream and downstream ends, there is no possibility to influence water level at the channel upstream side (at weir/reservoir) solely by manipulation of water level at its downstream side (i.e. at SHPP forbay). Therefore, two separate, mutually independent regulating systems are necessary.

The first one, for governing of the weir/reservoir water level, comprises regulating gate (with actuator of electric or hydraulic type), located at the joint of the weir and the channel, with appurtenant level metering device and automatic governing device. Its bloc-diagram scheme is presented at Fig. 2.

The second one, for governing of the SHPP forebay water level, comprises turbines, located at the SHPP powerhouse, with appurtenant level metering device and automatic governing device. Its bloc-diagram scheme is presented at Fig. 3.

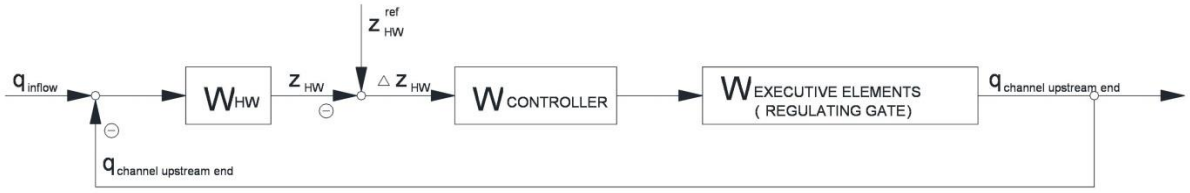

Figure 2. Bloc-diagram scheme of AHLG for SHPPs with headrace channel of non-selfregulating type. Governing loop 1 (weir/reservoir water level)

Figure 3. Bloc-diagram scheme of AHLG for SHPPs with headrace channel of non-selfregulating type. Governing loop 2 (forebay water level)

Hereafter, results of headwater level governing analysis for a case study SHPP (SHPPs with weir and derivation channel of non-selfregulating type) are presented.

4. CASE STUDY

Brief data of the plant:

- name, location	SHPP Moravica, Serbia,
- year of initial commissioning and reconstruction	1911. and 2019,
- dam type	concrete weir, with spillway,
- average annual river inflow	6.7 m³/s,
- guaranteed discharge	0.69 m³/s,
- type of conveyance waterway	open-air non-selfregulating channel,
- length of the channel	90 m,
- SHPP installed discharge	9 m³/s,
- turbine rated head	9 m,
- SHPP installed power output	700 kW,
- average annual energy generation	2.23 GWh/year,
- number of units	1,
- type of governing controller for loop 1 (reservoir)	PI-controller with local feed-back,
- type of governing controller for loop 2 (forebay)	PI-controller with local feed-back.

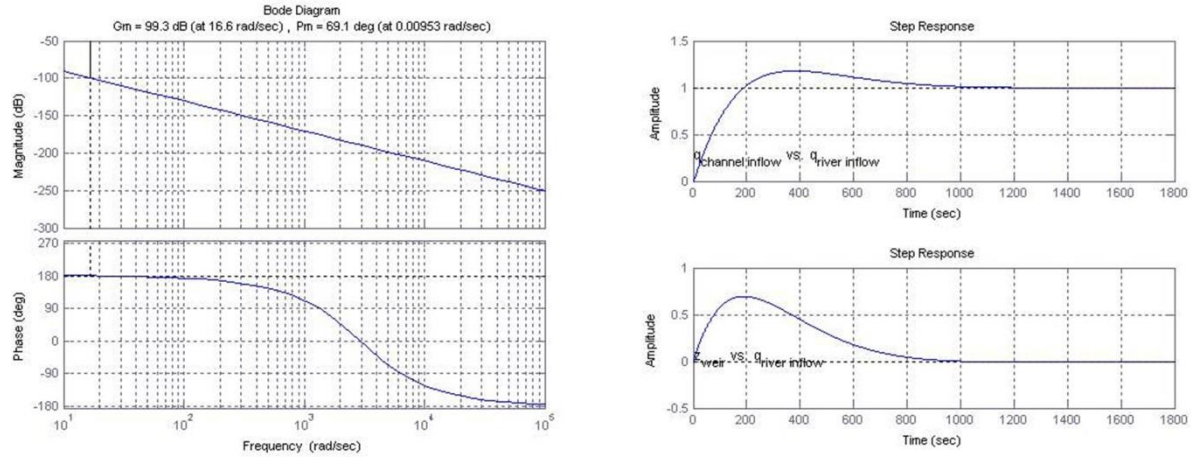

Figure 4. Governing loop 1 (reservoir water level). Bode chart of the open-circuit governing loop and time histories of step-responses (channel inflow vs. river inflow disturbance and reservoir water level vs. river inflow disturbance)

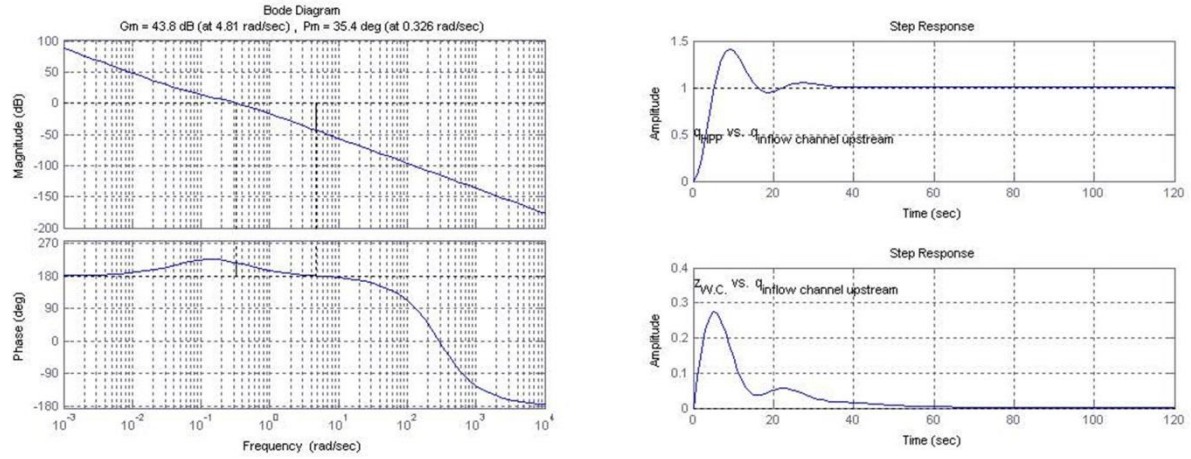

Figure 5. Governing loop 2 (forebay water level). Bode chart of the open-circuit governing loop and time histories of step-responses (SHPP discharge vs. channel inflow disturbance and forebay water level vs. channel inflow disturbance)

As can be seen from the obtained numerical simulation results, both governing loops avail with stable and quality transient behaviour (favourable value of relative overshoot and short restitution times), thanks to appropriate adoption of governor architecture and the setting values of the controllers. Bode charts (logarithmic amplitude- and phase- frequency characteristics) evidence on sufficient stability reserve margins, whereas time histories of step-responses evidence smooth elimination of disturbance effect and transition onto new steady-state conditions. Reservoir transient process attenuates within 15 minutes, whereas forebay transient process attenuates within approx. 1 minute. This assures precise governing of the water levels at reservoir (weir) and forebay, thus adequately fulfilling both ecological and energetic requirements set forth for this SHPP.

5. CONCLUSIONS

It is of utmost importance to clearly identify all necessary hydrotechnical functions which are to be fulfilled during exploitation of a SHPP and to implement them by installation of appropriate hydromechanical and auxiliary equipment. Implementation of automatized systems for headwater level governing of adequate architecture and setting parameter values allows for precise maintaining of necessary value of reservoir water level. In long term, this assures fulfilment of both ecologic and energetic requirements of SHPPs.

For the existing SHPPs which undergo refurbishment (reconstruction, upgrading, modernization of power generating equipment), implementation of automatized systems for headwater level governing leads to increase of energy generation and revenues.

Abstract: *The three-point bending test is a widely used and important method for evaluating the mechanical properties of materials. Its versatility, applicability, and ability to provide valuable information on flexural strength, stiffness, and fracture toughness make it a valuable tool in materials science, engineering, and biomedical research. Digital Image Correlation (DIC) provides a high-resolution and full-field measurement of deformation during the bending process. DIC also allows for the calculation of strain fields, which can be used to determine material properties such as Young's modulus and Poisson's ratio. This is particularly important in understanding the strain distribution and identifying potential failure mechanisms in the material. In this paper, the potential application of the 2D Digital Image Correlation method on three-point bending tests is presented.*
Keywords: 2D Digital Image Correlation method, three-point bending, material testing, 3D printing,

1. INTRODUCTION

Three-point bending testing is a widely used method for evaluating the mechanical properties of materials. This test involves applying a load to a specimen at two points, while a third point acts as a support. The specimen is subjected to bending stress, allowing the measurement of important parameters such as flexural strength, stiffness, and fracture toughness [1].
The three-point bending test has a variety of use cases in different fields. In the field of materials science, it is commonly used to assess the mechanical behaviour of various materials, including ceramics, metals, polymers, and composites[1, 2]. For example, in dental stress analysis, the three-point bending test is used to evaluate the bond strength between ceramics and titanium in dental prosthetics [1]. In the study of fabrics, a modified version of the three-point bending test is used to evaluate the bending properties of textiles [3]. Additionally, the three-point bending test has been applied to study the mechanical behaviour of cancellous bone, providing valuable information on the structural support and flexibility of this tissue [4].
The importance of the three-point bending test lies in its ability to provide valuable information about the mechanical properties of materials. By subjecting a specimen to controlled bending stress, this test allows the determination of key parameters that are crucial for material characterisation and design. Flexural strength, for example, indicates the ability of a material to withstand bending loads without failure, making it an important parameter for structural applications [2]. On the other hand, stiffness reflects the resistance of a material to deformation under bending stress and is essential for understanding its load-bearing capacity [5]. Fracture toughness, another important parameter,

[1]nmitrovic@mas.bg.ac.rs

measures the resistance of a material to crack propagation and is crucial for assessing its resistance to failure [6].
The applicability of the three-point bending test extends to a wide range of materials and testing conditions. It can be performed at various temperatures, including extremely high temperatures, allowing the evaluation of material behaviour under different environmental conditions [7]. Furthermore, the test can be adapted to different specimen geometries and sizes, making it versatile and adaptable to specific research needs [5]. The three-point bending test is also applicable to both quasi-static and dynamic loading conditions, enabling the assessment of material behaviour under different loading rates [2].
Digital image correlation (DIC) is a non-contact optical measurement technique that has gained significant popularity in material and structure testing [8–13]. It involves analysing the displacement and strain fields of a specimen by tracking the movement of unique patterns or markers on its surface. DIC provides a high-resolution and full-field measurement of deformation, making it a valuable tool for understanding the mechanical behaviour of materials. In the application of three-point bending tests, DIC offers several advantages. Firstly, it allows for the measurement of both global and local deformations during the bending process. This is particularly important in understanding the strain distribution and identifying potential failure mechanisms in the material. DIC can capture the deformation of the specimen in real time, providing valuable insights into the behaviour of the material under load [14].
Furthermore, DIC enables the calculation of strain fields, which can be used to determine material properties such as Young's modulus and Poisson's ratio. By analysing the strain distribution along the length of the specimen, researchers can assess the material's stiffness and its ability to withstand bending stress. This information is crucial for designing and optimizing structural components [15]. DIC also allows for the visualization of stress concentrations and the identification of potential failure locations. By tracking the displacement and strain fields, researchers can identify regions of high stress or strain, which can help in understanding the failure mechanisms and improving the design of materials and structures [15].
The aim of this paper is to present the potential application of the 2D Digital Image Correlation method on three-point bending testing.

2. MATERIALS AND METHODS

The three-point bending specimens used in this study were fabricated in SolidWorks CAD software, with dimensions of 10 × 5 × 5 mm, Fig. 1. A total of 5 specimens were made. The specimens were printed using the RepRap X400 (Rep Rap, Germany) 3-D printer. The infill pattern for all samples was concentric with 30% of the infill density. The layer height was 0.2 mm, with 2 layers on top, 2 on bottom, and 2 on both sides. In this study, the commercially available thermoplastic polymer PLA (RepRap, Germany) was used. PLA is a biodegradable, non-toxic organic polymer derived from biobased resources.
All experiments were carried out on the Shimadzu AGS-X tensile testing machine (Shimadzu, Japan) with a maximum load of 100 kN. The surface of the specimen must have a pattern to clearly allocate the pixels in the camera images (facets). Consequently, the pixel area of the reference image can be assigned to the corresponding pixel area of the target image. The surface of a sample was coated with a black paint point to generate a random high-contrast stochastic pattern. All images were recorded using a 35 mm lens and acA-2500 Basler camera (Basler, Germany) with 5 MP camera resolutions. Continuous specimen lighting was provided by an LED lamp (Fig. 1).

3. RESULTS AND DISCUSSION

2D-DIC is a non-contact and full-field measurement technique used extensively in material testing. This method tracks the movement of the markers placed on the surface of the specimen during

deformation. The resulting displacement data can be used to calculate the strain and stress in the specimen.
The results of the displacement in the Y direction are presented in this paper. The displacement field was analysed using 3 sections (Sections 1, 2 and 3), two points (Points 1 and 2) and one point-point distance, as shown in Fig. 1. Experimental data are also represented in graphics as time and section length functions. Figure 1 shows a representative image of the Displacement Y field results for the maximum force before the break.
The highest displacement values in the Y direction of around 10 mm are recorded below the grip of the tensile testing machine, on the lower part of the specimen where Section 3 is located. The tests revealed a slight displacement difference between the upper and lower parts of the specimen, as can be seen in the Section Diagram in Figure 1. What is interesting here is that the point-point distance change represents the thickness reduction of the specimen of around 0.25 mm. Overall, these results suggest that DIC can be used for localized displacement and strain field analysis and improvement in the standard three-point bending testing of material.

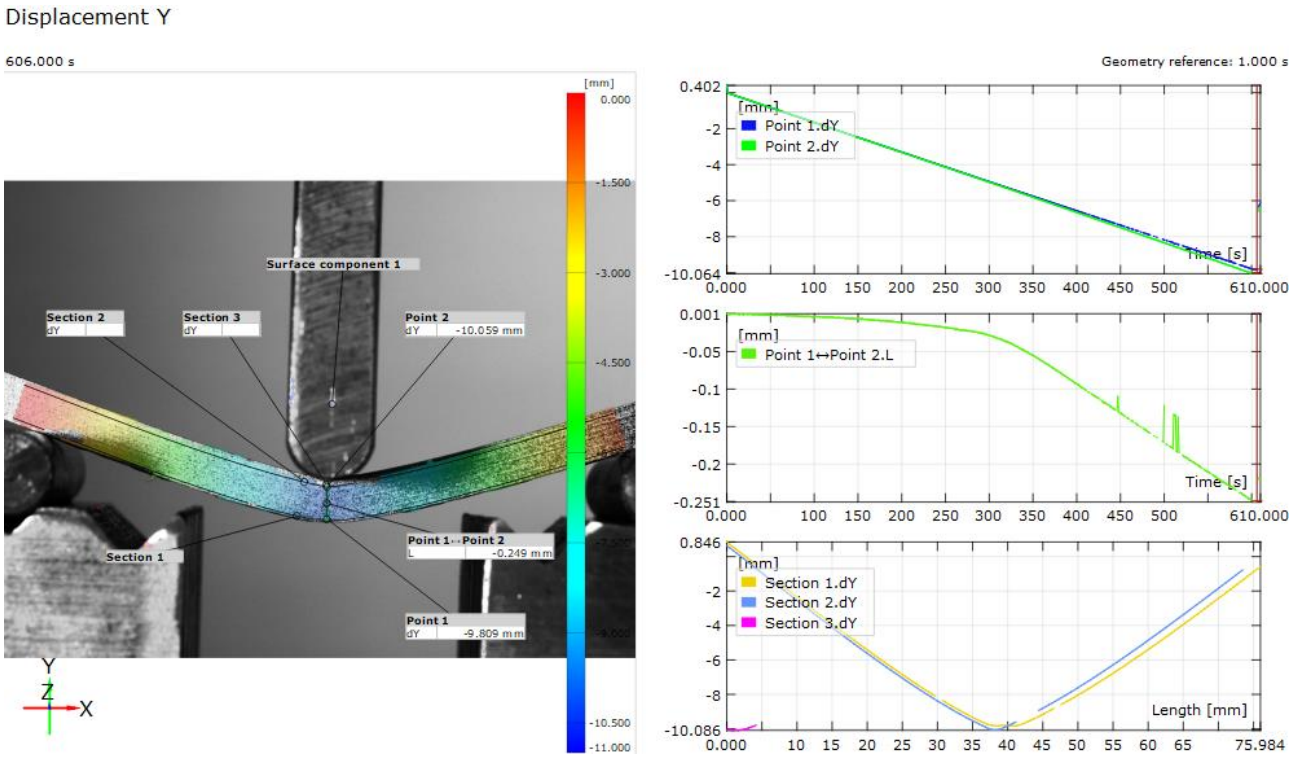

Figure 1. Displacement Y before the specimen brake

4. CONCLUSION

In conclusion, the three-point bending test is a widely used and important method to evaluate the mechanical properties of materials. Its versatility, applicability, and ability to provide valuable information on flexural strength, stiffness, and fracture toughness make it a valuable tool in materials science, engineering, and biomedical research.
The use of DIC in three-point bending tests offers a comprehensive and detailed analysis of the behaviour of the material. It provides a full-field measurement of deformation, allowing for a more accurate assessment of the mechanical properties of the material. DIC can capture global and local deformations, providing information on the distribution of strains and potential failure mechanisms. Additionally, DIC enables the calculation of strain fields, allowing for the determination of material properties such as stiffness. In general, DIC is a valuable tool in material testing, particularly in the application of three-point bending, as it enhances our understanding of material behaviour and aids in the development of more reliable and efficient materials and structures.

This research was supported by the Ministry of Education, Science and Technological Development of the Republic of Serbia under Project 451-03-68/2022-14/200105.

Abstract: *In this paper an application of smart production systems in vocational education is described. The goal of this project is the industrial automation of the production process, which is based on the fusion of CNC (Computer numerical control) machines and industrial robots, the application of artificial intelligence in the production of machine parts with the use of CNC simulators, the increase in the use of information technologies, new software and hardware platforms in teaching, especially in order to raise the quality of practical work teaching, through the creation of functional realizations of assemblies, devices and systems - Project Based Learning, as well as Work Based Learning. It is planned to introduce modern digital techniques of design, analysis and synthesis of practical, functional realizations of technical assemblies, devices and systems, in the syllabus of the subjects related to the above-mentioned knowledge items. In other words, the goal is to introduce new opportunities, primarily in the domain of practical exercises, such as hardware and software environments for the development of digital devices, automation of production processes, reduction of production time, increase in productivity, and elimination of scrap and support for Industry 4.0.*
Keywords: Smart production system, Industry 4.0, Robotics, CNC machine, CAD/CAM

1. INTRODUCTION

The assertion of world economists, that automation, computerization and application of robots are the first three things that developing and countries in transition should approach in order to bridge the gap between themselves and developed countries is fully justified [1,2,3]. In the future, the development of human civilization will depend more and more on the position of science and its application, and less and less on the amount of work invested and the simple amount of resources that increase its strength [4,5,6,7]. With the development of Industry 4.0, the application and therefore the production of automated and computerized machine tools, automatic management and control systems, transport systems and robots increases, while the production using classic machines and systems decreases [7,8,9]. The implementation of this project would involve the application of smart production systems with the application of the CAD/CAM/CNC concept (Computer Aided Design/ Computer-Aided Manufacturing/ Computer Numerical Control) and support for the fourth digital revolution in vocational education [9, 10].
This research paper presents project proposal "Application of smart production systems in vocational education" that aims to innovate existing subjects - more precisely, a group of subjects on accredited study programs, in master professional and basic vocational studies, which are implemented in the Computer-Mechanical Engineering Section (CME Section), of the Academy of applied technical studies Belgrade. The three subjects are selected from the master's vocational

[1]djdihovicni@atssb.edu.rs
[2]nratkovickovacevic@atssb.edu.rs
[3]adjurdjevic@atssb.edu.rs

studies (MVS) and three subjects from the basic vocational studies (BVS), which are implemented in study programs (SP) in the technical and technological field, namely: Computer Mechanical Systems (MVS level), Mechanical Engineering (BVS level) and Mechatronics (BVS level).
The subjects included in the project proposal are, in the master's vocational studies (at SP MVS CME): Mechatronic systems (implemented in the autumn-winter semester), Industrial plants and automation, and Artificial intelligence methods (both implemented in the spring-summer semester). From the basic professional studies, the courses CNC System Programming (implemented in the autumn-winter semester), Sensors and actuators, and Basics of Industry 4.0, are included for which classes take place in the spring-summer semester, in the CME Section in Belgrade and at the same time in the Higher Education Unit in Valjevo.
Apart from the six subjects mentioned, the proposed innovations would have a positive and favourable impact on other subjects from study programs of the CME Section (e.g., Machine Learning, Automatic Control and Digital Electronics, all at BVS level).

2. PURPOSE AND DESCRIPTION OF THE PROJECT PROPOSAL

Real-time machine CAM (computer-aided manufacturing) programming represents a fundamental change in the way the tool path moves, resulting in extended tool life, shortened cycle times and better machine utilization. Unlike traditional CAM software, by applying advanced software that has been developed in recent years, information about machine kinematics and dynamics is used for setup, programming, optimization and simulation. In this way, CAM programmers make better tool path choices, resulting in improved machining performance [6,7,8].
The purpose of innovating subjects for master's and undergraduate studies is to enable students to acquire and assimilate knowledge of complex concepts, through experience gained in practice and acquire competencies, useful or necessary for the automation of the production process and the application of smart production systems with the support of Industry 4.0 [10,11,12]. The expected result of innovation of the mentioned courses is that students develop skills and competencies in all levels of Bloom's Taxonomy: in addition to remembering, understanding and applying knowledge, analysing and evaluating technical solutions, students will also be able to create this way. The idea of this proposal is to awaken the need for experimentation in students, develop entrepreneurial ideas and overcome limitations in the process of designing and building specified technical solutions.
Description of selected subjects in undergraduate vocational studies:

- Sensors and actuators: Introducing students to the basic types and characteristics of sensors and transducers, which are used in mechanical engineering and the process industry. The goal of the course is for students to gain an understanding of the basic principles of measurement and control, basic notion regarding the servo drive: measurement of motion parameters and variables, dimensions or position, types of drives that are used in practice and understanding the operational correlation of measurement and motion control. This course provides a solid foundation for understanding automation;
- Programming of CNC (Computer numerical control) systems: The aim of the course is to acquire knowledge about modern CNC machining systems and learn about the basic differences in the design of technology for CNC machining systems compared to classical ones in terms of application, productivity, costs and overall processing efficiency;
- Basics of Industry 4.0: The aim of the course is to acquire knowledge regarding the concept of the flexible production systems - FPS as well as to become able to develop, improve and organize the production in FPS, to reach the desired level of automation, and the management of FPS.

Description of subjects from the master professional level study:

- Mechatronic systems: Gaining in depth theoretical and practical knowledge regarding mechatronic systems and a mechatronic approach to design, developing a multidisciplinary approach in solving engineering tasks, in product design or physical realization, through a

combination of courses in the fields of modelling mechanical and electrical systems, system management, electronics, computing and computer controlled and monitored systems;

- Industrial plants and automation: Familiarization with advanced concepts in the field of automatic control and training for application and verification of acquired knowledge on concrete physical processes, objects and systems, mastering methods for synthesis, design and adjustment of control systems (through the design and tuning of the regulators);
- Methods of artificial intelligence: Acquisition of applied knowledge and skills in the field of artificial intelligence. Application of artificial intelligence methods such as expert systems, neural networks, fuzzy logic, as well as machine learning algorithms in diagnostics in operation and decision making regarding the condition of machines in production.

Work and teaching methods to be implemented to achieve learning goals are:

1. Lectures are oral, explanation, presentations using computers, dialog, and interactive methods;
2. Simulation - programming methods (simulation of examples from practice, practical work on the computer, writing and testing of programs);
3. Laboratory - experimental methods: creating software models and exploring modes of operation of various systems varied by adding regulator or parameter tuning (using Matlab and Simulink), making experiments in physical programming i.e. building simple electronic projects controlled by microcontroller board (e.g. Arduino Uno) or single board computer (Raspberry Pi), creating exercises using software to support Industry 4.0 and applying smart production systems using simulators for numerical control, in programming industrial controllers, such as Step 7, Logo Siemens, Fatek, Trilogy; in visualization and control of technological processes the software systems are used (e.g. Promotic Scada, Delphi Scada, braumSistems); in robotics the software Robotics Studio, Robot Simulation Software, Robot programming software are implemented, and in artificial intelligence and machine learning examples in practice are derived using Matlab and Python software;
4. Taking the exam.

Evaluation of learning outcomes and monitoring of teaching quality:

- At the end of the semester, students will perform an online evaluation of the lessons and practical exercises in the context of using multimedia techniques. Based on the processed evaluation results, corrections and additions will be made to the course content for the following years of study, creation of on-line surveys, questionnaires, which students would fill out, to rate their satisfaction with the new way of teaching.

3. GENERAL AND SPECIFIC COMPETENCES

Description of goals acquired after taking these innovative subjects, namely Sensors and actuators, Programming of CNC systems, Basics of Industry 4.0, Mechatronic systems, Industrial plants and automation, and Methods of Artificial Intelligence states that all will contribute to the development of students' digital competencies, as well as the following general and specific competencies.

General competences that students should develop during practice oriented teaching are:

- Ability to learn;
- Ability to analyze and synthesize;
- Ability to apply knowledge in practice;
- Ability to adapt to a new situation;
- To successfully plan and perform troubleshooting;
- Obtaining high level of quality, maintaining it and assessing the quality;
- Information management skills;
- Ability to work independently and in a team;
- The ability to have a creative approach to solving practical problems;

- The ability to evaluate one's own and others' work through comparisons;
- Ability to create technical solutions for development of products and services;
- Cooperation, communication and problem solving in teamwork;
- Knowledge of using the computer programs and computer equipment (understood in the broadest sense).

Specific competencies that students should develop during practice oriented teaching are:

- Knowledge of design elements and principles;
- Integrating the principles of design and adhering to legal requirements and relevant standards;
- Ability to design using digital tools and hardware;
- Ability to create and design from an idea or conceptual sketch to a functioning prototype and a finished device, system or service;
- Ability to work on adequate software and hardware platforms (Arduino Uno, Raspberry Pi, programmable logic controllers - PLCs, supervisory control and data acquisition – SCADA systems);
- Simulation of CNC machine and robot levelling procedure using a special digital levelling device. Levelling the machine means setting machine up and aligning it - bringing its horizontal axes into a parallel position with the horizontal plane (or bringing its vertical axis to a perpendicular direction to the horizontal plane). This device has the ability to connect to mobile devices and computers via Bluetooth connection. Information about the position of the work table, or some other reference part of the machine, is sent in real time to the mobile phone of the service technician who performs the adjustment. In this way, the service technician does not need to go to the machine after setting each foot of the machine to check the angle, nor there is a need for another service technician who would constantly read the data during levelling;
- Simulation of robot and CNC machine communication via CNC simulator. If the robot would receive information when the protective door of the machine is open, i.e. for the machine to have information that the robot is outside the working area and can close the door, they need to communicate with each other over an interface and protocol, which can be successfully simulated through additional M-functions such as options for working with peripheral devices;
- Using the CNC simulator, and to display the communication between the machine and the computer or server via the ETHERNET network interface;
- Support for Industry 4.0 by simulating an application for remote machine monitoring. The machine must be connected to the Internet over the cabled (Local Area Network – LAN) or wireless (e.g. WiFi) network. The WiFi option on the machine’s side provides a wireless connection between the control unit and the LAN. The status of the machine can be monitored from a computer or mobile phone. Notifications, warnings, and alarms and can be generated for the start of the cycle, the end of the program, as well as possible alarms on the machine, or any changes to the program, number of revolutions, or rapid movements. All notifications are sent to
  a mobile device or an email account;
- Simulation of the calibration of the CNC machine, i.e. the correction of the movement of the axes of the CNC machine as a whole, which directly influence the precision of the produced part. Testing is performed using Windows-based software that guides the operator through each step.
  A useful option is the so-called "Generator of NC programs" which helps in writing programs for the machine tool. In many cases, existing test templates are used. Quick access to templates is done by simply searching for existing files;
- Connecting all the elements of the flexible production cell into one simulation unit;
- After composing the simulated flexible production cell using a CNC simulator with the generation of NC programs in the ESPRIT CAM software [13];

- Simulation of the installation of the Vision Sensor, which can be installed on the support above the box with work-pieces, and on the robot arm itself. The digital image is converted into a symbolic description that is in machine-readable format and that the device can 'understand' and use. From the point of view of connection to other sciences and engineering fields, Machine Vision represents a combination of areas as: Machine Learning, Robotics, Optics, Digital Signal Processing, Image Processing, Video Processing, Geometry, and others;
- The ability to perceive the technological tasks of industrial robots, manifested through the robotic manipulation with objects, performing pick-and-place and/ or the assembling tasks that the robot performs in several stages, such as: recognizing an object, approaching a recognized object, grasping the object with the appropriate orientation of the grasper's fingers and with right intensity of grasp**, moving the object to another location, and the like.**

Description of the use of digital technologies in teaching:

- The introduction of digital technologies, new methods and techniques into the content of these courses would improve students' competencies in designing, programming and testing. Students work independently in consultation with professors during lectures and exercises. Practical exercises within the course would involve solving specific tasks, and deriving solutions in laboratory for problems arising in specific situations or taken from practice.

By implementing innovations in this group of subjects, students will master working with modern technologies and a real-world equipment that the current course content did not cover. Conditions will be created for students to independently reflect, evaluate, communicate, collaborate, and analyze, test and simulate devices, machines, and technological systems.

4. CONCLUSION

The aim of the project is, in addition to innovating existing subjects, to improve the competences of professors and teachers as well as students in the domain of digitization and Industry 4.0, information communication technologies and entrepreneurial competences for the purpose of providing higher quality of teaching. The result of the implementation of the project should be: ability to work on CNC machines using a simulator, understanding of a flexible production cell consisting of two units - a CNC machine and an industrial robot in order to master production processes related to Industry 4.0, creating greater autonomy and increasing the productivity of the system, application of advanced machine learning techniques, digital literacy of students, development and installation of a smart production system with the application of artificial intelligence methods and the cybernetic model, improving the quality of the teaching process and increasing the use of information communication and other contemporary/ modern technologies in the educational process.

Abstract: *Welding is a major joining process in modern manufacturing, primarily used for creating metal structures and components, as well as maintenance and repair operations. Welding, compared to other production processes, is regarded as a hazardous procedure that can have long-term detrimental consequences for persons and the environment. It's critical to be aware of these consequences and consider the possibility of employing environmentally friendly methods. Each welding process has distinct risks and pollutant exposures, thus choosing the proper technique for a given application with the lowest risk of hazards is critical. This article includes a technical and environmental overview of welding operations, as well as information on the major pollutants and their estimations. The effect of welding conditions, parameter optimization, operation, and materials on the formation of key contaminants is investigated and analyzed. The purpose of this study is to raise awareness of the dangers of welding contaminants to the environment and human health. It also suggests ways to mitigate these risks and promotes the development of green welding technology.*
Keywords: fumes, gases, health dangers, welding processes

1. AIMS AND BACKGROUND

Welding plays a significant role in manufacturing, particularly in industries that use complex metal components and structures. It is a metal-joining fabrication process that employs high heat, pressure, or a combination of the two, with or without filler material, to create a strong and permanent connection between the assembling metal parts. The solidification of the molten metal at the interface of the joining parts results in metallurgical bonding, which forms a solid welded joint with improved properties over the base metal [1]. Today, there are numerous welding processes available for a wide range of applications, which can be divided into two categories: fusion welding and pressure welding. Fusion welding processes use electric arc, gas, electrical resistance, and high energy to generate heat at the location of the joint. Pressure welding also known as solid-state welding uses mechanical pressure to achieve coalescence through friction or explosion. Welding technologies also differ in terms of their economic performance and environmental impact, because of this, selecting a technology for a specific application is crucial for welding costs and environmental burdens [2]. In the manufacturing sector, there is no clear preference for welding technologies; however, basic material properties and other conditions that arise from the specific case of application, such as the number of joints, shape, and dimensions, loading, connection purpose, and so on, are important considerations. Electricity, radiation, heat, flames, fire, explosion, noise, welding fumes, fuel gases,

[3]martin.petreski@mf.edu.mk
[4]nikola.avramov@mf.edu.mk
[5]jelena.djkokikj@mf.edu.mk

inert gases, gas mixtures, and solvents are the most dangerous aspects of welding. However, it is considered that the most dangerous welding byproducts are fumes and gases. Welding processes generate a complex mixture of fine and ultrafine aerosols and gaseous harmful substances that are due to the intensive heat that vaporizes the base metal, and the electrode coating condenses into small particles [3, 5]. These chemical agents are fumes and particulates with aerodynamic diameters of less than 1 μm and can be easily inhaled and attached to human lungs causing serious illness to the affected individual [4, 5]. The welding fume and particulate matter mainly consist of particles from the evaporated electrode and a little part of the basic material with chemical compositions that depend on the welding technique, parameters, electrode, basic metal, and flux composition [6]. Metal oxides with chemical particulates such as lead, nickel, zinc, iron, oxide, copper, cadmium, fluorides, manganese, chromium, and gases such as carbon monoxide, nitrogen oxides, and ozone are the main components of the emissions [6, 7]. A summary of all the chemical, physical, and radiation hazards are shown in Table 1[8]. The gaseous by-products originate from chemical reactions, ultraviolet irradiation of atmospheric elements, or shielding gases. Together with welding nanoparticles, they represent a significant source of air pollution, and their size and distribution should be monitored and evaluated. Several factors influence the volume of fumes and gases produced (welding parameters, arc length, electrode, shielding gas, welder experience, humidity, welding technique). As a result, there are compelling reasons to address the type and methodology used during these processes to ensure a working environment with the least amount of air pollution possible.

Table 1. Common hazardous byproducts during welding
Source: National Institute for Occupational Safety and Health, 2022 [8]

Fume	Aluminum, Cadmium, Chromium, Copper, Fluorides, Iron, Lead, Manganese, Magnesium, Molybdenum, Nickel, Silica, Titanium, Zink
Gases	Carbon Dioxide, Carbon Monoxide, Nitrogen oxide/dioxide, Ozone
Radiant energy	Ultraviolet, Visible, Infrared
Other Hazards	Heat, Noise, Vibration

The purpose of this article is to provide an overview of the major pollutants that affect worker health and the environment during welding. The results of several experimental studies on various welding processes are summarized to broaden knowledge and raise awareness of the potentially toxic effects of welding emissions.

2. RESULTS & DISCUSSION

2.1 Air pollution from welding

The hazardous air pollutants present at high temperatures during metal vaporization are the main source of concern in the welding process. As a result, electric arc welding is thought to emit these pollutants in substation quantities. Other welding processes, such as pressure welding, produce fewer fumes and are thus considered green welding technologies due to their lower operating temperatures Friction stir welding (FSW) and magnetic pulse welding (MPW) produce less pollution and emit no hazardous fumes because they do not require flux or fillers. Outgassing is also eliminated with diffusion welding. When compared to standard shielded metal arc welding (SMAW) and gas metal arc welding (GMAW), other techniques, such as laser arc hybrid welding (LAHW), have the lowest direct environmental impact. However, because the composition of the used wire is directly related to the composition of the fumes, gas tungsten arc welding (GTAW) emits fewer fumes than SMAW and GMAW. SMAW is considered a process that has negative health effects because there is a tendency to form hexavalent chromium [7]. Furthermore, high rates of toxic compound emissions are generated during SMAW stainless steel welding [7]. Plasma arc welding (PAW) is like the GTAW process and emits similar levels of air pollutants [7]. GMAW welding of aluminium produces more ozone than GTAW welding. Despite these environmental advantages, some of these techniques are

impractical for specific applications or large jobs, so fusion welding processes remain the preferred method among manufacturers.

2.2 Polluting components

The chemical elements found in fumes are complex and highly dependent on the metal mixtures that evaporate at different rates and at different temperatures. Because most steels contain iron, silica, chromium, and nickel in varying amounts, the rates at which the alloying elements evaporate are also affected by element concentration. The fumes are primarily composed of manganese (Mn), nickel (Ni), chromium (Cr), cobalt (Co), and lead (Pb). Gaseous pollutants or greenhouse gases such as carbon dioxide (CO_2), carbon monoxide (CO), nitrogen oxides (NO_x), and ozone (O_3) are also present. The precise level of risk is determined by fume composition because each of these chemical elements and gases has a unique toxic effect that must be effectively controlled. Some of the chemical components in fumes and glass byproducts are discussed in the following paragraphs. When welding stainless steel or high alloy steel, chromium is measured in significant quantities. The concentration of hexavalent (Cr+6) depends on the shielding gas, and it is a dangerous toxic compound with mutagenic potential that can cause lung cancer [8]. Nickel is commonly found when welding stainless steel and nickel alloys. It is a human carcinogen, and some studies show that the cancerogenic potency of different materials can vary significantly [8]. Dermatitis, pneumoconiosis, asthma-like lung disease, renal dysfunction, and respiratory tract irritation are also at increased risk [3, 4, 8]. Iron, in the form of iron oxide, can also be found in fumes. It is considered irritant dust with a low risk of causing chronic lung disease after inhalation, but these particles have been observed to accumulate in alveolar macrophages and the lung interstitium [8]. Welders develop pneumoconiosis known as siderosis because of long-term exposure to arc welding fumes [4]. Manganese can be found in most welding fumes, particularly when it is used as a flux agent in the coatings of SMAW electrodes, flux-cored electrodes, or as an alloying element, or when it is present in high concentrations in the base material [8]. As a symptom of chronic manganese poisoning, it affects the eyes and nose, and the central nervous system, and causes chemical pneumonitis and kidney damage [4]. The coatings of metal electrodes and flux-cored electrodes contain silica and fluorides. The silica is amorphous and non-cytotoxic, as opposed to the highly cytotoxic and crystalline form associated with silicosis [8]. Inhaling fluorine-containing gases has been shown to irritate the eyes, nose, and throat as well as harm the lungs, and occupational pulmonary exposure to particulate fluorides has been linked to occupational lung disease [3]. In addition, there is bone and joint damage, gastrointestinal symptoms, fluid in the lungs, and kidney dysfunction [3]. Long-term fluoride fume exposure can cause skeletal or dental fluorosis [4]. Exposure to zinc or zinc oxide in fumes is mostly caused by heated galvanized coatings on the base metal, which can cause acute respiratory illness [14]. Aluminum is found in fumes because it is used as an additive in many steels and nonferrous alloys, as well as welding electrodes, coatings, paint, electro-plated or sprayed elements, and filler wires [8]. Welding with aluminum encourages the formation of the pneumo-toxic gas Ozon, which can irritate the lungs. When welding copper and its alloys or using copper-coated GMAW electrodes, high concentrations of copper are possible. Vaporized copper and cadmium are metals known to cause metal fume fever [3]. Cadmium is an element that is used in the production of fluxes found in flux-cored electrodes on occasion [8]. Cadmium in welding fumes has been linked to acute chemical inhalation lung injury, and it is one of only a few welding-related exposures that can be fatal [8]. During arc welding processes, a large quantity of gases such as ozone, nitrogen oxides, carbon monoxide, and carbon dioxide are released. The airborne vapors around the arc undergo oxidation, which is aided by ultraviolet radiation from the welding arc, to produce phosgene, a pulmonary irritant gas [9]. Arc welding gases can be produced by shielding gases, decomposition of electrode coatings and cores, arc reaction with atmospheric constituents, ultraviolet light reaction with atmospheric gases, and decomposition of degreasing agents and organic coatings on the metal welded [9, 15]. Ozone is an allotropic form of oxygen produced by arc welding's UV radiation, which ionizes oxygen. The rate of ozone formation is determined by the wavelengths and intensity of ultraviolet light produced in

the arc, which is influenced by the material being welded, the type of electrode used, the shielding gas, the welding process, and welding variables such as voltage, current, and arc length [9]. Ozone is a severe respiratory irritant that can cause extreme discomfort, nausea, coughing, and bronchitis at levels above 0.3 ppm, and pulmonary edema at levels above 10 ppm for several hours [8]. Nitrogen oxides are produced during welding processes because of direct oxidation of atmospheric nitrogen at high temperatures [8, 9]. When inhaled, nitrogen oxides have been shown to irritate the eyes, mucus membranes, and lungs [4]. Excessive pulmonary irritation and edema can result from exposure to extremely high concentrations [8]. Carbon monoxide is a toxic and dangerous gas produced during welding because of the action of UV radiation on carbon dioxide [8, 9]. Carbon dioxide and carbon monoxide are produced because of the decomposition of organic compounds in electrode coatings and cores, as well as the decomposition of inorganic carbonates in coatings [8]. It impairs the blood's ability to absorb oxygen, resulting in headaches, nausea, dizziness, confusion, death, cardiovascular symptoms, and carbon monoxide poisoning [4]. In a recent study, carbon monoxide, sulfur dioxide, and nitrogen gases were detected and measured in the air at the same time, resulting in significant negative effects, as shown in Table 2 [12].

Table 2. CO_2, SO_2, and NO_x emissions during welding
Source: G. Amza and D. Dobrotă in Metalurgija, 51, 2012[12]

Welding process	**CO_2**		**SO_2**	**NO_x**
	Min	**max**	**SO_2/t seam**	**NO_x/t seam**
SMAW	0.280	0.5	0.64	0.154
Submerged automatic arc welding (SAAW)	0.175	0.21		
GMAW and GTAW	0.205	0.24		
Oxyfuel welding	0.312	0.55		

According to the data presented, industrial activity for manufacturing welded constructions can be considered an environmental pollutant, particularly to the atmosphere, as evidenced by air quality monitoring results. The emissions are strongly influenced by the diameter and composition of the electrodes, the workpiece composition and coatings, travel speed, voltage, current, arc length, welding position, and deposition rates, so fumes can be reduced or increased depending on the choice [10]. The weight of fumes generated is a percentage of the weight of deposited metal or the length of the electrode used. It is found that 95 % of the welding fumes are generated from the additional material and only about 5 % from the base material [13]. Table 3 shows typical ratios of different welding processes and metals, the maximum rate of welding fume is achieved if the GMAW continuously welds on the carbon steel with 10lb/h or 0.09 lb/h (0.9%) [11]. The situation is different for stainless steel, the generation of fume with the same welding process is 0.7lb/h. If the welding processes last for half an hour, then the values of the fumes are going to be divided by two.

Table 3. Welding fume ratios
Source: Source: *Welding fume control: regulations and processes, 2008 [11]*

Welding	**Metal Type**	**Range Weight of Fumes/ Weight of Deposited Material**
FCAW	Carbon Steel	0.9-2.4%
	Stainless Steel	0.9-2.4%
SMAW	Carbon Steel	1.1-5.4%
	Stainless, High Alloy	0.3-1.4%
GMAW	Carbon Steel	0.3-0.9%
	Stainless Steel	0.6-7%
	Copper/Aluminum	0.5-1.6%

Emission amount and variations in the fume formation rate (FFR) are heavily influenced by the type of welding and the operating conditions, as shown in Fig. 1 for various processes based on electrode type [10].

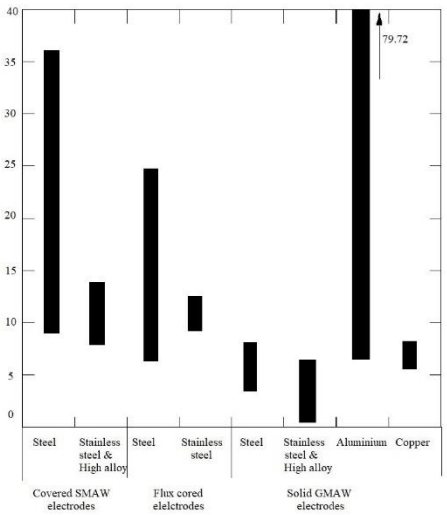

Figure 1. Particulate emissions from various arc welding processes
Source: Development of particulate and hazardous emission factors for electric arc welding, Final Report, 1994 [10]

The GMAW uses a shielding gas to protect the molten metal from the atmosphere to reduce oxidation and other reactions and provide a better quality of the weld. Usually, this gas is an inert gas mixture of argon, helium, or carbon dioxide and can intensify the production of toxins such as nitrogen oxides and ozone. Flux-cored arc welding uses flux with a high level of fluorides and silicates that vaporize and produce gases that protect the liquid melt from impurities.

2.3 Parameter considerations and operational conditions

The mechanisms that cause fume formation are complex, but changes in process parameters and operational conditions can help to reduce fume emissions and provide a healthier working environment. A recent investigation on fume emission when welding mild steel (MS) and stainless steel (SS) with the GMAW process at various current and voltage settings revealed that heat input and FFR are directly connected, meaning that with higher current or voltage there will be higher FFR so to lower the amount of fume generated welders should use the lowest current intensity as possible [16]. Also, it is concluded that the use of MS as base metal produces more fume when compared to SS, so there is a strong connection between fume rate generation and the chemical composition of the metal to be welded. Welding voltage and current both affect fume generation. The length of a welding arc can also influence fume generation. A longer arc gives the droplet more time to react and emit fumes. As the voltage increases, so does the amount of welding fume produced. The current levels in solid wire GMAW rise as current levels rise, depending on the shielding gas used. Metal transfer changes from short-circuiting to globular to fine droplet spray as the electrode current density increases. This change also has an impact on arc stability, which in turn has an impact on fume levels.

3. CONCLUSION

There is an urgent need to reduce air pollutants to protect the environment and workers' health. The composition of the consumable electrode alloy, the base metal being joined, and the presence of any surface materials or coatings on that base metal, all influence the substances found in the welding environment. When it comes to keeping fume exposures to very low levels, the challenges are significant. The only way to achieve and maintain low levels of exposure is to carefully select consumables and welding processes, as well as to use proper ventilation and personal protective equipment. Also, a study of various base materials revealed that stainless steel produces a greater quantity of nanosized particles than carbon steel, therefore the proper choice of base metal is crucial. When selecting a base metal, consider choosing the one that emits less fume and can be welded with a low fume emitting process, considering the type of electrode and, if necessary, the type of shielding

gas for emission control. Fume levels in gas-shielded processes are influenced by the reactivity of the gas blend as well as its influence on the type of metal transfer required. When high percentages of argon are used, it is possible to achieve stable, finer droplet transfer at moderate current levels. When shielding gases contain more than 20 percent carbon dioxide, transfer remains globular within these same current ranges. Welding fume levels rise as the percentage of CO_2 in the shielding increases. Prior to deciding on a specific welding process, the amount of fume must be considered; whenever specifications and conditions allow, the process generating the least amount of fume should be chosen. Overall, all welding processes can result in a significant concentration of nanosized particles being deposited in the lungs of exposed welders, but according to data from various studies, the lowest level of airborne particles transferred in the alveolar region of the lungs was associated with FSW, followed by TIG and metal active gas welding (MAG) [7]. While FCAW produces the most fumes, submerged arc welding (SAW) produces the least. To reduce fume emissions, the proper current, arc voltage, arc length, travel speed, and welding electrode angle should be chosen by the operator to ensure quality welds.).

ANALYSIS OF RESEARCH ON OPTIMIZATION MODELS AND ALGORITHMS FOR PLANNING PREVENTIVE MAINTENANCE OF MACHINE SYSTEMS

Stojko Biočanin[1], The Academy of Applied Technical Studies Belgrade
Milica Timotijević[2], College of Applied Studies Aviation Academy

Abstract: *The paper presents a complete overview of various optimization models and algorithms related to preventive maintenance planning. An overview of works that use models and given applications of preventive maintenance planning in production systems, service systems and special purpose systems is presented.*
Keywords: Model, Preventive maintenance, Algorithm.

1. INTRODUCTION

Modern organizational systems for maintenance are oriented towards achieving efficient and effective procedures and work processes in order to satisfy the needs of their customers - consumers of services for which they are competent in the maintenance of technical systems. The effectiveness and efficiency of maintenance is very precisely dictated by the requirements of clients - customers. Most organizational maintenance systems are capable of offering quick repairs at low prices, all thanks to the knowledge economy. The basis of the knowledge economy is the knowledge industry, which is supported by planning, production equipment, production methods, maintenance methods, science and technology. Modern maintenance systems start processes with maintenance planning, which interacts with the knowledge economy and industry. They mutually create incentives (causes and effects) for more efficient and effective maintenance processes.
That is the reason why optimization models and algorithms in the field of maintenance have been dealt with by many world researchers and authors. Special interest was directed to the planning of preventive maintenance of technical systems, where various optimization deterministic and stochastic models and algorithms were used.

2. EXACT ALGORITHMS

For the maintenance of technical systems in semiconductor production, Yao et al. [1] optimized preventive maintenance planning by means of the Analytical Hierarchy Process (AHP) method, which was developed by Thomas and Maatu in the early seventies of the last century. They proposed different approaches in defining the problem of optimal maintenance periodicity of technical systems. They developed a Markov decision process and optimized this model via a mixed integer linear programming model. They defined a profit maximization from the production of a group of tools, as an objective function, and took a time dimension for the preventive maintenance activities by introducing a limitation of assets that can be out of use during maintenance interventions. In doing so, they defined an optimization model by means of non-linear functions. In order to achieve the global optimum, they transformed non-linear functions into linear ones. In doing so, they used the optimization software EasyModeler and OSL (Open Software License). In addition, they used the AutoSched AP as a simulation software to create a simulation model to evaluate the realization of the

[1]sbiocanin@atssb.edu.rs
[2]timotijevic.milica93@gmail.com

proposed optimization model. In their analysis of the operational problem of preventive maintenance in a planned time period of one week, with 11 constraints, they compared the obtained results with the actual preventive maintenance plan. Later, Yao and a group of scientists extend their earlier optimization model to make it more general and show its application through numerical examples.

Jayakumar and Asgarpoor, [2], presented a linear programming model to optimize the maintenance policy for system elements with reduced quality, reduced reliability and uncontrolled failures. They determined the optimal average time for small and large overhauls of preventive maintenance based on maximizing the readiness of a certain technical element, assembly or aggregate. They used MAPLE and LINGO software to solve linear programming models utilizing Markov decision processes.

Duarte et al., [3], presented a model and algorithm for the optimization of system maintenance with a series of elements - components. In their research, they assumed that all components have a linearly increasing failure rate, with a constant failure growth factor, thus making it difficult to manage the maintenance of technical systems. In addition, they assumed that the objective function is cost minimization, subject to individual and total downtime/failure constraints. In terms of maintenance activities, they defined preventive and corrective maintenance for each component. Finally, their algorithm optimizes the time interval between maintenance activities for each component during the planned period. Canto, [4], presented an optimization model for planning preventive maintenance of the power plant through planned periods. He considered the total cost of various operations as an objective function and used Bender decomposition to solve mixed-integer linear programming models.

Budai et al. [5], presented two mixed-integer linear programming models for preventive maintenance planning problems. These authors take the objective function for both models to be total costs, including depreciation costs, maintenance costs, and costs of unscheduled maintenance activities. They present and solve preventive maintenance planning problems using GAMS software to execute optimization models. They use CPLEX as optimization software to find the optimal preventive maintenance plan. They apply their model to a railway maintenance planning case study. In addition, they develop four heuristic optimization algorithms, two for each model, and compare the research results obtained from the exact algorithms and state the methodological advantages of each solution.

Nonlinear optimization models have also been developed for this purpose. Thus, Tam et al., [6], developed three well-known nonlinear optimization models based on: a) minimization of total costs with the targeted achievement of reliability, b) maximization of reliability for a certain financial expenditure or budget and c) minimization of total costs if the risk of occurrence is accepted expected costs due to the termination of operation of technical systems and maintenance costs on which elements of reduced reliability have been identified. They use MS-Excel Solver as the optimization software that uses the generalized reduced gradient (GRG) algorithm to solve nonlinear optimization models. Using these models, the optimal maintenance intervals for a multicomponent system can be determined, however those models only consider maintenance activities for components and do not consider replacement activities.

Alardhi et al.,[7], presented a binary integer linear programming model to find the best preventive maintenance plan in the separate and coupled cogeneration plants. These researchers defined equipment readiness maximization as an objective function, taking maintenance timelines, maintenance process execution duration, logistics operations, asset constraints, maintenance personnel availability, efficiency measures, and demand as a set of constraints. They were implementing this model in Kuwait in two factory plants with seven units and 42 pieces of equipment, during the 52 planned weeks. In doing so, they used LINGO as an optimization software for model optimization. In addition, they performed a sensitivity analysis on this model to assess efficiency and analyse the impact of moving the planned time limit in operation, reducing assets and increasing the need for maintenance strategies.

Panagiotidou and Tagaras [8], by applying nonlinear programming (NLP) methods, developed an optimization model that optimizes preventive maintenance plans in the production process. These authors considered two different states of components of technical systems, controlled and

uncontrolled, before total failure. They use time to change and time until cancellation as random variables and express it with the help of Weibull and Gamma distributions. In addition, in order to maintain the optimal preventive maintenance plan, they combine the concepts based on the lifetime and condition of the equipment in the optimization model, while realizing the minimum total cost, solving it by applying the Karush-Kuhn-Tucker (KKT) optimality conditions. Finally, they presented several numerical examples to demonstrate the effectiveness of their methodology. Shirmohammadi et al., [9], developed a nonlinear lifetime-based optimization model to determine the optimal preventive maintenance plan for single-component systems. They defined two types of decision variables: the time between preventive replacements and the lifetime of the element (until complete failure). They predicted expected maintenance costs, replacement costs, and total maintenance costs as the cost function, taking the cost per unit time as the objective function. To solve the optimization model and show the effectiveness of the proposed model, they used the MAPLE software.

In solving engineering problems, dynamic programming, as a frequently used optimization technique, has a wide application for obtaining optimal maintenance and replacement activities. Canfield, [10], studied optimization models of preventive maintenance focusing on various aspects of the failure function related to system reliability. He stated that preventive maintenance activities do not change or affect the failure rate increase, so the developed failure function is constant with maintenance activities. For his study, he considered the increasing failure rate, based on the Weibull distribution and determines the optimal maintenance costs, defining the average amount of system operating costs and applying dynamic programming as a solution approach.

Robelin and Madanat, [11], developed a maintenance optimization model for bridge decks through a Markov chain process. In this paper, optimization models are classified into two categories: (1) optimization models for systems with physically based deterioration (deadlocks), and with a limited number of decision variables, and (2) simpler optimization models for deterioration systems with a larger number of decision-making variables. They applied Markov chain methodology with the states based on the history of increasing failure rates and maintenance activities and used a dynamic programming as a solution and business decision-making approach.

3. HEURISTIC AND META-HEURISTIC ALGORITHMS

The genetic algorithm, as the main optimization approach, has been presented in several research papers. Usher et al, [12], presented an optimization model for maintenance and replacement of parts in small component systems. The authors determined the optimal preventive maintenance plan for the new system depending on the increase in failure frequency, considering time as the value of money for all future costs, the increasing failure rate over time, and the use of improvement factors to improve maintenance workflows. In addition, they performed a comparison of results between random search, genetic algorithm, as well as the known algorithms and constraints.

One of the most significant studies in the field of reliability and maintenance optimization for multi-component and multi-state systems was performed by Levetin and Lisnianski, [13]. The authors defined a multi-state system as a system in which all or some components have different levels of states, from adequate functioning to a complete failure, and system reliability as its ability to satisfy certain level of operation. They formulated an optimization model to determine preventive maintenance activities that affect the effective lifetime of components. Their model is based on a cost minimization depending on the required level of reliability. They applied a universal generating function technique and used a genetic algorithm to determine the best maintenance strategy. Levetin and Lisnianski presented additional research in which an optimization model is developed to determine optimal scheduling and switching in multi-state, parallel-connected systems. They considered an increasing frequency of failures based on the expected number of failures over time intervals and defined the sum of the costs of maintenance activities together with the costs of insufficient operation due to component failures. They used a universal generating function approach and applied a genetic algorithm to find the optimal maintenance strategy.

Wang and Handschin, [14], developed a new genetic algorithm by modifying, by crossover and permutation, the basic operators of the standard genetic algorithm based on the specific characteristic of the preventive maintenance planning problem for power supply systems. They improved the time complexity of genetic algorithm research by considering an integrated coding method, with specific code and transparent constraints. Thus, they ensured faster convergence in solving problems and prevented the creation of unresolved issues. As an implementation methodology, an object-oriented programming approach is applied. In doing so, the effectiveness of the new genetic algorithm is shown through theoretical analysis and simulation results, all in order to make a comparison with the traditional genetic algorithm. Tsai et al., [15], in their optimization model of preventive maintenance considered two activities: imperfect maintenance and replacement of parts. They designed the imperfect maintenance activities based on the concept of improvement factors, which are determined by a quantitative assessment procedure. They used a genetic algorithm to find optimal preventive maintenance activities while taking system lifetime per unit cost as the objective function. As a case study, they tested a mechatronic system to demonstrate the effectiveness of their model and algorithm. Cavory et al., [16], presented an optimization model to plan the best preventive maintenance tasks for all machines in a single product production line. The authors assumed that each machine should be assigned to each operator and that the overall throughput of the line should be considered as an objective function to bring it to the perfect operation. As the first step, they formulated an optimization model and analysed it using an analytical approach. Then, these researchers used C++ for some programming and applied a genetic algorithm to find the best variant of preventive maintenance. In addition, to confirm the results they designed an experimental design to establish and analyse the parameters of the genetic algorithm and used the Taguchi method and statistical analysis. Finally, this approach was applied to an actual automotive engine production line. Leou, [17], showed an optimization model to find the optimal preventive maintenance plan for a multi-component system. It considers the total costs of operations and maintenance work processes together with reliability as system criteria and transfers them to an objective function, defining the degree of impairment in relation to the required reliability. In addition, it defines maintenance personnel and maintenance duration as system constraints. He applied this optimization model to a case study with six electric generators and used a genetic algorithm as an optimization methodology to determine the best preventive maintenance plan.

Han et al., [18], considered the recursive nature of failure rates between preventive maintenance cycles and developed a nonlinear optimization model based on repair costs, preventive maintenance costs, and production loss costs in a production system. They applied a genetic algorithm as an optimization technique and stated that their model can be considered in decision support systems for maintenance of technical systems.

Brice et al., [19], considered cost and readiness as system criteria in their research. They optimized the model including cost as an objective function and availability as a constraint using a genetic algorithm to find the best preventive maintenance plan. They used a time-dependent Birnbaum importance factor to generate an ordered sequence of first control periods and used MATLAB to calculate system readiness via a Monte Carlo simulation approach.

Limbourg and Kochs, [20], proposed several techniques to represent decision variables in preventive maintenance planning models using heuristic and meta-heuristic optimization algorithms. The authors tested various non-standard approaches and compared them to the binary representations with the help of a heuristic algorithm, and the research results demonstrated the effectiveness of their approaches. In addition, they implemented certain modified crossover and permutation procedures in the genetic algorithm and showed improvements in the performance of their algorithm in terms of search time and accuracy. Another study of the application of genetic algorithms for maintenance optimization was conducted by Lapa et al., [21]. They considered flexible maintenance intervals and stated the advantage of this assumption over conventional methodologies. They developed a model that includes preventive and corrective maintenance activities and their associated costs, number of losses, system reliability and failure probability. Since their model is a large-scale nonlinear optimization model, they used a genetic algorithm as the solution procedure. Additionally, and as a

case study, they applied their model to technical systems - high pressure plastic injection machines, in order to measure the effectiveness of their methodology.
Verma and Ramesh, [22], grouped the systems and subsystems of a large construction plant into higher modular assemblies (HMA) and applied the multi-objective preventive maintenance planning method. They modelled this problem as a constrained nonlinear multi-objective mathematical program, where reliability, cost, maintenance period discrepancy, and initial maintenance time factor are the elements of the objective function and use a genetic algorithm to solve this model.
Shum and Gong, [23], presented the application of a genetic algorithm to optimize the planning of preventive maintenance of production machines. They assumed that the frequency of maintenance and replacement of parts, together with the purchasing strategy and the volume of maintenance manpower, are the decision variables, and the total cost is an objective function. They examined the impact of these costs on the optimal maintenance plan under realistic conditions.
Other meta-heuristic algorithms have been used as combinatorial optimization techniques to solve maintenance planning problems. Samrout et al., [24], used the ant colony algorithm or ant theory to optimize a problem that was previously optimized with the help of a genetic algorithm. They defined a series of maintenance and control periods for the components and used MATLAB for the simulation.

4. HYBRID ALGORITHMS

Kim et al., [25], combined a genetic algorithm with simulated effects for the optimization of the problem of scheduling large-scale and long-term preventive maintenance and parts replacements. In their research, the probability of acceptance of the simulated effects method was taken as a measure of individual survival in the genetic algorithm. Using this approach, they achieved a near-optimal solution in a short period of time compared to the exploration time of a simple genetic algorithm. As a case study, they optimized the long-term maintenance planning problem of a thermal system.
Tan and Kramer, [26], developed a general framework for optimizing preventive maintenance in chemical process operations. They used the Weibull distribution for failure rates and considered different maintenance activities that could be implemented. They developed a methodology that combines Monte-Carlo simulation with a genetic algorithm to solve opportunistic maintenance problems with a non-deterministic objective function. They applied their approach to two case studies to compare the results obtained from the proposed model with the results obtained from an analytical approach and a Monte-Carlo simulation with a neural network. Finally, they stated the advantages of their approach over other approaches.
Marseguerra et al., [27], developed a condition-based maintenance model (CBM) for the multi-component systems and used a Monte-Carlo simulation model to predict the level of degradation in a continuously observed system. They applied a genetic algorithm to optimize the degradation level after maintenance activities in a multi-objective optimization model where profit and completion are the objective functions. In addition, they considered a simulation model to explain the dynamics of the load-dependent degradation process in components with different loads. Considering the obtained research results, they stated that the combination of genetic algorithm with Monte-Carlo simulation is an effective approach for solving combinatorial optimization problems.
Shalaby et al., [28], developed an optimization model for preventive maintenance planning of multi-component and multi-state systems. They defined a series of preventive maintenance activities as the decision variables, and the sum of preventive maintenance costs, minimum repair costs, and downtime costs as an objective function. In addition, they considered system reliability, minimum intervals between maintenance activities, and personnel availability as constraints of their model. Finally, a combination of genetic algorithm and simulation was used to optimize this model.
Allaoui and Artiba, [29], presented a combination of simulation and optimization models in order to solve a hybrid job flow scheduling problem with maintenance constraints and multiple objective functions, based on flow duration and due date. In addition, they considered a set-up time, clean-up time and transport time in this model and stated that the implementation of the algorithm can be

affected by numerous dead time intervals. Finally, they proved that the efficiency of the simulated process effect algorithm is better than the heuristic algorithms with the same conditions.
Suresh and Kumarappan, [30], developed an optimization model and used a combination of genetic algorithm with the simulated effects. These authors applied their method to determine the preventive maintenance plan in the power supply system. They stated that this method can create better conditions if certain changes and modifications are made in the procedure of this solution. As a case study, they tested this method on 62 units of the state electricity system of Victoria.
Samrout et al., [31], presented yet another paper on the combination of the ant colony algorithm and the genetic algorithm for the optimization of the large-scale preventive maintenance problem. They divided the objective function of their problem into two parts and then used each algorithm to improve those parts separately. They note that using a hybrid algorithm for a large-scale problem is more efficient in comparison to a simple algorithm.

5. MULTI-OBJECTIVE ALGORITHMS

Multi-objective models of preventive maintenance optimization are presented in several works. Kralj and Petrović, [32], introduced a new approach in planning preventive maintenance in thermal systems. These authors developed a large-scale multi-objective combinatorial optimization model with three objective functions and a set of constraints. They considered the minimization of total fuel costs, the maximization of reliability in terms of expected unused energy, and the minimization of technological uncertainties as the objective functions. In addition, they defined the duration of maintenance, continuity of maintenance, period of maintenance, sequence of maintenance of thermal units of the same class, limitation of simultaneous maintenance of thermal units, and limitation of total maintenance capacity depending on manpower and resources for limitations. They developed a software for multi-objective preventive maintenance planning based on a multi-objective branch-and-bound algorithm implemented in FORTRAN. Finally, these researchers applied their method to a real system of 8 power plants with twenty-one thermal units and with 11 maintenance classes, all for a planned time period of 31 weeks.
Chareonsuk et al., [33], developed a multi-criteria preventive maintenance optimization model to find the optimal preventive maintenance intervals for the components in a manufacturing system. In this study, the authors considered the failure frequency based on the lifetime of the components by fitting the Weibull distribution to the data, and defined the expected total cost per unit time and the reliability of the production system as the main criteria. Furthermore, they used PROMETHEE (Preference ranking organization method for enrichment evaluations) as a solution approach, and defined alternative decisions as preventive maintenance intervals. Using this approach, they can prepare decisions by combining the importance of priority functions for the entire set of criteria. As a case study, they applied their methodology in a paper mill and used PROMCALC as the optimization software. Finally, they stated the advantage of their approach in which decision makers and managers can include different criteria in this model and perform sensitivity analysis on optimal solutions.
Konak et al., [34], presented an extensive study on multi-objective genetic algorithms and their applications in reliability optimization problems. They conducted 55 research papers and demonstrated solving techniques and methodologies.
Quan et al., [35], developed a new multi-objective genetic algorithm for optimizing preventive maintenance scheduling problems. They defined the problem as a multi-objective optimization problem considering the minimization of manpower idle time and the minimization of maintenance time, as well as stated that there is a trade-off between the objective functions. As a solution procedure, they used the utility theory instead of the dominance-based Pareto search to determine non-inferior solutions and demonstrate the advantage of this method through a numerical example.
Taboada et al., [36], presented a new study in this area. They developed a multi-objective genetic algorithm to solve multi-state reliability plan problems. These authors used a universal moment generating function to measure reliability and completeness criteria in a system. They applied their approach to two examples: the first is a system of five units connected in series, in which each

component has two states, functioning properly or with failure, and the second is a system composed of multiple subsystems with three units connected in series. In this system, each component has multiple states with different levels of realization, ranging from normal operation to the complete failure. They used MATLAB and demonstrated the efficiency of their approach in terms of research time.

6. CONCLUSION

Preventive maintenance planning is widely used in manufacturing and production systems. Most of the research focuses on single-component systems or simple and specific systems. That's why these researches are not always applicable to real and general systems. There is not enough research in the field, which relates to life expectancy reduction models with an improvement factor. The presented models of preventive maintenance planning, which deal with multi-component systems, can be applied to a wide range of systems. Progress in research represents the development of mathematical and statistical models that are presented as an improvement factor for ineffective preventive maintenance activities.

Vujadin Aleksic[3], dInstitute for Testing of Materials-IMS Institute

Abstract: *The structural and mechanical heterogeneity of a welded joint affects its resistance to cracking in both the elastic and plastic regions. Therefore, it is important to define the test method and the position of the fatigue crack. The behavior of an elasto-plastic material during stable crack growth can be described by the J-Δa diagram. As the crack propagates, a point is defined on the curve that represents the critical value of the J-integral. The aim of this experiment is to determine JIC value and the procedure is reflected in the determination of the R-curve, i.e. the J–Δa curve, which consists of the value of the J-integral for uniform crack increments Δa. In this paper, two SEN(B) specimens with the fatigue crack in the parent material (PM) and weld metal (WM) were tested according to standard ASTM E1820 at room temperature (RT) as well as three specimens with the fatigue crack in the weld metal (WM) at RT, -20 0C, -30 0C.*
Keywords: J-integral, J-R curve, HSLA steel, welded joints

1. INTRODUCTION

NIOMOL 490K belongs to the class of molybdenum microalloyed steels, of yield strength min. 490 MPa and specified nil-ductility transition (NDT) temperature of –60 ºC, produced by Slovenian Steel work company ACRONI Jesenice. This steel grade is designed for welded pressure vessels exposed to dynamic loads, operating at temperatures below zero, and that is why it must have acceptable toughness. The successful application of this steel depends on the grade deterioration of the properties of the base metal during welding [1].
The impact of plastic strain around the crack tip is very important for materials with pronounced plasticity, which include high-strength low-alloy steels used for welded structures. That is why it is necessary to introduce parameters that are not limited by the linear-elastic behavior of the material: crack tip opening displacement CTOD (δ) and - J-integral. The analysis of fatigue parameters must be possible even after the occurrence of significant plastic strains [2].
Procedure for determining J_{Ic} using the J-R curve (J-Δa dependence) consists of the value of the J-integral for uniform crack increase Δa, which for each load /unload point can be defined based on the total of elastic and plastic components [3,4]:

$$J(i) = J_{el}(i) + J_{pl}(i) \tag{1}$$

Elastic component of J-integral from the Eq 1

$$J_{el(i)} = \frac{K_i^2 \cdot (1 - v^2)}{E} \tag{2}$$

where are E - elasticity modulus, K_i - stress intensity factor and v - Poisson's ratio.

Plastic component of J-integral from the Eq 1:[5]

$$J_{el(i)} = \left[J_{pl(i-1)} + \frac{\eta_{1-i}}{Bb_{i-1}} A_{pl}^{i-1,1}\right]\left(1 - \frac{\gamma_{i-1}}{b_{i-1}}(a_i - a_{i-1})\right) \quad (3)$$

here are: $A_{pl}^{i-1,1}$- the increment of plastic zone under a load-displacement record from step i – 1 to i, b and η are constants.
Based on the calculated data, *J-R* curve can be created (*J-Δa* curve) using a fitted regression line, Fig. 1. Using the regression line, the J_{Ic} was obtained. After determining the J_{Ic}, the K_{Ic} can be determined very easily.

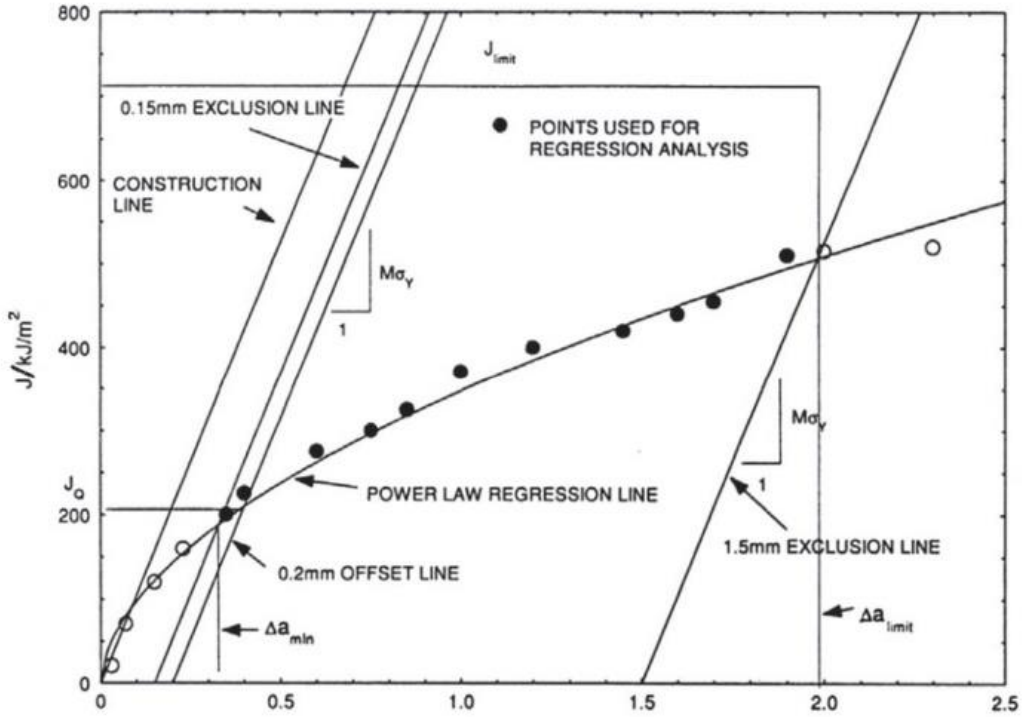

Figure 1. Standard procedure for selecting relevant points for determining J_{Ic}

2. MATERIAL AND EXPERIMENTAL PROCEDURE.

The investigated material is micro-alloyed high strength steel, commercial mark NIOMOL 490K steel, of yield strength min. 490 MPa and specified nil-ductility transition (NDT) temperature – 60°C, produced by Slovenian Steel work company ACRONI Jesenice. It is primarily applied for dynamic loading conditions and at low temperatures.
The results of the chemical composition of the investigated steel used for fabrication of butt-welded plates of 30 mm thickness are given in Table 1. The results of tension tests obtained at RT of the parent material (PM) and the welded joint (WJ) are shown in Figs. 2 and 3 respectively, and their tensile properties (mean values) were determined using 3 PM specimens and 3 WJ specimens, are listed in Table 2.

Table 1. Chemical composition of NIOMOL 490K, wt. %

Material	Yield strength $R_{p\,0.2}$, MPa	Ultimate strength R_m, MPa	Fracture strain, %
PM	544	610	26.47
WJ	620	650	25.5

The influence of the heterogeneity of the structure and mechanical properties of the welded joint is primarily reflected in the position of the fatigue cracks tip as well as the properties of the area through which the fracture propagates. The experiments were conducted on fatigue precracked single edge notched bend SEN(B) specimens, Fig 4., extracted along the length of the welded seam, using single specimen elastic compliance method according to ASTM E1820 standard. Plane-strain fracture toughness KI were determined in order to evaluate the behaviour of the welded joint in the presence of a crack-type fault, as the most dangerous of all structural faults.[6]

The test was performed at three different temperatures (RT, -20°C and -30°C) on an electromechanical testing machine, SCHENCK TREBEL RM 100, Fig. 5. The crack tip opening is obtained by special extensometer, with a measuring accuracy of ± 0,001 mm.

Figure 5. SCHENCK TREBEL RM400 testing machine
Source: original copyright

Based on the data collected from the testing machine, diagrams load F – crack tip opening CTOD was drawn and then the J–Δa dependence is constructed, Fig 6. The critical J-integral value, J_{Ic}, is obtained from the regression line. After obtaining J_{IC} values, values of the critical stress intensity factor (SIF) K_{Ic} were determined using Eq 4. [3]

$$K_{Ic} = \sqrt{\frac{J_{Ic} \cdot E}{1 - \nu^2}} \tag{4}$$

where E denotes elasticity modulus of the investigated steel and ν its Poisson's ratio. Results of critical J-integral and SIF values, J_{Ic} and K_{Ic}, are presented in Tab. 3.

3. RESULTS AND DISCUSSION

The structure and mechanical heterogeneity of the welded joint influence the crack development in the elastic and plastic regions. Therefore, it is necessary to define the position of the fatigue crack when examining fracture mechanics.[2]
The obtained values for WM are within the limits of the linear values for this type of steel and are reported in Tab.3.
We can see that values for WM obtained by testing specimens at the RT are $J_{Ic} = 222$ kJ/m^2, $K_{Ic} =$ 226 MPa m$^{1/2}$, at the temperature -20^{0}C, obtained values are $J_{IC} = 147$ kJ/m^2, $K_{Ic} = 184$ MPa m$^{1/2}$ and at the temperature -30^{0}C, values are $J_{Ic} =$118 kJ/m^2, $K_{Ic} = 165$ MPa m$^{1/2}$.

4. CONCLUSION

Great interest in the application of fracture mechanics testing of welded joints encountered limitations already at the beginning, because at least 10 specimens should be examined to determine some of the fracture mechanics parameters of the welded joint. The application of fracture mechanics to the examination of welded joints is large, and the reason is, first of all, a better and more complete understanding of the behaviour of a welded joint with a crack based on data analysis is obtained in those tests.[8]

LANDING OPTIMIZATION OF A SMALL SOUNDING ROCKET

Dragan Šaler[1], *The Academy of Applied Technical Studies Belgrade*
Milan Grujić[2], *The Academy of Applied Technical Studies Belgrade*

Abstract: *Sounding or research rockets are able to carry with them special containers in which it is possible to place various scientific instruments. The purpose of these instruments can be to perform scientific experiments or measure the desired parameters of the atmosphere during suborbital flight. Small sounding rockets, depending on the purpose, are able to reach heights of several thousand meters. Their advantage is reflected primarily in low manufacturing and exploitation costs, the possibility of quick preparation and conducting experiments. Also, it is possible to work with them in research areas that are not accessible by stratospheric balloons or orbital satellites.*
Keywords: sounding rocket, streamer, parachute, descent time, landing speed.

1. INTRODUCTION

Due to constant changes in the lower layers of the troposphere, which are most often caused by many pollutants, as well as disrespect with standards and regulations that control the release of harmful substances, large and frequent climate changes occur and these affect many aspects of humane lives. That is why there is a need for constant control of this space and continuous monitoring of all important parameters in it, such as: temperature, pressure and air humidity, content of harmful substances, intensity of UV radiation and the like. These tests can be performed using small sounding rockets.

2. SMALL SOUNDING ROCKETS

A small sounding rocket can be used to analyze the lower layers of the troposphere up to a height of 2000-5000 m. Its construction contains three basic systems, namely:

- The propulsion group, i.e. the solid fuel rocket engine, which will ensure that during operation (combustion in the chamber) a sufficient total impulse and the amount of energy that will enable the successful execution of the flight are created.
- The sounding module, which contains all the necessary electronic equipment, instruments and sensors for precise measurement of the desired parameters during descent. It must have sufficient strength to ensure safe operation and prevent any damage during flight. Collected data can be stored in the module's memory or sent directly using the transmitter. The sounding module should also have its own power source, and preferably a GPS.
- A descent system that should ensure reliable and safe activating the parachute or streamers and safe descent and landing of equipment.

According to flight technical requirements (flight up to 2000-5000 m height), a small sounding rocket should have a maximum mass of 15-18 kg, a mass of the sounding model of several kilograms and a body diameter of about 100 mm. A suitable commercially available solid fuel engine is also required. The flight course of a sounding rocket can be divided into three phases.

[2] mgrujic@atssb.edu.rs

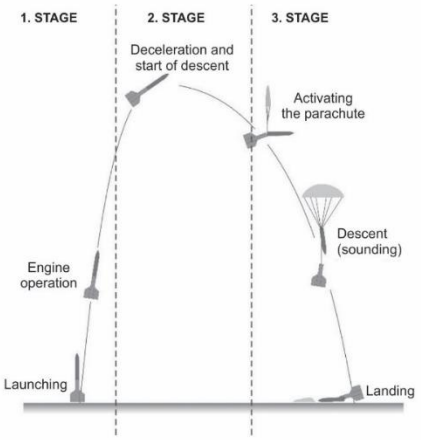

Figure 1. Phases of sounding rocket flight
Source: original copyright

During the first phase, while the rocket is on the launch pad, the engine starter is activated, which ignites the rocket fuel (propellant charge) and on that occasion, in the combustion chamber, the chemical energy of the fuel is converted into the kinetic energy of the burned gases, which, thanks to the nozzle, create thrust that drives rocket. The operation of the engine lasts only a few seconds, during which the rocket has a high acceleration [1, 2].
In the second phase, after the engine stops working, the rocket continues to move by inertia and slows down to the maximum altitude and speed v=0. Then it starts to descend. In the third phase, at a certain altitude and safe speed, the parachute is activated, which ensures a slow descent and time to make all the necessary measurements. At the end of this phase is landing with a sufficiently low speed rate that prevents unwanted damage to the equipment [3, 4]. Next chapter shows the calculation for determining the parameters during the third phase of the flight of a small sounding rocket.

3. DESCENDING AND LANDING OF THE ROCKET

The start of the descent is the moment the parachute (or streamer) is activated, which takes place slightly below the maximum flight altitude, at a relatively low speed, which enables correct opening and prevents the ropes or connections from breaking upon activation. The activation system can be mechanical or using a timer.
The distance of the rocket landing from the launch site can be large, which is usually affected by unplanned atmospheric elements such as wind speed or the formation of vertical thermal currents. That's why a streamer (rectangular strip) is often used instead of a parachute, which ensures a closer landing of the rocket but has a higher decay speed.
The two most important parameters in this flight phase are:

- t time from parachute activation to landing (sounding time). It is defined by the required time during which all necessary measurements will be performed.
- v speed of landing that ensures the safety of the equipment during the impact on the surface of the earth.

4. CALCULATION OF DESCENT TIME AND LANDING SPEED

The results obtained by the calculation differ from the actual values. The reason is the participation of several atmospheric parameters, horizontal and vertical currents, which are variable in a short period of time and cannot be predicted in advance. As the streamer gives more approximate results, it will be used in further analysis [5]. A rocket on a streamer can be viewed as a rigid body of mass m moving vertically downwards with speed v.

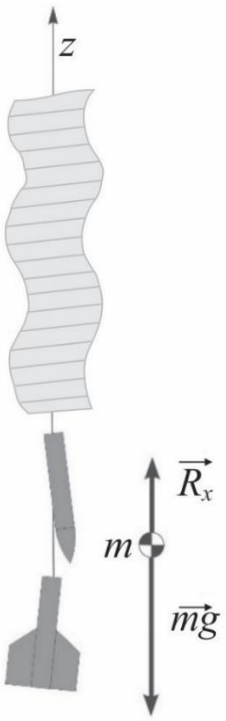

Figure 2. Distribution of forces acting on the rocket during descent.
Source: original copyright

According to Newton's second law is:

$$ma = mg - R_x \tag{1}$$

The force of air resistance acts vertically upwards and is proportional to the square of the instantaneous velocity *v*:

$$R_x = \frac{1}{2}\rho v^2 c_x S = Nv^2 \tag{2}$$

Where are: ρ - air density, c_x - drag coefficient and *S*- characteristic surface. [6, 7]

$$ma = mg - Nv^2 \tag{3}$$

$$m\frac{dv}{dt} = mg - Nv^2 \tag{4}$$

so it is:

$$dt = \frac{m \cdot dv}{mg - Nv^2} \tag{5}$$

The integral of the previous equation is:

$$\int_0^t dt = \frac{m}{N} \cdot \int_{v_0}^{v} \frac{dv}{\frac{mg}{N} - v^2} \tag{6}$$

so it's descent time: [8]

$$t = \frac{m}{N} \cdot \left[\sqrt{\frac{N}{mg}} \cdot \operatorname{arctanh}\left(v \sqrt{\frac{N}{mg}} \right) \right]_{v_0}^{v} \tag{7}$$

Since the functions tanh and arctanh are inverse, it can be written:

$$t = \sqrt{\frac{m}{Ng}} \cdot \left[\tanh^{-1}\left(v \cdot \sqrt{\frac{N}{mg}} \right) - \tanh^{-1}\left(v_0 \cdot \sqrt{\frac{N}{mg}} \right) \right] \tag{8}$$

The total mass of the system can be seen as the mass of the rocket (mass of the structure, engine without fuel, equipment) and the mass of the streamer, that is:

$$m = m_r + m_s \tag{9}$$

So equation (8) can be written in the form:

$$t = \sqrt{\frac{m_r + m_s}{\frac{1}{2}\rho c_x S g}} \cdot \left[\tanh^{-1}\left(v \cdot \sqrt{\frac{\frac{1}{2}\rho c_x S}{(m_r + m_s) g}} \right) - \tanh^{-1}\left(v_0 \cdot \sqrt{\frac{\frac{1}{2}\rho c_x S}{(m_r + m_s) g}} \right) \right] \tag{10}$$

Since hyperbolic functions are inverse, the descent speed can be obtained from equation (8) or (10):

$$v = \sqrt{\frac{mg}{N}} \tanh\left[t \cdot \sqrt{\frac{Ng}{m}} + \tanh^{-1}\left(v_0 \cdot \sqrt{\frac{N}{mg}} \right) \right] \tag{11}$$

With increasing time *t*, the tangent-hyperbolic function tends to 1, so the landing speed is:

$$v_{pr} = \sqrt{\frac{mg}{N}} \tag{12}$$

5. OPTIMIZATION OF STREAMER PARAMETERS

The main goal of such a system is definitely minimization of the mass. Like the masses of the rocket base, propulsion group and equipment are defined by the requirements of the structure itself, it is necessary to define the parameters of the rocket descent system. As mentioned earlier, in this case, the streamer will be considered due to the smaller deviation of the calculated and actual values. In this case, the condition is that the system provides the necessary descent time with the condition of minimum mass, as well as its dimensions. It is recommended that the aspect ratio of a rectangular streamer be 1:10. For financial reasons and legal regulations, optimization and tests were not performed on real sounding rockets, but on rockets of smaller dimensions. Their dimensions are 0.350 m high and 0.03m in diameter, with a mass of 0.025 kg. For the propulsion unit, a rocket motor with solid fuel of total impulse I_t=1.5 Ns and with a working time of 0.75 s was used. According to the calculation, with this rocket it is possible to reach a height of about 150 m.
In order to optimize, the BOX method according to the complex algorithm was used, for which it was created. [9]

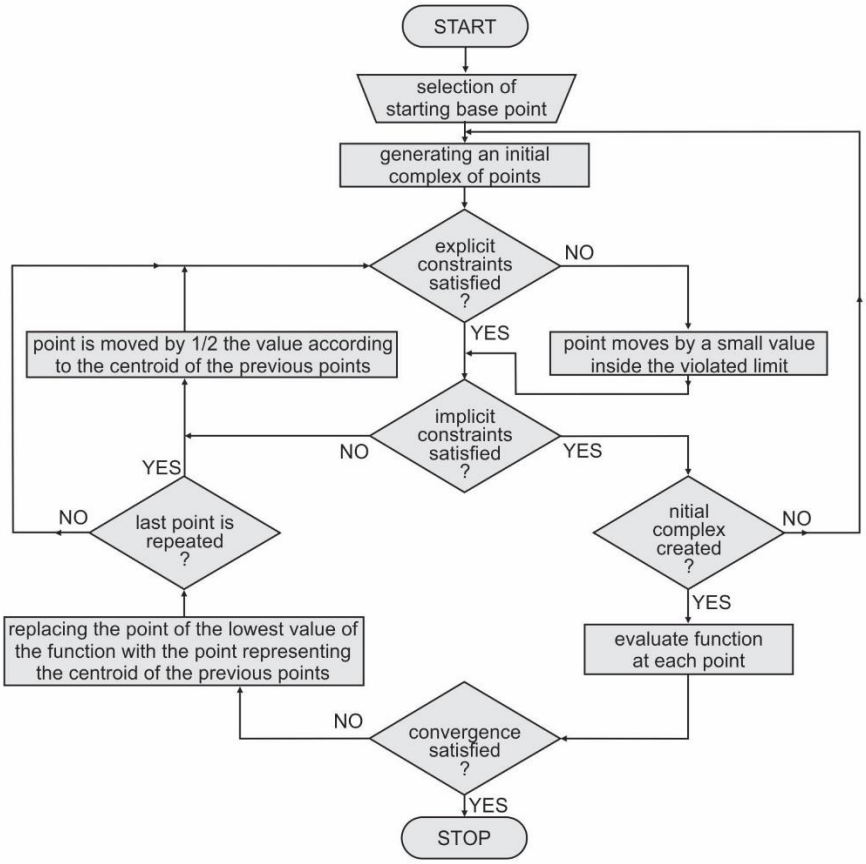

Figure 3. Optimization algorithm according to BOX's method.
Source: original copyright

In the given problem, it is necessary to find the maximum of the objective function, which is represented by equation (10). It is dependent on two variables with given constraints in the form:

$$t = f(m_s, S) \rightarrow max \tag{13}$$

$$0{,}005 \leq m_s \leq 0{,}01 \tag{14}$$

$$0{,}15 \leq S \leq 0{,}3 \tag{15}$$

The results obtained are: descent time t=55.03 s, streamer mass m_s=0.0075 kg and streamer area S=0,173 m^2 (1,32x0,132 m).

During the test, ten launches were performed with the same rocket with the same streamer. This was performed in calm weather and in the early morning hours when the currents in the atmosphere are minimal in order to minimize the unwanted effects of horizontal and vertical currents. Achieved descent times ranged from t=51 sec to t=62 sec, and only one time was below the calculated value of 55.03 sec.

6. CONCLUSION

Small sounding rockets are, among other things, practical for measuring the physical and chemical parameters of the lower layers of the atmosphere, the pollution of which significantly affects both human life and the entire flora and fauna. Due to their low cost of production and exploitation, simple use and quick production, they can have a great usage in specific research of air quality in endangered environments. The paper deals with the parameters of the final phase of the rocket's flight, descent and landing, which were confirmed by experiment.

SYSTEM SCALING RENORMALIZATION PROBLEMS IN BIO-THERMODYNAMICS: I) Yeast cell colony size scaling, as an opportune model

Milanka Plavsic[1], The Academy of Applied Technical Studies Belgrade
Milenko Plavsic[2], Engineering Academy of Science of Serbia

Abstract: *The existence of scaling relations between components of cell growing colony i.e. the production of proteins, single cell- and complete colony- growth, is considered in theoretical aspects and applying to yeast as an opportune model. The relations of methods applied with bio-thermodynamics principles accepted nowadays, are expound.*The *growth of each yeast wild type colony considered, is scaling regularly, with protein production in its cells, and with practically the same exponent, although the size of cells varies due to division. It indicates that the system expansion gradient at those two levels is the same, and wall coordinated and balanced by thermodynamics energy, and entropy parameters. It is very important for further bioengineering system design, especially in the frame of the new industrial trends.*
Keywords: Bio-thermodynamics, scaling principles, universality theory, yeast, Industry 4.0 concept

1. INTRODUCTION

The **scaling properties** of some objects in nature have been recognized very long time, as can be seen from some writings of Euclid, Archimedes, some members of Pythagorean School and through centuries and millennia, up to Galileo, Reynolds and present day papers. But, the research of deep logics of rules, relating scaling lows into common theoretical core, started with the rise of modern thermodynamics, and the new mathematical areas, as well [1-10]. In a similar way, the first ideas about problems of **nowadays bio-thermodynamics** rose already in writing of Schrodinger, Krebs, and Monod but, it waited with growth until polymer science came to enough high level of understanding of macromolecular structure and properties [5-15].That research has been founded on Paul Flory's thermodynamics theories on macromolecular systems, and Linus Pauling's quantum mechanical theories of peptide bond, α-helix, etc., and on their initiative of founding the new sciences related to bio-polymers (i.e. molecular biology, bio-medicine),what also lead to e.g. recognition of essential role of protein-chlorophyll conjugates in conversion of sun light to bio-energy (what makes even 65 TW from about 10 PW of the radiation energy coming from sun to the earth) [11-17].The interest grow at that time also, due to new developments of satellite technology, and planning for human traveling to the Moon, what raised in 1970s a numerous issues on human body response to thermodynamically completely different conditions, ever faced (where polymers also are important, as bio-protecting materials). It supported further the development of cryobiology but, also research on cell dehydration properties. Naturally, it generated also high interest of food and beverages industrial producers for more efficient work and conservation, with its help, as it was in First Ind. Revolution for classical thermodynamics help, for efficient use of heat, and recently for preservation of vaccines and medical samples [3, 11-14].The issues of climate changes and other environment impacts to life processes also supported development of bio-thermodynamics in the next period. Additional impact came from bio-medicine by cell engineering developments, and

[1] mplavsic@atssb.edu.rs
[2] plavsic@tmf.bg.ac.rs

discovering stem cells generation in adults, what followed with creations of the whole organs, out of them [12-14],
The research of genetics, developed in parallel with disciplines mentioned, then naturally establish close relations with those polymer-based sciences, but all of that generated also the whole set of interdisciplinary research fields, even more than 30 new disciplines, with names ending with - omix (e.g. proteomics, genomics [17,18]). Nowadays quite obvious is the need that those research results, abundant but, each focused on some narrow aspects, should be connected all together, and make available for some broad engineering, practical, purposes in modern bioengineering. Bioengineering is included, in that sense, into 3 main holders of Industry 4.0 concept, together with artificial intelligence and robotic production [11, 18].
To be able to fulfill such tasks, nowadays bio-thermodynamics also tries to make unified theoretic background connecting 3 fields of research: on bio-polymers, on living cell cultures and tissues, and on metabolic functions at all levels of cell systems. For example, temperature (T), pressure (P), acidity (pH), additives and solutes etc., influence a protein molecule performance in the cell, but that all influence also the following activity of that cell, and clusters of those cells, and living systems as a whole e.g., activity of medical-lab culture, or cells in a bio-reactor, but also cells in tumors-to be cured. Besides that applicative approach, bio-thermodynamics considers fundamental issues as cell growth, division, aging and human organism aging as a whole [18-27]. All those mechanisms must follow basic thermodynamic lows, but their balancing at different system levels, from a macromolecule to the organism, is a complex problem. For example, what are relations between three fundamental processes of living systems grow and development: protein production in a cell, the cell growth, and the corresponding cell cluster growth (not to extend for now the cell growth mechanism to the mechanisms of organism growth and cell replacement issues). Only recent years are available relevant experimental techniques to study and compare those processes in parallel, thanks to AI with modern cytometric and spectroscopic arrangements [3, 18, and 22] in complete agreement with **Industry 4.0 concepts**, causing significant advances in medicine and agronomy last years. In both of them appears the problem of coordination system processes, at different levels. In particular, in agronomy it starts with molecular activity of plant cell, up to huge systems outputs, from large surface plantation. The **smart management** here is needed, to provide efficient use of robot work in variety of conditions recently made by manual work and now requires adjustment to appropriate **technological operations** with plenty of details, what requires help and control of some AI center. The activates of such kind are still in development, but as a promising support from bio-thermodynamics aspect can be the application or rarefaction theory, with modified OUT method e.g. S16 rRNA sampling, modified now to cell colony levels relations, all with possibilities of the help from **nucleic acids sequencing AI platforms** (active nowadays or adapted to the new tasks in the future). (See section 2.3). In other words, bio-thermodynamics in involved in numerous nowadays activates but one of the main problems common to all is quantification of level relations. For illustration of that, we consider here the growth of cell colony from macromolecular production inside a cell, till change of colony size, using scaling as appropriate method for all levels and baker yeast as an opportune model, been of extensively studied, and best known system in microbiology.

2. THEORETICAL BACKGROUND

2.1 Scaling lows of Landau and Flory and foundations of modern thermodynamics

This year passed exactly 200 years since baron Cagntard de la Tour as the first, detected a critical point, measuring transition temperatures at high pressures, by lucid combination of experimental methods from several fields. Interestingly, he was interest for fermentation production of alcohol and the first critical temperature T_C, he found for alcohol, so bio-thermodynamics may origin from the same roots as criticality?! But, the both where not appropriately understood than, in modern management terms, although the interest for evaporation methods, and steam engine was very high.

But, it encouraged T. Andrews in further measurements of pressure-volume relations and making liquid-vapor coexistence curves and so the first, but very useful, phase diagrams. In 1873 (50 years after de la Tour) showed J.D. van der Waals that Andrews diagrams can be explained theoretically by equation of state, that he formulated based on mean field approach. The deviations of van der Waals theoretical curves from Andrews experimental, in the biphasic area, soon explained Maxwell in qualitative and quantitative manner, using the second law of thermodynamics and his theories on molecular motions. So in 1870s emerged new approach to thermodynamics, based on direct description of thermal molecular dynamic, as through the fundamental papers of Maxwell in 1971 (naming such mathematical description of system particle thermal motions, The Statistical Mechanics), papers of Boltzmann in 1875 (with his formula on entropy as a measure of systems ordering) and of Gibbs, in 1876 (with his description of thermal equilibrium of particle systems). Still, the behavior of systems close to critical point staid mysterious, e.g. all basic parameters of state, when approaching the critical point T_C, were observed to follow the scaling lows, with the same exponent for each kind of parameter, no matter what is the chemical structure of a liquid substance used, and with diverging behavior at the critical point [15]. For example, the change of the heat capacity is described by characteristic scaling exponent α with:

$$C_P \propto |T - T_C|^{-\alpha} \tag{1}$$

The new approach to the problem, and also to unusual behavior of liquid helium transitions, especial its superconductivity and magnetic properties, started Lev Landau in 1937. But for the magnetic properties, the fundamental influence has head also, the theoretical model of Ising, published in 1924, who considered magnetic dipole moment orientation changes with the field [3,4] through magnetic spin vectors **S** orientations. Landau used both, Gibbs thermodynamics and Ising models for the start [15]:

$$C_P = -T\left(\frac{\partial^2 G}{\partial T^2}\right)_P \tag{2}$$

But, Landau assumed that Gibbs free energy density (G_{dns}) change, with spin ordering, can be represented by power series of spin density field variable $\mathscr{S}$ (**X**),what is later called the order parameter, and where **X** represents the space coordinates:

$$G_{dns}(T,\mathscr{S}) = \mathrm{G}_0 + a(T)\mathscr{S}^2 + \frac{1}{2}b(T)\mathscr{S}^4 + \ldots \tag{3}$$

For thermodynamic equilibrium, Gibbs free energy tends to minimum, so:

$$\frac{\partial G_{dns}}{\partial \mathscr{S}} = 2\mathrm{a(T)}\mathscr{S} + 2\mathrm{b(T)}\mathscr{S}^3 = 0 \tag{4}$$

Likewise can be expended the parameter $a(T)$ around the critical point $a(T) = a_0 (T\text{-}T_C) + \ldots$so we obtain in the first approximation two solutions for order parameter: the trivial $\mathscr{S}=0$ and the relation:

$$\mathscr{S}_0^2 = -\frac{a}{b} = -\frac{a_0}{b_0}(T - T_C) \tag{5}$$

That gives values for $C_P = (a_0^2 / b_0)\ T$ for $T<T_C$ and $C_P = 0$ for $T > T_C$, and results with scaling exponent $\alpha = 0$. In addition, it leads to scaling of order parameter that can be related for helium to magnetic susceptibility (that can be measured) and indicate the change of particle ordering as reason to special properties. In thermodynamics it is analogy to compressibility, and leads to introduction of a new kind of universal exponent, related to system ordering, assigned β:

$$\mathscr{S}(\mathrm{T}) \propto |T - T_C|^{\beta} = |T - T_C|^{\frac{1}{2}} \tag{6}$$

Landau continued work on those problems till 1953 collaborating with Ginsburg and introduced, for better description of ordering, a new kind of scaling, described by correlation length ξ, very useful parameter, to quantify cooperative coupling in the system, with scaling exponent assigned ν :

$$\xi \propto |T - T_C|^{-\nu} \tag{7}$$

In the next 1954 year, published M. Gell-Mann with F.E. Low the paper on electromagnetic coupling in molecular systems under photon propagator at high energies, and described it with the

coupling parameter $g(\boldsymbol{\mu})$ at the energy scale $\boldsymbol{\mu}$ and reference scale M. They also realized that the effective scale can be taken at arbitrarily $\boldsymbol{\mu}$ and vary following theory results at that other scale [16]:

$$g(\kappa) = G^{-1}\left[\left(\frac{\kappa}{\mu}\right)^{d} G_W(g(\mu))\right] = G_W^{-1}\left[\left(\frac{\kappa}{M}\right)^{d} G_W(g(M))\right] \tag{8}$$

where G is Wegner's scaling function. They elaborated further this rescaling problem, in the range of infinitesimal transformations, but later a number of authors focused on deeper understanding of its physical meaning and possible generalizations of the process: B. Windom, A. Patashinski, V. Pokrovsky, L. Kadanoff, M. Fisher, K. Wilson and some others. So in 1971 Ken Wilson succeeded in formulation of rigorous mathematical procedure for renormalization of critical phenomena named Renormalization Group, and with only a couple of papers published on the subject, deserved The Nobel Prize for physics in 1982, what is probably, the unique case for the theory work, in the history of The Prize, but was for results of fundamental importance and such a complex task [10] Meanwhile, but after Landau published his first theory, developed Lars Onsager analytical procedure for solution of Ising model in two dimensions, what provide possibilities for verification of all results mention above, in two dimension cases (the analytical solution of three dimensional Ising model, nobody succeeded to solve, till now) [1,27].Those verifications confirmed the value Landau obtained for α=0, and also experimentally determined value (recently in satellite) α=0.0127. But the correct value for β is (1/8) and not (1/2) what Landau obtained. Also other exponents from the universality class, calculated in the mean field approach, differ from rigorous, analytical solution e.g. scaling exponent γ of isothermal compressibility close to critical point is (7/4) and not 1, and corresponding scaling exponent for system density is δ =15, not 3 -from mean field approach Polymer networks and percolation scale in 0.56 to 1.29 range [1, 26, 27] With exact values of scaling exponent values was possible to develop functional relations between them. It indicates special importance of correlation length exponent ν and scaling exponent related to volume η, while all others can be derived from them, with help of Renormalization Group.

In parallel with scaling universality theory foundation in theoretical physics and in the same period of time, Flory developed in polymer science the theory on interactions dominated by the large chain structure. It provides possibilities to obtain scaling exponents independently and staring from completely different aspects. Moreover, it gives directly the correct value of the 3D universal exponent ν=3/5=0.6 (from Universality approach is now 0.62± 0.02), what is here of special interest for bio-thermodynamics [1,5]. Because of restricted space available here, we can describe it only in short, but we shall point here to possible derivation in analogy steps to the methods above. The essential difference between those approaches is in Landau development for model with large number of particles in agreement with classical thermodynamics principle and Flory development for the model of single polymer chain, but with large number of conformations, in agreement with the Concept of Macromolecular Statistical Mechanics, he introduced in science [6-9]. According to that, we can describe the coiled polymer molecule states, with Gibbs free energy:

$$G_{coil} = U - TS \cong N_m k_B T B_V \frac{N_m}{\frac{4}{3}\pi R^3} + \frac{3k_B T R^2}{2N_m a^2} \tag{9}$$

Here N_m is number of chain links, k_B the Boltzmann constant, B_V thermodynamic second virile coefficient, $\boldsymbol{R}$ radius of the coil with a describing link dimensions. According to equilibration principles: $\partial G_{\text{coil}} / \partial \boldsymbol{R} = 0$ so we obtain:

$$-\frac{k_B T B_V N_m^2}{R^4} + \frac{k_B T R}{N_m a^2} = 0 \tag{10a}$$

Solving for $\boldsymbol{R}$ gives explicitly the scaling of the size, that macromolecule takes in space, by excluding the other particles from that volume, according to **Flory's Theory of excluded volume,** and complementary to **Einstein's model of the thermal vibration**s in thermodynamics [1,7,15].

$$R \propto (B_V a^2)^{1/5} N_m^{3/5} \tag{10b}$$

2.2 Nucleic acid thermodynamics

Flory contributed also with first theoretical papers on DNA and RNA thermodynamics, considering interactions inside the volume excluded, and the volume opened, to other molecules. Now it is a large field, growing fast due to both, hybridization reactions and sequencing methods, that are managed today up to commercial level, and in number of disciplines.

2.3 Extension of the scaling principles and AI support of it

First established in thermodynamics, the Scaling Universality Theory extended to number of other sciences, from classical and quantum electrodynamics, nuclear structure, all up to cosmology, **giving to thermodynamics again leading position** in Ind.04 concept of 3 holders(as it had in The first Industrial Revolution) but now further progress is not possible to manage without help of AI. Such extension into bio-sciences started with **bio-thermodynamics**. We try to illustrate it, in this short contribution, by cell bioengineering issues, both theoretical and practical, using yeast model.

3. EXPERIMENTAL DATA, MATERIALS AND METHODS

Baker yeast cells have been cultivated very long time through human history for production of food, beverages, conservation some of the products by fermentation, but also present time fundamental scientific research e.g. in genomics [17-27]. In the course of time, is accumulated a huge amount of data in the literature on its colony grow, cell grow, and cell structure to properties [18-25].The relations between colony size and number of cell at some stage of development are nowadays quite obvious, but for management of design, or activity predictions, in cell engineering, medical control of tissue growth, and many agricultural tasks, is of special interest the scaling with time. In particular could be useful, relating cell systems grow, to present level of polymer scaling in science, and AI tools. So we analyzed data on the increase of colony, cell and polymer content size, of yeast as an opportune model. Here, we related time properties of sampling from the same system, or systems grown at identical conditions, media and temperature (YEP+2%glucose, 30 ^{0}C). In the next paper of this series of investigations, will be compared the system grow at different temperatures. Data presented are from Beckman Counter Multisizer or Coulter Electronics Counter and protein content from flow fluorescent cytometer and some obtained by cell lysing and polymer characterization [22].

4. RESULTS AND DISCUSSION

First we made qualitative analysis of the numerous data as described in the previous section making correlations of a system size with time during growth looking for self-similarity that Saccharomyces crevisiae strains expose, both of wild type (WT) and natural and synthetic generated mutants, by nowadays methods (many controlled, in addition, by hormones and/or inhibitors). Keeping in mind that those correlation represent averaged effects, because some cells decrease due to division, but other grow, with protein production, at the same time, 3 different system scaling behavior can be isolated (a) average size of cells is the same, and system grow dominantly by increasing the number of cells e.g. for WT (b) some cells size is high but, growing number is lower (c) dominant number of buds is 1 or 2 or 3 (what has influence upon actin skeleton orientation, and protein order, changing density, according to recent papers). So we restricted further research on WT strains cell number growth, with low budding, and obtained similarity coefficient 1,22 (with coefficient of determination R^2=0.993) and for proteins in a cell 1.1 (R^2=0.991) with scaling exponents for both of 1.2±0.1. Those results are in agreement with theoretical, for network directed percolation scaling [1-4], and polymer polarity [7-9], but restricted for now to wild type yeast behavior, and for other systems are needed more data, from phosphorescent flow cytometer with AI support.

5. CONCLUSION

Scaling and Renormalization Group are among most important theoretical methods now, for relating structure and properties from nano- to macro-levels, established in modern thermodynamics and extended to classical and quantum electro-dynamics, nuclear structure, field theory, etc., but still not enough in bio-sciences. For that is bio-thermodynamics the most convenient way, as can be seen from modern AI applications to cell system analysis, as we illustrated in yeast case, obtaining both, practical parameters for comparison between strains colonies behavior, and the scaling of protein production. Results indicate indicates that the system expansion gradient at those two levels is the same, and wall coordinated and balanced by thermodynamics energy and entropy parameters.

INFLUENCE OF LAMINATE STACKING AND FIBER VOLUME FRACTION ON NATURAL FREQUENCIES OF COMPOSITE KEVLAR 49 ARAMID – 3501 – 6 EPOXY PLATES

Aleksa Maljević[1], Institute Vlatacom
Milan Ignjatović[2], Institute Vlatacom

Abstract: *This research addresses the influence of the material design of Kevlar 49 Aramid – 3501 – 6 Epoxy on the natural frequencies of composite plates. The goal of the research is to obtain direct functionality of natural frequencies on material design, that can be used in engineering practice when designing composite flight vehicle components, such as aircraft stabilizers and missile fins. The modal analysis represents the desired dynamic behavior of elastic bodies and therefore it must be performed in the initial design of these components. Material design is varied with variations of symmetric lay-up and fiber volume fraction. Natural frequencies and normal modes of an investigated plate are obtained using a numerical approach.*
Keywords: Natural frequencies, Modal analysis, Composites, Finite element method

1. INTRODUCTION

In the present paper, the dependency of natural frequencies of thin, non-tapered composite plates on the type of layup and ratio of individual components in the composite is investigated. Every dynamic aeroelastic phenomenon, such as flutter, aeroservoelasticity, buffeting, gust, etc., is in direct correlation with normal modes of flight vehicle structure. Since it is well-known that all of the aeroelastic effects can have disastrous and catastrophic effects on aircraft structures, it is of paramount importance to investigate its natural frequencies, even in the initial design, and therefore tailor the composite to sustain external loads. The first two mode shapes are analyzed, which describe the dynamic behaviour of composite plates as first bending and first twisting.
Modal analysis is a primary engineering tool for the prediction of the dynamic behavior of flexible structures and its application can be found in solving numerous various engineering problems [1]. Within the scope of modal analysis, natural frequencies, normal modes, and shapes are studied, to obtain a mathematical model that describes the potential dynamical behavior of the mechanical system. Natural frequencies directly represent the rate of oscillations of elastic bodies in a state of free vibrations. Modal analysis provides a set of simple harmonic motions of the structure, while each harmonic is described with one natural frequency, and combines them in one linear set. Since a flexible structure can have infinite mode shapes, while studying modal analysis of a structure, one must observe only those modes that influence a large portion of the mass of the structure.
The effect of material design, in terms of laminate stacking and fiber volume fraction on normal modes of composite structures used as missile fins is investigated. These structures are, because of their flexible design, inclined to structural stability loss. For this research, it was arrogated for the composite to be formed from two individual components: Kevlar 49 Aramid – 35016 – 6 epoxy.

[1] aleksa.maljevic@vlatacom.com
[2] milan.ignjatovic@vlatacom.com

The design of material is analyzed by varying laminate, with a variation of the individual lamina, and by varying volume fraction of fiber in the composite. The usage of composite materials in the aerospace industry is shown in Figure 1. Composite materials have a high contribution in the share of materials used in the aerospace industry because of their unique possibility to tailor to a specific engineering requirement.

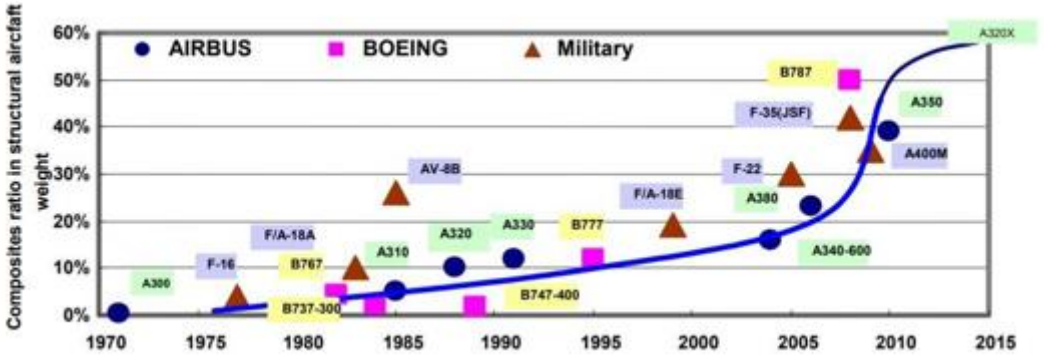

Figure 1. Application of composite materials in aerospace [2]

2. INTRODUCTION

2.1 Material Model

Design and manufacturing of composites is far more expensive and demanding than of conventional materials. Today, composites can be designed using numerous analytical and numerical theories. In the scope of this research, popular Classical Laminate Theory (CLT) was used in material design for the analysis of laminate, because it determines complex stress–strain fields with high accuracy. CLT's foundations rely on Kirchoffs research of thin plates and expand it in terms of stacking individual plates (laminas) into integrated lay-up [3].

Bearing in mind the goal of this research to determine the effect of layup type and share of fiber in composite, different types of composite Kevlar 49 Aramid – 3501-6 Epoxy are analyzed. Since the dynamic behaviour of a structure depends on its natural frequencies, which depend on inertial and stiffness of a structure, material properties are of significant importance in modal analysis. It was arrogated to analyze three types of this material, which was achieved with varying fiber volume fractions, and six types of symmetric laminate, with the aim that inside the lamina doesn't occur shear-coupling effect.

Mechanical properties of laminae can be obtained with the application of micromechanics, or with various experiments of test tubes on tensile strength tester. In this research, methods of micromechanics were performed on individual material components in the composite for determination of mechanical properties of the specially orthotropic lamina are listed here:

$$E_1 = E_f^1 V_f + E_m V_m$$

$$\nu_{12} = V_f \nu_f + V_m \nu_m \tag{1}$$

$$E_2 = \frac{E_m}{1 - \sqrt{V_f}\left(1 - \frac{E_m}{E_2^f}\right)}$$

$$G_{12} = \frac{G_m}{1 - \sqrt{V_f}\left(1 - \frac{G_m}{G_2^f}\right)}$$

Individual phase mechanical properties in above relation (E_m, E_f, G_m, ν_{12}) are obtained from material datasheet, found in literature [4]. Each composite phases are designed to be in range of $60 - 40\ \%$ for V_f, as this composite is used as missile airframe. Obtained mechanical properties of material analyzed in current paper are presented in Table 1.

Table 1: Kevlar Aramid 49 – 3501 – 6 Epoxy mechanical properties

$V_f[/]$	$\rho[g/c\ m^3]$	$E_1[MPa]$	$E_2[MPa]$	$G_{12}[MPa]$	$\nu_{12}[MPa]$
0.4	1.358	54980	5687	3849	0.338
0.5	1.384	67650	5913	4614	0.337
0.6	1.402	80320	6132	5625	0.336

The mentioned approach is applicable to the design of unidirectional laminae (UD), which are the subject of this research. Laminate is designed to be quasi-isotropic (QI) and symmetric to the neutral surface. The mentioned approach of designing a laminate is often used in the preliminary design of missile fins, because this approach disables shear – coupling effect and maintains in-plane stiffness independent of laminae orientation [5].

The laminates that are analyzed within this research are described with following layup models: $[0_4, 0_2]_s$, $[0_4, 10_2]_s$, $[0_4, 22.5_2]_s$, $[0_4, 45_2]_s$, $[0_4, 60_2]_s$, $[0_4, 75_2]_s$, $[0_4, 90_2]_s$, $[10_4, 0_2]_s$, $[22.5_4, 0_2]_s$, $[45_4, 0_2]_s$, $[60_4, 0_2]_s$, $[75_4, 0_2]_s$, $[90_4, 0_2]_s$. Mechanical properties of analyzed laminates are obtained following forms:

$$E_x = E_y = 2(1 + \nu_{xy})G_{xy}$$
$$G_{xy} = \frac{1}{2}G_{12} + \frac{1}{8}E_1\frac{(E_1 + E_2 - 2\nu_{12}E_2)}{E_1 - 2\nu_{12}^2 E_2} \quad (2)$$

2.2 Modal Analysis

Various approaches can be carried out for determination of dynamical behaviour of flexible body – analytical, numerical and experimental. Analytical methods are of great importance for mechanical systems that can be described with simple mechanical-mathematical model [7], due to their great accuracy. Experimental modal analysis is quite expensive and tedious and it requires additional equipment depending on intensity of frequencies, such as mechanical excitation systems, electromagnetic exciters (shakers) and acoustic systems [8].

A thin clamped laminate, representing a missile fin, has infinite number of degrees of freedom, and therefore its governing equation of motion can be described with second type of Lagrange's equation:

$$\frac{d}{dt}\left(\frac{\partial E_k}{\partial \dot{q}_j}\right) - \frac{\partial E_k}{\partial q_j} = -\frac{\partial E_p}{\partial q_j} + Q_j \quad (3)$$

Since overall energy of the described system is a function of generalized coordinates, if the expressions for kinetic and potential energy were included in equation (3), the following system of equations would become non-linear and extremely demanding for analytical solving. Therefore, a method of linearization is implemented to the equation (3), and keeping in mind the phenomenon of free-vibration, the dynamic behavior of the mentioned system becomes described in reduced matrix form:

$$[M]\{\ddot{u}\} + [K]\{u\} = 0 \quad (4)$$

In relation (4), $[M]$ and $[K]$ are used to represent mass and stiffness matrix of the system, respectively. It is common to assume harmonic particular solution to equation (4):

$$\{u\} = \{\varphi\}\sin(\omega t - \alpha) \tag{5}$$

In relation (5), ω represents natural frequency of the oscillating system, φ represents a harmonic function of mode shapes and α is a phase difference. The natural frequencies are determined by solving the characteristic equation of the system described with relation (4), which follows as:

$$([K] - \omega^2[M])\{\varphi\} = 0 \tag{6}$$

Natural frequencies of a cantilevered plate, representing a missile fin clamped to the missile body, can be determined with the application of Rayleigh-Ritz theory for cantilevered beam. In the following relation, modes of a plate are represented in terms of material and geometrical properties and type of boundary condition:

$$\omega_n = \frac{\lambda_n}{b^2}\sqrt{\frac{D}{\rho t}} \tag{7}$$

In the previous relation n represents number of natural frequencies, λ_n is a function of geometry of a plate, ρ is material density, t is material thickness, D represents flexural rigidity of a plate, and for composite plates it can be computed as:

$$D = \frac{E_x t^3}{12(1 - \nu_{xy})} \tag{8}$$

For the purpose of this research modal analysis was performed using the finite element approach. Plate is modeled with four-node quad elements. Lancoz algorithm was used for calculation of real solutions, due to its speed, simplicity and accuracy [9]. Geometry of a clamped plate used to represent missile fin is given on Figure 2, with all units in millimeters. Commercial software Femap/Nastran was used for numerical modal analysis. The fineness of the mesh was examined until the results converged. Size of all elements equals to *4* millimeters. FEA model has *1875* elements with *1976* nodes. Boundary condition that is applied to the root edge of a plate is commonly used to represent missile fin clamped to the missile body.

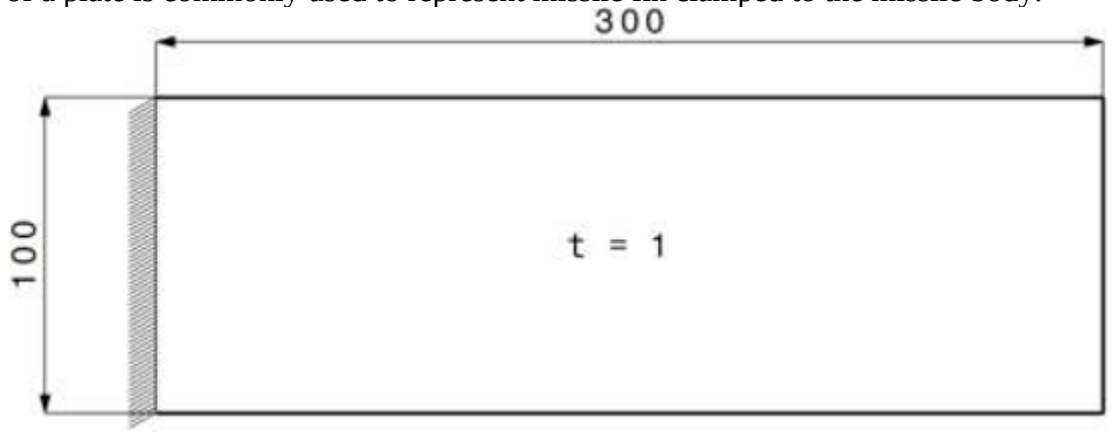

Figure 2. Geometry model

3. RESULTS AND DISCUSSION

Based on the results of numerical modal analysis, the polynomial functionality between fins natural frequency and type of laminate was found. The error of polynomial approximation in regression model is described with a statistical measure R^2, which represents the percentage of a dependent variable that is described with independent variable. Shape of first two modes are presented in Figure 3.

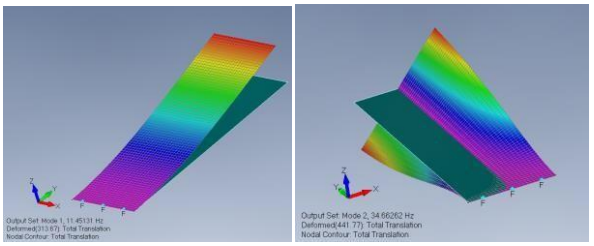

Figure 3. First two mode shapes (first bending – left, first twisting – right)

Analyzing the obtained results, in terms of the first two modes, it was observed that an appropriate QI stack must be designed for laminate to have required bending and torsional stiffness. In accordance with that, divergence in bending and torsional stiffness between contrary types of symmetric QI laminates can reach up to 62% and up to 30%, respectively. Such changes in stiffness are extreme, and they can induce disastrous effects on the airframe structure.

In the following text, the obtained numerical results, with appropriate polynomial approximation are shown graphically in Figures 4 and 5, and afterward, the formed polynomial functionality of natural frequencies compared to the type of laminate and fiber volume fraction is tabulated in Table 2.

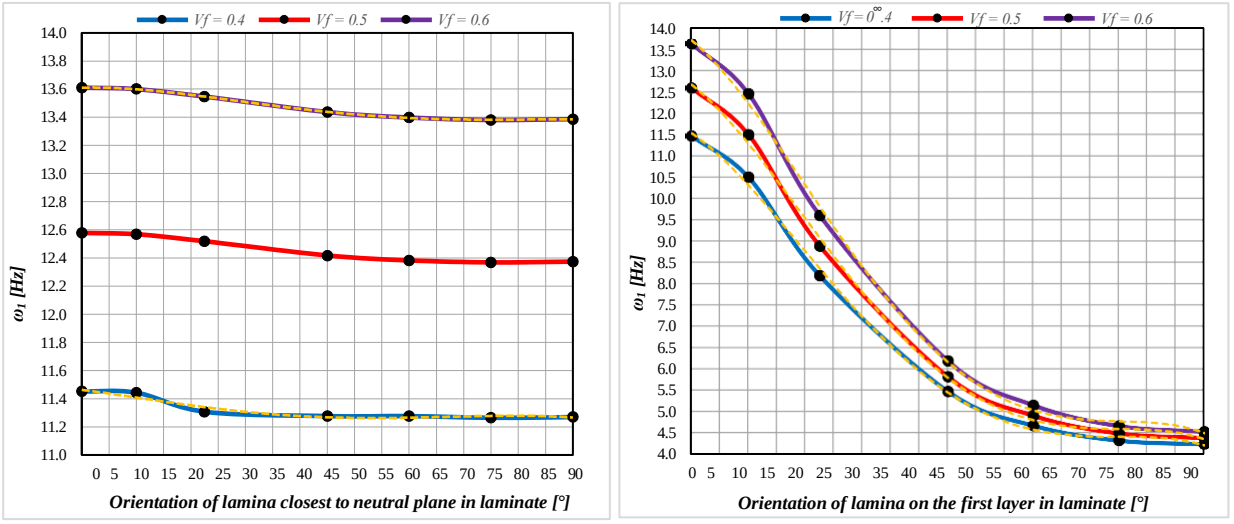

Figure 4. First mode natural frequency as a function of laminate lay-up and fiber volume fraction

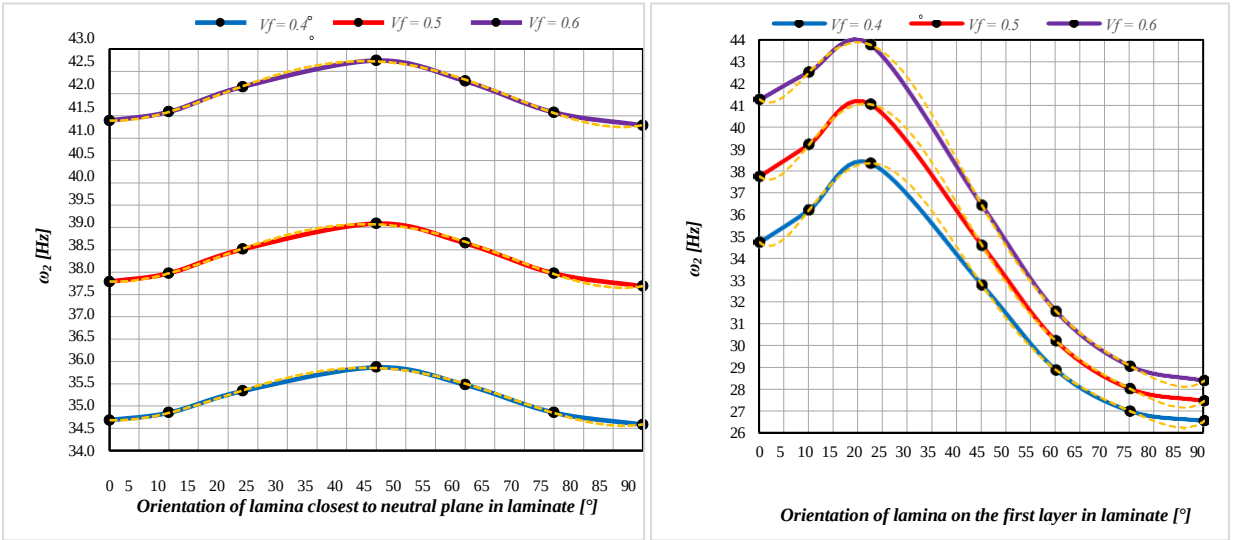

Figure 5. Second mode natural frequency as a function of laminate lay-up and fiber volume fraction

4. CONCLUSION

Within the scope of this research it was found that laminate stacking and fiber volume fraction of Kevlar 49 Aramid – 3501-6 epoxy have significant influence on natural frequencies and modal shapes of rectangular plate. Based on the results collected within this work, when designing aircraft components made of Kevlar 49 Aramid – 3501-6 epoxy, engineers can use obtained dependencies of natural frequencies on laminate design, in order to achieve satisfactory composite material that can withstand calculated aerodynamic loads. In the further research, laminate stacking and fiber volume fraction of Kevlar 49 Aramid – 3501-6 epoxy on static and dynamic aeroelastic effects will be analyzed.

This research was supported by the Vlatacom Institute in scope of the P172 project, which is gratefully acknowledged.

FIRE RESISTANCE OF BOILER ROOM THE BUILDING STRUCTURE

Milivoje Filipović[1], The Academy of Applied Technical Studies Belgrade
Ivan Aranđelović[2], Faculty of Mechanical Engineering, University of Belgrade

Abstract: *This A significant limitation of the methodology for determining the class of fire resistance, defined by the group of standards DIN 18230, is the inapplicability to industrial facilities in which energy is produced or distributed. The aim of this paper is to define a new methodology for determining the necessary fire resistance of the building structure of a boiler room.*
Keywords: fire risk; fire load; fire resistance time of structures.

1. INTRODUCTION

W. Halpaap was developed methodology for determining the necessary fire resistance class for industrial building structures based on the previous research for metal constructions made by Gellinger and Boe in the period from 1959 to 1964. A historical overview of the methodology and more references can be found in paper [1]. This methodology was standardized in the form of German technical standard DIN 18230 [2], which was modified several times in the period from 1964 to 2010.
Two methods for fire risk assessment were standardized based on the research of the Swiss engineer Gretener (references can be found in paper [3]) which were carried out in the period from 1961 to 1968: (1) The Swiss Society of Engineers and Architects (SIA) published SIA81 method in 1981 and SIA2007 in 2007; (2) The Austrian Fire Brigade Association published TRVB 100 Technical Recommendation in three versions issued in 1975, 1987 and 2010. Using the results of Gretener's research, author Purt [4] recommended a new methodology in 1972, which was standardized by the European Fire Alarm Manufacturers Association (Euroalarm).
A significant limitation of the DIN18230:2010 standard is its inapplicability to facilities in which energy is produced or distributed. In paper [5] a new approach is presented in order to determine the necessary fire resistance of the building structure of a boiler room where liquid or gaseous fuels are used. This results was extended to boiler room where solid fuels are used in [6].
The aim of this paper is to determine the necessary fire resistance of the building structure (FR) of a general boiler room. The analysis will include boiler rooms with boilers that use gaseous fuels such as mixtures of methane and other gases (i.e. natural gas, city gas or landfill gas) or LPG, liquid fuels such as oil fuels and alcohol-based fuels, solid fuels and cases in which one type of fuel is primary and the other is alternative. The proof of the adequacy of the class of fire resistance for building structure will be given independently using the Purt methodology (according to the Euroalarm standard) while the obtained results will be verified by using the Gretener methodology (according to the TRVB 100:2010 recommendations).
Assumed fire prevention and protection measures include:

1.1. Installation of an automatic fire alarm system;
1.2. Constant presence of the person on duty next to the fire control panel;
1.3. Sufficient number of fire extinguishers before the arrival of the fire brigade;

[1] mf.tehnikum@gmail.com
[2] iarandjelovic@mas.bg.ac.rs

1.4. Existence of appropriate fire hydrant installation;

1.5. Professional fire brigade located up to 5 km from the building;

1.6 Access to the boiler room is provided from three sides for the purpose of fire-fighting, i.e. there is at least one opening that can be used for fire-fighting purpose on every 20 m of the walls that border the fire sector.

Other assumptions include:

2.1. Mechanical ventilation system is applied, which provides adequate explosion protection, but without smoke and heat control system;

2.2. The boiler room is rectangular shape with single fire compartment, which is less than 40 m wide, and with an area of less than 3000 m^2 in which there are no other facilities;

2.3. The boiler room is located on the ground floor;

2.4. There are no other floors below and above the boiler room;

2.5. The building in which the boiler room is accommodated is free-standing or it is part of an industrial building;

2.6. No combustible materials are built into the boiler room construction;

2.7. Installed boiler heating duty is less than 1 GW;

2.8. No fuel is stored in the boiler room.

2. SPECIFIC FIRE LOAD AND FIRE RISK CLASS FOR BOILER ROOMS WITH LIQUID OR GASEOUS FUELS

In Euroalarm tables, only boiler rooms that use solid fuels are considered. Tables given in TRVB 126:1987 do not define which type of fuel is used in the boiler room, but based on the adopted coefficient of fire risk class S = 1, it can be concluded that these are fuels of class IV fire hazard, i.e. solid fuels. Since no combustible materials are built in the construction of the fire sector in which the boiler room is accommodated, it follows that the fixed specific fire load is $Q_i = 0$. It also can be assumed that fuel amount that can be found in the boiler room is sufficient for no more than 15 minutes of operation and that the boiler efficiency is higher than 50%. Based on the above assumptions, the total specific fire load can be calculated using the following equation:

$$Q = Q_m = \frac{P \cdot t_w}{A} \tag{1}$$

where Q is specific fire load [MJ/m^2], Q_m is movable specific fire load [MJ/m^2], P is installed boiler heating duty [MW], t_w is total combustion time and A is boiler room area [m^2]. Hence

$$t_w = 2 \cdot 15 \cdot 60 \text{ s} = 1800 \text{ s}. \tag{2}$$

In this study the fire hazard class I (for gaseous fuels), is adopted because this is the most unfavorable case.

3. PURT METHOD.

3.1 Purt method for boiler rooms with liquid or gaseous fuels

For the application of Purt method it is necessary to determine two parameters: fire risk of the structure construction and fire risk of the structure contents. The fire risk of the structure contents is a coefficient that qualitatively shows the harm to people and equipment. It is calculated using the equation:

$$R_S = H \cdot D \cdot F \tag{3}$$

Where H is the harm to people coefficient, D is the harm to property coefficient and F is the smoke effectiveness coefficient.
In this case study, H equals to 1 because there is no expected harm for people, D equals to 2 because expensive equipment is installed in the boiler room and because interruption of the boiler operation causes stoppage of the supply of thermal energy to consumers, and F equals to 1, because there is no danger of smoke and corrosive gases.
Hence, the fire risk of the structure contents (R_s) equals to 2, which means that installation of fire alarm system, is necessary in the boiler room, except in the case of installation of the fire extinguishing system, which is a technically unacceptable solution due to the large area and height of boiler rooms.
Fire risk of the structure construction is a coefficient that qualitatively shows the hazard for the building construction and is calculated using the form:

$$R_0 = \frac{[(P_0 \cdot C) + P_k] \cdot B \cdot L \cdot S}{W \cdot R_i} \tag{4}$$

where P_0 is the structure content fire burden coefficient; C is the structure content combustion coefficient; P_k is the structure construction material fire burden coefficient; B is the size and position of the fire sector coefficient; L is the extinguishing start delay coefficient; S is the fire sector width coefficient; W is the structure's carrier construction fire resistance coefficient; and R_i is the fire risk reduction coefficient.
Based on the introduced assumptions, it follows that S equals to 1.6, because of the adopted fire hazard class I; P_k equals to 0, because Q_i equals to 0; B equals to 1, because the boiler room is located at the ground floor and with area less than 3000 m^2, L equals to 1.1 because the nearest professional fire brigade is 5 km away. If the width of the boiler room is less than 20 m, S equals to 1, otherwise S equals to 1.1. For the margin of safety in this paper the following values are adopted: $S = 1.1$ and $R_i = 1$.
Since the installation of a fire extinguishing system is not a technically acceptable solution, it is necessary to choose the coefficient W so that $R_0 < 2$ as follows:

$$\frac{P_0 \cdot 1.94}{W} < 2, \tag{5}$$

that is

$$P_0 \cdot 0.97 < W. \tag{6}$$

Based on the previous inequality, the results are shown in the table 1, in which the last raw gives the values of the necessary fire resistance of the building structure (FR).

Table 1. Fire resistance of the building structure with width more than 20 m

Source: [5]

Q_m [MJ/m^2]	0÷ 251	252÷502	503÷ 1004	1005÷ 2009	2010 ÷4019
P_0	1.0	1.2	1.4	1.6	2.0
W	1.0	1.3	1.5	1.6	2.0
FR [min]	<30	30	60	90	240

If we assume that the boiler room is less than 20 m wide, S equals to1. Thus, from equation (6) one can derive results given in table 2.

Table 2. Fire resistance of the building structure with width equal or less than 20 m
Source: [5]

Q_m [MJ/m^2]	0÷ 251	252÷502	503÷ 1004	1005÷ 2009	2010 ÷4019
P_0	1.0	1.2	1.4	1.6	2.0
W	1.0	1.3	1.3	1.6	1.8
FR [min]	<30	30	60	90	180

3.2 Purt method for boiler rooms with solid fuels

From tables given in EUROALARM standard P_0 equals to 1, because movable specific fire load Q_m equals to 251 MJ/m^2 for boiler rooms and C equals to1.2 because the fire hazard class III (for solid fuels) is adopted. Since no combustible materials are built in the construction of the fire sector in which the boiler room is accommodated, it follows that the fixed specific fire load is $Q_i = 0$ thus P_k equals to 0. Coefficient L equals to 1.1 because the nearest professional fire brigade is 5 km away. If the width of the boiler room is less than 20 m, S equals to 1, otherwise S equals to 1.1. For the margin of safety in this paper the following values are adopted: $S = 1.1$ and $R_i = 1$.
Since the installation of a fire extinguishing system is not a technically acceptable solution, it is necessary to choose the coefficient W so that $R_0 < 2$ as follows:

$$\text{for } R_i = 1: \frac{1{,}45 \cdot B}{W} < 2, \text{ for Ri = 1,2: } \frac{1{,}2 \cdot B}{W} < 2 \text{ and for Ri = 1,3: } \frac{1{,}12 \cdot B}{W} < 2, \tag{7}$$

which implies

$$\text{for } R_i = 1: 0{,}725 \cdot B < W, \text{ for Ri = 1,2: } 0{,}6 \cdot B < W \text{ and for Ri = 1,3: } 0{,}56 \cdot B < W. \tag{8}$$

From equation (8) it can be concluded than fire resistance of the building structure (FR) depends only on the area and height of the boiler room. The previous condition is met when W equals to 1, which is a case for all boiler rooms with area less than 10 000 m^2, from which it follows that it is sufficient to provide the supporting structure of the boiler room that is fire resistant for 30 minutes.

4. GRETENER METHOD

4.1 Gretener method for boiler rooms with liquid or gaseous fuels

The decision on the necessary fire-fighting measures is made on the basis of the calculated value of the factor of preventive fire-fighting measures ($S_G \cdot F_G$) and the estimated value of the fire resistance of the building structure (F_G). The following equation is used to determine the $S_G \cdot F_G$ factor:

$$S_G \cdot F_G = \frac{(G + 4.42) \cdot B_G}{6.25} \tag{9}$$

because there are no installed smoke and heat control systems in the building, where G is the geometry factor of the fire sector. Since the boiler room is provided with fire extinguishing access from three sides, i.e. there is at least one opening on the walls that limit the fire sector on every 20 m, G is calculated according to the equation:

$$G = \frac{A \cdot b}{10^5} \tag{10}$$

Where A is area of the fire sector [m^2] and b is width of the fire sector [m]. In this case the most unfavourable scenario is assumed: A = 2000 m^2 and b = 40 m when G = 0.8 it follows that

$$S_G \cdot F_G = 0.84 \cdot B_G \tag{11}$$

where B_G is specific fire hazard factor calculated from the equation:

$$B_G = Q_G \cdot C_G \cdot R_G \cdot K_G \cdot A_G \cdot P_G \cdot E_G \cdot H_G \tag{12}$$

where E_G is fire brigade intervention factor, A_G is the factor of fire activation, P_G is people harm factor, Q_G is specific fire load factor, C_G is factor of combustibility, R_G is smoke hazard factor, K_G is corrosion hazard factor and H_G is building height factor.
Based on the assumptions, in this case C_G equals to 1.6, because of the adopted fire hazard class I, $R_G = K_G = P_G = A_G = 1$. Factor H_G equals to 1 because the boiler room is located on the ground floor and E_G equals to 0,83 because the nearest professional fire brigade is 5 km away.
As mentioned before, the decision on the necessary fire protection measures is made on the basis of the calculated value of the factor of preventive fire-fighting measures ($S_G \cdot F_G$) and the estimated value of the estimated value of the fire resistance of the building structure (F_G).
Therefore, in this case specific fire hazard factor can be calculated as:

$$B_G = Q_G \cdot 1.6 \cdot 1 \cdot 1 \cdot 1 \cdot 1 \cdot 1 \cdot 0.83 = 1{,}328 \cdot Q_G \tag{13}$$

The results of equation (13) are shown in table 3.

Table 3. Fire resistance of the building structure based on Gretener's method

Source: [6]

Q_m [MJ/m^2]	200 <	300 <	< 400	< 600	< 800	<1300	<1700	<2500
Q_G	1.0	1.1	1.2	1.3	1.4	1.5	1.6	1.7
B_G	1.33	1.46	1.59	1.73	1.86	1.99	2.12	2.26
$S_G \cdot F_G$	1.12	1.23	1.34	1.45	1.56	1.67	1.78	1.90
FR [min]	<30	<30	<30	<30	<30	F30	F30	F30

4.2 Gretener method for boiler rooms with solid fuels

Based on the assumptions, in this case $Q_G = C_G = R_G = K_G = P_G = A_G = 1$. Factor H_G equals to 1 because the boiler room is located on the ground floor and E_G equals to 0,83 because the nearest professional fire brigade is 5 km away.
Therefore, in this case specific fire hazard factor can be calculated as:

$$B_G = 1.6 \cdot 1 \cdot 1 \cdot 1 \cdot 1 \cdot 1 \cdot 0.83 \cdot 1 = 0.83 \tag{14}$$

It follows that:

$$S_G \cdot F_G = 0.90 \cdot 0.83 = 0.75 \tag{15}$$

From the results it can be concluded that it is sufficient to provide the supporting structure of the boiler room that is fire resistant for 30 minutes.
If boiler room is with installed capacity lower than 500 kW or with area smaller than 150 m^2, factor G can be calculated from equation (10). In this case the most unfavourable scenario is assumed as A = 150 m^2 and b = 40 m when G = 0.06 it follows that

$$S_G \cdot F_G = 0.72 \cdot B_G \tag{16}$$

Based on previous result from equation (16) B_G = 0.83 and equation (14) follows that:

$$S_G \cdot F_G = 0.72 \cdot 0.83 = 0.6 \tag{17}$$

From the results it can be concluded that it is sufficient to provide the supporting structure of the boiler room that is fire resistant for 30 minutes, even in case where automatic fire alarm system is not installed in the boiler room.

5. CONCLUSION

Standardized Purt's and Gretener's procedures were used to assess fire risks. The differences between the applied methods are that Purt's procedure does not consider the approaches of fire engines and the probability of fire activation while Gretener's procedure does not consider the consequences of fires other than human losses. Considering the initial assumptions from the results it can be concluded that for boiler rooms where solid fuels are used for generating energy it is sufficient to provide fire resistance of the building structure of 30 minutes.

Abstract: *The influence of temperature on fatigue crack growth parameters was analysed by testing a new generation of unalloyed chromium-molybdenum steel additionally alloyed with vanadium intended for elevated temperature applications. The paper contains a comparison of the fatigue threshold ΔK_{th} and the fatigue crack growth rate da/dN of the untreated steel specimens taken from the pipe tested at room temperature (RT) and working temperature (HT) of 540 °C .*
The microscopic fracture surfaces of the test specimens are shown. The results of the fatigue crack growth parameters correspond to the SEM micrographs of the fracture surfaces.
Keywords: Fatique treshold, Crack Growth Rate, SEM.

1. INTRODUCTION

Analysis of the state of stress and deformation at the tip of a growing fatigue crack using linear elastic fracture mechanics methods led to the formulation of the Paris equation for all metals and alloys, which relates the fatigue crack growth rate to the stress intensity factor (SIF) range at the crack tip [1-5]:

$$\frac{da}{dN} = C \cdot (\Delta K)^m \tag{1}$$

Although the Paris equation of crack growth is not valid in the entire region, between low rates near the fatigue threshold ΔK_{th}, and higher rates K_{Ic}, the large linear middle part of the curve covered by the Paris equation turns out to be by far the most important from a practical point of view, as it allows at the same time to contrast between creation and growth of a fatigue crack. The application of the Paris equation has proven to be particularly fruitful in the field of fatigue of structures made of materials of elevated and high strength [6].
As the structure under certain conditions will not be endangered until the crack reaches a critical size, it is possible, with previous analyses, to allow the exploitation of the structure with the crack during the crack growth period. Knowing the speed of crack growth and its dependence on the acting load is important information for the decision on further exploitation. Standard ASTM E647-15e1, "Standard Test Method for Measurement of Fatigue Crack Growth Rates" prescribes the measurement of the fatigue crack growth rate *da/dN*, which develops from an existing crack, and the calculation of the SIF range, ΔK, which means that the specimen should have a fatigue crack.

2. EXPERIMENT

Research for this work was done on a virgin pipe with an outer diameter of ∅270 mm, length of 275 mm and a wall thickness of ≠34 mm, obtained from the Nikola Tesla B thermal power plant. The chemical properties of analyzed chrome-molybdenum alloy steel of the new generation additionally alloyed with vanadium designed for elevated temperatures application, are given in Table 1 [7].

Table 1. Chemical composition of as-received steel, % wt.
Source: original copyright

C	Si	Mn	P	S	Al	Cr	Mo	V
0.12	0.37	0.65	0.01	0.01	0.004	1.042	0.24	0.16

Mechanical properties of material tested at RT and HT are shown in Tables 2.

Table 2. Mechanical properties of tested material at RT and HT
Source: original copyright

Temperature	Elasticity modulus E, GPa	Yield stress $R_{p0.2}$, MPa	Tensile strength R_m, MPa	Elongation A, %	Poisson's coefficient v
RT	197	363	458	26.8	0.3
HT	138	214	300	29.4	0.3

2.1 Determination of crack growth rate

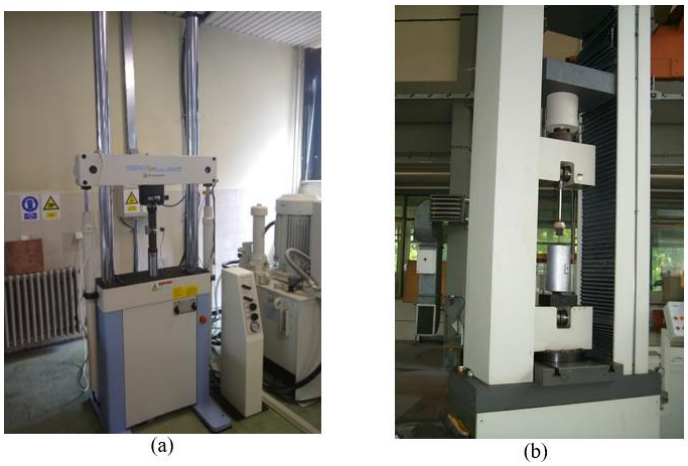
To determine the fatigue crack growth rate da/dN and the fatigue threshold ΔK_{th} at RT, the standard CT-50 specimen was used, Fig.1 (a), while the test at HT was performed on the modified C(T) specimens shown in Fig.1 (b).

(a)

(b)

Figure 1. CT-50 specimens for fatigue crack growth rate testing at room temperature (a) and modified C(T) specimens for fatigue crack growth rate testing at elevated temperature(b)
Source: original copyright

The tests for the fatigue crack growth rates da/dN as well as the fatigue thresholds ΔK_{th} determination at RT were performed on the servo-hydraulic test machine shown in fig. 2(a). The test was performed in crack growth control. This servo-hydraulic system realizes a sinusoidal variable load in the range of - 100 to + 100 kN.
Testing at HT was done on an electromechanical testing machine shown in Fig.2 (b). The test was performed in position control. Because of the more complete assessment of the behavior of the material under the effect of variable load, and taking into account the dimensions of the specimens, the critical case of the effect of variable load was performed, variable load with stress ratio $R = 0.1$.



(a) (b)

Figure 2. SHIMADZU SERVOPULSER (a) and electromechanical test machine for dynamic tests (b)
Source: original copyright

Depending on the applied variable load expressed through the change in the range of SIF, ΔK, curves are drawn in double logarithmic coordinates (log da/dN - log(ΔK)). Testing of precracked specimens, the values of the following parameters of the Paris equation were obtained: coefficient C and exponent m, fatigue threshold ΔK_{th}, and fatigue crack growth rate, da/dN, at the value ΔK = 25 $MPa\ m^{1/2}$. Those results are shown in Table 3.

Table 3. Fatigue crack growth parameters for specimens with a notch in BM
Source: original copyright

Specimen	Test temperature °C	Fatigue threshold ΔK_{th}, MPa√m	Coefficient C	Exponent m	da/dN, µm/cikl, at ΔK=25 $MPa\sqrt{m}$
Spec. BM-1RT	20	23,2	$2{,}98 \cdot 10^{-8}$	2,66	$0{,}253 \cdot 10^{-3}$
Spec. BM-2RT		20,4	$2{,}02 \cdot 10^{-7}$	2,15	$0{,}303 \cdot 10^{-3}$
Spec. BM-3 RT		19,7	$7{,}33 \cdot 10^{-7}$	1,85	$0{,}396 \cdot 10^{-3}$
Spec. BM-1 HT	540	16,3	$1{,}44 \cdot 10^{-6}$	2,34	$2{,}69 \cdot 10^{-3}$
Spec. BM-2 HT		15,5	$7{,}51 \cdot 10^{-6}$	1,89	$3{,}29 \cdot 10^{-3}$
Spec. BM-3HT		15,1	$4{,}77 \cdot 10^{-6}$	2,05	$3{,}50 \cdot 10^{-3}$

Characteristic diagrams of fatigue crack growth rates, da/dN - ΔK, for specimen tested at RT and at a HT are shown in Fig. 3.

Figure 3. Diagram of da/dN - ΔK dependence of the specimen tested at (a) RT and (b) HT
Source: original copyright

3. ANALYSIS OF RESULTS

The influence of the notch position and the initiation of the crack, as well as the test temperature, have a decisive influence on the values of the fatigue threshold ΔK_{th}.
The fatigue threshold values, ΔK_{th}, range from 21.1 $MPa\sqrt{m}$ at RT and decrease to 15.6 $MPa\sqrt{m}$ at HT, Table 3.

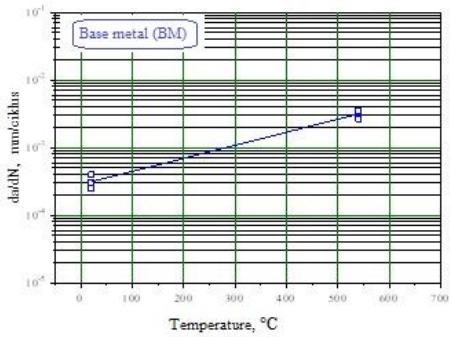

Figure 4. Change in *da/dN* value with increasing test temperature
Source: original copyright

The influence of the test temperature on the rate of fatigue crack growth, *da/dN*, is shown graphically in Figure 4. We can see that with increasing temperature, the rate of fatigue crack propagation, *da/dN,* also increases. The average obtained value of fatigue crack growth rate at RT is 0.317 *μm/cycle*, while at HT it is ten times higher and is 3.16 μm/cycle.

4. CONCLUSION

Fatigue crack growth parameters are the basis for assessing the safety of the operation of structural elements containing a crack that will not lead to failure in the time period between two consecutive inspections. A comparison of the fatigue crack growth rate at room and operating temperatures shows that the fatigue crack growth rate of chrome-molybdenum alloyed steel of the new generation additionally alloyed with vanadium for elevated temperatures application, increases with increasing operating temperature.

LARGE-SCALE THREE-DIMENSIONAL PRINTERS IN INDUSTRY 4.0

Goran Nestorović[1], The Academy of Applied Technical Studies Belgrade
Dragan Kreculj[2], The Academy of Applied Technical Studies Belgrade
Milan Vasić[3], The Academy of Applied Technical Studies Belgrade

Abstract: *The emergence of Industry 4.0 has brought forth transformative technologies with the potential to revolutionize manufacturing processes. Among these, large-scale three-dimensional printers have gained significant attention due to their ability to fabricate complex and customized objects on an unprecedented scale. This paper presents an overview of the applications, benefits, challenges, and future prospects of large-scale three-dimensional printers in the context of Industry 4.0. It explores the advancements in additive manufacturing techniques, materials, and software solutions that enable the realization of large-scale printing. Additionally, the paper discusses the integration of these printers within smart factories and the impact on supply chains, production flexibility, and sustainability. Through a comprehensive analysis, this paper highlights the potential of large-scale three-dimensional printers to drive innovation and efficiency in the manufacturing landscape of Industry 4.0.*
Keywords: large-scale 3D printing, additive manufacturing, Industry 4.0, smart factories, emerging trends.

1. INTRODUCTION

Industry 4.0 represents a transformative shift in manufacturing, driven by the integration of advanced technologies and digitalization. This paradigm revolutionizes traditional production methods by interconnecting cyber-physical systems, artificial intelligence, data analytics, and automation. Industry 4.0 enables intelligent and autonomous manufacturing processes, leading to unparalleled levels of efficiency, productivity, and customization. It builds upon earlier industrial revolutions, but uniquely merges the physical and digital realms, creating the so-called smart factories and value chains. Within this context, large-scale three-dimensional printers, also known as additive manufacturing systems, play a pivotal role. These printers have the potential to revolutionize production, offering advantages such as improved efficiency, reduced lead times, enhanced customization, and increased sustainability.

In the era of Industry 4.0, large-scale three-dimensional printers play a crucial role in transforming the manufacturing landscape. These advanced printers, also known as additive manufacturing systems, have the capability to fabricate complex objects with precision and efficiency. By utilizing a layer-by-layer approach and a variety of materials, including metals, polymers, and composites, large-scale three-dimensional printers enable manufacturers to achieve unprecedented levels of design freedom and customization. They offer benefits such as reduced production time, cost savings, and the ability to produce intricate and personalized products. Furthermore, these printers facilitate the integration of smart factories and the optimization of supply chains by enabling on-demand production and reducing reliance on traditional manufacturing processes. As a key enabler

[1] gnestorovic@atssb.edu.rs
[2] dkreculj@atssb.edu.rs
[3] mvasic@atssb.edu.rs

of Industry 4.0, large-scale three-dimensional printers are driving innovation, efficiency, and flexibility in the manufacturing sector.

2. ADDITIVE MANUFACTURING PROCESSES FOR LARGE-SCALE PRINTING

Additive manufacturing processes for large-scale printing are revolutionizing the way in which objects are produced. These processes involve the layer-by-layer fabrication of three-dimensional objects using difficult techniques. In a large-scale printing, advanced techniques, like fused deposition modelling (FDM) and selective laser sintering (SLS), are commonly employed. FDM utilizes thermoplastic filaments that are melted and extruded through a nozzle, while SLS employs lasers to fuse powdered materials together. Large-scale printing requires industrial-grade printers capable of handling sizable objects. These additive manufacturing processes enable design flexibility, intricate geometries, reduced material waste, and customized production. They find applications across various industries, including aerospace, automotive, healthcare, and construction, revolutionizing manufacturing possibilities in the era of highly demanding Industry 4.0.

3. TECHNICAL-TECHNOLOGICAL SOLUTIONS OF LARGE-SCALE 3D PRINTERS

A gantry-based solution is essentially an upscale version of additive manufacturing for construction purposes. In simple terms, it can be described as a "giant 3D printer" equipped with an actuator that allows movement along the X, Y, and Z axes in Cartesian coordinates [1]. Notable examples of gantry-based developments include Contour Crafting and D-Shape.

3.1 Contour Crafting (CC)

Contour Crafting (CC) is a highly promising gantry-based 3D printing technical system developed specifically for the construction industry (Figure 1). It involves the extrusion of successive layers of material, typically cement-based paste, in an on-site process [2]. The CC system comprises a gantry system and a nozzle, similar to those used in precast concrete fabrication. However, unlike precast concrete production, contour crafting is fully automated, eliminating the need for on-site personnel to monitor the discharge system. Actuated and computer-controlled trowels to smooth are utilized and ensure the accuracy of the printed material's planar and free-form surfaces. Maintaining a consistent viscosity level is a key challenge in contour crafting, as it directly influences structural strength and surface finish quality [3].

Figure 1. D-Shape 3D Printing
Source: www.archdaily.com/949531

3.2 D-Shape

D-Shape utilizes a process similar to the inkjet powder bed method, where a binder is selectively sprayed onto the printing material. Upon contact with the powder material, the binder initiates the solidification process, adding a new layer. The solidification process typically takes 24 hours to

complete. D-Shape is a gantry-based powder-bed 3D printer designed for factory settings, capable of printing architectural structures with dimensions up to 6×6×6 m. Objects printed using D-Shape technology can exhibit a compressive strength of up to 235-242 MPa [2].
Excess powder not involved in the structure acts as temporary support during solidification. Once printing is finished, the object is removed from the loose powder bed, and the surplus powder can be reused for other structures (Figure 2). While D-Shape was initially designed for off-site production of complex structural elements, ongoing research explores its potential for on-site printing, using available construction materials, such as sand and binder substances [4].

Figure 2. D-Shape 3D Printing
Source: www.newatlas.com/d-shape-3d-printer/21594

Contour Crafting and D-Shape have made significant advancements in scaling up additive manufacturing for construction. However, both methods have notable limitations. D-Shape faces criticism for its unreliable hydration of cementitious powder and the subsequent need to remove and clean the excess powder, which adds time and effort to the process. On the other hand, Contour Crafting to vertical extrusion is limited, resulting in 2.5D typologies rather than true 3D structures. Contour Crafting uses 3D-to-2D slicing software similar to small-scale 3D printing techniques. Each layer consists of a contour line and a honeycomb-like filling pattern, with adjustable filling density based on requirements. However, this technique presents challenges when printing cantilevered structures, as weak interfacial zones between printed layers may occur [2].

4. INTEGRATION OF LARGE-SCALE 3D PRINTERS IN SMART FACTORIES

Integrating large 3D printers into smart factories is a transformative step towards redefining manufacturing processes. This chapter in the paper presents the multifaceted aspects of this integration, encompassing essential chapters on cyber-physical systems and digital twins, supply chain optimization and distributed manufacturing, human-machine collaboration and the implications for the workforce, as well as sustainability and environmental impact. By examining these key dimensions, we uncover the potential for enhanced efficiency, flexibility, and sustainability in smart factories.

4.1 Cyber-Physical Systems and Digital Twins

Cyber-Physical Systems (CPS) and digital twins are integral components in the integration of large 3D printers into smart factories. CPS refers to the integration of physical and digital systems, enabling real-time monitoring and control. Digital twins are virtual replicas of physical assets, providing insights, predictive analytics, and optimization. Together, CPS and digital twins facilitate efficient production planning, remote monitoring, and predictive maintenance, enhancing the overall productivity and performance of smart factories (Figure 3).

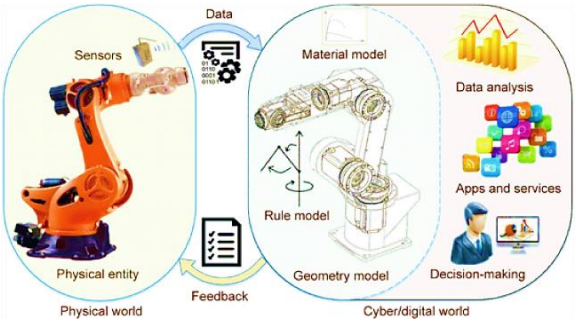

Figure 3. D-Shape 3D Printing
Source: www.engineering.org.cn/en/10.1016/j.eng.2019.01.014

4.2 Supply Chain Optimization and Distributed Manufacturing

Supply chain optimization and distributed manufacturing have a crucial role in the integration of large 3D printers into smart factories. Supply chain optimization aims to streamline production processes, reduce costs, and enhance flexibility by leveraging real-time data and analytics. Distributed manufacturing decentralizes production, enabling localized production and reducing transportation and inventory costs. Together, these approaches transform the supply chain, facilitating efficient and responsive manufacturing within smart factory ecosystems.

4.3 Human-Machine Collaboration and Workforce Implications

Human-machine collaboration and the associated workforce implications are key considerations in integrating large 3D printers into smart factories. Collaboration between humans and machines allows for improved efficiency, accuracy, and productivity in manufacturing processes. However, this integration also raises some questions about workforce skills, training, and job roles. Balancing automation with human expertise becomes crucial to ensure a smooth transition, redefining job responsibilities and fostering a collaborative environment that maximizes the potential of both humans and machines in smart factory settings.

4.4 Sustainability and Environmental Impact

Sustainability and environmental impact are critical aspects to consider when integrating large 3D printers into smart factories. These printers offer the potential for reduced material waste, energy consumption, and carbon emissions compared to traditional manufacturing methods. By utilizing eco-friendly materials and optimizing production processes, smart factories can minimize their environmental footprint. Additionally, the ability to produce on-demand and locally can reduce transportation-related emissions and promote sustainable practices, making a significant contribution to a greener and more sustainable manufacturing industry.

5. FUTURE PROSPECTS AND EMERGING TRENDS

There are diverse opinions regarding the future of 3D printing technology. While fully printed buildings are yet to exist [5], the progress in automation and robotics suggests the possibility of large-scale, fully automated 3D printing. Proficiency in software skills becomes crucial for future engineers, as they collaborate with automated and 3D printing technologies. Moreover, 3D printing holds promise for space exploration, with NASA's "3D Printed Habitat Challenge" aiming to develop innovative capabilities for building homes in space. Sustainability is another area where 3D printing can make a significant impact, allowing for environmentally evaluated building materials and sustainable designs tailored to the environments [6].
This chapter explores future prospects and new trends in the integration of large-scale 3D printers in smart factories. Two significant areas of focus are 3D printed metal and plastic bridges, as well as

Artificial Jntelligence (AI) and Machine Learning (ML) applications. The use of printing techniques from different additive materials enables the creation of complex and functional bridges with improved structural integrity and performances. Moreover, the integration of AI and ML enhances the capabilities of large-scale 3D printers, enabling real-time monitoring, predictive maintenance and intelligent decision-making. These advances promise exciting possibilities for the future of smart factories and the manufacturing industry as a whole.

5.1 3D printed projects connect communities and countries

As a highly significant project in the realm of Industry 4.0, 3D-printed bridges stand out prominently. These bridges not only showcase architectural masterpiece, but also represent noteworthy construction projects, that can be completed within a remarkably short timeframe. The first 3D-printed bridges emerged in 2016, and since then, numerous countries have embraced additive manufacturing for constructing these structural connections. Among the most impressive examples is the bridge in Amsterdam, showcased in this paper (Figure 4). A 3D-printed metal bridge was installed in Amsterdam's Red Light District, created by Dutch company MX3D using WAAM (Wire Arc Additive Manufacturing) technology. The bridge was fabricated through generative design, an iterative process that generates multiple design outputs to meet specific criteria, utilizing inputs from sounds, images, and CAD models. In addition to its unique aesthetics, the bridge with sensors is equipped, to record data on crowd behavior, deformations, loads, vibrations, and movements. These data enable the creation of a "digital twin" that provides real-time insights for project managers to understand the bridge's evolution [7].

Figure 4. MX3D Bridge in Amsterdam
Source: www.3dnatives.com/en/3d-printed-bridge-051120214

One of the highly interesting techniques and technologies in this field is 3D printing of plastic bridges. In 2018, Shanghai Mechanized Construction Group Co (SMCC) and Polymaker collaborated to develop a 3D printed pedestrian bridge. The bridge, made from plastic and measuring 15.25 m long and 3.8 m wide, weights 5,800 kg. An XXL printer with a print volume of 24 m long by 4 m wide was used. The applied material was ASA (acrylonitrile styrene acrylate) infused with fiberglass [7].

5.2 Artificial Intelligence and Machine Learning Applications

Artificial Intelligence (AI) and Machine Learning (ML) are playing a pivotal role in the integration of large-scale 3D printers within the realm of Industry 4.0. These advanced technologies are revolutionizing the manufacturing landscape by enhancing efficiency, customization, and productivity. When applied to 3D printing, AI and ML algorithms enable intelligent design optimization, real-time monitoring, and predictive maintenance. One notable AI application is generative design, which utilizes algorithms to explore countless design possibilities based on specific criteria. This approach helps to optimize the structural integrity, material usage, and performance of 3D-printed objects, leading to lighter and more efficient designs.
Another significant application is real-time process monitoring and quality assurance. AI algorithms can analyze sensor data from the 3D printing process to detect anomalies, identify defects, and

ensure consistent quality throughout production. That is helpful to eliminate errors, reduce waste, and enhance overall manufacturing efficiency. Furthermore, AI and ML in simulation software are employed, for virtual testing and optimization of 3D-printed models. These simulations allow manufacturers to predict and analyze the behaviour of printed structures under different conditions, enabling design improvements and risk mitigation before physical production. Software solutions, such as Autodesk's Netfabb, Materialise Magics, and Siemens NX integrate AI and ML capabilities to streamline the 3D printing workflow. These tools offer functionalities, such as automated support generation, design validation, and material optimization, enhancing the overall efficiency and accuracy of a large-scale 3D printing.

6. CONCLUSION

The emergence of Industry 4.0 has unveiled the significant potential of large-scale 3D printers in reshaping production processes across various industries. These printers offer substantial benefits, including enhanced production efficiency, reduced material waste, and expanded design flexibility. Nonetheless, the current challenges, such as technological limitations, cost implications, and the need for advances in additive manufacturing techniques, material properties, and software solutions, must be meticulously addressed. Future solutions should prioritize the development of multi-material printing, real-time process monitoring, and seamless integration with AI and ML technologies.

The integration of large-scale three-dimensional printers into Industry 4.0 represents a significant leap in manufacturing capabilities. These printers offer unmatched customization, efficiency, and sustainability advantages. While D-Shape excels in printing large architectural structures, it faces challenges related to material hydration and post-processing. Contour Crafting streamlines in-situ construction through automated, layer-by-layer extrusion but is limited to vertical extrusion. The adoption of Cyber-Physical Systems and Digital Twins optimizes monitoring and predictive maintenance, while supply chain optimization and distributed manufacturing drive cost reduction and environmental sustainability. Human-machine collaboration reshapes workforce roles, and sustainability initiatives gain traction with reduced waste and eco-friendly materials. The integration of artificial intelligence and machine learning augments printer capabilities, ushering in a transformative era within Industry 4.0. Embracing these solutions promises to unlock new levels of innovation, efficiency, and sustainability within the dynamic landscape of Industry 4.0.

STRAIN BEHAVIOR ANALYSIS OF STEEL S235JRH RING SPECIMENS

Milan Travica[1], Innovation Center of Faculty of Mechanical Engineering
Nenad Mitrović[2], Faculty of Mechanical Engineering, University of Belgrade
Aleksandar Petrović[3], Faculty of Mechanical Engineering, University of Belgrade

Abstract: *Different pipe manufacturing techniques, such as the manufacture of seamless pipes in the oil sector employing a conical shaft, necessitate data on the circumferential strain and stress condition of the pipe. The purpose of this study was to evaluating the displacement, strain, and stress behavior of a pipe ring tensile specimen (PRTS) in the hoop direction, as there was a lack of a standardized testing methodology. Five single S235JRH steel PRTS were tested for the study. The study describes how to test S235JRH steel PRTS with a Digital Image Correlation approach. The 3D Digital Image Correlation technique methodology was used to record the evolution of the strain. In the break zone and almost equivalent locations, all Single PRTS fractured. The experimental ultimate strength value's deviation value (also known as the real stress value) is greater than the theoretical ultimate strength value.*

1. INTRODUCTION

In an effort to establish a uniform distribution of strain and stress, many initiatives, such as those presented in [1moj rad] [2] and [3], have been made in recent years to improve the shape of testing specimens. Gaining useful experimental data that precisely depicts a well-defined distribution of stress/strain fields is the goal of testing methods such as shear, strain tests in plane, and tensile tests. With regard to metal sheets in particular, the information may be used to assess the material qualities of anisotropic materials. Due to the form of the tube, examining pipe materials is not as straightforward as examining metal sheets. Simple processes are still employed in [4] and [5] to cut specimens from flattened pipes and test them in tensile tests. Nonetheless, the flattening process adds residual stresses and pre-existing strains in the material, which impact the behaviour of the pipe material and, ultimately, the accuracy of material parameter identification, as indicated in the publications [6,7].
The study field of Digital Image Correlation (DIC) method has grown at a rapid rate during the last two decades. The use of the DIC method for evaluating Pipe Ring Tensile Specimens (PRTS) with various geometries is covered in the papers [7, 8-11]. Table 1 publications [7, 8] performed a numerical analysis and compared the numerical analysis findings to the DIC technique results.
The purpose of this research is to evaluate the strain behaviour of S235JRH steel PRTS in the hoop direction using the DIC technique.

[3] apetrovic@mas.bg.ac.rs

2. MATERIAL AND METHOD

2.1 Material

PRTS were fabricated of structural steel S235JRH for this study. PRTS specimens have pipe size of DN32 (42.4 x 2.8 mm). According to the published study [1] five Single PRTS were generated in total (Fig.1a).

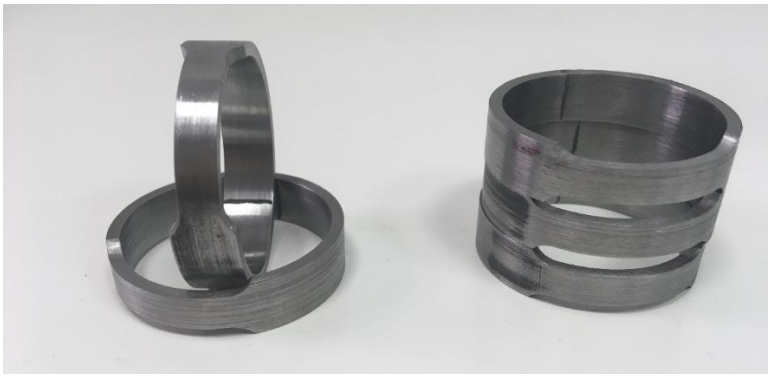

Figure 1. The PRTS of S235JRH material

Figure 2. Experimental setup

Fig.2 depicts the experimental setup. Shimadzu tensile testing equipment AGS-X (Shimadzu, Japan) was used for the tensile testing. The same PRTS tool that was used in the study [1] was utilised for testing using D blocks. The Aramis 2M system (Fig.2) employs the 3D DIC method [1]. Calibration was performed as part of the experimental setup. Several research [1,12, 14] go into considerable depth about the mode of operation, calibration, object preparation, and measuring procedure. The test procedure consisted of the following steps shown in [1].

Table 1. Aramis setup settings

Parameter	Value
Resolution of two CCD cameras	1600 × 1200 pixels
Camera lenses	50 mm
Measuring volume	105 mm×75 mm×55 mm
Facet (subset) size	25×20 pixels
Calibration deviation	0.027

3. RESULTS AND DISCUSSION

All of the PRTS that fractured did so on the side where the camera was pointed. The average value of these break forces for all PRTSs is shown on Fig.3. All PRTS readings indicated minimal variations in brake force.

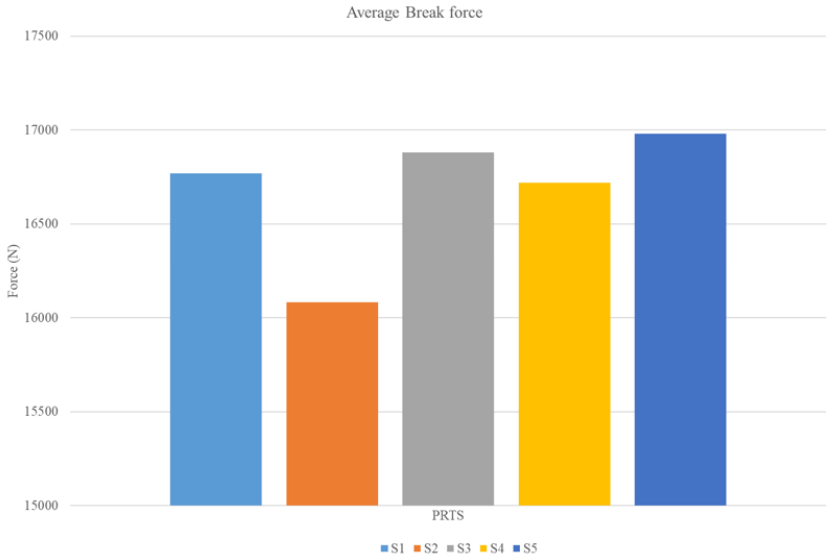

Figure 3. Average break force values

Figure 3 shows the results of a representative Single PRTS-S1 specimen. In this research, the DIC measurement findings for the Misses strain are provided. Four points (stage points 0-3) and two sections (Sections 0 and 1) were used to investigate the strain field in Figure 4 (Stage points 0-3). The intersection of the D blocks is where Section 0 is situated horizontally (black line). Vertically positioned on the Area of interest, Section 1 is orthogonal to Section 0 (yellow line). Stage points are positioned at the conclusion of each Section. Stages 0 and 1 were put on Section 0, while Stages 2 and 3 were put on Section 1. The experimental data shown in Fig. 4 demonstrates that the intersection of the D blocks is where the highest strain values are recorded. The highest von Mises values, which are 35%.

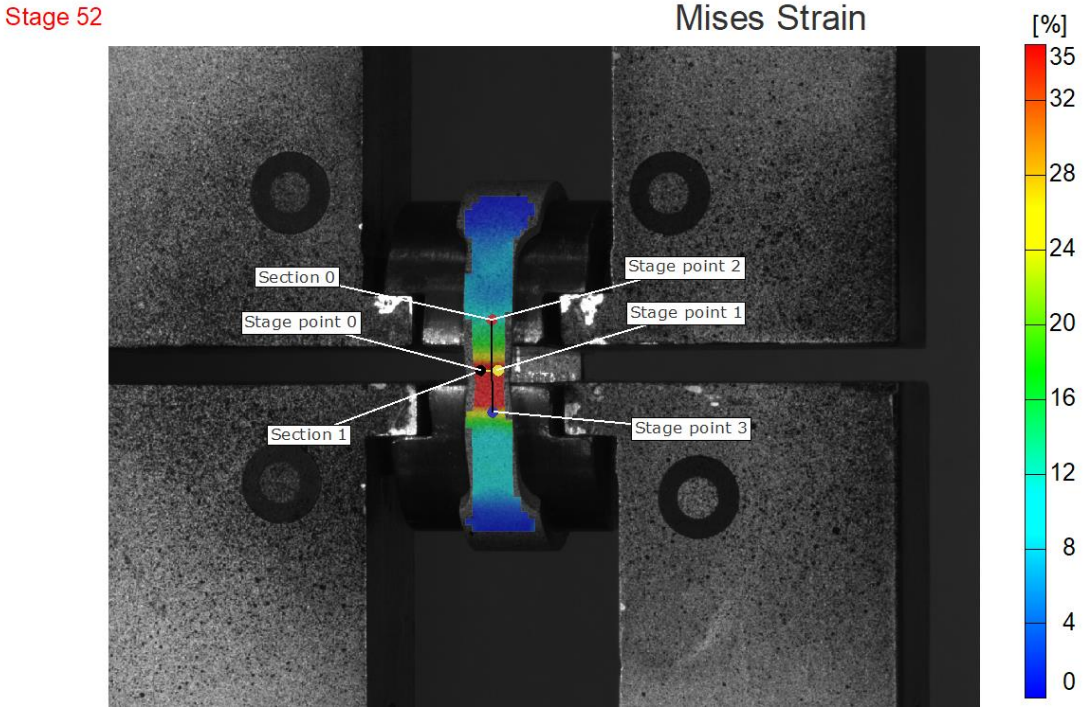

Figure 4. Von Misses strain field on PRTS S1

4. CONCLUSION

Based on prior work [1] with plastic PRTS, identical steel PRTS with a single configuration were created and evaluated using the same methods.
The above findings lead to the following conclusions:

- Fractures of all Single PRTS occurred in the break zone and almost identical places;
- All PRTS readings indicated minimal variations in brake force;
- The experimental data shown in Fig. 4 demonstrates that the intersection of the D blocks is where the highest strain values are recorded. The highest von Mises values, which are 35%.

This research was funded by Ministry of Education, Science and Technological Development Republic of Serbia, grant number 451-03-47/2023-01/200213 from 03.02.2023.

Abstract: *The present study delves into the implications of altering various design parameters on the performance of structural systems. With a focus on the implications for dynamic behavior and overall system responsiveness, the research investigates the effects of modifications in key structural elements. Through a comprehensive analysis of specific design variables, such as cross-sectional dimensions, material properties, and geometric configurations, the study sheds light on how these changes influence structural characteristics and performance metrics.*
Keywords: Modification, variables, frequencies, dynamic characteristics

1. INTRODUCTION

In the field of structural engineering, the effects of altering design parameters have gained significant attention due to their potential impact on the performance and behavior of various structural systems. With a growing emphasis on optimizing structural designs for enhanced functionality and reliability, it becomes imperative to comprehend the implications of design modifications on the overall dynamic response and stability of these systems. Throughout the history of structural engineering, the focus of research initially revolved around static optimization methods, primarily centered on minimizing weight while adhering to displacement or stress constraints for various static loading conditions. The two main approaches, analytical and numerical methods, were commonly employed. Analytical techniques, including mathematical calculations and variational methods, were utilized for simpler geometric optimization problems. Although these methods provided theoretical insights into optimization concepts, their practical application was limited, particularly in complex structural systems comprising diverse structural elements. An optimization criterion was established as an example of an analytical approximation, where an iterative procedure was employed to fulfill the requisite optimization conditions. While analytical criteria were effective in some cases, they were occasionally intuitive and less robust. In contrast, numerical methods were developed to minimize specific functions directly with imposed constraints, leveraging the advancements in numerical

mathematics and high-speed computing. These iterative procedures offered near-optimal solutions, often involving a finite number of design variables. Notably, reducing the number of structural variables played a pivotal role in mitigating the computational challenges associated with these methods. The integration of mathematical programming techniques with the finite element method emerged as a powerful strategy, enabling efficient and direct approximations. However, the applicability of this technique diminished in large-scale systems with increased degrees of freedom due to computational complexities and associated costs. As the field advanced, the focus gradually shifted toward dynamic modification, leading to a substantial body of literature exploring dynamic optimization methodologies. In the work "Sensitivity Analysis and Optimal Design of 3D Frame Structures for Stress and Frequency Constraints" by O. Sergeyev and Z. Mroz [1], the problem of determining the optimal position of nodes and cross-sectional elements of linear-elastic spatial frame structures with given stress and eigen frequency constraints is studied. It is assumed that the frames are loaded with active loads, including temperature and self-weight. Stress analysis includes tension, bending, shear, and torsion of the beam frames. A series of quadratic programming problems were used to obtain optimally designed construction. Sensitivity analysis was also provided in the case of different or repeated eigen frequencies with analytical differentiation by design parameters. The work also provides illustrative examples of optimal design of simple and complex frames, especially the case of bimodal optimal solutions. The work "Solution Existence of the Optimization Problem of Truss Structures with Frequency Constraints" by W. H. Tong, J.S. Jiang, and G.R.Liu [2] provides the basic theory for determining the existence of a solution to the optimization problem of truss structure with frequency constraints. This theory states that natural frequencies do not change if the truss is uniformly modified and that the constraint of eigen frequencies is usually the key constraint in determining the existence of a solution to the optimization problem of the truss's dynamic problem. Based on this theory, a practical problem is presented, in which the existence of a solution is discussed based on various optimization algorithms. An illustrative example is provided to demonstrate the application of this theory in finding the optimal design of truss structures. These academic works showcase the extensive research and development in the field of sensitivity analysis, experimental data refinement, and model updating in structural dynamics. They highlight the complexity and challenges in accurately modeling and predicting the dynamic behavior of mechanical structures and provide valuable methods and techniques to enhance the accuracy and efficiency of structural analysis and optimization.

2. ABOUT FREE OSCILLATIONS

2.1 Theoretical background

If an elastic structure is displaced from its equilibrium position at the initial moment $t_0 = 0$ (by imposing a suitably chosen initial displacement), the structure can undergo harmonic oscillations. This oscillatory motion is a characteristic of the structure and depends on the distribution of mass and the stiffness of the structure. In the presence of damping, the amplitudes of the oscillations will progressively decrease, and if the magnitude of damping exceeds a certain critical value, the oscillatory motion will cease entirely. On the other hand, if there is no damping, the oscillatory motion will continue, with amplitudes of oscillation depending on the imposed initial displacements, and frequencies of the free undamped oscillations of the structure (mechanical system) which do not depend on the initial conditions but on the mass and stiffness of the system. The study of free undamped oscillations is very important in determining the parameters of the dynamic response of the structure. Assuming, therefore, that there are no external forces (the external force vector is a zero vector), particular solutions to equation

$$[M]\cdot\left\{\ddot{\underset{\sim}{Q}}(t)\right\}+[K]\cdot\left\{\underset{\sim}{Q}(t)\right\}=\left\{\underset{\sim}{P}(t)\right\}. \tag{1}$$

can be sought in the form

$$\{Q\} = \underline{\{Q\}} \cdot e^{i\omega t} \quad . \qquad (2)$$

$$(e^{i\omega t} = \cos\omega t + i \sin\omega t)$$

After double differentiation of equation (2) and substitution into equation (1), it follows

$$[[K] - \omega^2 [M]] \cdot \underline{\{Q\}} = \{0\} \quad . \qquad (3)$$

The matrix equation (3) represents a system of homogeneous linear algebraic equations with unknown coefficients $\underline{\{Q\}}$. There is a trivial solution $\underline{\{Q\}} = 0$, which is not interesting because it implies no motion. Homogeneous algebraic equations (3) will have other solutions different from zero if the condition is fulfilled (1).

$$\left|[K] - \omega^2 [M]\right| = 0 \quad . \qquad (4)$$

Equation (4) is written in the form of a determinant and, in its expanded form, represents an nth-degree polynomial in ω^2, known as the characteristic equation or, as is known, the frequency equation. In general, it will have n roots: ω_1^2, $\omega_2^2, ..., \omega_n^2$. Since $[K]$ and $[M]$ are positive definite matrices, all the roots of the characteristic polynomial are real positive numbers, introducing the following notation: $\omega_1^2 < \omega_2^2 < ... < \omega_n^2$. To solve characteristic polynomials of higher degrees, it is necessary to apply numerical methods [3]. The quantities $\omega_1, \omega_2, ..., \omega_n$, represent the circular frequencies of the free undamped oscillations of the elastic structure, the squares of which are often also referred to as eigenvalues. Oscillations corresponding to these frequencies are called principal oscillations of the system. The lowest frequency is often called the fundamental circular frequency, and the first principal oscillation of the system, which has that frequency, is called the fundamental oscillation, as in the resulting motion of the system, oscillations at the lowest frequency are of primary importance. If any of the roots of the characteristic equation ω_j^2 were substituted into the system of equations (3), then, since it is a homogeneous system of algebraic equations, one of these equations would be consistent, i.e., dependent, so there would not be n independent equations but n-1. Then one equation is omitted from the system as redundant, and the remaining equations need to be divided by any unknown from the vector $\underline{\{Q_j\}}$, assuming it is different from zero. Therefore, it is not possible to determine the absolute values of amplitudes from the system (4), only their ratios. Finally, by introducing any eigenvalue ω_j^2 into equations (4), it is possible to determine the eigenvector $\underline{\{Q_j\}}$, so it is said that ω_j^2 and $\underline{\{Q_j\}}$ represent an eigenpair. The elements of the eigenvector $\underline{\{Q_j\}}$ physically represent the ratios of the displacements of individual masses in the case when all masses oscillate with the same circular frequency ω_j, or they indicate how many times the amplitude of the corresponding principal oscillation of one coordinate is greater or less than the amplitude of the other coordinate for the same principal oscillation, and are called coefficients of the jth principal mode of oscillation of the system with the eigenfrequency ω_j, and the vectors $\underline{\{Q_j\}}$ are also called modal vectors, where $j = 1,2,...,n$. The vectors $\underline{\{Q_j\}}$ can also represent amplitude vectors if it is assumed that one amplitude is equal to unity (usually the first, the one by which the algebraic equations (4) are divided). The coefficients of the principal modes of oscillation represent the physical constants of the system that depend only on the dynamic parameters of the system and do not depend on the initial conditions of the motion. Their total number is $n \cdot (n-1)$. Eigenvectors have the important property of orthogonality with respect to the mass matrix and the stiffness matrix, which can be expressed in matrix form as:

$$\underline{\{Q_i\}}^T \cdot [M] \cdot \underline{\{Q_j\}} = \delta_{ij} \quad , \qquad (5)$$

$$\underline{\{Q_i\}}^T \cdot [K] \cdot \underline{\{Q_j\}} = \omega_i^2 \delta_{ij} \quad . \qquad (6)$$

If the vectors $\left\{\underline{Q}_j\right\}$ are arranged to form the columns of a matrix, the resulting matrix represents the modal matrix, which represents the transformation from generalized to principal coordinates, in which system (1) can be represented as a system of n uncoupled differential equations, as is customary in the Theory of Oscillations [3-5] and [8].

2.2 Characteristics of changes. Modification coefficients

The characteristics of changes and modification coefficients in the context of structural engineering often refer to the parameters that are altered or adjusted within a structural model to account for various factors such as material properties, environmental conditions, or design requirements. These modifications are implemented to improve the performance, efficiency, or other specific attributes of the structure. The modification coefficients are numerical factors that represent the extent to which certain parameters or elements within the structural model are adjusted or altered. These coefficients are typically determined through various analytical or experimental techniques, and their application can have a significant impact on the overall behavior and response of the structure. In structural analysis and design, modification coefficients are used to account for uncertainties, variability, or dynamic changes in the structural properties or loading conditions. By adjusting these coefficients, engineers can achieve better accuracy, reliability, and safety in the design and performance of structures. Modification coefficients play a crucial role in sensitivity analysis, model updating, and optimization processes, allowing engineers to fine-tune the structural parameters to meet specific design objectives or constraints. They are often employed in the context of finite element analysis (FEA) or other computational modeling techniques to ensure that the structural design meets the required standards and performance criteria. Certainly, the relationship between eigenvalues and frequencies is a well-established concept in structural dynamics. The eigenvalue, representing the square of the frequency, holds a crucial position in the analysis of dynamic systems. By its nature, the eigenvalue can be considered a fundamental parameter, often regarded as a simpler variable compared to the frequency itself. When discussing modifications to the eigenvalue, it is essential to understand the implications for the overall system dynamics and structural behavior. Expressing the modified eigenvalue involves considering the adjustments made to the fundamental characteristics of the structure, which can influence its vibrational properties and dynamic responses. These modifications may stem from various factors, such as changes in material properties, geometric alterations, or adjustments in the boundary conditions. The expression of the modified eigenvalue encapsulates these changes and provides insights into the transformed dynamics of the structure. By analyzing the modified eigenvalue, engineers can gain a deeper understanding of the system's behavior under different operating conditions and make informed decisions regarding structural modifications and optimizations. The modified eigenvalue can be expressed as follows [8]:

$$\lambda + \Delta\lambda = \left(\omega + \Delta\omega\right)^2 = \omega^2 + 2\omega\Delta\omega + \left(\Delta\omega\right)^2 \tag{7}$$

that is,

$$\Delta\lambda = 2\omega\Delta\omega + \left(\Delta\omega\right)^2 \tag{8}$$

If relative modification relations are introduced as follows $\psi = \frac{\Delta\lambda}{\lambda}$, $\xi = \frac{\Delta\omega}{\omega}$, the previous equation can be written in the form

$$\psi \cdot \lambda = 2\omega^2 \cdot \xi + \omega^2 \cdot \xi^2 \quad \Rightarrow \quad \psi = 2 \cdot \xi + \xi^2 \tag{9}$$

and for small changes in frequencies, the approximate linearized form holds $\psi \approx 2 \cdot \xi$.

For example, if the frequency increase is 10%, the following calculation applies:

$$\left.\begin{array}{ll} \omega' = \omega + \Delta\omega = 1.1\omega & \xi = 0.1 \\ \lambda' = \lambda + \Delta\lambda = \left(\omega'\right)^2 = 1.21\lambda & \psi = 0.21 \end{array}\right\} \quad \psi_{priblizno} = 2\xi = 0.2 \tag{10}$$

However, if the frequency increase is 30%, the following holds:

$$\left.\begin{aligned} \omega' &= \omega + \Delta\omega = 1.3\omega & \xi &= 0.3 \\ \lambda' &= \lambda + \Delta\lambda = (\omega')^2 = 1.69\lambda & \psi &= 0.69 \end{aligned}\right\} \quad \psi_{priblizno} = 2\xi = 0.6 \tag{11}$$

The disparity between linearized and exact values can potentially lead to discrepancies, highlighting the necessity of retaining nonlinear forms for larger frequency changes.

In the case of a beam element with a rectangular cross-section, whose dimensions are $b \times h$, the axial moment of inertia for one of the principal axes is $I_z = \frac{b^3 h}{12}$. If structural modifications are made by altering the dimensions b and/or h, the relative modification ratios, $\psi = \frac{\Delta b}{b}$ and $\xi = \frac{\Delta h}{h}$, and the corresponding modification coefficients, α_e and β_e, in this case would be as follows:

$$\alpha_e = (1+\psi)^3 (1+\xi) - 1,\ \beta_e = (1+\psi)(1+\xi) - 1 \tag{12}$$

In tables 3.2-3.5, the relative modification ratios are indirectly represented through the relationships of axial moments of inertia and cross-sectional areas for some characteristic profiles, as illustrated by the corresponding diagrams.

From the above diagrams, the following conclusions can be drawn. The red line denotes the relative ratios of axial moments of inertia for one of the principal central axes of the corresponding cross-section, while the green line represents the other axis. As the beam's bending stiffness is proportional to the corresponding axial moment of inertia, a suitable choice of profile type can significantly increase the natural frequencies of the system during the original structure's construction phase. It is evident that the U-profile is more suitable for one direction, whereas the I-profile is better for the other direction. Box profiles are acceptable since they exhibit the same properties in both directions [6-8].

3. CONCLUSION

In conclusion, the study of structural behavior, underscores the significance of precise calculations and modification elements. These elements, play a pivotal role in understanding and enhancing the operational performance of structures. The mathematical pursuit of modification involves the optimization of various parameters, considering constraints and non-linear functions. Sensitivity analysis serves as a cornerstone, providing essential insights into the behavior of the objective function. While conducting sensitivity analyses in real-world scenarios can be challenging, the alternative approach of parameter distribution analysis within specific elements serves as a practical substitute. Ultimately, achieving the desired natural frequency for a structural system often demands extensive computations and analyses of multiple structural variations. This approach is pivotal in ensuring the effective and reliable performance of structures in practical applications.

SELECTED ACHIEVEMENTS IN THE RESEARCH OF THE DIAGNOSTICS OF THE LACK OF COMBUSTION IN THE ENGINE AND CHANGES IN THE INSTANTANEOUS ANGULAR VELOCITY OF THE CRANKSHAFT

Stojko Biočanin[1], The Academy of Applied Technical Studies Belgrade
Milica Timotijević[2], College of Applied Studies Aviation Academy

Abstract: *The paper presents selected achievements in the research of diagnostics of lack of combustion in engine cylinders. The variation of the angular speed of the crankshaft of the engine is an extremely unfavorable phenomenon, however this "disadvantage" contains a large amount of information about the work processes that take place inside individual cylinders of the engine. Several diagnostic concepts are presented with the measurement techniques used.*
Keywords: Dijagnostic, Angular velocity, Crankshaft, Misfire, Engine, Measurement.

1. INTRODUCTION

Legal regulations regulate in-vehicle diagnostics, for which the term "On Board Diagnostics" or "OBD" for short is used in technical practice. The first such regulations (OBD I) were officially introduced in 1987 in the United States of America*, i.e.* the federal state of California, and were valid for all passenger vehicles sold on its territory, including imported vehicles.
OBD II regulations came into force in 1996, and compared to OBD I, they are significantly more complex because they provide for the control of a larger number of devices and specify strictly permitted limits for changing the characteristics of individual engine subsystems. Today's OBD II protocol, from the aspect of fault diagnosis, in its specification requires an assessment not only of the final parameters of the state of one of these subsystems (regular or irregular), but as a preventive measure, it also requires the reporting of suspicious behavior in the operation of an engine subsystem. The main control functions of OBD II in the diagnostic process are: constant checking of exhaust gas emissions, early signaling of errors and the use of diagnostic functions that greatly simplify fault finding and their resolution by professional personnel.

2. DIAGNOSTICS OF THE LACK OF COMBUSTION IN THE ENGINE AND CHANGES IN THE CURRENT ANGULAR VELOCITY OF THE CRANKSHAFT

There are several methods for detecting an occasional misfire in one of the engine's cylinders. The method of controlling angular speed variations of the crankshaft proved to be the most suitable. In this paper, only one detail of the complex tests will be presented, conducted by experts from the companies "Audi" and "Robert Bosch" on a large number of vehicles with engines of 4, 6, 8 and 12 cylinders, with manual and automatic gearboxes [1]. The point is that the possibility of correct misfire detection is directly related to the number of engine cylinders. Research has shown that for engines with more than six cylinders, the requirement to detect "misfire" in all operating modes and for positive torque values cannot be fully met. Figure 1 precisely illustrates the limits of the possibility of correctly detecting the occurrence of "misfire" for engines with 4, 6, 8 and 12 cylinders [1]. The

[1]sbiocanin@atssb.edu.rs
[2]timotijevic.milica93@gmail.com

position of these limits depends on the vehicle construction, engine type, suspension system, applied transmission, etc.. It is obvious that with engines having a larger number of cylinders (8 and 12) there are areas where it is impossible to correctly detect the occurrence of "misfire". However, it can be said that these limitations are not to be critical, because vehicles during exploitation usually work very little in conditions of speed and load where the detection of "misfire" is difficult. The problem of uneven rotation of the crankshaft of a reciprocating internal combustion engine appeared simultaneously with the first version of this engine. The variable torque acting of the motor during one working cycle is a consequence of the periodically changing total tangential force of the motor mechanism, to which this torque is directly proportional.

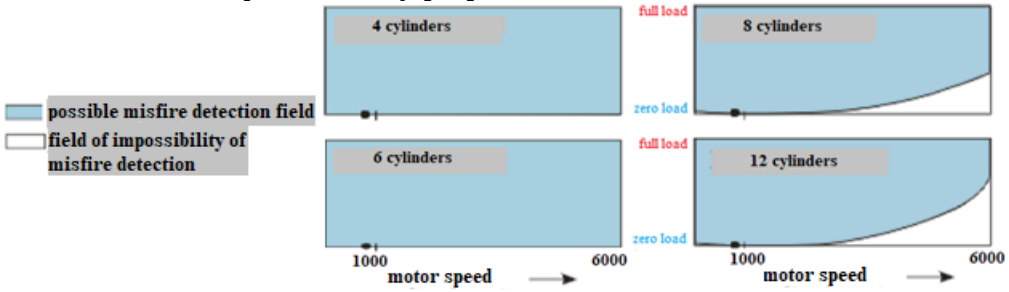

Figure 1. Limitations on the ability to detect misfires in the engine cylinders
Source: Klenk, M., Moser, W., (Robert Bosch GmbH); Meuler, W., Wimmer, W., (Audi AG), paper 930399: Misfire Detection by Evaluating Crankshaft Speed – a Means to Comply with ODB II

Due to this character of the torque change, even with constant resistance that the motor would overcome, in some phases there is an excess, and in others a torque deficit. Excess torque is communicated to the movement system of the engine (and connected machines), increasing the speed or kinetic energy of their rotative parts. On the contrary, the lack of work of the tangential force, when combustion ends in the observed cylinder and in the next one the working cycle has not yet started, will be accompanied by a slowdown, and thus a reduction in the kinetic energy of these parts. These changes depend on the number of engine cylinders and the operating mode and in principle are repeated periodically.

Since reciprocating internal combustion engines (ICE) are used exclusively as power units, variations in the angular velocity of the crankshaft represent an extremely unfavorable phenomenon, which is considered one of the serious drawbacks of their existing concept. However, this "disadvantage" contains a large amount of information about the work processes that take place inside individual engine cylinders.

Among the measuring techniques of the last decades, the existing toothed rings on the rim of the engine flywheel [2] or specially made and mounted toothed discs [3] in combination with magnetic inductive converters have been most often used. This concept is generally accepted since, in addition to the low price, it ensures stable operation of the encoder independent of the engine speed with minimal risk of negative environmental effects.

In parallel, research was conducted with the aim of correctly identifying and using the information contained in the angular velocity of the engine crankshaft, using suitable mathematical apparatus and different evaluation criteria, for diagnostic purposes [4, 5]. Thus, by controlling variations in the angular speed of the crankshaft in modern passenger vehicles, one of the key requirements of the "OBD II" regulations is fulfilled, namely the diagnosis of the phenomenon of lack of combustion in individual engine cylinders (in Western literature, the term "misfire" is used for this phenomenon)[1]. Engine torque and cylinder pressures are parameters of fundamental importance, which were previously considered very difficult to obtain during conventional vehicle use. According to [4], when trying to determine the fluctuations of the engine torque of a four-cylinder engine, the fact that the engine is connected to its load via elastic elements and that the entire system is one elastic assembly, which can be replaced by an equivalent torsional system (Figure 2), was taken into account.

For this cause, a mathematical model with four degrees of freedom was developed, which includes four inertial masses, such as: the engine (including the crankshaft with connecting rods), the flywheel, the torsional oscillation damper and, most importantly, the inertia of the vehicle itself, i.e., the brakes.

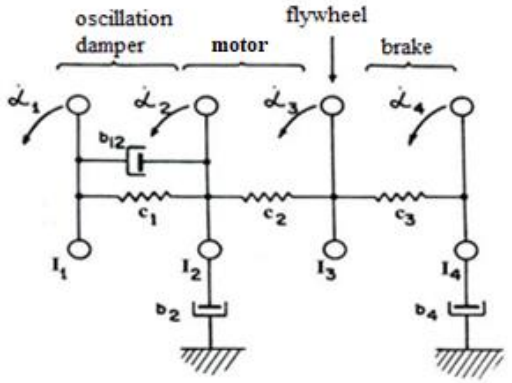

Figure 2. Propulsion system model
Source: Citron, S. J., O′Higgins, J. E., Chen, L. Y., Cylinder by cilinder engine pressure and pressure torque waveform determination utilizing speed fluctuation (SAE Paper 890486)

Taking into account the total variable motor torque and the "constant" load torque, after identifying the corresponding stiffness coefficients (c_1, c_2 c_3) and damping (b_{12}, b_2 и b_4), the fluctuations of the motor torque waveforms were reconstructed via FFT – Fast Fourier harmonical analysis transforms using the angular fluctuation data of flywheel speeds *(a)*.
A similar, but far more complicated mathematical model was applied to the large twenty-cylinder V50 diesel engine of the company "Warstila" with a nominal power of 20 MW and a total cylinder volume of 200 dm^3, intended for electrical power production [5]. With that engine, each cylinder was equipped with an "independent" fuel supply system, and the engine itself was an extremely "torsion-elastic" system with 13 degrees of freedom.

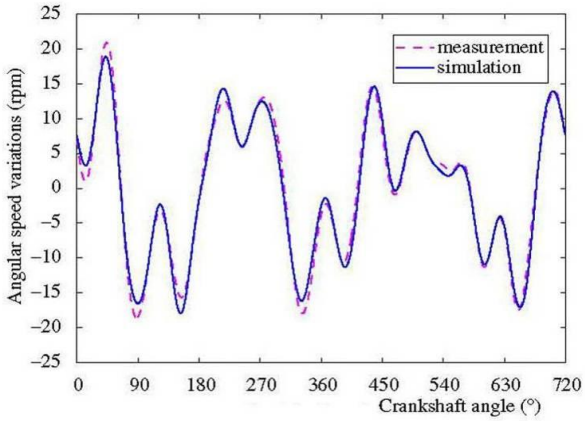

Figure 3. Measured and calculated fluctuations of the free end of the crankshaft of the 20-cylinder diesel engine "Warstila"
Source: Desbazeille, M., Randall, R.B., Guillet, F., Badaoui, M.El., Hoisnard, C., Model-Based Diagnosis of Large Diesel Engines Based on Angular Speed Variations of the Crankshaft, Mechanical Systems and Signal Processing 24 (2010), pp. 1529–1541

By using neural networks and many other sophisticated solutions, the authors were able to explain and reconstruct the fluctuations of the angular velocity of the free end of the crankshaft (Figure 3), for different states of correctness of the working processes in the engine cylinders. With this, they laid the foundations for the use of a technique known as "pattern recognition" for the purpose of detecting malfunctioning working processes in one of the engine's cylinders.
In addition, worthy of attention is the research presented in [6], where the authors set the theoretical foundations and then demonstrated practical results in order to detect both lack of combustion and

poor compression on one or more cylinders in a four-cylinder diesel engine with a volume of 1,6 dm^3. Through a complex "energy model" that included the variable flow of angular velocity of the crankshaft, two "energy indices" were defined that were calculated for each of the engine cylinders: compression index and expansion index. The validation of the method was carried out by monitoring the changes in these indices during a series of tests on the test bench, where the input parameters of the model were varied: the number of revolutions per minute, the coefficient of excess air whose real values are ranked in the range from 0 (no combustion) to 1 (regular combustion), the engine filling coefficient, which for the naturally aspirated variant of the engine was ranked in the range of 0 to 1, and for the supercharged variant of the engine could be greater than 1, the cross-sectional area of the gap between the cylinder and the piston sealing rings.

Finally, a brief review will be given of the tests of angular velocity fluctuations of the crankshaft of the turbocharged variant of the engine from the V46 family, which bears the V46-TKA mark, described in [7]. During the development of various variants from the family of twelve-cylinder diesel engines of the V46 series (635 kW, 735 kW, 882 kW), and especially in forced turbocharged variants, unusually high temperatures of the exhaust gases of some cylinders were observed, which exceeded the permitted 700 ºC. This phenomenon represented a signal of shortcomings in the performance of work processes in individual engine cylinders. Through a series of measurements of the angular velocity of the crankshaft of the engine and the camshaft of the high-pressure pump, the cause of the mentioned phenomenon was found in the strongly expressed amplitudes of fluctuation of these angular velocities [8]. By measuring the angular speeds of the crankshaft at its free end and at the end of the power output, it was concluded that the V46-TKA engine represents an extremely "torsion-elastic" system, as evidenced by the diagram of the relative angular displacement of those ends at full load and at 2000 min^{-1}, shown in Figure 4.

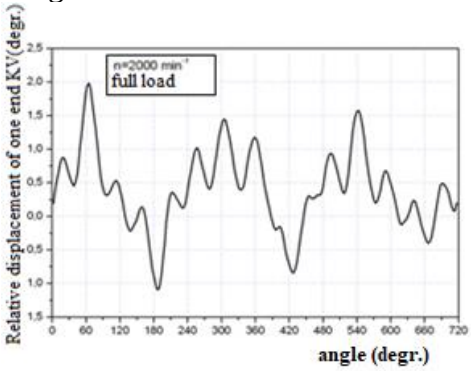

Figure 4. Relative displacement angle of one end of the crankshaft in relation to the other end in the V46-TKA engine for the regime n = 2000 min^{-1}, full load

Source: Bulatović, Ž. Possibilities of diagnosing the working process of the engine based on the change in the angular velocity of the crankshaft, Master thesis, Belgrade, 2008.

From the diagram in Figure 4, it can be seen that the maximum value of the relative displacement angle of one end of the crankshaft in relation to the other end is +1.982º, and the minimum is -1.091º. This means that the value of the maximum deformation amplitude for the given conditions is about 3.073º of the crankshaft. This diagram explains the cause of the totally different, even phase-shifted "flows" of angular velocities of the crankshaft at its free end and at the end of the power output.

The angular velocity measurement itself was performed by using an optoelectronic position sensor at the free end of the crankshaft, and at the end of the power output, towards the brake, a toothed disk coupled with an inductive sensor. By using the internal "clock" with a resolution of 2 MHz, which was utilized the acquisition module ADS2000 and special adaptive software, the creator of which was the late prof. Dr. Rade Jankov, the time intervals $\Delta\tau_i$ between adjacent increments of the optoelectronic sensor were measured and recorded in digital form. After the complex processing procedure explained in [7], diagrams of angular velocity fluctuations of the crankshaft at its ends were obtained. The regime of n = 2000 min^{-1} and full load are shown in Figure 5. These differences can be clearly seen on the comparative diagrams of the measured crankshaft angular velocity for 2000

min^{-1} at full load, which is also shown in Figure 5 (end 1 on the diagram is its free end, and end 2 is the end through which the power is taken). The marks 6L, 1D, 2L, 5D etc. on the tops of the given diagrams represent the mark of the cylinder in which the working process was taking place at "that moment", and it is quite clear that no clear correlation can be drawn between the development of these working processes and the fluctuations of the angular velocity crankshaft.

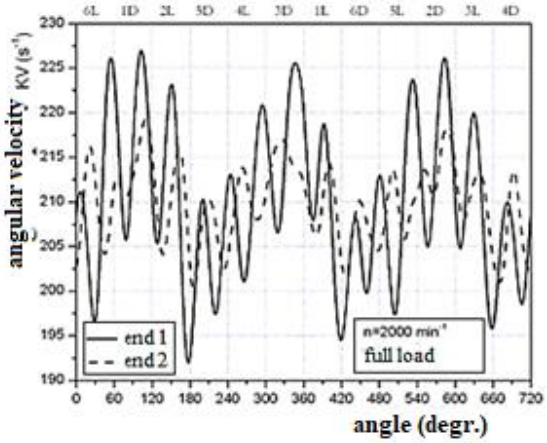

Figure 5. Comparison diagram of the measured angular velocities of the crankshaft at its different ends for the regime n = 2000 min^{-1}, full load

Source: Bulatović, Ž. Possibilities of diagnosing the working process of the engine based on the change in the angular velocity of the crankshaft, Master thesis, Belgrade, 2008.

The results of these tests are very reminiscent of the results given in [5], a fragment of which is also shown in Figure 3. It can be said that such, at first glance, chaotic and illogical diagrams of crankshaft angular velocity fluctuations can often be found in professional literature when in question engines of higher power and dimensions. Understanding this phenomenon and explaining its physicality is possible only if such test objects are viewed as "torsionally elastic" systems. A mathematical model that would manage to reconstruct and explain the angular velocity fluctuations of the crankshaft of the V46-TKA engine would be similar to the models presented in [4,5] and would have seven degrees of freedom. This arises from the fact that the equivalent torsional system would be composed of six identical concentrated masses representing the six crankshaft segments and a seventh mass representing the laboratory brake. Each of these masses, under the influence of a variable coercive torque (equivalent to engine torque), as well as internal stiffness and damping, would rotate with a characteristic angular velocity, and the diagrams of the angular velocities of the first and sixth masses would correspond to the diagrams of the measured angular velocities at the free end and at the at the end of the power output of the crankshaft, analogous to the diagrams shown in Figure 5.

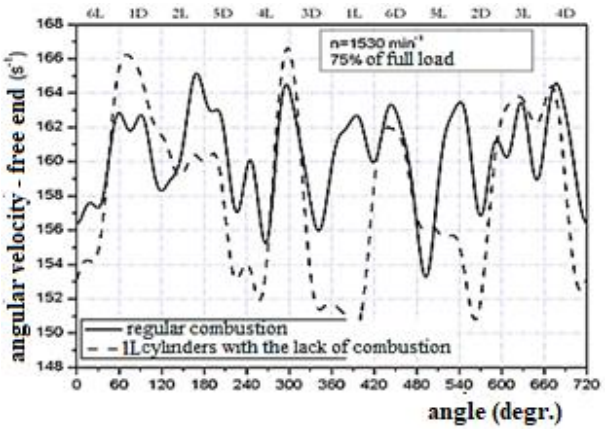

Figure 6. Angular velocities of the free end of the crankshaft at the regime of n = 1500 min^{-1} and 75% of full load

Source: Bulatović, Ž. Possibilities of diagnosing the working process of the engine based on the change in the angular velocity of the crankshaft, Master thesis, Belgrade, 2008.

It is shown that the diagrams presented in Figure 5 are not the product of any stochasticity, on the contrary are the result of the real response of the system for certain operating modes, which are absolutely repeatable every time the system is under identical conditions in terms of variable coercive moment, internal stiffnesses and internal dampings, which was also proven experimentally [7,9]. In the relation to that, it follows that the angular speed of the crankshaft of the V46-TKA engine can be used to detect the correctness of the working processes in its cylinders. This is supported by the diagrams shown in Figure 6, which represents the fluctuations of the angular velocity of the free end of the crankshaft at mode n = 1500 min^{-1} and 75% of full load, where the difference between the measured curves for two different conditions is clearly visible: regular combustion in all cylinders and the lack of combustion in the first left cylinder of the engine.
The experience gained during many years of work on the development of turbocharged variants of the V46 series engine made it possible to connect the cause of the appearance of unacceptably high exhaust gas temperatures with the dynamics of the high pressure pump (HPP) drive. The elements of the HPP drive, together with the crankshaft and the HPP itself, form a complex oscillatory system. The measurements showed the change in the angular speed of the HPP camshaft during one revolution, with clearly defined six periods and an extremely large amplitude of the angular speed (dashed line in Figure 7).

3. CONCLUSION

From what was written in the paper, it can be concluded that today technical diagnostics represents a serious and unavoidable discipline in the field of exploitation of internal combustion engines. The application of digital microprocessors and microcontrollers, as well as ultra-fast analog-to-digital and digital-to-analog converters, gave the engine a new quality because they enabled complex management of the engine's working process. On the other hand, possibilities of adaptive control of the work of almost all vital subsystems of the engine, as well as the quality of the working process itself, have expanded, in order to immediately identify and eliminate possible malfunctions.

Nenad Šekularac[3], Faculty of Architecture, University of Belgrade

Abstract: *Problem of rational use and lack of quality wood raw material for producing veneer boards, can be solved using poor quality wood raw materials for design composite veneer board. Poplar LVL panels do not have structural use because of its mechanical properties. Fiber reinforced composites can improve mechanical properties of wood-based panels, and thus enable the structural use of poplar panels. Synthetic fibers can reinforce panels, minimize the negative properties of wood raw material and improved dimensional stability of the board. This paper presents the results of experimental testing of the panel shear tests of unreinforced and reinforced seven-layer LVL (laminated veneer lumber) poplar veneer panels. The aim of the research is to determine the influence of woven carbon fibers on the improvement of the panel shear test of LVL, in order to test the potential of using this composite material as a structural element. The orientation of fibers has a strong influence on the reinforcement. The main research task is investigation the effects of orientation of the carbon fibers and their position in the panel construction on the shear properties of the panel. This research present possibility of applying poplar veneer to design structural elements in LVL using epoxy adhesive.*
Keywords: mechanical properties; LVL; CFRP; epoxy.

1. INTRODUCTION

Wood as a natural material used throughout history as one of the most commonly materials in construction. As natural material wood have great potentials for use in construction, due to its availability, easy processing and good physical and mechanical properties. The disadvantage of wood raw material is that not every type of wood is suitable for structural use, especially fast-growing soft species. Domestic wood species like poplar wood are very common in south Europe. The two leading countries that encourage the use of poplar in the construction industry and its structural application are Italy and Spain. With its 32,000 ha, Serbia is the 5th country in Europe in terms of the area of poplar plantations [1]. Lower load capacity and weaker mechanical characteristics compared to other species used for structural timber, make poplar is a less represented species in the construction industry. In order to make the best possible use of wood raw materials, wood-based products were made. Products based on veneer layers, plywood and laminated veneer lumber (LVL) are of special importance, and they stand out additionally due to their mechanical and aesthetic performance. Advantage of composite products like LVL and plywood is on distributing the errors through the panel and eliminating them in production. This reduce the variability in material properties, and equalize the mechanical properties of the product in the longitudinal and transverse direction. In order to improve mechanical properties of wood raw material and wood-based products, various

[3]nenad.sekularac@arh.bg.ac.rs

strengthening techniques have been investigated throughout history. Strengthening timber construction with synthetic materials has been the subject of research studies since the 1960s [2].
The pioneers of using polymer composites - glass fiber reinforced polymers (GFRP) for strengthening of wood were Wangaard and Biblis [3]. During early 2000s, these authors continued to improve this idea, and examined the bending properties of three- and five-layer plywood reinforced with glass fiber fabric using phenol-based adhesives [4]. More intensive research in this area was made in the last ten years, and they mostly focused on bending properties of composite product created from wood veneer and fiber reinforced polymers. The research of mechanical propeties of reinforced veneer based panels or LVL, can be defined into two types of reinforcement - carbon or glass fibers. The flexural strength and modulus of elasticity were tested on three- and five-layer boards made of pine veneer, reinforced on the outside with two-way woven glass mesh in two layers, impregnated with polyester resin [4]. Examining the influence of the amount of fibers on the buckling of GFRP-reinforced veneer panels when exposed to compressive stresses and their behavior when exposed to different temperature conditions was investigated by Choi (S.W) and others [5, 6]. Investigation of the influence to mechanical and physical properties of panel using glass fabrics reinforcement with fibers oriented in two directions and their position in the veneer panel construction show significant improvements, especially to modul of elasticity and modul of rupture [7, 8]. An examination of the influence of the amount of carbon fibers in the strengthening of plywood with CFRP products on its mechanical properties and, above all, on its bending properties was presented in research by Brezović et al. [9]. Strengthening of veneer-based panels with carbon fibers oriented in two directions and analysis of their position in construction on the mechanical properties of the plywood [10] shows an increase in flatwise bending strength, tensile strength, and Young's modulus of elasticity. Just a few researches analyse the examination of the panel shear properties of composite LVL or plywood panel. For the structural application of these panels, it is very important to examine that mechanical properties.
Depending on the design and position in the construction, panels can be exposed to different types of loads, differ is primarily in their direction and position, which means that the elements are exposed to different type of stress. Panels used as diaphragm due to their small static height cannot accept bending perpendicular to the plane of the plate, and the diaphragms are designed as complex cross-sections of veneer plates and substructures. In these constructions, veneer based panels have the role of accepting shear forces perpendicular to the plane of the plate when the structure is exposed to a horizontal load, or shearing in the plane of the plate that occurs as a result of bending under the effect of gravity load. Potential of new reinforced material is to use panels as structural element, to unconventional way. This implies to use panel for folds, polygonal shells and structures formed in a constructive system of reciprocal constructions. To use panel as desribed, it needs to have exceptional resistance to in-plane compression and tension, as well as perpendicular to planar and panel shear.
This research investigates the possibility of producing composite panels based on veneer reinforced with CFRP. The aim of the research is to determine the influence of woven carbon fibers on the improvement of the panel shear test of LVL, in order to test the potential of using this composite material as a structural element. The main research task is investigation the effects of orientation of the carbon fibers and their position in the panel construction on the shear properties of the panel.
The focus is on the investigation of the possibility of applying this material as structural elements in architectural buildings, especially those exposed to forces in the plane of the plate, like beams, polygonal shells and folded structures.

2. MATERIALS AND METHODS

2.1 Veneer

In this study, constructive poplar veneers, produced by peeling (rotary-peeled veneers) at a thickness of 4 mm and humidity of 7 ± 1%, were selected for the formation of LVL panels. All veneers are cut to dimensions of approx. 550 × 550 × 4 mm. Reinforced and control LVL panels were formed from

all veneers. Four set of sheets were formed using epoxy adhesive (EK panels). Three types of reinforced sheets and one type of non-reinforced sheet were formed. LVL panels were produced in the laboratory at the Faculty of Forestry.

2.2 Adhesives

Epoxy adhesive Mapei "MapeWrap 31" was applied in all layers, between the veneers as well as between the veneers and the fiber reinforced polymer (FRP). The adhesive was formed in a mass ratio of A:B = 4:1 (according to Technical sheet [11]). The same amount of adhesive was applied to each glueline and each layer of CFRP wood on both sides of the carbon fabric. Epoxy adhesive properties show in Table 1.

Table 1. Epoxy adhesive properties
Source: [11]

Technical properties	Epoxy	
	Resin – A	**Hardener - B**
Density ρ (20°C) (g/cm^3)	1.05	1.12
Brookfield viscosity (mPa·s (25°C))	17000	110

2.3 Woven carbon fiber

The unidirectional "plain-weave" type of knitting carbon fiber, MapeWrap C UNI-AX 300/40", weighing around 300 g/m^2, was used for reinforcement. The physical and mechanical properties of the CFRP fabric are shown in Table 2.

Table 2. Physical and mechanical properties of MapeWrap C UNI-AX 300.
Source: [12]

Technical properties	**MapeWrap C UNI-AX 300**
Mass (g/m²):	300
Density (kg/m³):	1800
Equivalent thickness of dry fabric (mm):	0.164
Load resistant area per unit of width (mm²/m):	164.3
Tensile strength (MPa)	≥ 4900

2.4 Manufacturing LVL

All panels are produced as seven-layer panels with six veneer sheets oriented in the longitudinal direction, and the central, fourth veneer sheet oriented perpendicular to the grain of the outer veneer sheets. Reinforcements are placed between the veneer layers, according to the following scheme, shown in Figure 1:

- Combination 1 (K1) – reinforcement placed in the first and sixth glueline (S1‖6‖), unidirectionally oriented, carbon fibers placed longitudinally, parallel to the grain of outer veneer;
- Combination 2 (K2) – reinforcement placed in the first and sixth glueline, parallel-oriented as outer veneer, and the third and fourth glueline - perpendicular to the direction of orientation of the outer veneer sheets (S1‖3⊥4⊥6‖);
- Combination 3 (K3) – reinforcement placed in two layers perpendicular to each other, forming a mesh in two directions. The fabrics are placed in the first and sixth glueline (S1‖⊥6⊥‖), taking into account the symmetry of the cross-section;
- Combination 4 (K4) – unreinforced panels, i.e. control reference samples.

For each combination, 3 panels measuring 50×50 cm were formed. All plates were pressed in a laboratory press for 15 minutes from the moment of reaching a temperature of 100°C in the central layer at a pressure of 1.5 MPa. After that, they were stored for a week for additional curing. After that, 30-mm edges were trimmed off of the panels, and samples were cut from the panels. Samples

dimensions 150x50 mm, were conditioned in standard climate (20±2)°C and (65±5)% relative humidity during 30 days.

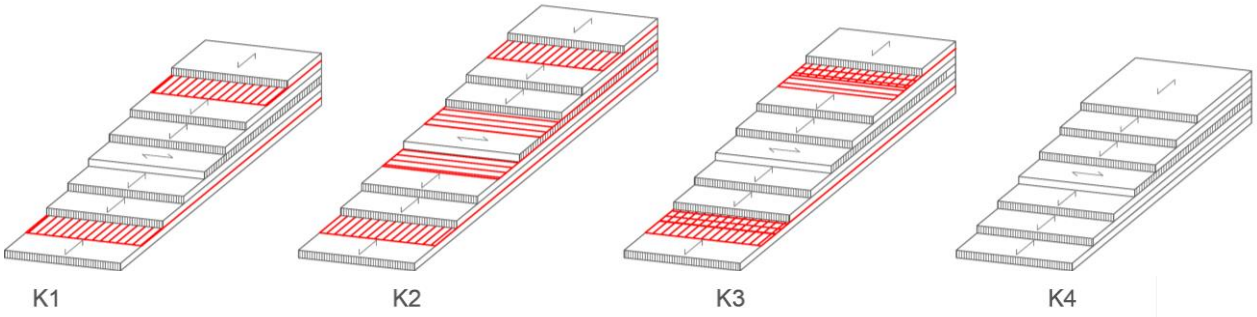

Figure 1. Strengthening configuration of reinforced and unreinforced LVL panels

Determination of shear strength perpendicular to the plane of the panel or panel shear test was performed according to the standard [13] SRPS CEN/TS 14966:2010 Wood-based panels - Small-scale indicative methods for testing certain mechanical properties using a small-scale indicator (Figure 2).

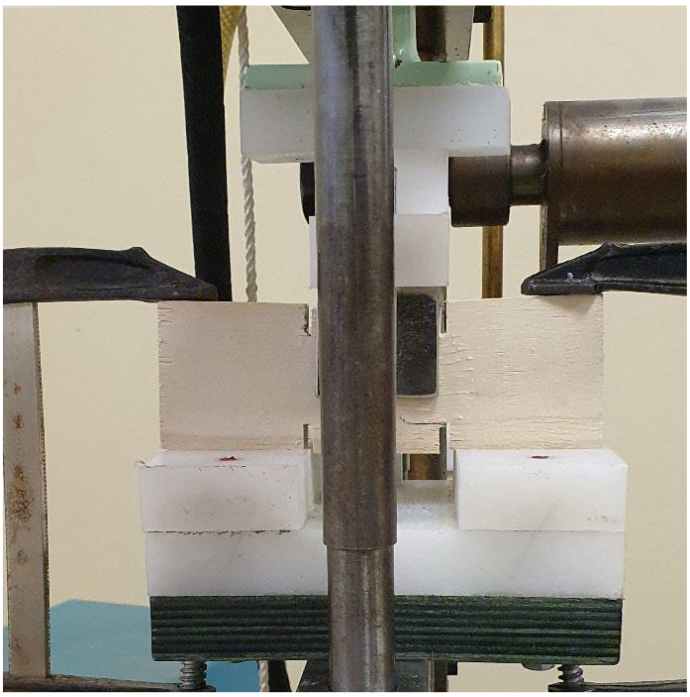

Figure 2. Fracture of the test sample due to shear stress.
Source: original copyright

3. RESULTS AND DISCUSSION

The test results for the test samples are shown in Table 3. For reinforce with two longitudinal, two longitudinal sheets and two perpendicular sheets, and sheets in disposition like a mash, the critical panel shear strength has increased by about 20.42%, 22.04%, 44.75%, respectively, compared to the untreated plate. These results show that higher panel shear load can be achieved using fiber reinforcement in two directions.

The best results are for combination K3, where carbon is oriented like mesh, in bi-directional orientation. In all tested samples, fracture occurred due to exceeding the shear stress. The fracture starts in the central sheet of veneer, whose wood fibers are transversely oriented in relation to the outer sheets of veneer, in the direction of the pressure force. In all other layers, shear occurs, which is manifested by the compression of fibers. Complete crush and cutting of the wood fibers does not occur, the fabric helps the test sample remains coherent (Fig.3).

Table 3. Shear properties of RLVL and LVL in edgewise directions, epoxy adhesive.
Source: original copyright

Combination	$f_{v,0,edge}$ (N/mm^2)	x (%)
EK1	15.16	20.42%
EK2	15.36	22.04%
EK3	18.22	44.75%
EK4	12.59	

Note: $f_{v,0,edge}$ – average shear stress, x – increase of average shears stress relative to EK4

Figure 3. Panel shear test - characteristic fracture for EK1
Source: original copyright

For combination 2 the mechanical damage of the test samples is less expressed compared to EK1. All test samples have the same forms of damage. In this combination the possibility of splitting along the longitudinal fibers of the wood was reduced.

On all the test samples of Combination 3 the fracture occurred by shear stress, but the deformations on the samples are very small, and on some of them are noticeable. Plastic deformation occurred on the test samples due to compression and crumpling of the fibers at the point of weakening of the material.

In all test samples from the control, unreinforced plates of Combination 4, failure occurred as a result of shear stresses. In relation to reinforced samples, the fracture of the test samples is quite expressed. The fracture tends to complete fracture of the test sample EK4.

4. CONCLUSION

In this study, laminated veneer lumber and reinforced laminated veneer lumber were produced with poplar veneer bonded with epoxy adhesive (EK). Reinforced laminated veneer lumber was produced by inserting woven carbon fiber between veneers, and some of their mechanical properties were tested. Reinforcement of EK3 panels, where the carbon fabric is placed in the first and sixth glueline in two layers, like mesh, oriented perpendicularly to each other, shows a much higher degree of increase panel shear capacity. The force at which the fracture occurred increased by 57.05%, while the percentage of improvement in shear stress is 44.75% compared to the control sample (EK4). In the test samples from these plates, it was observed that the degree of damage is the lowest compared to all tested test samples. The conducted research confirmed the possibility of applying the newly obtained poplar veneer composite material for the design of structural elements in LVL using epoxy adhesive. In this way, the use of technically weaker wood in the construction industry is encouraged and the use of wood raw materials is rationalized.

ACKNOWLEDGEMENTS

This research was funded by The Ministry of Education, Science and Technological Development which is financing the scientific research work of the University of Belgrade - Faculty of Forestry in 2023. on the basis of the Agreement on the realization number: 451-03-47/2023-01/200169.

This research was supported by the University of Belgrade, Faculty of Architecture, LAB—architectural engineering laboratory—structural problems of architectural buildings and laboratory of architectural space—form, function, and materialization; Faculty of Forestry, LAB—laboratory for the testing of chipboards and laboratory for testing wood properties. We would like to thank Mapei SRB d.o.o Beograd for providing carbon mesh for testing.

Abstract: *Robotic systems that use pneumatic actuators in the form of grippers are in very frequent use in automated production systems. In order to ensure their reliable operation over a long period of time, the compressed air they use should meet the prescribed standards, that is, it must be of appropriate quality. In pneumatic systems, each of the elements can affect the quality of compressed air in different ways, but the key components for realizing its desired quality are dryers and filters. The paper presents a case study through which, using an example from the food industry, the influence of refrigerator dryers on the quality of compressed air was pointed out.*
Keywords: Compressed Air Quality, Refrigerated Dryers

1. INTRODUCTION

Automated systems are an extremely important part of any modern production. For the purposes of realizing automatic movements, pneumatic actuators are most often used. Consequently, control processes are realized as pneumatic, electropneumatic or systems driven by programmable logic controllers. Within the framework of automated systems, robotized systems are particularly important, which most often use electric motors for their drives, and various types of pneumatic grippers are used for gripping. Common to all these systems is that for their correct, reliable and long-lasting operation, compressed air of appropriate quality [1,2] must be provided.
The question of the quality of compressed air is directly related to the composition of ambient air, the condition and type of system for the production, preparation and distribution of compressed air and the types of applications that use compressed air. This issue was standardized in 1991. with the adoption of the ISO 8573-1 standard [3], which defined three types of pollutants: solid particles, water and oil. However, this standard does not define what quality of compressed air is needed for which application, but that is left to pneumatic equipment manufacturers and users in production systems who can use certain recommendations [4]. If the required quality for a certain application is known, a special problem is how it is technically possible to achieve that quality [4]. The main components for realizing the desired quality are dryers [5] and filters [6,7], where dryers reduce the moisture content in the air and filters remove particles and oil.
However, even if the required quality is well defined and the compressed air preparation system is well chosen, there may be problems with the quality of the compressed air and all the consequences that this may have if any of the elements in the preparation system break down or do not function in accordance with expected results. In that sense, this paper provides a brief overview of the quality standards of compressed air, the methods of measuring components of compressed air quality and,

[1]vuketa90@uns.ac.rs
[2]seslija@uns.ac.rs
[3]vladimirjurosevicvl@uns.ac.rs
[4]valentina.mladenovic@vts-zr.edu.rs

through a case study, the influence of the functioning of refrigerator dryers on the quality of compressed air in terms of water content.

2. COMPRESSED AIR QUALITY

As mentioned, the quality of compressed air for general use is defined by the ISO 8573-1 standard. In the first part, pollutants are defined and compressed air quality classes are given. For the permitted level of pollution, a number is defined that identifies the quality class as shown in table 1, in relation to three types of pollutants:

1) solid particles, where the maximum allowed number of particles per cubic meter of compressed air is defined for three different groups of particles according to their size,
2) water, which implies the maximum allowed amount of humidity and liquid water in compressed air, and
3) oil, which means the maximum allowed amount of liquid oil and oil aerosols in compressed air.

The designation of cleanliness classes according to the ISO 8573-1 standard consists of specifying the name of the standard and the revision year, followed by the numbers indicating the cleanliness class in parentheses.

Table 1. Compressed air quality standard ISO 8573.1:2010 [3]

Class	Solid particulate				Water		Oil
	Maximum number of particulates per m^3			Mass concentration [mg/m^3]	Vapour pressure dewpoint [℃]	Liquid [g/m^3]	Total oil (aerosol liquid and vapour) [mg/m^3]
	0,1-0,5 [μm]	0,5-1 [μm]	1,0-5 [μm]				
0	As specified by the equipment user or supplier and more stringent than Class 1						
1	≤ 20.000	≤ 400	≤ 10		≤ -70		≤ 0,01
2	≤ 400.000	≤ 6.000	≤ 100		≤ -40		≤ 0,1
3	-	≤ 90.000	≤ 1.000		≤ -20		≤ 1
4	-	-	≤ 10.000		≤ +3		≤ 5
5	-	-	≤ 100.000		≤ +7		-
6	-	-	-	$0 < c_p \leq 5$	≤ +10		-
7	-	-	-	$5 < c_p \leq 10$	-	$C_w \leq 0,5$	-
8	-	-	-	-	-	$0,5 < C_w \leq 5$	-
9	-	-	-	-	-	$5 < C_w \leq 10$	-
X	-	-	-	$c_p > 10$	-	$C_w > 10$	> 5

c_p - mass concentration of solid particles [mg/m^3]
C_w - maximum water concentration [g/m^3]

Particle filters of different gradations are used to achieve the desired quality in terms of solid particles, and coalescent filters are used to achieve the desired quality in terms of oil content. Achieving the desired quality in terms of liquid water and water vapor content is, for the most part, achieved by using appropriate dryers. In modern conditions, three types of dryers are generally used for this: refrigerated, adsorption and membrane dryers.

Refrigerated dryers, or subcooling dryers, condense moisture from compressed air by lowering the temperature of the air that is cooled in heat exchangers with some of the cooling agents. These dryers achieve saturation points less than or equal to 3°C at system operating pressure, which corresponds to the fourth class of compressed air quality. Adsorption dryers are used to achieve better quality (classes 1, 2 and 3), while the third and fourth quality classes can be achieved with the use of a membrane dryer in terms of liquid water and water vapor content.

3. MEASUREMENT OF COMPRESSED AIR QUALITY COMPONENTS

Compressed air quality is measured individually for each of the contaminants defined by the standard ISO 8573-1. Special devices called solid particle counters are used to measure the number of particles.

They are the most expensive of all devices used to measure compressed air quality and very few factories, except pharmaceutical companies, own them. Pharmaceutical factories that work under the Good Manufacturing Practice (GMP) system have the obligation to validate, i.e. prove the parameters at the entrance and exit of the production facilities, and thus they must also validate the quality of compressed air. The operation of solid particle counters can be based on several different principles. However, in the field of measuring solid particles in compressed air, systems based on the principle of machine vision are most often used, because their application makes the measurement very fast and accurate. Hygrometers are used to measure the humidity of compressed air. Their work is based on different phenomena, some of which are:

- hygroscopic properties of some substances, for example hair strands, which lengthen in wetter air and shorten in drier air (hygrometer with hair),
- on the absorption of water vapor from a known amount of gas where the humidity is determined by measuring the absorbed vapor (absolute humidity determination or absolute humidity),
- on condensation, i.e. determining the dew point where the air cools until it condenses and
- on a change in the electrical conductivity of an electrolyte, for example lithium chloride (electrolyte hygrometer), etc.

Special test tubes are used to measure the oil, which must be suitable for the type of oil used in the system. Below are some of the devices used to test the quality of compressed air. In this case, the following equipment was used to determine the required parameters of compressed air quality:

- Festo AirBox [8], a device that can be used to determine the amount of moisture and oil in compressed air and
- Dräger indicator tubes, which are used together with the AirBox device, to determine the amount of moisture and oil in the compressed air.

3.1 AirBox, type GHDA-FQ-M-FDMJ-A

AirBox (Fig. 1) is a mobile device designed for two types of measurements, depending on how the compressed air is delivered to the device itself:

- measurement of compressed air flow, and
- measuring the amount of water and oil in compressed air.

3.1.1 Flow measurement

The measurement of compressed air flow is based on the flow of air past a surface that is continuously heated. The air current absorbs heat energy from the hot surface and the sensor measures the flow rate necessary to maintain a given temperature on the surface. The measured flow represents the amount of air that flows through the device in a unit of time. Flow values are recorded in the device's internal memory. In addition, pressure and air temperature are measured by pressure during each flow measurement.

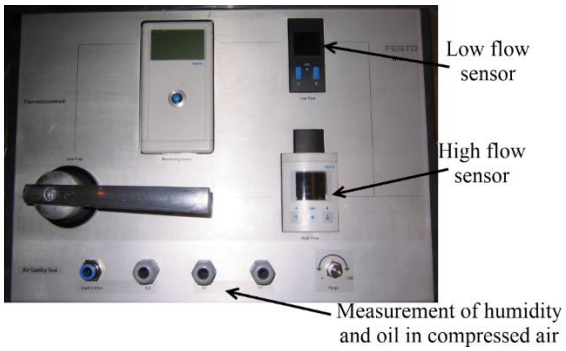

Figure 1. AirBox, type GHDA-FQ-M-FDMJ-A

3.1.2 Measurement of water and oil content

When measuring the dewpoint and the amount of oil in compressed air, a chemical reaction method is used. This method involves the use of tubes with chemical reagents. Reading of dewpoint and amount of oil in the air is done directly, based on the color change, which occurs as a result of the reaction of water/oil from the compressed air and the chemical substance in the tube.
Three types of Dräger indicator tubes (Fig. 2) were used during the experimental research:

1. Dräger indicator tube 5/a-P (Fig. 2a),
2. Dräger indicator tube 10/a-P (Fig. 2b), and
3. Dräger indicator tube 1/a (Fig. 2c).

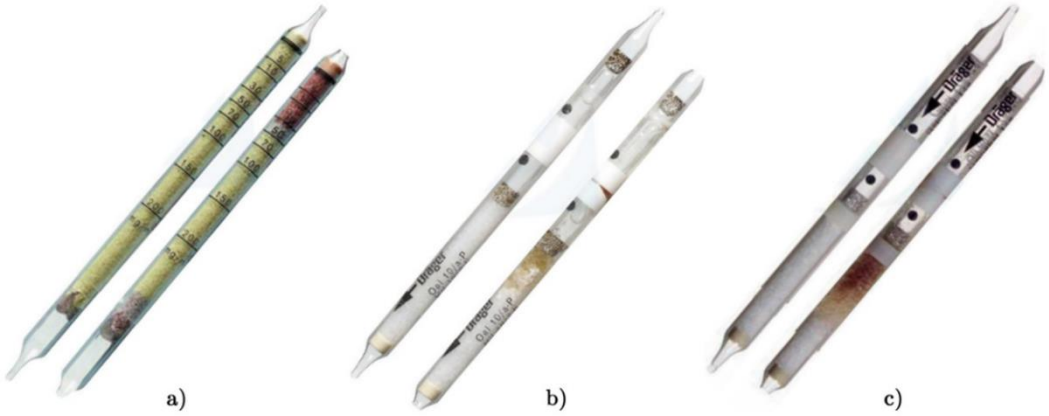

Figure 2. Dräger indicator tubes: a) 5/a-P, b) 10/a-P, i c) 1/a

A chemical reaction causes a change in the color of the crystal in the indicator tube, and based on the degree of color change, the amount of moisture and oil in the compressed air is determined.

4. CASE STUDY

A food industry factory [9] has automated the line for packaging of products into boxes by installing a large number of modern tripod robots at the end of the line, where the products that are already individually packed arrive. The robots are equipped with sophisticated machine vision systems that dynamically recognize the products on the conveyor belt and deliver the desired coordinates to the robot in real time. The robot grabs the products with a pneumatic gripper, transfers them to the boxes that also move in a parallel sequence with the product line, and places the products in the boxes.
After a long successful operation, problems appeared in the functioning of the pneumatic grippers on this line. After visual observation, it was concluded that the only possible reason is a change in the quality of the compressed air.
In order to confirm the assumption, as well as to find the cause of the problem, it was requested to measure the quality of the compressed air in terms of the content of liquid water and humidity as well as liquid oil and oil aerosol and vapor in a certain number of places.
In order to confirm that the quality is inadequate, two measurements were made at the points of air consumption, immediately before the robot, after additional air preparation in the preparatory group. For the adequate operation of these consumers, the fourth class of air quality in terms of water content is necessary.
In order to establish the cause of inadequate air quality, measurements were carried out after each of four compressors. As for Atlas Copco compressors of the GA FF series, which have built-in refrigerator dryers, it is expected that these dryers provide air in the fourth quality class, that is, that the dewpoint is less than or equal to 3°C.
In order to determine the time of compressed air flow through the indicator tubes, when determining the quality of compressed air at the observed measuring point, it is desirable to know the type of

compressor oil used in the factory. That is why, before the measurements were made, the client received information that the same oil was used for compressors, and that is Atlas Copco Roto Injectfluid.
An overview of the results of all measurements is given in Table 2.

Table 2. Overview of all measurements and quality class identification

No	Measuring point	Dewpoint [℃]	Quality class	Oil quantity [mg/m^3]	Quality class
1.	„K4“ (compressor 4)	-5	4	1	3
2.	„K5“ (compressor 5)	-12,5	4	1	3
3.	„K1“ (compressor 1)	>10	>7	1	3
4.	„K3“ (compressor 3)	>10	>7	0	1
5.	„ROBOT 2“	7,5	6	1	3
6.	„ROBOT 9“	7,5	6	0	1

Two of the 4 measuring points showed extremely poor results in terms of water content (compressors K1 i K3).
As for compressors that have built-in refrigerator dryers, it is obvious that these dryers do not work or not work properly. The problem is that all compressors are connected to the same tank, which is otherwise technically correct, but in the event of a malfunction, the following problem arises. In the tank, there is a mixing of quality class 4 air (correctly prepared air) and moist air with a significantly higher amount of moisture given by two faulty dryers. From there, the poorly prepared air in terms of water content is distributed into the main line. It should be noted that the first two compressors give the expected, fourth class and that this should be the case throughout the main line. However, the quality of compressed air is unfortunately spoiled by two compressors that do not work as they should.
When it comes to the presence of oil, it was determined that the analyzed system is in a relatively good situation, as class 1 or 3 is achieved. The compressed air after compressor 3 is somewhat better prepared in terms of oil content (class 1), while all other measurements of compressed air after the compressor give class 3.
Two measurements were made at the places of compressed air consumption. Measurements were made in the robot line and it can be seen that obtained dewpoint is slightly lower (7,5°C) as a result of the mixing of relatively dry air after the refrigerator dryers with dewpoints of -5°C i -12,5°C and incoming air without drying. Although these measurements were made after the preparation group, it was not able to significantly affect the dewpoint reduction.
This compressed air is still insufficiently prepared because quality class 6 was achieved, while the quality in terms of oil content remained at the same level (class 1 or 3).

5. CONCLUSION

Refrigerator dryers are responsible for achieving the fourth class in terms of water and moisture content in the compressed air preparation system. However, if their failure or insufficient performance occurs, there is a change in air quality, which can cause serious consequences for the functioning of the system and the lifetime of all pneumatic components.
In this particular case, based on the results of air quality measurements in terms of water and moisture content at two out of four measuring points in the compressor station, it is concluded that this is an extremely bad result. As for compressors that have built-in refrigerator dryers, it is obvious that these dryers are not working or are working improperly.
Based on these results, the factory requested the immediate intervention of a service technician and, after the repair, repeated measurements were made on the critical compressors. This time, the expected result was obtained, i.e., the required fourth quality class in terms of water and moisture content was achieved.

Measurements on the points of consumption, on the robot line, were made after the preparatory groups and it can be seen that in terms of moisture, quality class 5 or 6 was achieved, while the quality in terms of oil content remained at the same level (class 1 or 3).
If something like this happens in practice, after eliminating the cause, it is necessary to inspect the pipeline and clean it because the main pipeline is exposed to extremely humid air for a long period of time. Also, it is necessary to change all the filter cartridges on all the preparation groups because they were exposed to a significant amount of water and moisture in the compressed air. For the prevention of such events, it would be good to introduce regular quality checks of compressed air before the most important and sensitive consumers.
In this paper it is pointed out the problems in the functioning of pneumatic systems in production lines, which occur very often in practice and can have significant negative consequences for the production process. The reasons for the occurrence of these problems can be different. One of the most significant is insufficient expertise of the person whose responsibility it is to supervise and maintain an automated systems that use compressed air.

Abstract: *A continuous and sufficient supply of top-quality water is imperative for the proper development and survival of bees. Beekeepers often rely on a variety of water containers, each afflicted with numerous shortcomings such as limited capacity, irregular water availability, and subpar sanitation. This analysis aims to investigate the different categories of bee drinkers essential for meeting the water needs of bees. Additionally, we will conduct an in-depth examination of the pros and cons associated with each type of waterer to gain insights into their effectiveness and their impact on bee colonies. Ultimately, we will determine the most suitable waterer for the unique conditions and demands of beekeeping operations.*
Keywords: water, bee drinkers, bees

1. INTRODUCTION

Water is an indispensable element in the lives of all living beings, and this is especially true for bees. Maintaining a continuous supply of water to bees is a key aspect of successful beekeeping and the preservation of bee colonies. Water is essential for bees in multiple aspects of their existence [1,2].

The first and basic function of water in bee society is to cool the hives [1]. Bees actively use water to regulate the temperature inside the hive, especially during hot summer days. Bees collect water and use it to cool the interior of the hive and preserve optimal conditions for the development and survival of the colony.

Another important role of water in the bee world is the dilution of honey [1]. Honey is a key source of energy for bees, but sometimes it can become too thick. The bees then use the water to separate the honey so they can consume or store it. This is essential for their nutrition and survival.

Furthermore, water plays a key role in the development of young bees. The bees use the water to prepare the beebread to feed the larvae. This is a vital step in the process of reproduction and renewal of the bee colony.

For bees to perform these vital functions, it is necessary to ensure the availability of clean water in their environment. Lack of water can have serious consequences for the health and productivity of the bee colony. Dehydration of bees can lead to a decrease in honey production, poor brood quality, and a decrease in the number of bees in the hive. The amount of water required by the colony depends most on the amount of bee brood and the external temperature. Water fluxes of honeybees can be very high at the colony level. For example, average annual requirements of 120 kg of nectar,

[1]ijevtic@mas.bg.ac.rs
[2]obrad.drakulovic70@gmail.com
[3]gmladenovic@mas.bg.ac.rs
[4]mmilosevic@mas.bg.ac.rs

20 kg of pollen, and 25 litres of water for a single wild colony are estimated [3]. This applies to honeybees in cold temperate conditions [4].
The way bees access and use water can vary depending on the environment and weather conditions. Bees will usually look for water sources near their hives, such as streams, lakes, fountains, or even dew drops on plants [5]. However, it is important to pay attention to the quality of water consumed by bees. Unfortunately, in some cases, the water that bees find may contain harmful substances.
This problem often appears in areas of intensive agricultural activity. The use of various chemicals for crop protection and weed control can lead to pollution of surrounding waters. When collecting water, bees can unknowingly introduce these harmful substances into the hive, which can have serious consequences for their health [6].
In addition, during longer periods of drought, water sources often dry up, making it even more difficult to supply water to bees [5]. Bee diseases (for example: American foulbrood - *Paenibacillus larvae*) can be spread by endospores, the form that allows survival in extreme conditions (in water and soil) and to have active form as soon as it reaches the brood [7]. While cleaning the beehive bees take out waste from possibly infected brood and their parts are scattered around the beehive, as well as the excrement, that can end up in a water bowl.
Therefore, for the preservation of bees and bee colonies, it is important to carefully monitor and ensure access to clean water to ensure their successful operation in the ecosystem.
In this analysis, it is shown the different types of drinkers that are essential for the proper supply of water to bees. In addition, were discussed in detail at the pros and cons of each of these waterers, in order to better understand their effectiveness and impact on bee colonies. Finally, it presents which type of drinker fits best in the different conditions and needs of beekeeping operations.

2. TYPES OF DRINKING BOWLS FOR BEES

The paper presents the design and implementation of drinking bowls for bees, emphasizing simplicity and accessibility. These bowls can be easily installed in gardens, parks, and urban areas, providing bees with a reliable source of clean water. A bee drinker is one of the important elements in beekeeping equipment that allows bees access to water, which is crucial for their nutrition. Drinking bowls for bees can be of different types and sizes, depending on the needs of the bee colony and the environment in which it is located [5]. A key aspect of the drinkers is to ensure that the bees can get to the water easily, but at the same time prevent the water from becoming contaminated or evaporating too quickly. Waterers are placed near the hive so the bees can get to water quickly without wasting too much energy.
There are different types of hygienic bee drinkers, each with its own characteristics and advantages. Some of them are presented in the paper [5]. In practice, various devices are often used to feed bees. Figure 1. is just a part of the various drinker cans that can provide water for their bees. Caring for bees and their needs, including providing water, is crucial for any responsible beekeeper. With this type of watering can, there is a big problem with hygiene, because the containers are constantly open, and contamination of the water can occur.

Figure 1. Bee drinkers as an open container [5].

Another example of a drinker can for bees described in the paper [5] is a traditional drinker can for bees. This drinker can is in the form of a wooden board on which water drips from a barrel placed on top (see Fig. 2). Slanted slats are placed on the board, which allow the water to stay on it as long as possible. The advantage of this drinker is that a large number of bees can take water, and a constant flow of water is present in these drinkers. Since this drinker hole is also open like the previous one, the tendency to create parasitic diseases is much higher, and therefore this watering hole is not suitable for use.

Figure 2. Wooden drinker for bees [8].

In recent times, inverted glass containers closed with a perforated cover or a piece of cloth are being used more and more often as hygienic drinkers for bees [5]. These containers meet hygienic requirements, and their price is low. The advantage of these watering cans is that the bees do not drown in the water, so there is no danger of droppings coming into contact with the water due to the position of the bees when drinking water. The lack of these drinkers necessitates the constant presence of a beekeeper who must regularly refill the containers because these watering cans are suitable for feeding bees up to 10 hives. Another disadvantage of these drinkers is that the wet cloths used to close the waterers are prone to bacterial growth. Also, these drinkers are ineffective due to the lack of water under the direct influence of the sun, which leads to an increase in the temperature of the water.

The automatic drinker is another option for bees seeking refreshment (see Fig. 3). In these drinker cans, the water level is regulated by a float, like in a water tank. The advantage of this watering can is the large amount of water that can be used to water a large number of bees at the same time. Regrettably, the drawback of this method lies in the barrel's potential lack of cleanliness due to the large landing surface from which bees take water and which is easily contaminated.

Figure 3. Automatic drinker for bees [9].

One of the patents that was made concerns a honeybee breeding apparatus, which is strategically placed within beehives to dispense feeding liquid for bee breeding [10]. More specifically, it focuses on an automated honeybee breeding apparatus, which ensures precise feeding liquid delivery, minimizing the chances of supply paths becoming obstructed by bees' secretions. The primary aim is to streamline the feeding process and maintenance, particularly cleaning [10].
Another one of the patents is the smart hygienic bee water drinker, a closed system that completely and simply solves the problem of watering [1]. This drinker can provide a sufficient amount of hygienically correct water and safe drinker of the bees. The device enables the application of high standards in accordance with the food safety policy, which was not possible until now. The bee trough is a central gathering place for water-carrying bees from all hives in the apiary, allowing water from one container to be available to all [1].

3. CONCLUSION

This paper provides an overview of existing bee-drinking fountains with all their advantages and disadvantages. While they can play a vital role in supporting bee health, it is essential to weigh the benefits against the potential drawbacks of these drinkers. Careful management and environmental considerations are crucial when deciding to introduce drinking bowls for bees, ensuring that they are a net positive for these vital pollinators.
In some further research, it is possible to choose the most optimal materials for making drinkers, as well as various methods of producing them. Some of the possible solutions are 3D printed drinkers with carefully selected materials and printing processes.

EFFECT OF TANNIN ON INCREASING UF ADHESIVE PERFORMANCE

Tamara Tešić[1], Faculty of Forestry, University of Belgrade

Abstract: *The aim of this study was to evaluate the potential use of tannin in urea formaldehyde (UF) wood adhesives formulations. Tannins have been largely studied as wood additives and wood adhesives. In a perspective of a desirably increased utilization of natural raw material in the wood timber industries, this study provides specific information on the use of tannin to improve the performance of UF resins. Tannin-based UF resins were prepared and adhesive properties were tested. The results of tensile strength determination obtained showed that the tannin addition in UF adhesive formulation gives a better performance compared to pure UF adhesive. Therefore, it can be concluded that tannin-based UF adhesive can be good candidate for the application as wood adhesive due to better improvement in term of adhesive and mechanical properties to produce an environmentally-friendly wood adhesive.*
Keywords: wood adhesive, tannin, bio-adhesives**,** UF resin, tensile shear strength

1. INTRODUCTION

Phenolic resins are the first synthetic polymer that has been industrially produced since 1911 [1]. Modern times dictate a high demand for wood panels and other wood products, which causes the use of large amounts of wood adhesives. Formaldehyde-based adhesives account for approximately 90-95% of the total amount of wood adhesives used in the wood industry. Urea formaldehyde (UF) is the dominant type of adhesive in the production of wood-based panels, with a consumption of about 11 million tons of solid resin per year [2]. The global dominance of UF resins is due to favourable characteristics such as good binding properties and high reactivity, but these resins also have certain disadvantages related, first of all, to poor water resistance and formaldehyde emission (FE) [3]. A wide field of adhesive technology today can be "covered" using renewable materials, which can show equal or even better performance than their commercial variants based on oil and its derivatives. Lignin, tannin and proteins are raw materials that in numerous experiments have proven to be a good alternative for existing thermos reactive amino based adhesives. Tannins are, after lignin, a major source of polyphenol components all over the world, but their extraction potential is much higher than in the case of lignin [4]. As tannin is unique in its composition and abundantly available, the development of value-added products offers a sustainable alternative. It is emerging as a green substitute for the wood adhesives, produced from petroleum-based resources, specifically phenol and resorcinol [5, 6]. Copolymerization of tannins with synthetic adhesives decreases FE from synthetic resins in wood composites and acts as formaldehyde scavengers in phenol formaldehyde (PF), melamine formaldehyde (MF) and UF resin [7].

[1] student.tamaratesic2262002@sfb.bg.ac.rs
[2] milica.rancic@sfb.bg.ac.rs
[3] danabb@ffh.bg.ac.rs
[4] ivana.grmusa@sfb.bg.ac.rs

Tannin-formaldehyde resins have been commercially available for several years and are characterized by very low FE and fast pressing times. However, formaldehyde is still an essential component. Therefore, low or no aldehyde tannin bio-adhesives have been developed.
Tannin bio-adhesives provide very good adhesion, high moisture tolerance, no need for combination with petroleum-based adhesives and offer many suitable cross linkers [8]. Generally, tannin is considered as an additional component that can be mixed with typical UF resins in different ratios [9]. Recently, a novel tannin-modified UF resin was reported by substituting a part of the urea with tannin for preparing the tannin–urea–formaldehyde resin (TUF) [10]. Presence of tannin caused lower formaldehyde emission (even though, it should be clear that too much tannin addition can cause gelation), but also effectively improved the bonding properties of conventional UF resin, especially in terms of water resistance, which is considered a green renewable approach for the synthesis of TUF resins. The joining of tannin introduced some aromatic rings and enhanced the structural rigidity of TUF resins, while improving the stability against hydrolytic degradation. The curing temperature of TUF resins fluctuated around that of UF resin, although TUF resins exhibited higher thermal stability with respect to UF resin.
In this work, new adhesives based on commercial UF resins and tannin were prepared and tested for the application as wood adhesives. The effect tannin on UF adhesive characteristics - the tensile shear strength was investigated.

2. EXPERIMENTAL SECTION

2.1 Materials

Two different commercial UF resins (UF1 and UF2) were provided by domestic company (Serbia). Tannin sodium salt was purchased from CHIMAR HELLAS SA (Greece). Ammonium chloride was purchased from Centohem (Serbia). Beech (*Fagus sylvatica*) logs were selected from a known locality and growth conditions (beech from mountain Goč). Afterward, primary boards with the desired orientation of growth rings were cut.

2.2. Tensile shear strength determination

2.2.1. Preparation of wood samples

The sawn timber was dried in a semi-industrial conventional kiln (Nigos MC 3000, capacity 0.8 m^3). The most homogeneous groups of testing samples were selected for further experiments.

2.2.2. Preparation of UF-tannin adhesive

Firstly, the adhesive solid content of UF resin was determined to be used for further adhesive formulations and analyses. Every formulation was prepared in concentration calculated using solid weight relative to UF resin solid content. Ammonium chloride salt solution (concentration of 20%) was used as hardener for all samples in the concentration of 1% w/w. Tannin was added to UF adhesive in 3% by weight.

2.2.3. Characterization of UF adhesive

Adhesives obtained in this research was performed according to the following standards: determination of pH (SRPS EN 1245:2012); determination of density (SRPS EN 542:2009); determination of conventional solids content and constant mass solids content (SRPS EN 827:2009); determination of tensile shear strength of lap joints for wood adhesives (SRPS EN 205:2017); and adhesives were classified according to standard for classification of thermosetting wood adhesives (SRPS EN 12765:2017).

The FTIR-ATR spectra were obtained with an FTIR spectrometer (iS20, Thermo Nicolet) with a resolution of 4 cm^{-1} in the wavelength region 4000–525cm^{-1}, using a diamond single reflection attenuated total reflectance (ATR). All spectra were obtained with 32 scans, and the background measurement was made using air.

2.2.4. Determination and optimization of glue-line quality

The adhesive mixes were applied by a rubber roller onto one surface of the two wood specimens to be bonded (200 g/m^2). Assembling was always performed in parallel grain directions. The ply without direct application of the adhesive mix was always in the bottom position to improve the penetration into its structure. Again, a special effort was made to have the taper as low as possible, guaranteeing equal penetration conditions for all samples. Five joint samples were pressed in a hydraulic press at 120°C and 1.5 MPa for 15 minutes. Before testing, the single lap shear test specimens (150 mm × 20 mm × 5 mm) were conditioned at 20 ± 2°C and 65 ± 5% relative humidity for one week. The lap shear test will be conducted according to SRPS EN 205 standard test on a hydraulic test machine (Wood tester WT4) with a measuring scale of 50 kN at a testing speed of 6 mm/min loading rate in tensile mode with the load direction always parallel to the grain in all tested specimens. The failure zone (shear area 20 mm × 10 mm) was examined using a light microscope to determine the proportion of wood failure and the thickness of the wood layer in the wood failure. Ten replications were performed for each set of parameters. An analysis of variance (ANOVA) was applied to obtain centralized values and standard errors.

3. RESULTS AND DISCUSSION

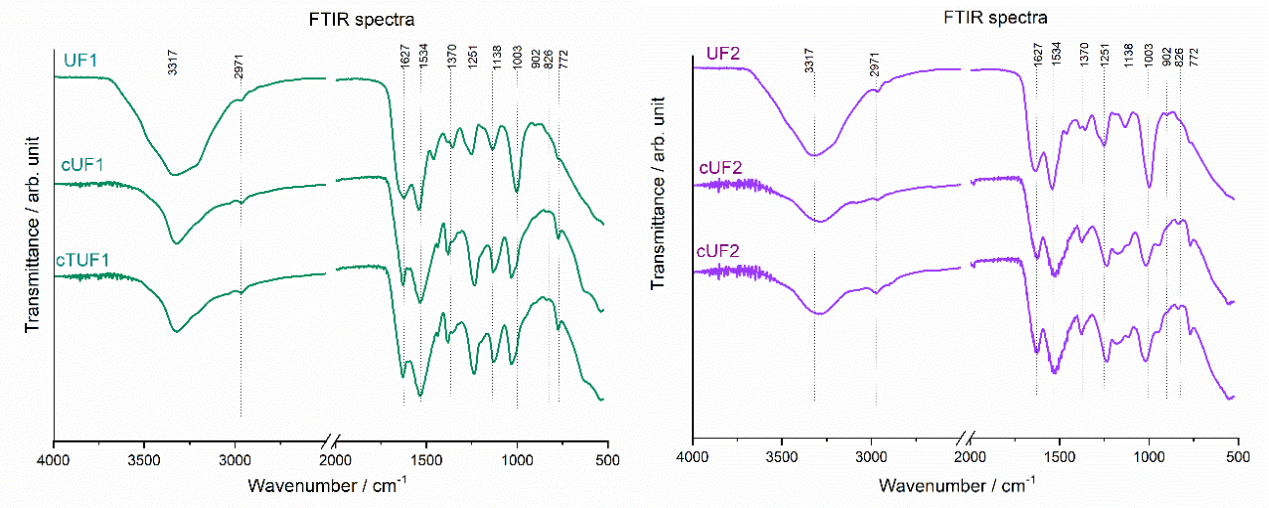
For any type of bio-based wood adhesives, it is important to effectively evaluate their prospects for wood composite application and understand the adhesive/wood interaction to gain scientific insights to guide the adhesive development in terms of the mechanical strength, water resistance, thermal and rheological properties of the adhesives, as well as the adhesive penetration. To interpret the measured bonding strength of wood adhesives, it is also essential to take into consideration the type of the failure or separation occurred in the mechanical tests. There are four main types of failure modes for the adhesive bonded wood composites: (a) cohesive failure of the adhesive; (b) adhesive failure (c) mixed failure - a combination of (a) and (b) - and (d) wood cohesive failure or wood failure. Since the UF resin, as the most important type of adhesive for the preparation of wood-based panels, due to good performance and low price, display poor water resistance and high formaldehyde emission, some modification of the UF resin is essential.

Figure 1. Cross-linked (cured) pure UF resin (cUF1, cUF2) and with tannin (cTUF, cTUF2)
Source: Authors

Herein, we prepared new adhesives based on commercial UF resins (UF1 and UF2), cured alone (cUF1 and cUF2) or with tannin (cTUF1 and cTUF2) characterized them and evaluated their adhesive properties by determination of the tensile shear strength (Figure 1).

3.1. FTIR analysis

Fourier transform infrared (FTIR) spectroscopy was used to characterize the chemical structures of the resins. Cross-linking of UF resin with tannic acid was confirmed via FTIR spectroscopy. The obtained FTIR spectra of commercial UF adhesive emulsions examined in this work are given in the Figure 2a) for UF1 adhesive and in the Figure 2b) for UF2 adhesive. Spectra of cured resins alone or with tannin were also presented on Figure 2. Spectra of cured adhesive mixed with tannin (cTUF) have not shown significant differences in regard to the spectrum of cured UF adhesive alone (cUF).



a) **b)**

Figure 2. FTIR-ATR analyses of pure UF adhesive emulsion, and pure UF and TUF after curing (cUF and cTUF)
Source: Authors

The wide bands at 3317 cm^{-1} represent stretching vibration of O–H and N–H and originate from the presence of byproducts such as water and excess formaldehyde that can hydrogen bond to the CH_2OH, NH_2, and NH functional groups present in the observed resins but their intensities decreased in cured samples. A sharp but small peak occurring at 2971 cm^{-1} belongs to the stretching C-H vibrations which may be the result of the contribution of dimethylene ether bonds (CH_2-O-CH_2), hydroxymethyl (CH_2OH) and methylene bonds (N-CH_2). The characteristic bands that appear at 1627, 1534, and 1251 cm^{-1} represent amide I (C=O stretching vibration in -CONH), amide II (stretching vibration of C-N and deformation of vibration of N-H in NH-CO), and amide III and all amide bands increase during curing. The methylene ether bridge (–CH_2–O–CH_2–) characteristic absorption peak at 1138 cm^{-1} belongs to the C–O stretching vibration of hydroxymethyl and becomes stronger after curing compared with UF resin, indicating reaction of UF resin and tannin and formation of new ether linkages. Weak band at 1370 cm^{-1} in UF emulsion, becomes sharp and strong after curing. This area of UF polymer spectra is usually assigned to C-H vibrations in CH_2 and CH_3 structures. Peak at 1035 cm^{-1}, assigned to hydroxymethyl group (–CH_2OH) in cUF and cTUF resin decreased when compared with UF resin, indicating the possible reaction between UF resin and tannin from hydroxymethyl groups. The peaks about of 1003 cm^{-1} were assigned to ν(C-O-C) of ether linkage and decreases with crosslinking due to breakage of ether bonds. A small peak at 772 cm^{-1} which appears in cured samples is the characteristic absorption peak of iron structure that is formed.

3.2. Tensile shear strength determination

The tensile shear strengths of examined adhesives are shown in Figure 3. The tensile test results of the samples demonstrated that the resin mixed with tannin had better performance than

corresponding pure cUF resin. Compared to UF resin, shear strength increased after the addition of tannin. Theoretically, in previous studies, the higher molar ratio of aldehyde to urea is used to enhance the cross-linking of the cured resin [11]. However, in that case, emission of formaldehyde has become one of the major causes of indoor air quality deterioration, which can negatively affect human health. Some authors showed that addition of tannin to UF resins in particleboards appears to decrease formaldehyde emission over a period of time proportional to the amount of tannin added but the improvement of the strength performance caused by the denser cross-linking was offset by the decrease of the amount of UF resin [11]. In that case, the formaldehyde emission of tannin-UF resin decreased but the bonding strength was also decreased compared with pure UF resin. Additionally, Zanetti et al. [12] used condensed tannins to improve the heat resistance of UF resins and the result showed that high percentage of tannin in UF-tannin blend improves the overall UF thermal resistance in a great extent. However, in this study, tannin was used to substitute some of UF resin, to reduce formaldehyde emission and to produce an environmentally-friendly wood adhesive along with enhanced adhesive properties. The higher shear strength of cTUF compared to cUF might be result of the better water resistance of the product arising from the reaction between tannin and UF resin.

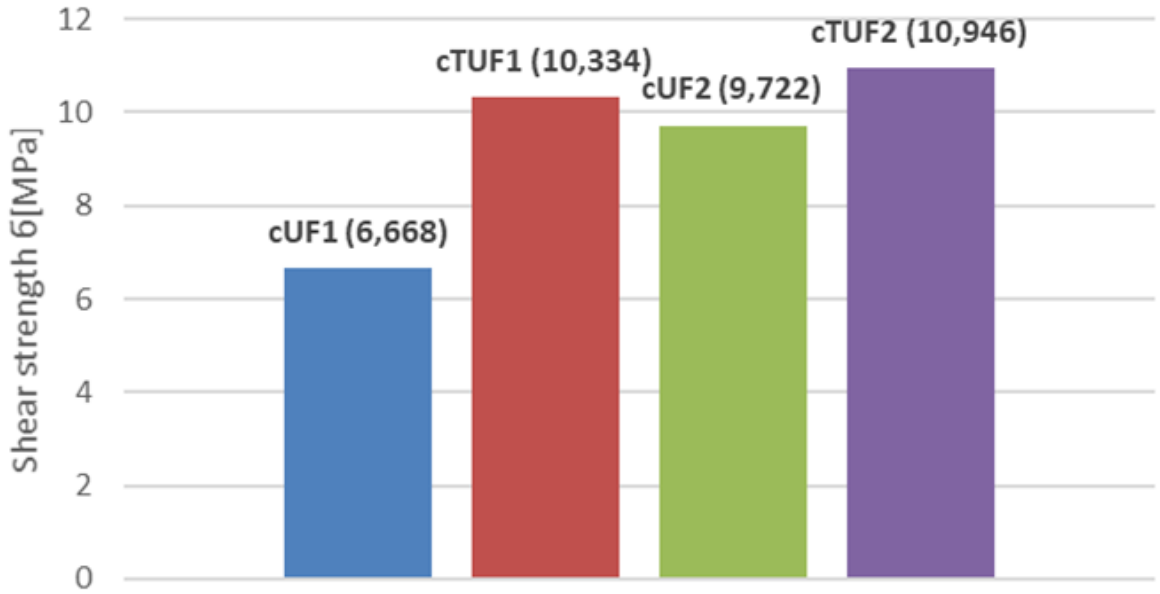


Figure 3. Shear strength of beech wood specimens bonded with pure, commercial UF resin and with the one with added tannin (TUF)
Source: Authors

Figure 4. The failure zone of tested samples
Source: Authors

The diverse types of failure after completion of the adhesion tests, i.e., cohesive, adhesive, and substrate failure, were considered by analysing the surface of both specimens through high-resolution imaging. Cohesive failure was considered when both samples presented adhesive on the overlapping surfaces; adhesive failure means that only one of the overlapping surfaces had adhesive, whereas substrate failure indicates breakage of the substrate itself so that the bonding surface was not altered. Examination of the failure showed that all samples had a 100% fracture trough wood (Figure 4).

4. CONCLUSION

Wood adhesives based on UF resin and tannin were prepared, characterized and their adhesive and mechanical properties were investigated to determine their potential as wood adhesives in order to reduce formaldehyde emission. Based on characterization processes, it was found that UF-tannin adhesives showed higher tensile shear strengths than corresponding pure UF adhesive. It was shown that 3% of tannin addition in UF adhesive formulation gives a better performance compared to pure UF adhesive. Therefore, it can be concluded that tannin-based UF adhesives can be good candidates for the application as wood adhesives due to better improvement in term of adhesive and mechanical properties to produce an environmentally-friendly wood adhesive.

ACKNOWLEDGEMENTS

This research was funded by The Ministry of Education, Science and Technological Development which is financing the scientific research work of the University of Belgrade - Faculty of Forestry in 2023, on the basis of the Agreement on the realization number: 451-03-47/2023-01/200169.

EDUCATION AS A PILLAR OF SUSTAINABLE AGRITOURISM IN SERBIA

Radomir Stojanovic[1], Western Serbia Academy of Applied Studies

Abstract: *Education occupies an important place in a wide range of activities that support one business activity, in the specific case agritourism. This especially applies to individuals and families who are just starting their entrepreneurial venture in agritourism in Serbia. Education is combined with other numerous incentive measures, but the order in which these measures are implemented is important. First, education is carried out, and only then comes financial support (non-refundable loans, subsidies, loans under more favorable conditions). This is because only sufficiently educated agritourism service providers can provide sufficiently high-quality services, be competitive in the tourist market and make their business sustainable in the long term. It is especially important that the offer holders in agritourism accept the Lifelong learning (LLL) concept. This means that they are ready to constantly improve their existing knowledge, as well as acquire completely new skills. In addition to the readiness of the offer holders in agritourism to constantly learn, the quality of the educators, i.e. the persons who will create and implement the educations, is also important.*
Keywords: Agritourism, education, sustainable business, Serbia, incentive measures

1. INTRODUCTION

There are several serious reasons why agritourism in Serbia must be supported by education, as the first and basic measure in the system of institutional support. The first reason is that the largest number of offer holders in Serbian agritourism do not have formal education in the field of tourism. In other words, beginners and entrepreneurs in agritourism generally do not have theoretical knowledge about agritourism because they did not graduate from one of the high schools, colleges or faculties that train personnel for tourism, more precisely catering.

Another reason is that beginners in agritourism generally do not have previous practical experience in tourism. This means that the vast majority of them did not work in an agritourism facility (eg ethno restaurant, apartments, rural houses for rent to tourists), or if they did, they did not manage a business in agritourism. The third reason is modern tourists. They have high expectations from providers in agritourism and often prefer quality service to a lower price. Today, guests in agritourism are not satisfied with a "beautiful view", friendly hosts and "clean air".

They are looking for much more than that - additional content, local products, authentic atmosphere, intangible content (Storytelling, Living history/heritage), activities in nature, excellent hygiene, respect for ecological standards, quality accommodation, a certain level of business communication with guests, etc. [1]. Changes in (agri)tourism (both on the supply side and on the demand side) are a constant and dynamic phenomenon. The only way for agritourism offer holders to understand these changes, to respond to market changes in a timely manner, as well as to adequately respond to the needs and expectations of modern tourists, is to be educated.

[1]radomir.stojanovic@vpts.edu.rs

2. ELEMENTS OF EDUCATION IN AGRITOURISM

2.1 Principles in the creation and implementation of education in agritourism

In the last two decades, a large number of educations in the field of tourism, especially agritourism, have been held in Serbia. Those educations differ from each other in many indicators (content of lectures, quality of educators, duration of lectures, method of financing). Nevertheless, educations have fundamentally improved the offer of agritourism in Serbia. Also, it was education that encouraged a large number of individuals, families and companies to start their entrepreneurial venture in agritourism. When creating education in agrotourism, certain principles must be respected. In the first place, that the offer in agritourism is based on the needs and expectations of modern tourists, then that business in agrotourism is based on valid regulations in the field of (agri)tourism, as well as that the basic principles of the tourism profession are respected. A particularly important principle is the one that talks about the sequence of implementation of incentive measures. According to this principle, education is the first step and a prerequisite for the implementation of all other incentive measures ("first knowledge, then money") [2]. In order to respect the mentioned principles, it is important that the person commissioning the training, the creator and the implementer of the training have clear answers to the questions listed in table 1 beforehand.

Table 1. Elements of education in agrotourism
Source: [3].

Who are the educations intended for?	Target groups
What do we want toachieve by educations?	Goals of education
What knowledge and information do we want to transfer to the beginners?	Content of education
Who should initiate and realize educations?	Holders of education
How will the education be implemented?	Way and quality implementation of education

2.2 Target groups for education in agritourism

The trainings are primarily intended for residents of rural areas who are already engaged in agritourism or have a serious intention to start an entrepreneurial venture in that activity. These are mostly families from rural areas who see agritourism as a chance for additional income or as a basic activity. In recent years, completely new categories of education participants have appeared. It refers to heirs, that is, people who live in cities but have inherited houses and country estates. They do not want to sell what they inherited, but want to start a business in the field of agritourism. We should also mention the returnees to the countryside (people who lived in urban areas for a certain period of time and decided to return to their properties in rural areas), returnees from abroad, as well as private companies that recognized the benefits of investing in agritourism. Common to all mentioned categories of new offer holders in agritourism is that they also need education because they are mostly beginners in the agritourism business. Business owners in agritourism are not the only target group for education. Employees in local administration should also be involved in training. This refers to: employees and officials in municipal administrations (in the sectors of economy, tourism, entrepreneurship), in offices for local economic development, in municipal Commissions for the categorization of accommodation and rural tourist households; employees in local tourism organizations (LTO); members of farmers' associations, women's associations, entrepreneurs' associations; NGO representatives, journalists in print and electronic media… [4].

2.3 Objectives of conducting education in Serbian agrotourism

The objectives of the training are determined depending on the category of participants. For those participants who are just planning to engage in agritourism, the education aims to encourage them, to point out the specific benefits of engaging in agritourism, to familiarize them with the regulations

(Act on Tourism, Act on Hospitality, regulations and other by-laws); to familiarize them with the characteristics of future guests and the process of categorizing accommodation facilities.
The goals are somewhat different for those who are already engaged in agrotourism. They should improve their existing knowledge and be provided with specialized training (foreign languages, marketing with a special emphasis on the Internet and social networks, fair appearances, food services, etc.). The members of the municipal/city Committee for Categorization should be trained for the proper implementation of the categorization procedure (they get to know the regulations and procedures in detail). In addition to the specified specific goals, there are also general goals.
The participants of the training should be encouraged:

- to mutual business association (from local to international level)
- to accept the position that they are not mutual competitors but collaborators and "allies",
- to provide quality service continuously.

2.4 Defining the content of education in agritourism

Only when you know who the participants are and what the goals are, you can start creating the content of the training. The objectives of the training are determined depending on the category of participants. The theoretical and practical part of the training usually includes the following topics: familiarization with the current regulations, characteristics of modern tourists, application of the Central Information System (CIS) of E-tourists, categorization procedure; furnishing rooms, apartments and houses for tourist accommodation; residence tax, food and beverage services; additional services, attitude towards guests, dealing with conflict situations; pricing, promotional activities, sales channels; relation to the environment (to local authorities and inspections; cooperation with travel agencies, tourist guides and the media). Special training content is created for municipal administration employees and members of the Commission for Categorization. The same applies to employees of local tourism organizations (LTO).
Specialized educations are focused on certain aspects of business and require a higher level of prior knowledge of the participants. In practice, there is a lack of such training, especially those related to communication with guests, application of digital technologies, creation of websites and profiles on social media.

2.5 The process of initiation and organization of education

The initiators, organizers and financiers of agritourism education in Serbia are competent institutions at the local, regional and national level, often in cooperation with foreign and international organizations. These are municipalities, cities and their tourist organizations[2]; Regional Development Agencies (RDA), Regional Tourist Organizations (RTO), network of Regional Chambers of Commerce; Ministries responsible for tourism, agriculture; professional associations, educational institutions[3] ... Among the foreign institutions, the German GIZ should be mentioned[4], American USAID, SDC from Switzerland, United Nations Development Program (UNDP), EU. Education in

[2] The local level, although the lowest in the hierarchy of government, is particularly important. Municipalities and cities will to have the greatest benefit from educated offer holders in Serbian agritourism (through a greater number of tourists, greater spending by tourists, higher tax revenues).

[3] A large number of higher vocational schools and faculties from Serbia, Republika Srpska, FBiH, Slovakia, Greece, Romania and Slovenia formed a consortium, in order to participate in the project related to agritourism under entitled "Next Destination Serbia: Agritourism Landscapes Development (LANDS). They are active in the project representatives of the non-academic community also participated (four regional development agencies- RDA from Užice, Sarajevo, Niš and Mostar). The project lasted from 2017 to 2021. It was also created in that period realized a large number of educations [5].

[4] A well-known German organization called „Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ)“ is currently implementing the project "Support to youth in rural areas in Serbia". The project lasts four years (2020-2024) and is implemented throughout Serbia. Within the aforementioned project, a large number of educations were held in relation to agrotourism (for beginners as well as for those who already have experiences in agritourism). The domestic partner is the Ministry of Tourism and Youth [6].

agritourism in Serbia is often carried out as part of larger and broader projects. This means that education is not the only one, but it is the first and basic activity where participants (beginners in business, entrepreneurs...) acquire basic knowledge that they later build on through other business support instruments. It should be emphasized that education in agritourism is carried out through the partnership of a large number of participants, mainly from the public and state sectors. This is especially important for municipalities in Serbia that do not have enough money or professional staff to independently finance, organize and implement education. In practice, this means the following: one institution (e.g. the Ministry) finances the project, another institution (e.g. the Regional Development Agency or the Serbian Chamber of Commerce) implements it, while the third partner (e.g. the municipality) is the immediate implementer. Education in agritourism is often realized within the framework of "cross-border cooperation" projects (Serbia Hungary, Serbia-Romania, Serbia-Bulgaria).

2.6 Method of implementation and quality of education in agrotourism

The success of an education in agritourism will depend on numerous factors. The key factor is the educator - the person who will create and then implement education. That person must have practical experience and not just theoretical knowledge about agritourism. In addition, the educator must establish an interactive relationship with the participants (two-way communication between the educator and the course participants)[5].

Education must be adapted to the participants (their level of knowledge, their free time[6], that the venue is accessible to attendees). The focus must be on acquiring practical knowledge (without unnecessary theory) which the participants will be able to apply directly in practice - in communication with guests, when creating an offer, when equipping accommodation facilities, etc. All this in order to enable the participants to independently run their own personal or family business in agritourism[7].

Many participants will meet for the first time not only with professional terms from agritourism, but also with numerous aspects of business in this type of tourism. This means that every education must first have a theoretical and then a practical part (workshop). The workshop involves the acquisition of knowledge such as: application of the E-tourist portal, preparation of mandatory documents (contracts with travel agencies, creation of menus, price lists, house rules and inventory lists); simulations of different situations in the host-guest relationship and resolution of conflict situations. During the entire duration of the lecture, the educator must cite examples from practice (both positive and negative) and explain them, so that the participants do not make mistakes, especially those typical for beginners in business.

Fieldwork can significantly improve the quality of any agritourism education. This means that the educator visits several agritourism providers and provides them with expert advice on the spot, i.e. points out the good and bad aspects of their business. The education organizer must try to avoid the most common mistakes in agritourism education. It happens, not so rarely, that the educator does not have practical knowledge of agritourism, that he maintains an "academic level" so the participants cannot follow him (they do not understand what he is telling them), that he gives them incorrect or outdated information because he does not follow trends in agritourism, i.e. does not know enough about this issue.

[5] A special form of education is mentoring with selected participants. This form of education is increasingly being applied in agritourism in Serbia.

[6] Education usually lasts one day, two or three combined days, but series of lectures are also organized (eg once a week for a month). Verbal and visual methods are used.

[7] The most common form of business in agritourism in Serbia is the rural tourist household. It has to be categorized. In addition to accommodation and food services, it can provide numerous additional facilities, including the possession of a mini camp.

3. CONCLUSION

The quality of the offer in agritourism in Serbia has improved significantly in the last fifteen years. This was undoubtedly contributed by a large number of educations that were conducted in all parts of the country. This is clear evidence that education is one of the pillars of business in agritourism, that is, one of the prerequisites for long-term sustainable business. Education should be seen as the first step in the system of business support in agritourism. However, it is not enough for agritourism business owners to attend training only once. Sustainable business means that entrepreneurs in agritourism must constantly improve their knowledge and business skills by taking part in appropriate education throughout their career. On the other hand, the content and form of education must also be changed and improved in accordance with the changes in the tourist market.

CULTURAL HERITAGE AS A GENERATOR OF SUSTAINABLE DEVELOPMENT OF TOURISM IN LOCAL COMMUNITIES IN THE COUNTRIES OF THE WESTERN BALKANS

Jelena Premović[1], Faculty of Economics, University of Pristina & Faculty of Economics and Engineering Management

Abstract: *Intangible cultural values and heritage represent a significant factor in promoting certain tourist destinations. The countries of the Western Balkans have a rich intangible cultural values and heritage age that can be a important generator of not only tourism development, but also the overall sustainable development of local communities in the whole region. Within the project Perspectives of interregional cooperation of local communities in the countries of the Western Balkans - in the fields of science, education, culture, economy, tourism and sustainable development various researches were carried out in order to determine the real potential of intangible cultural values.*
Keywords: Intangible cultural values, cultural heritage, tourism, motives, Western Balkans

1. INTRODUCTION

Tourism is a social phenomenon and an activity immanent to human nature that has existed in various forms since the beginning of human society. From the ancient times, the slave and feudal social system in which we find the first outlines and beginnings of the movement and today's tourist trips, through the period of the so-called "oligo tourism" from the middle of the 19th century to the Second World War, the period up to 1950, then through the so-called "poly tourism" which includes the period from 1950 to 2000, up to the modern and postmodern tourism of today - tourism gradually developed to become one of the most significant indicators and models of economic and general social development today.
The connection of modern tourist products with numerous economic and non-economic activities has the effect that the socio-economic effects of tourism are multiple. The development of tourism creates the necessary prerequisites for the initiation of a number of other economic and non-economic activities and activities, which means that tourism represents a significant factor for the initiation of overall economic and economic development. (Premović & Arsić, 2018).

2. THE BASIC MOTIVES AND NEEDS FOR TOURIST TRAVEL

Travels, as a form of manifestation of various human needs and motives, have appeared since the beginning of human society, from mythical ancient times and nomadic conquests of new spaces until today and the mass tourist trips we are witnessing. At the same time, throughout the long history of human existence, the motives and needs for travel have changed under the influence of different cultures and eras and parallel to the development of human society and man as an individual.
The main reason why each individual decides to go on a tourist trip is his inner needs and different ways of satisfying them, since the majority of these needs cannot be satisfied in the place of residence, i.e. "at home". The opinions of numerous scientists on the subject of human needs are different and consequently there are numerous theories of motivation. Incentive or motive represents an internal force or force that moves, stimulates and inspires each individual towards the fulfillment of needs or

[1] jelena.premovic@gmail.com

the achievement of certain goals, while motivation is a complex psychological process of encouraging and directing an individual to act in a certain way in the direction of realizing his needs and achieving goals and a desired state.

One of the most widely used and cited theories of motivation is the theory defined by Maslow. Maslow structured all the different human needs into a well-known hierarchical structure of needs that includes five basic categories or levels of human needs. Hierarchical structure of needs means that the individual tries to satisfy the most important needs first, and when he fulfills them, he tries to fulfill all other needs according to the degree of importance, i.e. according to their hierarchy. These are: physiological needs, the need for security, love, belonging and attachment, the need for appreciation and the need for personal development and new experience (self-affirmation, self-actualization or self-realization).

The need for rest, sports and recreation can be satisfied through tourist trips and it belongs to tourist needs - self-affirmation needs. The needs of self-actualization or self-affirmation can be satisfied within the framework of visiting various cultural contents and cultural manifestations. Only when all primary (existential) needs are satisfied, it is possible to realize touristic needs as needs of a higher order, i.e., secondary needs.

"Tourist motives arise under the influence of needs and other internal incentives that act from the inside and spatial stimuli, as goals that determine from the outside." They encourage a person to be active in a certain direction, that is, the individual tends to get closer to the object of his desires, the tourist object" (Čomić, Đ., 1990). There are authors who believe exactly the opposite, stressing spontaneity, unplannedness, unexpectedness and the factor of surprise as the key elements of every quality trip. This group of opinions also includes the opinion of John Steinbeck, according to which "people do not go on a journey. Travels go to them." Therefore, they should not be specially planned and analyzed, but rather indulged and enjoyed (Premović, Arsić, 2020).

Regardless of different approaches in the interpretation of key tourist needs and motives, there is an almost unique attitude that the factors that influence their creation can be of objective and subjective nature. Objective factors include socio-economic and cultural (cultural) factors such as: social structure of the population, degree and level of education, vocational training or occupation, quality of the environment and the like. Subjective factors are internal psychological processes: specific needs, interests, desires and emotions, which can move an individual to travel. Various motives and needs therefore encourage individuals to travel as tourists to a destination outside their place of permanent residence, i.e. residence. The most common reasons for traveling by most tourists are as follows: the need for rest and relaxation, "getting away from everyday life", the need for health, wellness, fitness, sports and adventure, religious reasons and religious needs, the need for art, sightseeing and sightseeing, the need to get to know each other new, attending seminars, conferences and exhibitions, business reasons, visiting friends and relatives, shopping and others.

3. INTANGIBLE CULTURAL VALUES AND HERITAGE AS A GENERATOR OF TOURISM DEVELOPMENT

Natural, anthropogenic, human and cultural factors are the most important factors that influence the creation of tourist offers and the performance of tourist activities in a destination. In recent decades, the importance and role of cultural factors in the further sustainable development of tourism has been highlighted more and more. The trend of increased tourist interest in new experiences, events, knowledge and experiences is becoming more and more evident. The so-called the cultural dimension as an intangible component of tourism is important both from the position of supply and from the position of tourist demand. Culture has a significant influence on the behavior of individuals and their contribution to the process of economic and social development, as well as on their economic choices and business decision-making. When talking about culture and national cultural heritage in the function of creating a tourist offer, it should be borne in mind that cultural heritage does not include only material objects, but that cultural heritage also consists of "the social and cultural relationship that a human community has towards these objects, importance that gives them a place in its value

system, i.e. in the experience of oneself as a community. Oral literature, customs or culturally shaped awareness of oneself, as a member of the community, are also part of it". (Žikić, 2010). In this sense, as Žikić concludes, cultural identity is a part of the intangible cultural heritage of the community in which it is constructed. Accordingly, national culture is based on a clear idea of one's own identity, but also on the possibilities of expanding and opening its development perspectives and its verification at the international, multicultural and transcultural level (Premović, Pejanović, 2018).

In countries and tourist destinations that have a developed tourism economy, significant multiplier effects of the influence of tourism activities can be observed. Tourism can and should play a particularly important role in the overall socio-economic development of underdeveloped countries and regions, including the Western Balkan region. As a separate economic activity, tourism is developed and developed differently in the countries of the Western Balkans. In addition to Montenegro, which is recognized as a tourist destination and where tourism is the leading economic activity, in other countries of the region tourism as a revitalizing factor of economic and social development was recognized only at the beginning of this century, which is why it is in the initial phase of development. However, it is noticeable that Albania has been investing in the promotion of coastal tourism in recent years, while Serbia is trying to position itself on the map of Southeast Europe and the region as a tourist destination for spa, mountain and increasingly event tourism. The current situation created under the influence of the global pandemic caused by the Kovid 19 virus certainly presents new challenges and opportunities for finding new and sustainable solutions for the further development of tourism before the countries of the Western Balkans (Premović, J, 2022).

Tourism provides an opportunity to travel and get to know other places, continents, nations, and religions. He encourages interest in researching the traditions and customs of other peoples and countries, different forms of culture, in learning foreign languages, information and communication technologies, and the like. The development of tourism increases the general level of education and culture of the local population that participates in tourism activities. By creating and constantly developing awareness of the essential richness of diversity and respect for different cultures, religions, nations and lifestyles, tourism enables the establishment of stronger ties and relations between peoples. The change of the individual and collective-social value system under the intense influence of tourism through the change of the quality and style of life, represents significant socio-cultural effects of the influence of tourism (Premović, J, 2021).

Making a decision about traveling and choosing a certain destination is influenced by various motives that, viewed from the perspective of the time horizon, have changed as a result of the dominant influences of different social epochs and cultural identities. Contemporary trends in the motives and expectations of tourists show a growing interest in learning about different forms of intangible cultural heritage. The number of visits to important museums, galleries, protected cultural and historical monuments, archaeological sites, as well as numerous celebrations and manifestations of different contents is increasing. Observed tendencies of increased interest of tourists in various cultural contents influenced the development of cultural and event tourism (Vukadinović et al., 2018).

The intangible cultural component has a significant potential for further improvement and development, not only of tourist activities, but also of overall socio-economic development in the countries of the Western Balkans. Local communities in the countries of the Western Balkans have significant potential for the development of tourism activities through the improvement of the offer of cultural and event tourism and the promotion of their authentic intangible cultural values.

Tourism and the exercise of tourism through various tourist trips represents a special way of life. Tourism provides an opportunity to travel and get to know other places, continents, nations, and religions. He encourages interest in researching the traditions and customs of other peoples and countries, different forms of culture, in learning foreign languages, information and communication technologies, and the like. The development of tourism increases the general level of education and culture of the local population that participates in tourism activities. By creating and constantly developing awareness of the essential wealth of diversity and respect for different cultures, religions, nations and lifestyles, tourism enables the establishment of stronger ties and relations between peoples.

Tourism as a mass social phenomenon can significantly influence the reduction of numerous prejudices, above all linguistic, cultural, religious and national ones. Tourism broadens the horizons and cognitive-value horizons of all participants in tourism... Getting to know new cultures and getting to know other people, with their customs, traditions, religion, habits, represents a significant positive social impact of tourism. This group of positive influences certainly includes the acquisition of new knowledge and the expansion of knowledge about precisely those new spaces, religions, customs and cultures.In this way, tourism can have a positive effect on increasing the degree of tolerance, understanding and acceptance of diversity of all kinds among the population of the Western Balkans. (Premović, J, 2021).

Cultural habits and practices that can become specific tourist products and services, especially if they are contextualized and organized around events, such as various festivals, are inexhaustible resources for the (re)interpretation of the physical environment of the city (authentic natural environment, architecture, historical-archaeological sites and buildings and the like). Events, from family gatherings and celebrations to public festivals, as the "soft fabric" of cities and local communities, always give a different meaning to the same or changed physical space, and perhaps above all else, they provide the best "certificates" of city and local identity (Premović, Pejanović, 2018). That is why it is important that the local and national tourism policy, if it wants to attract demanding and spiritual tourists, focuses on active cooperation with the organizations of the city society, local artists and cultural creators.

Within the project Perspectives of interregional cooperation of local communities in the countries of the Western Balkans - in the fields of science, education, culture, economy, tourism and sustainable development various researches were carried out, of which a particularly important segment was precisely on the topic of the local population's knowledge of their own cultural heritage and the influence and role of various forms of culture on tourist trips to other communities in the Western Balkans. One of the studies that was conducted in the area of the Autonomous Province of Vojvodina - in the South Bačka District, which is the most developed in the area of the province, showed that the level of knowledge and awareness of cultural heritage and heritage among respondents of a younger age (pre-university age - students up to the age of 18) is very low. Namely, research has shown that the local population is not sufficiently familiar with the intangible cultural heritage of the local community in which they live. However, as a positive trend we can point to the level of openness and willingness to learn about the specific cultural identities of the younger population with the cultural heritage of other local communities in the Western Balkans region.

4. CONCLUSION

Getting to know new cultures and getting to know other people, with their customs, traditions, religion, habits, represents a significant positive social impact of tourism. This group of positive influences certainly includes the acquisition of new knowledge and the expansion of knowledge about precisely those new spaces, religions, customs and cultures. In this way, tourism can have a positive effect on increasing the degree of tolerance, understanding and acceptance of diversity of all kinds among the population of the Western Balkans. With the expansion of cognitive and value horizons, tourism also develops awareness of the importance of preserving nature and the environment by preserving the authenticity of natural, cultural and anthropogenic heritage at the local and regional level. The results of research carried out within the framework of the actuarial project show that these possibilities have not yet been adequately used, but the fact that awareness of the possibilities of improvement is growing, especially among the younger population, is encouraging.

The paper is part of the research within the International scientific and professional project: Perspectives of interregional cooperation of local communities in the countries of the Western Balkans - in the fields of science, education, culture, economy, tourism and sustainable development.

ANALYSIS OF THE REAL NUMBER OF TOURIST OVERNIGHTS BASED ON THE ESTIMATION OF WATER CONSUMPTION IN ZLATIBOR

Vladimir Živanović[1], Zlatibor Tourism Organization
Nevena Majstorović[2], Zlatibor Tourism Organization

Abstract: *Zlatibor tourist resort* face *the problem of a large number of unregistered accommodation and not up-to-date management of tourist traffic. This makes it difficult to monitor the real number of tourist arrivals and overnight stays, which affects the creating development policies and further activities aimed at the development of the destination. It also prevents a realistic assessment of the impact of tourism on the environment and the local community and timely response. For Zlatibor, as one of the most developed tourist destinations in Serbia, it is important to find a way to summarize the real size of tourist traffic, which can be achieved by comparing and using data on water consumption at the destination. In this paper, with the help of a methodology that has already been applied in the major tourist centers of Europe, the calculation of the actual number of overnight stays of tourists at the destination is presented and compared with official statistical data.*
Keywords: Zlatibor, tourist overnights, tourist traffic, water consumption

1. INTRODUCTION

Zlatibor is a mountain tourist center located in southwestern Serbia and is one of the most visited tourist destinations in Serbia and the region. The tradition of developing tourism on Zlatibor is 130 years long, and the year 1893 is taken as the beginning of organized tourism on this mountain, when the king of Serbia, Aleksandar Obrenovic, visited Zlatibor [1]. Throughout the long history of development, this tourist center has gone through various phases and forms of development, changing the structure of tourist destination itself and the tourist offer, as well as accommodation capacities. Tourism is the most developed and important economic sector of the municipality of Cajetina, to which the territory of the Zlatibor mountain administratively belongs. Tourism is an activity that is influenced by global trends and is very sensitive to environmental changes. These changes are mainly related to the needs and wishes of tourists, but also the continuous development of the offer in order to meet the requirements of specific tourist demand [2] . For this reason, regular monitoring of tourist traffic is very important in creating a development policy and planning the further development of the destination. A better and more extensive knowledge of trends in the development of tourism ultimately leads to a greater chance of defining appropriate strategies to achieve a competitive advantage [3].
In recent years, the destination Zlatibor has faced the problem of a large number of unregistered accommodation, which makes it difficult to assess the real tourist traffic on an annual basis, but also in the peak tourist season. The real situation in destination is that there are a much larger offer of accommodation than registred beds capacities, and tourists who stay in unregistered accommodation are not part of the official tourist traffic statistics. The destination

[1] zivanovic@zlatibor.org.rs
[2] cepic@zlatibor.org.rs

faces another problem, which is that a large number of registered accommodations do not keep up-to-date records of tourist arrivals and overnight stays. This problem is particularly pronounced in the accommodation capacities owend by private individuals, while hotels and other accommodation facilities that operate as legal entities keep up-to-date records of tourist arrivals and overnight stays. Many studies have shown that other destinations around the world face similar problems, where data from official statistics underestimate the real volume of tourists staying at the destination, who are accommodated in unregistered facilities. That is why it is difficult to monitor the real scope of the tourism sector in the destination, which creates problems when planning the development of the destination, but also makes it difficult to analyze the market for the needs of the public and private sectors [4]. In their research, Martín and Salinas [5] point out that it is necessary to know the actual tourist traffic and data on the seasonal concentration of tourists and due to the amount of pressure exerted on the destination due to tourist activity and the carrying capacity of the destination.

One of the ways in which it is possible to estimate the real tourist traffic at the destination is the water consumption model, which is an innovative proposed methodology for estimating the real size of the tourist traffic [4]. The aim of this paper is to show, based on the methodology presented in the professional literature, the approximate volume of actual tourist traffic in relation to the tourist traffic registered by official statistics, through the pattern of water consumption in the city of Zlatibor.

2. METHODOLOGY

The methodology applied in this paper to calculate the real tourist traffic realized on the theritory of Zlatibor city through a secondary indicator such as water consumption, relies on research that was carried out in 2022. and published in July 2023. for the Balearic Islands area, by Gonzalez-Perez , D.M.; Martín Martín, J.M.; Guaita Martínez, J.M.; Morales Pachon. The work methodology is adapted to the local region and available information provided by the Public Utility Company for water supply "Vodovod Zlatibor". The territorial unit that this paper deals with is the Zlatibor city, as the tourist center of the mountain that generates the highest percentage of tourist traffic. The years 2021. and 2022. were taken as reference years for this research, and according to the same model, the calculation of the real volume of tourist traffic can be performed for other years or individual months.

The data made available for inspection by the Municipal Public Company for water supply "Vodovod Zlatibor" includes the invoiced amount of water separated by categories and time frames from the monthly to the annual level. Of the separate categories of water consumption, the data on the invoiced amount of water in the "residential-holiday" category are relevant for this paper. Meters for water consumption connected to the public water supply network under this category include buildings such as houses, villas, individual apartments and all other buildings that are not registered as residential buildings intended for permanent living.

To calculate the total number of overnight stays, according to the water consumption indicator, according to the recommended model, it is necessary, in addition to the total water consumption in the corresponding category, to establish the average water consumption per tourist per day. In this work, the value accepted in the professional literature was used, which is proposed by Gossling [6]. that one tourist consumes an average of 350 liters of water per day for accommodation needs and 20 liters per day within the activities related to their stay, which makes average consumption of 370 liters per tourist per day. One inhabitant of the town of Čajetina consumes an average of 140 liters of water per day (data from "Vodovod Zlatibor"). Data grom professional literature is that the water consumption of one tourist per day is two to three times higher than the water consumption of a local population [7]. When we consider

these two data the suggested amount of water consumption of 370 liters per tourist per day can be taken as relevant in this case as well.
The number of overnight stays obtained by this methodology excludes the traffic generated in hotels, resorts, guesthouses, inns, lodgings and campsites because the category of users of the public water network "residential-holiday" whose consumption is observed in this case excludes the consumption of water in facilities connected to the public water network as legal entities. Company "Vodovod Zlatibor" monitors the consumption of water by legal entities in the territory of the settlement of Zlatibor under the special category "business facilities". From the category "business facilities" it is not possible to single out only water consumption realized in facilities intended for tourist accommodation. For this reason, the number of overnight stays achieved in tourist accommodation facilities that are registered as legal entities was added to the final number of overnight stays obtained by the methodology of calculating water consumption for holiday facilities. This is information that is relevant for use because all tourist accommodation facilities that are legal entities at the destination are categorized according to current regulations and the number of overnight stays that is officially maintained in the Central Information System maintains real traffic in this category. In this way, data on the actual number of overnight stays at the destination were obtained and compared with official statistical data.

3. RESEARCH RESULTS AND DISCUSSIONS

Tables 1. and 2. show the data needed to calculate the real number of overnight stays according to the methodology used in the work. Data on the number of overnight stays and the number of tourists were obtained from official publications of the Statistical Office Republic of Serbia. Data on the number of overnight stays in accommodation facilities that are registered as legal entities were obtained from the Central Information System in the field of tourism and hospitality, while data on water consumption are official data of Municipality pblic company "Vodovod-Zlatibor". The data refer to the years 2021. and 2022. and refer to the town of Zlatibor.

OS = C*w* / 370 l + OS*h*	C*w* – water consuption in cathegory „holiday facilities“
OS – overnight stays	OS*h* – overnight stays in hotels and other legal entities

Table 1. Data on tourist traffic and water consumption by selected categories for 2022.
Source: Statistical Office Republic of Serbia, Municipality Company “Vodovod Zlatibor” and CIS e-tourist

	Overnight stays (SORS)	**Tourist arrivals (SORS)**	**Water consumption/„holiday facilities“ in m³**	**Water consumption / „residental“ in m³**	**Overnight stays/ accommodation facilities - legal entities**
January	71.964	19.036	24.461	9.504	55.092
February	53.592	15.778	42.976	17.172	44.895
March	30.666	10.370	48.224	18.787	24.722
April	35.619	14.955	55.182	13.898	33.831
May	37.532	13.252	52.269	21.613	35.864
June	42.613	14.265	33.352	16.144	36.751
July	67.269	20.535	55.973	17.868	63.396
August	99.665	27.573	82.983	24.400	77.977
September	66.400	20.569	67.067	22.555	38.621
October	68.401	23.514	40.562	16.019	49.149
November	53.744	18.653	45.015	15.263	33.559
December	46.387	18.287	30.673	11.511	29.174
Total	**673.852**	**216.787**	**578.743**	**204.740**	**523.021**

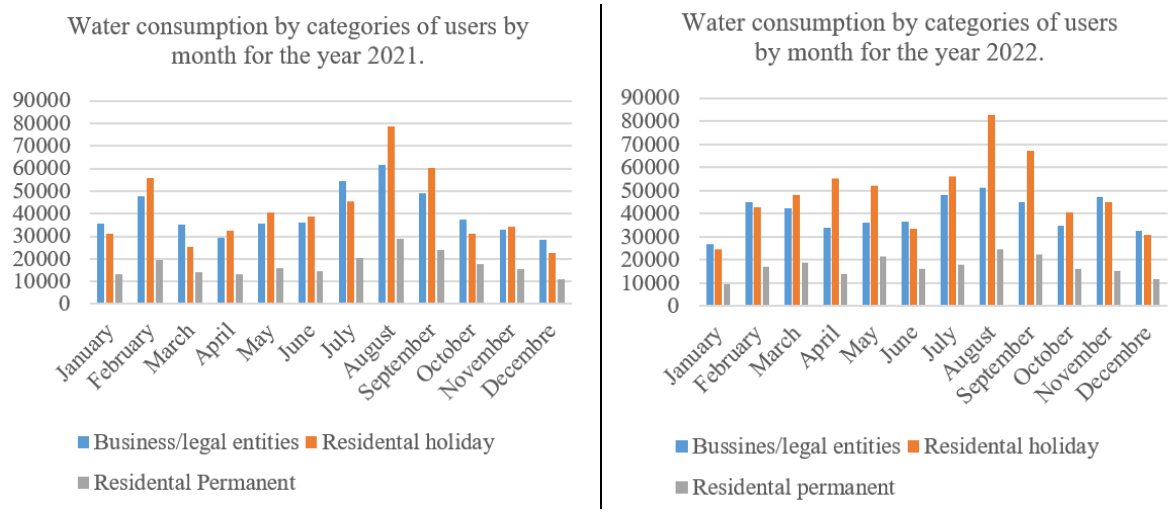
Based on the given methodology and the previously presented formula, it was found that more than 200 percent overnight stays are achieved in Zlatibor on an annual basis than registered by official statistics, and the obtained data are shown in table 3. Based on this methodology, it is possible to calculate the number of overnight stays accomplished at the destination by month. For the seasonal nature of business, which is characteristic of tourism, it is interesting to know how much tourist traffic was actually realized in the months of the highest and lowest tourist traffic on Zlatibor. Such a drastic difference in the turnover that is officially recorded and the turnover obtained by this methodology is due to a large number of unregistered accommodation. The problem in monitoring real tourist traffic also arises due to the non-up-to-date management of traffic in the domestic crafts sector, i.e. irregular registration of tourists in the Central Information System. Official statistical data can be used and are used to monitor the trend of growth or decline in tourist traffic at the destination, but they do not represent the real picture of tourist traffic in any way.
The data on the number of overnight stays obtained by the water consumption estimation methodology include overnight stays in unregistered facilities for tourist accommodation, but also include persons staying at the destination in their own weekend facilities, as well as seasonal workers and all persons staying for any other reason. and who do not have a registered permanent place of business or residence in the territory of the settlement of Zlatibor.

Table 2. Number of calculated overnight stays (OS) and official registred overnights stays

Period	Official statistics data	Data obtained by the water consumption method	%
2022	673.852	2.087.191	209,74 %
2021	600.405	1.881.381	213,35 %
August 2022	99.665	302.255	203,25 %
March 2022	30.666	155.057	405,63 %
August 2021	100.488	297.080	195,64 %
March 2021	23.661	88.440	273,78 %

Graphs 1. and 2. show water consumption by user category for the town of Zlatibor, by month. The graph clearly shows that oscillations in water consumption vary by month, which, along with data on tourist traffic, is a clear indicator of pronounced peaks with the highest tourist traffic. During the seasonal months, water consumption increases by about 240 percent compared to the months of reduced tourist traffic. Oscillations in water consumption in the "business" and "residential holiday" categories are followed by oscillations in the "residential facilities" category, so water consumption in this category also increases during the peak tourist season. This is one of the indicators that in households that are connected to the public water network as residential facilities, there are special accommodation units intended for accommodation of tourists. Although these oscillations are noticeable, they are not expressed in such a large percentage as the oscillations in the other two categories of users.

Chart 1. and 2. Water consumption by user categories by month for 2021. and 2022. in m³



4. CONCLUSION

Zlatibor, like numerous other destinations, faces the problem of a large number of unregistered arrivals and overnight stays of tourists that do not provide a relevant overview of tourist traffic. Methodology applied in this paper led to data that the tourist traffic recorded by official statistics is even three times lower compared to the estimated volume of tourist traffic. Such large differences in the exposed data indicate that there is a serious problem in the recording of traffic. Given data show that statistic in hotels and other accommodation facilities that operate as legal entities is managed up-to-date, and the problem is in sector where private individuals are oweners of accommodation. These data indicate that a large number of accommodation facilities are not officially registered and categorized according to the current law. This should be an important signal to undertake extensive activities to increase the number of categorized accommodation. In the first place, an important role must be played by the education of accommodation capacity owners, increased inspection supervision with advisory visits. Authorities at the local and state level can approach this problem by adopting various incentive measures for registered accommodation facilities and thus try to influence the reduction of this problem. A realistic volume of tourist traffic will enable the destinations to plan further development, manage capacities, but also to attract new investments and improve the offer. Monitoring tourist traffic plays a key role in the sustainable development of tourism. It enables the identification of potential problems such as over-consumption of resources, negative impacts on the environment, which then enables measures to be taken to conserve resources and preserve the authenticity of the destination.

SAFETY AND SECURITY STANDARDS AND PROCEDURES OF MODERN HOTELS

Radomir Stojanovic[1], Western Serbia Academy of Applied Studies
Branko Radeljić [2], Faculty of Science, University of Novi Sad

Abstract: *There are several reasons why the security aspect is becoming an increasingly important element in the business of modern hotels. The first reason is that tourists attach more and more importance personal security (life, health, property, personal data) during their time trips, including staying in an accommodation facility. Another reason is the stricter regulations which directly and indirectly protect the interests of consumers, in the specific case tourists or guests in accommodation facilities. The third reason is the aspiration of hoteliers to minimize the risks of endangering the safety of their guests, their staff and property because every unwanted event has a negative impact on their image as well as on the business result. Also, threats to security in tourism are not in the favor of the destinations, either for the same reasons as hoteliers. All of the above applies especially to hotels because they represent the highest quality and most complex type of accommodation offer, especially those of the highest categories (with four and five stars).*
Keywords: *Security, Hotels, Standards, Procedures, Tourism*

1. INTRODUCTION

The problem of security in hotel facilities implies knowledge from several different areas, because the forms of endangering the safety of guests, employees, equipment, buildings, installations, personal data... are also different. That is why the issue of achieving and maintaining a certain level of security in hotels must be implemented according to pre-established procedures, standards and regulations. The two sources of regulation should be clearly distinguished.

The first level is the hoteliers who adopt and implement their own internal procedures, whether it is an independent hotelier or a hotel chain of which it is part [1]. The second level is the competent state bodies that enact laws and by-laws, as well as the inspection bodies that control the implementation of those regulations in practice. It is especially important that all employees (including managers of all levels) are familiar with the regulations, possible risks, and procedures in case of a specific form of security threat. This is only possible through constant education of all employees, but also following regulations and modern technologies in the field of security in tourism and hotel industry.

[1] radomir.stojanovic@vpts.edu.rs
[2] branko.radeljic@gmail.com

2. THE MOST COMMON FORMS OF SECURITY THREATS IN HOTELS

2.1 Sources (causes) of security threats in modern hotels

The management of each hotel must identify potential sources (causes) of security threats, taking into account the specific conditions of their business (category of hotels, type of guests who visit them, additional facilities, local environment). However, common to all hotels is that there are four potential sources of threats to hotel security. These are guests, employees, third parties, as well as the owners (that is, the top management) of the hotel. All the mentioned potential sources can threaten the security of the hotel intentionally or unintentionally, that is, by their actions or inactions [2].

How can *guests* endanger other people's and their own safety in the hotel? In the first place, by their inappropriate behavior by entering into unnecessary conflicts with other guests and employees (causing verbal and physical conflicts, insulting employees; aggressive attitude towards guests, maids, waitresses, receptionists). The "target" of irresponsible guests can be the hotel's property and reputation. These are the theft of inventory (e.g. bathrobes, small inventory), attempts to escape from the hotel in order not to pay for the services they used, false accusations that their money or jewelry disappeared from the room or safe in order to hide the fact that they spent it in an inappropriate way (gambling, prostitution). It happens that guests completely unintentionally (carelessness) endanger their health (they slip in the bathroom or pool, they consume alcohol excessively) and their property (they leave their luggage unattended in the hotel lobby, they leave their car unlocked in the hotel parking lot). There are also known cases (in Serbia and abroad) of mentally unstable persons choosing a hotel as the place where they will commit suicide (jumping out of a hotel room window, "overdosing" on drugs or narcotics).

Employees in hotels (almost in all positions) can also threaten the safety of guests, other employees (their colleagues), tangible and intangible property of the hotel, but also their own personal safety. This refers to conflicts between employee-guest, employee-employee, but also criminal activities (theft of things and money from the guest room by an employee, for example, a maid...). It is specific to employees that they can abuse the guest database that every hotel has; to endanger the safety of food in the kitchen (accidentally or intentionally) as well as equipment (elevators, electrical installations, etc.). In addition, employees who do not know enough about security procedures or do not implement them can seriously threaten the hotel's business.

If *third parties* (persons who are neither hotel guests nor employees) threaten the security of the hotel, they usually did it on purpose. It is about criminal groups and individuals who rent a room (fake guests) or use additional facilities in the hotel (restaurant, sports and recreational facilities - swimming pool, wellness and spa center; night club; garage) in order to facilitate criminal activities inside the hotel (they ransacked rooms, stole guests' cars, robbed or cheated wealthier guests, especially in the most expensive hotels; carried out kidnappings and murders) and even carried out terrorist activities. "Third parties" certainly include cybercriminals. They can "attack" a hotel in order to obtain certain data about guests and hotel operations with the aim of abusing the collected data for criminal purposes.

It is also possible to *combine the mentioned sources, i.e. a connection (complicity)* between e.g. criminal groups (as third parties) and hotel employees, between hotel guests and employees as well as between third parties and hotel guests. For example, the hotel guest can participate in illicit (illegal) trade with local criminal groups; that an employee (eg a maid) "tips" wealthy guests to local criminals; that an employee (eg receptionist) sells confidential information about a hotel guest to an unauthorized person or criminal; that the terrorist has a guest or employee

as a helper (insider), etc. Although the intentional endangering of the safety of property and persons in hotels is not a very common occurrence, hoteliers should not rule out such a possibility.
And the *hotel owner (including top managers)* can be held responsible for compromising security in their hotel. In that case, it is about his lack of knowledge of regulations and non-compliance with procedures, which entails corresponding legal consequences.

2.2 The most common forms of security threats in hotels

Criminal activities are the most common forms of endangering security in hotels. The so-called is particularly endangered guest rooms (breaking the entrance door, entering through the window on the lower floors); then common areas (reception hall, restaurants...) through pickpocketing, scamming gullible guests, theft of luggage; then the hotel parking lot (break-in and theft of guests vehicles)[3]. Criminal activities certainly include endangering *the hotel's intangible assets* (guest databases and other confidential information) through cyber attacks and unauthorized provision of data to criminal groups by hotel employees. In this sense, criminals are particularly interested in employees in the IT sector of hotels, receptions and middle and higher level managers, i.e. all those who have access to sensitive data.
In addition to guests, *the hotel's employees can be at risk*, especially those in the laundry room (due to the fumes of detergents and other chemicals, due to vibrations and noise), then the security service (due to potential conflicts with guests and third parties), maids and valets (due to lifting loads by floors and rooms) as well as technical service (maintenance service).
Food safety, safe operation of elevators, electrical installations, swimming pools, wellness and spa centers are also important issues for every hotel. The safety of the above is primarily threatened due to non-compliance with standards and procedures, both by guests and employees.
However, certainly the most serious forms of endangering security are *terrorist activities and fires* because they endanger a large number of people, often with fatal consequences. By attacking guests in hotels, terrorists achieve a great propaganda effect, especially if the guests are from large and influential countries and if the hotel attacked is part of one of the international hotel chains. In addition, the hotel and the destination will have a serious drop in tourist turnover in a short period of time (immediately after the terrorist attack), a shaken image of a safe place for tourists, as well as economic damage [3].

2.3 External and internal procedures and standards relevant to hotel security

The hotel owner's responsibility for the state of security can be complete, partial or excluded. Every hotel owner has a legal obligation but also a moral responsibility to ensure the maximum possible level of security in his hotel. Risk is present in all activities, including tourism and the hotel industry. The only way to minimize the risk of security in the hotel is

- prevention and
- appropriate action when an unwanted situation occurs.

This means that all stakeholders must know and adhere to the appropriate standards, regulations and procedures. By "all interested parties" we mean hotel owners as *the most responsible for the safety of people* (guests and employees) and their property, ie their hotel business; employees (managers of all levels and workers) *who encounter security risks on a daily basis* and who will operationally implement appropriate procedures; *hotel guests (tourists) who must*

[3] To this must be added the threat to guests' privacy through unauthorized monitoring of guests' movements and recording of their activities (audio and video recordings).

also bear their share of responsibility by complying with regulations, instructions of employees in case of emergency situations and avoiding risky behaviors and all other activities that endanger their safety and that of others during their stay in the hotel; *inspection authorities whose task is to control compliance with regulations in the area of safety in hotels* and, if necessary (in case of non-compliance with regulations), impose appropriate sanctions in accordance with the law; other competent authorities (scientific institutes, ministries, educational institutions...) *that should work on constant improvement and innovation of safety standards and procedures.*

For modern hotels, the application of certain international standards is particularly important, of which the ISO standards (and substandards) are certainly the best known. They were developed by the International Organization for Standardization (ISO) and each of them refers to a specific aspect of business.

The ISO 9001 standard refers to the quality management system (QMS) in one business entity, including hotels. The main goal of this standard is for the hotel that applies it to meet the needs of its users (guests) while respecting legal norms [4]. The offer of each hotel is primarily based on the provision of services, which means that its quality must be in line with the needs and expectations of modern tourists. The standards of this series consist of: ISO 9000 (presents the concept of the management system and the terminology used), ISO 9001 (refers to the criteria that must be met in order to operate in accordance with the standard and to obtain a certificate), ISO 9004 (includes performance improvement guidelines as well as eight principles of quality management as a basis for guiding business policy while respecting the needs of all stakeholders, not just clients). ISO 9001:2015 represents a significantly improved version of this standard compared to revisions from 2000 and 2008.

Health protection and safety at work is regulated by the ISO 45001 standard. The goals of this standard are to support health protection and safety at work, to enable the prevention of incidents, to contribute to the reduction of injuries at work, to minimize damage to the safety and health of employees so as to simultaneously improve working conditions and protect the employer [5]. It should also be mentioned the "Law on Safety and Health at Work" which regulates "the improvement and implementation of safety and health measures at work for persons participating in work processes, as well as persons who find themselves in the working environment, in order to prevent injuries at work, occupational diseases and work-related diseases, general principles of prevention, rights of special groups of employees, employer's obligations...".

The document entitled "Act on risk assessment" (Article 16 of the law), which is adopted by the employer for all workplaces, is especially important, as well as to determine the method, measures and deadlines for eliminating or reducing the risk to the smallest possible extent [6]. Based on the criteria, the degree of risk is assessed for each workplace - unacceptable risk, high risk, moderate risk, low risk and negligible risk.

Food safety is especially important for every hotel. ISO standard 22000:2018 deals with this issue and refers to the entire chain of food production and distribution. The advantage of the mentioned standard is that it can be applied independently but is also compatible with ISO 9001:2000 and ISO 14001:2004. The application of the mentioned standard as well as HACCR[4] and HALAL standards has great marketing importance because it provides guests with psychological security that the food they consume in hotels is completely safe [7].

The ISO 14000 standard refers to environmental protection and aims to reduce the negative impact of a business entity (hotel) on the environment. Modern hotels are not only large consumers of electrical energy, water and chemicals, but also polluters of the environment. However, one part of the hotel has positioned itself on the market as an "ecological hotel" or

[4] „HACCR“ is acronym of Hazard Analysis Critical Control Point.

"eco hotel" because it operates responsibly towards the environment and uses renewable energy sources.
Hotels apply other standards that are no less important than those explained so far. The security of information assets is the focus of the ISO 27001:2015 standard, while ISO 31000 standard [8] is intended for risk management. Particularly interesting for hotels is the ISO 22320 standard for emergency management, as well as ISO 50001 standard, which deals with energy efficiency.
Apart from the mentioned ISO standards, hotels also use their own internal written procedures and standards, especially international hotel chains. Also, hotels have a video surveillance system, a physical security service, and fire protection systems that work around the clock. Safety procedures and standards in hotels have come to the fore especially during COVID-19[5]. In that period, the emphasis was on high hygiene and health standards regarding the use of personal protective equipment, serving meals, maintaining rooms and common areas. For the few hotel guests, the safety of their health was a key element when deciding which hotel to stay in. In addition, the representative Serbian Business Association of Hotel and Restaurant Industry (HORES) then launched the "Clean & Safe" campaign. Every hotel in Serbia that passed the strict certification at that time had the right to place the official mark of the campaign, in order to promote itself and gain a competitive advantage in the hotel market.

3. CONCLUSION

The existence of standards and clear procedures are the first pillar of safety in any hotel. This means that every hotelier must, as a first step, adopt appropriate standards and procedures in case of various risky situations in a timely manner. Another pillar of safety in the hotel is regular training of all employees through courses and simulations of risky situations. It is understood that the hotelier is obliged to familiarize the employees in detail with all standards and procedures. Both mentioned pillars can be seen as preventive activities. However, the most important thing will depend on the quality of the aforementioned preventive activities: how employees will act in real situations of jeopardizing security in the hotel. Also, hotel owners should cooperate with their colleagues in the country and abroad (exchange of information and experiences), all in order to improve the safety of guests, employees and property in hotels.

GUIDED TOUR AS A TYPE OF ANIMATION IN CULTURAL TOURISM

Slobodanka Stankov[1], Western Serbia Academy of Applied Studies,
Branko Radeljić[2], PhD student, Faculty of Science, University of Novi Sad

Abstract: *A guided tour or a walk accompanied by a tourist guide is based on the services of specialized staff in tourism - tourist guides, and represents an important segment of a travel in creating a tourist experience and the 'final' product of a tourism destination. The quality of the work of these staff is the last and key link in the assessment of the destination value chain. In creating the tourist experience and the 'final' product of the tourism destination, tourism animation plays an important role. Tourist animation aims to revive the tourist offer with new contents and contribute to its enrichment. By applying the concept of storytelling, tourist guides present and interpret attractions in the destination in an interesting way and thereby contribute to the quality of the service provided and used, but also to the creation of a tourist experience. The concept of storytelling is usually based on the principles of life seeing and life participating, which gives the guided tour elements of animation, and the tour guides assume the role of animators on the tour.*
Keywords: guided tour, animation in tourism, quality of service, free time, cultural heritage

1. INTRODUCTION

In accordance with contemporary trends in tourism, activities that play a supporting role in the destination value chain and that influence the degree of tourist satisfaction and their evaluation of the 'final' product of a tourism destination are of great importance [1]. It primarily refers to activities aimed at organizing tourists' free time in the destination. One of such activities is a guided tour, which is the scope of work of specialized staff in tourism - tourist guides. The quality of the work of tourist guides represents the last and key link in the evaluation of the destination value chain, and 'affects the complete satisfaction that the tourist takes with him from his travel' [2, 1].
A guided tour or a walk accompanied by a tourist guide is for many consumers a way to get to know an unknown destination in a comfortable, reliable, safe and interesting way. Well-designed programs and contents of the guided tour affect the quality of the organized free time of the consumer (tourist). Depending on the quality of guided tours as well as the degree of participation of tourists in their realization, the degree of tourist satisfaction or dissatisfaction with the purchased and used service is directly affected [3].
Tourist guides, with the quality of the service provided on a guided tour, have a direct influence on the formation of the tourism destination experience and on consumer satisfaction with the service provided and used. They are 'ambassadors of the destination' where they work and represent guided tour mediators who have the task of presenting and interpreting attractions in the destination to tourists in an interesting way, using the concept of storytelling. Thus, they assume the role of animators, and the guided tour becomes a type of animation through which tourists want to experience and learn something new.
Tourist animation represents an important component and an integral part of the contemporary tourism offer. As the main motive of contemporary travel, it aims to revive the tourism offer with new contents and to encourage guests to actively participate in them [4].

2. TERM AND MEANING OF GUIDED TOUR AND ANIMATION IN TOURISM

The term ‘guided tour’ comes from the word ‘tour’, which means a multi-day round trip, i.e. ‘a guided tour’, ‘a tour carried out by a group accompanied by a guide’ or ‘when one person gives orientation to a group of people and explains the surrounding landscape’ [5]. The definition indicates that a guided tour is based on the service of a tourist guide, and as such represents an important segment of a travel and the ‘final’ product of a tourism destination.

The first organized travel, based on the principle of ‘guided tours’, were created in the period of Grand tour. The English travel agency, ‘Thomas Cook and Son’, was the first to organize travel of this type in 1841. The travel was mostly based on discourse, i.e. verbal exchange of words. Unlike these journeys, modern journeys are based on visualization, i.e. are organized according to the principle of sightseeing. Sightseeing, observation and explanation of the observed scene by a professional licensed person represent a key aspect of contemporary travel and tourist experience [1].

In creating the tourist experience and the ‘final’ product of the tourism destination, tourism animation plays an important role. As a segment of the contemporary tourism offer, which encourages a more meaningful stay of tourists and affects their satisfaction during the travel, tourist animation represents ‘a set of services that satisfy the needs and wishes of tourists to experience the expected and desired tourism program, with which the organizer of the program increases tourist consumption’ [6], which indicates that animation appears as the main motive of travel in contemporary movements in tourism.

The term animation originates from the Latin word ‘anima’, which in translation means soul, revival, motivation, inner mood, etc. [6]. As an additional content that completes the free time of consumers in a tourism destination, the expansion of development is experienced with the appearance of mass tourism in the 50s of the XX century. The main goal of animation is to revive the tourism offer with new contents and to encourage guests to actively participate in them [7].

3. QUALITY OF THE GUIDED TOUR

The dynamic and intensive development of the tourism industry at the beginning of the 21st century influenced the focus on the tourism product, that is, on the quality of its intangible elements, but also on consumer satisfaction as a key element of loyalty. Today, quality represents the business policy of contemporary economic tourism entities, which is achieved by respecting the general principles, principles and standards of quality, as well as the system of total quality management (TQM) [8].

In contemporary tourism business, quality has become a decisive factor for success and competitiveness. Activities that play a key role in the destination value chain in attracting tourists, influence the satisfaction of their needs and have a positive effect on consumer satisfaction with the service provided and used are precisely based on the ‘quality concept’. On the other hand, the degree of tourist satisfaction with the provided and used service as an important qualitative indicator in the evaluation of the ‘final’ product of the tourism destination, stems from the ‘needs, demands and wishes of consumers’ [9] and directly affects the level of the tourist experience.

Service quality is defined by two aspects: the service provider and the service user. From the aspect of the service provider, i.e. stakeholders, the quality of the service indicates how well the delivered service pleased the expectations of the consumer, while from the perspective of the user of the service, quality implies the assessment of all links in the value chain of the tourism product of the destination, i.e. assessment of the quality of the services provided and used by all service providers.

As an important segment of the destination value chain, the quality of the guided tour affects consumer satisfaction and the level of tourist experience. The assessment of a guided tour, as an important link in the value chain, can be viewed from the aspect of outgoing and receptive tourism, that is, depending on the methodology of tour guiding and the methodology of the tourist guide's work.

The methodology of tour guiding refers to the realization of the task set before the tour guide[3], in order to satisfy consumers and all interest groups in the destination, through the implementation of all elements of the travel program, through the possession of knowledge and skills and preparation of the tour guide. The methodology of the work of a tourist guide includes actions from the preparation of the guide for the tour, the execution of all elements in the tour itinerary, i.e. to the travel program, to tasks upon completion of the tour.

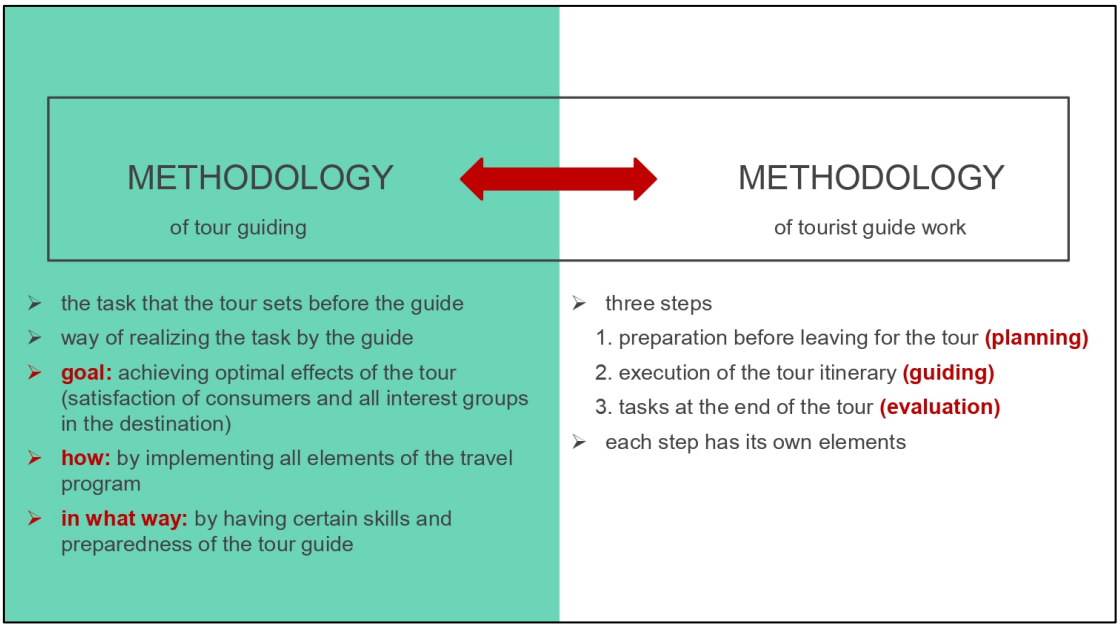

Figure 1. Methodology of tour guiding and Methodology of tourist guide work
Source: Screenshoot of Teaching material for the course Tourist guiding, prepared according to the [5, 11] author's textbooks

The sphere of outgoing tourism is related to the activity of tourist guides of a general nature. It is about staff hired by travel agencies (TA) tour operators for the realization of action travel arrangements, i.e. round-trip arrangements.[4] The service contact, as part of a trip organized in this way, begins at the moment of the guide's arrival at the meeting place and the departure of the group on a travel. From that moment, the process of evaluating the quality of the travel organizer service and the tourist product itself begins, and lasts as long as the escorted package tour travel program.
The sphere of receptive tourism is related to the activity of local tourist guides, i.e. guides who know the destination well where they work. We are talking about personnel who are 'tourism ambassadors' and 'destination experts'. The hiring of these staff is the responsibility of receptive travel agencies, whose offer is adapted to the needs and demands in the destination and is mainly based on one-day optional excursions, within which one or more attractions are visited.[5] The service contact within the guided tour begins with the departure of the group on an organized tour, when the process of

[3] Each task of a tourist guide consists of three components: navigation, presentation and logistics.
[4] Round-tours are multi-day tourist arrangements, on bus or combined transport. As part of these arrangements, more destinations are visited, and thus more attractions. A guided tour within which this type of arrangement is realized is known as an escorted package tour. Given that the program contents of the round-tours are mostly implemented in several foreign-receptive tourism destinations, for their realization it is necessary to engage local tourist guides, i.e. guide of destination experts. Thus, such activities acquire the character of a micro-tour, which means that several guided tours can be integral elements of one escorted package tour.
[5] Arrangements of the type of optional excursions, excursions and thematic one-day tours (e.g. wine tour, monastery tour, etc.) include visiting one or more attractions in the form of a half-day or full-day excursion, which can be organized on foot, by bus or other means of transport, outdoors and closed space. A tour within such arrangements is known as a guided tour. Such tours are organized exclusively within one tourism destination. They represent additional facilities in the destination and are intended mainly for guests on stationary or residential arrangements. Guided tour, as a segment of escorted package tour, also serve guests who come to the destination as part of an organized tourist package arrangement of the round-tour.

evaluating the tourist product of the receptive travel agency begins, then the evaluation of the guided tour as additional content in the destination, but also the evaluation of the entire integrated tourism product of the destination.
Based on the above, it can be concluded that tourist guides are the 'extended arm' of travel agencies, that is, they represent the last link in the chain of evaluation of the TA tourism product and the integrated product of the destination. Service contact with guests has a crucial role in achieving service quality, and it is achieved through the personal characteristics and behaviour of tour guides, which influence the guest's perception of service quality [8].
That the personal characteristics of the service provider have the greatest influence on its quality is indicated by surveys of consumer satisfaction, as participants in guided tours, on the quality of tourist guide services [11]. The interaction and time that the guides spend with consumers are key to the manifestation of their personal qualities, which consumers perceive as an integral part of the quality of the service. Enthusiasm, openness and warmth, self-confidence, creativity, determination, sensitivity, flexibility, intelligence, knowledge, awareness, organizational skills, energy, honesty and charisma are just some of the personal qualities that, according to consumers, guides engaged in guided tours should possess.

4. CONTEMPORARY TRENDS IN THE PROMOTION OF CULTURAL HERITAGE

Tourism, as a service sector, bases the quality of its services on the transmission of information, as an important factor for success and survival on the tourism market. It is generally known that the carriers of the tourist offer form their competitive advantage thanks to information [12]. Tourism today is dominated by digital channels, and the growth of SoMo networks (social networks and mobile devices) has contributed to the modernization of the sector [13].
The new trend in information development, Big Data (BD), BD analytics, analytics of massive data sets and business analytics, enables and supports business decision-making, as well as the design of efficient business models. Tourism destinations, companies and tourists are increasingly creating and implementing large data sets. It is predicted that research in tourism in the future will increasingly rely on BD, BD analytics and business analytics applying and including other types of digital technologies such as artificial intelligence and the Internet of things in different ways [12].
What is crucial is that the digitization of tourism has enabled the managers of tourism destinations to creatively promote the elements of the value chain of the tourism destination. DICRMS (Destination Integrated Computerized Information Reservation Management Systems), digitizes the entire tourism industry and integrates all aspects of the value chain. It works in a WAN network and is accessible via the Internet and mobile devices [14].
In the XXI century, in the era of the 'fourth industrial revolution', the application of the digital principle of business is of great importance, because it affects the increase in the competitiveness of the destination on the tourism market. Promotional activities were carried out by key stakeholders of tourism destinations through E-tourism (Web tourism) and Virtual tourism, which improve the functions and performance of the destination management system and become an important element in the evaluation of the value chain.
Virtual tourism began to develop intensively with the onset of the COVID-19 pandemic. It represents an innovative hybrid concept that creates a different dimension of travel. In the promotion of tourism destinations, it is used to improve the tourist offer by creating tourist products in an innovative way. Through this type of tourism, the service contents of all stakeholders in the destination can be presented and visited from a distance, primarily cultural service providers (theatres, galleries, exhibition centres, operas, museums, etc.) [12].
Cultural contents in contemporary tourism represent important motivators of tourist movements, whose digitization and presentation through virtual tourism contributes to the improvement of their visualization and accessibility to the general public, which additionally affects the development of the audience in culture and the creation of virtual tourists. This way of presenting cultural content is

easily accessible to sensitive social groups, especially people with disabilities, who represent a significant segment in contemporary cultural and tourist flows [12].
Today, virtual travel is mostly crucial in choosing a destination that a potential tourist wants to visit. Tourist destinations that have created and use virtual tours in their promotion have an advantage in the tourism industry. Virtual tours help potential tourists to experience destinations that they will probably not have the opportunity to visit by applying the concept of storytelling in the virtual world. The development of this type of tourism certainly represents and will represent a supplement to tourism traditional forms. Tourism stakeholders, who recognize and use the advantages of this technology, will not only create innovative additional content in the destination, but will also creatively promote the destination in a modern way. Examples of good practice in the promotion of cultural heritage in our country, through virtual tourism, are Manasija and Studenica Monastery, Golubac Fortress and Užice Old Town[6], as well as museums in Belgrade (National Museum, Museum of Contemporary Art, History Museum of Serbia, Nikola Tesla Museum, Aviation Museum, Museum of the City of Belgrade, etc.), etc.
In addition to virtual tourism, which appears as additional animation content in the organization of tourists' free time in the destination, in the realization of guided tours, especially guided walking tours, *life seeing*[7] and *life participating*[8] concepts are often applied. Their application is linked to certain localities in the destination when tourist guides through the concept of *storytelling*[9] present and interpret the attractions in the destination in an interesting way and thereby contribute to the creation of a tourist experience. Visits to sacral heritage, cultural values of rural and urban areas, getting to know traditions and customs based on the principles of *life seeing* and *life participating*, are the most visited animation activities organized by receptive TAs [15].

5. CONCLUSION

As an activity and the field of tourist guides work, a guided tour is a well-designed animation activity that presents and interprets attractions in the destination to tourists. The importance of tourist animation is based not only on the creation of a quality tourist offer for destination stakeholders, but also on the satisfaction of tourists with the service provided and used.
Tourist guides as the 'extended arm' of tour operators are most often responsible for consumer loyalty. The quality of the services provided on the guided tour has a direct influence on the formation of the experience of the tourism destination and the satisfaction of consumers with the purchased and used service. A quality tourist experience is created as a result of the interaction between tourists and service providers, local residents and other tourists.
By developing virtual tourism, additional contents created in the destination contributed to its competitiveness on the tourism market. Virtual tourism products or VR tours represent and will represent content that will be developed as a complement to traditional forms of tourism, because virtual tours and digitization are a trend in the development of tourism worldwide.

---

[6] The DiMSUE project is financed by the Ministry of Culture of the Republic of Serbia and co-financed by the City of Užice. The project holder is the Western Serbia Academy of Applied Studies. All information about the project is visible through the link https://stari-grad.uzice.rs/

[7] The *life seeing* concept is an important aspect in animating tourists in the destination. It is based on discourse and visualization. It is applied in all types of tourism, which indicates that it can be organized on different topics. It is closely related to the concept of storytelling, with which the guide or curator tells a story about the site being visited in an interesting way.

[8] The *life participating* concept also represents an important aspect in animating tourists in the destination. The concept can be subsumed under active vacation in the destination, because it implies the participation of tourists in the activities of the resident rural population, which indicates that it is closely related to agritourism.

[9] The concept of *storytelling* is one of the modern trends in the promotion of attractions in the destination. It is represented in almost all types of tourist movements and is related to all types of guided tours, in closed and open space. In addition to tourist guides, the concept is also applied by specialized/expert guides (curators in museums, galleries, halls, commercial organizations), who provide information and guide guests through objects of cultural, economic, historical and other significance.

INCENTIVES FOR AGRICULTURE IN THE CITY OF BELGRADE

Milos Spasojević[1], Faculty of Agriculture, University of Belgrade
Marija Popović[2], Faculty of Agriculture, University of Belgrade
Jasmina Đurasković[3], The Academy of Applied Technical Studies Belgrade

Abstract: *Agriculture is one of the most important branches of the economy of the Republic of Serbia and the city of Belgrade. The aim of the paper is to present and analyze the current financial incentives in the territory of the city of Belgrade, which are included in the programs of the Secretariat for Agriculture of City Administration of the City of Belgrade. These incentives are aiming the development of agriculture and rural development of the capital. These incentives are pay out from the budget of the city of Belgrade through several public calls. The largest part of these incentives is used by agricultural farms on the outskirts of city municipalities. To develop agriculture in the city of Belgrade, it is necessary to increase allocations for this type of subsidies, considering that many farms that apply remain below the line that indicates the expenditure of all funds. The method of description, content analysis, comparative method, and descriptive statistics methods were used in the work.*
Keywords: *incentives, agriculture, Secretariat for Agriculture, rural development.*

1. INTRODUCTION

According to the Farm Structure Survey 2018. [1], the total number of agricultural holdings in the territory of the Belgrade region was 30,033, and the utilized agricultural area covers an area of 145,533 ha. Dominants are farms with smaller agricultural land of up to 5 ha, which make up 77.8% of all agricultural farms and dispose of 31.1% of used agricultural land. There are the fewest farms with property over 100 ha, only 0.1%, and they have at their disposal 20.3% of the total used agricultural land. Fields and gardens are the most represented in the total used agricultural land with 77.5%, followed by meadows and pastures 10.7%, and then perennial crops with 10.43%.
Our country is known for possessing suitable natural resources for the development of agriculture, primarily related to soil quality, favorable climatic conditions, and availability of water resources. However, insufficient agriculture investment in the past led to the fact that natural resources cannot be fully utilized. Investment in agriculture and rural development is an important factor in increasing the volume and quality of production [2]. Greater incentives for agriculture are needed, which should be implemented with the national and regional incentives at the local self-governments level such as City of Belgrade.
The great importance of agriculture for the development of most cities and municipalities in Serbia has influenced the fact that about 110 municipalities/cities support the development of agriculture in their territory with their own budget funds. Budgetary funds for the agricultural sector allocated by cities and municipalities vary, both in terms of share in the total budget and purposes. The law regulates the obligation to coordinate measures to support agriculture and rural development, which will be financed from the budget of local self-government units, with the Ministry of Agriculture, Forestry and Water Management [3].

The aim of the paper is to present and analyze the incentives that the City of Belgrade, as a unit of local self-government, allocates for agricultural holdings, through the programs of the Secretariat for Agriculture of the City of Belgrade.

2. RESEARCH RESULTS

2.1 The call for applications of Secretariat for agriculture

Based on Article 13 of the Law on Incentives in Agriculture and Rural Development [4], the Decision on the Budget of the City of Belgrade for 2023 [5], Article 54 of the Statute of the City of Belgrade [6], the City Council adopted the Support Program for the implementation of agricultural policy and rural development policy for the year 2023, with the prior consent of the Ministry of Agriculture, Forestry and Water Management to the Program. Based on the adopted Program, the conclusions of the Mayor of the City of Belgrade, decisions were made on the announcement of all five Public Calls. Five public calls are announced:

1. Public call for submission of applications for the allocation of incentive funds in the field of fruit growing, vegetable growing and arable farming in the territory of the city of Belgrade for the year 2023 [7].
2. Public call for submission of applications for the allocation of incentives for the purchase of agricultural attachment machines in the territory of the city of Belgrade for the year 2023 [8].
3. Public call for submission of applications for the allocation of incentive funds in the field of beekeeping in the territory of the city of Belgrade for the year 2023 [9].
4. Public call for submission of applications for the allocation of incentive funds in the field of animal husbandry and milk processing on farms in the territory of the city of Belgrade for the year 2023 [10].
5. Public call for submission of applications for the allocation of incentive funds for the purchase of tractors in the territory of the city of Belgrade for the year 2023 [11].

The value of incentives in the period from 2015 to 2023 tends to grow. The only years when the value of incentives was reduced were the years when our country, like most of the world, was affected by the Covid 19 pandemic and when the reduced activity of both the economy and agriculture caused the budgets for this type of incentives to be directed to the health sector. The total value of incentives by year is shown in Graph 1, from which it can be seen that the first years when incentives in this form were introduced into the program of the then Secretariat for the Economy, within which the Directorate for Agriculture functioned, and from which it was transformed into the Sector through systematization and consequently to the independent Secretariat for Agriculture, the incentives amounted to slightly over 16 million dinars, so that in 2023 the budget for incentives would be valued to almost 450 million dinars. The number of applications from agricultural farms for subsidies exceeded the planned budget for these purposes every year, as well as in 2023, when 1,651 agricultural farms applied, and 1,120 received subsidies. For this reason, a further increase in the budget for this type of subsidy is expected.

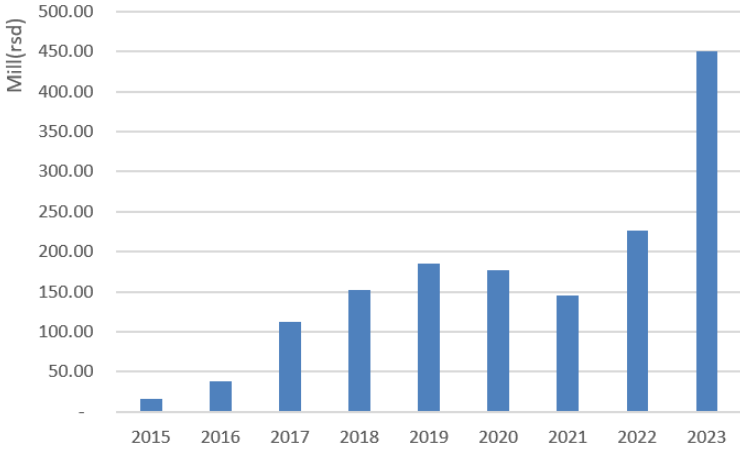

Figure 1. Value of incentives per year

Table 1 shows the types of costs for which Incentive funds are selected and the maximum amounts of acceptable costs:

Table 1. Types of eligible expenses and maximum amounts
Source: *Internal documentation of Secretariat for agriculture*

EQUIPMENT	QUANTITY	MAXIMUM AMOUNT (RSD)
Fruit growing, vegetable growing and arable farming		
anti-hail nets with drip irrigation system	from 0.25 ha to 1 ha	1,550,000.00
greenhouses with a drip irrigation system, or a sprinkler irrigation system	from 0.03 ha to 0.10 ha	1,500,000.00
wire fences for fencing perennial fruit plantations	from 0.25 ha to 5 ha	1,400,000.00
drip irrigation system for irrigating fruit plantations	from 0.25 ha to 5 ha	750,000.00
hydrant with or without water flow meter	1 pc	125,000.00
drip irrigation system with hydrant with or without water flow meter	from 0.25 ha to 5 ha	875,000.00
electric scissors for pruning fruit	1 pc	200,000.00
typhon with or without rain wings for irrigation of field crops, outdoor vegetable crops and industrial plants	1 pc	1,000,000.00
vacuum cleaner for collecting stone fruits	1 pc	350,000.00
Attachment machines		
Attachment machine for tractor	1 pc	500,000.00
Beekeeping		
Equipment and machines for beekeeping more closely defined in the Public Invitation	Several pcs	120,000.00
Animal husbandry		
Quality breeding heifers	3 pcs	750,000.00
Quality breeding sheep or goats	30 pcs	750,000.00
Animal husbandry equipment	Several pcs	400,000.00
Milk processing equipment	Several pcs	300,000.00
Tractors		
Tractor up to 60 kW with cab or protective frame	1 pc	1,000,000.00

Incentive funds are implemented on the territory of all 17 city municipalities that belong to the city of Belgrade as a local self-government. Table 2 shows the total amounts as well as the number of agricultural farms from the city municipalities that received incentives. Also, there is an average amount of subsidies that agricultural farms have received in certain municipalities. Here it can be seen that the peripheral municipalities achieved a higher number of incentives per farm, but this can be attributed to the number of farms that applied and received a subsidy for the purchase of tractors, which is 1,000,000.00 dinars, so this had the effect of increasing the average amount of subsidies per farm. Consequently, municipalities where there is a greater number of beekeepers or where this type of agriculture is more developed, will have a smaller amount of average subsidy because the maximum amount of incentive for beekeepers is 120,000.00 dinars.

Table 2. The number of subsidies by municipality in the territory of the city of Belgrade
Source: *Internal documentation of Secretariat for agriculture*

Municipality	Amount (RSD)	Number of farms	Average amount per farm
Mladenovac	131,600,006.05	242	543,801.68
Grocka	81,607,836.20	163	500,661.57
Lazarevac	51,255,290.77	138	371,415.15
Obrenovac	40,387,102.50	129	313,078.31
Sopot	39,266,745.70	98	400,681.08
Surčin	19,233,708.26	54	356,179.78
Palilula	18,123,365.33	44	411,894.67
Voždovac	13,660,748.18	42	325,255.91
Barajevo	13,499,290.12	56	241,058.75
Zemun	12,917,571.06	37	349,123.54
Čukarica	7,425,224.13	38	195,400.64
Savski Venac	5,824,168.13	9	647,129.79
Zvezdara	4,263,417.60	13	327,955.2
Rakovica	4,119,441.33	27	152,571.90
Vračar	3,617,173.34	8	452,146.67
Novi Beograd	2,181,039.45	17	128,296.44
Stari Grad	494,968.00	5	98,993.6
In total	**449,497,096.20**	**1,120**	**401,336.69**

As shown in Table 2, the largest number of subsidies was achieved by peripheral municipalities, given that there are many agricultural farms on the territory of these municipalities, which dispose of significant areas of agricultural land. Central municipalities in the city of Belgrade, such as Stari grad, Vračar and Savski venac, which objectively do not have agricultural land, and are on the list of municipalities where farmers received subsidies, are mentioned for the reason that the address of the agricultural holding is given as the address of the owner of the holding which in these cases is on the territories of these Municipalities, and not related to where the agricultural land is located. For this reason, it is logical to conclude that these agricultural farms from the central municipalities are predominantly located in the outskirts of the city of Belgrade, where there is also agricultural land that is cultivated.

3. CONCLUSION

Local self-government subsidies at the level of the city of Belgrade are implemented through the programs of the Secretariat for Agriculture. In 2023, 1,651 farms applied to five public calls implemented by the Secretariat for Agriculture, while 1,120 of them received subsidies, which indicates the need to increase the budget of the Secretariat for Agriculture to meet the needs of farms for this type of incentive [3]. Also, what is noticeable is that for many farms, the lack of large holdings is something that slows down further development and increase of productivity, in this regard, further consolidation of agricultural land is needed to overcome the problems of unprofitability of small holdings. A further increase in the budget for subsidies should go in the direction of channeling funds into public calls for the purchase of tractors, which would modernize agricultural mechanization in agricultural farms in the Belgrade region, and since the maximum subsidy for a tractor is 1,000,000.00 dinars, in this way the average amount would also increase subsidies per agricultural holding.
A further direction of research related to the subject of subsidies would be to compare the amount of subsidies, the distribution of subsidies by municipalities and the types of subsidies that change by year. It would also be important to investigate the effect of subsidies on the economic well-being of agricultural farms and the economic performance achieved by farmers in agricultural production. This

refers to the way in which the new mechanization acquired through the subsidy program affects the increase in profitability and more efficient work on the farm. The question opened by this work is whether the current level of subsidies is sufficient or whether it is necessary to increase their amount and, if so, to what extent. All these questions could be further topics of research in this area.

THE ROLE AND SIGNIFICANCE OF CULTURAL-HISTORICAL HERITAGE IN THE DEVELOPMENT OF CULTURAL TOURISM – EXAMPLE OF THE MILEŠEVA MONASTERY

Jelena Basarić[1], Institute of Architecture and Urban & Spatial Planning of Serbia
Andrijana Golac Čubrilo[2], Faculty of Arts, University of Niš

Abstract: *The Mileševa Monastery is the focal point of the Mileševa River canyon, abounding in heritage sites. Rich and unique cultural and historical heritage in this area is determined by the strong role of the Mileševa Monastery compound. Its values can be assessed from the aspect of material heritage, permeated with intangible (spiritual) heritage, set in a specific protected natural area. Cultural heritage can play a decisive role in defining culture and tourism development policies by taking into account the management of cultural values and their harmonisation with other types of tourism. Interaction between cultural and natural heritage, i.e., tangible, intangible and landscape values, calls for the integrative approach to protection and preservation of this area by introducing and also improving the concept of cultural landscape. The significance of cultural heritage can greatly affect the appeal of a tourist destination. This paper aims to point to the potentials of cultural and historical heritage, which will add to creating cultural and tourist identity of this area both in the local and international tourist markets.*
Keywords: Cultural tourism, Cultural and historical values, Development, Improvement, Preservation, Cultural heritage, Mileševa

1. INTRODUCTION

In accordance with the Law on Cultural Property [1] (*The Official Gazette of the Republic of Serbia* No. 71/94, 52/11- other law and 99/11- other law), the Mileševa Monastery, along with the Church of the Ascension of Christ, have been awarded the status of protected immovable cultural property. In 1947, the monastery was protected as cultural monument, while it was back in 1979 that it was categorised as a Monument of Culture of Exceptional Importance. It is the endowment of King Vladislav and dates back to the first half of the 13th century. This monastery was home to the relics of Saint Sava from 1236 to 1594. The Mileševa Monastery monumental thirteen-century frescoes stand for a masterpiece of Serbian and European art. They bear the portraits of several rulers from the Nemanjić dynasty and the composition The Myrrh-bearers at the tomb of Christ. In 1377, the coronation of King Tvrtko I Kotromanić took place in the monastery. Apart from the Mileševa Monastery, the town of Hisardžik, also known as Crna Stena (*Black Rock*), stands out as a location of cultural value. Along with its surrounding area, it was protected as a cultural monument in 1947. This mediaeval fortress, featuring stone walls and towers, was erected on an inaccessible rocky cape, a cone-shaped limestone outcrop, on the left bank of the Mileševka River. The first mention of it, as the town of Mileševac, was in the mid-fifteenth century. Since the second half of the 15th century, it was under the control of the Turks and since the 17th century it also became known as Hisardžik, with a small town at the foot of the fortress. Additionally, in the territory of the Municipality of Prijepolje, several sites of archaeological value have been identified, as well as some structures that belong to building heritage and enjoy previous protection, such as: the Ružica Church (archaeological site), the

[1]basaric.j@gmail.com
[2]golacandrijana@yahoo.com

Cave Church (a group of hermit cells), Crkvina, Aljinovići (archaeological site), the primary school building (building heritage), the village graveyard (archaeological site), and the watermills on the Sopotnica River (traditional building technique). Other significant and valuable cultural monuments have also been registered, these not being included in the system of protection (the Church of Saints Peter and Paul, the Church of Basil of Ostrog, the Church of the Davidovac Monastery, the Church of the Kumanica Monastery, the Catholic church in Prijepolje, the Ibrahim Pasha Mosque in Šarampovo and the "Big" or Mahmut Bey Mosque). In the early 1990s, by decision of municipal authorities, a regime of protected area was introduced around the monastery, with three different levels of protection: I, II, and III. The Mileševa Monastery compound is situated in the Mileševka River basin. The importance and significance of the monastery is additionally highlighted by the fact that it is situated in the immediate vicinity of the Special Nature Reserve of the Mileševka River canyon. In accordance with the relevant Decree of the Government of the Republic of Serbia [2] (*The Official Gazette of the Republic of Serbia* No. 104/14), pursuant to the provisions of the Law on Nature Protection [3] (*The Official Gazette of the Republic of Serbia* No. 36/09, 88/10, 91/10 – corr. and 14/16), the reserve was declared Protected Area of Exceptional Importance.
According to the data provided by the Statistical Office of the Republic of Serbia, the total number of tourists in the Republic of Serbia for the year 2021 was 2591293, of which 1720054 (about 66%) were domestic and 871239 (about 34%) were foreign tourists. Prijepolje belongs to the region of Zlatibor and, based on data, this municipality has recorded the least number of visitations in comparison to other municipalities of the region, in the aforementioned year. The total number of overnight stays is 2.3 for domestic and 1.6 for foreign tourists. This is an insignificant per cent, less than 1% of the overall tourist visitations [4] (Општине и региони у Републици Србији, 2022). According to the official data of the Ministry of tourism and Youth that applies to the categorized facilities in the Republic of Serbia (until October 2023), the Municipality of Prijepolje does not possess any such facilities [5].

1.1 The Mileševa Monastery

The Mileševa Monastery belongs to the „Raška school" group of monuments and is one of the many endowments of the Nemanjić dynasty members. The main monastic church, which is dedicated to the Ascension of Christ, was presumably built in the third decade of the 13th century, following which frescoes were painted [6, 7, 8]. Prince Vladislav, the second son of Stefan-the-First-Crowned, erected the church as his own mausoleum. The relics of Vladislav's uncle, Saint Sava, the founder of the Autocephalous Serbian Church and its first Archbishop, were kept in this monastery for a period of time [9, 8, 10]. Once it was built, Mileševa became the second most important Serbian church. The only church whose reputation was greater than that of Mileševa was Studenica, the endowment of Stefan Nemanja, who was Vladislav's grandfather and the progenitor of the dynasty. As is the case with other endowments of the Nemanjić family members, in addition to its role as a place of worship, Mileševa served the purpose of glorifying the cult of the ruler.
Originally, Mileševa was a single-nave church with a single dome a semi-circular apse on its eastern and narthex on the western side. To the left and the right of the central part of the church, there are two rectangular choirs, which initially may have served as vestibules. The proskomedia and the diaconicon were built somewhat later, next to the apse, and by the year 1236, an exonarthex was built on the west side, along with two lateral chapels. It was erected at the request of the ktetor's uncle, Saint Sava, whose relics were brought to Mileševa from Tarnovo, Bulgaria, in 1237 [6, 7]. The exterior parts of the church are influenced by Romanesque art, which is indicative in the remains of the sculptural decoration [8], as well as on the representations of models of the original church held by the ktetor Vladislav on the frescoes in the nave and the narthex [6].
Although its original appearance changed substantially, the Church of Mileševa has an enormous historical and artistic importance. Apart from its appearance repeating some of the earlier Nemanjić endowments (Studenica and Žiča), it is also home to some of the most fascinating frescoes of the time, which bear witness to the power of its ktetors. A noteworthy fact is that the programme of the

fresco decoration in Mileševa was created by Saint Sava [11, 12], while Vladislav commissioned the best artists from Greece to paint the walls of his endowment. Following the example of Studenica, they decorated the walls with frescoes in which they replicated the appearance of mosaic, while for representing the scenes in the nave, they used a golden background.

What is striking about the Mileševa Monastery frescoes is their outstanding monumentality. The monastery has several portraits of the Nemanjić family members, one of which is an exceptional portrait of the ktetor, Vladislav. This portrait is positioned directly above his sarcophagus, on the south wall of the nave. Vladislav is represented while, led by the Theotokos, bringing a model of the church to an enthroned Christ. Apart from this portrait, another one, of distinct beauty is the portrait of Saint Sava, shown in the Nemanjić family tree. The portrait is on the eastern wall of the narthex. Next to him is Stefan Nemanja, the progenitor of the dynasty, shown as a monk. Other members of the dynasty are painted one after the other on the northern wall: the then king Stefan-the-First-Crowned with his sons, Radoslav, co-ruler at the time, and Prince Vladislav, who is again shown here with a model of the church in his hand [13].

Still, what the Mileševa Monastery is most famous for is the fresco of The Myrrh-bearers at the tomb of Christ, i.e., the figure of the angel depicted in it, after which the entire composition was named and is known as The White Angel. This fresco is positioned above the grave of Vladislav, the ktetor, on the south wall of the nave [8]. Since the exonarthex served as a place for the tomb, where the relics of Saint Sava were kept for a period of time, the whole space is decorated with the episodes of the Last Judgment [6, 14].

2. THE CONCEPT OF CULTURAL TOURISM

Culture and tourism stand for and are a reflection of any nation's identity, which is confirmed by innumerable examples of famous tourist destinations in Europe and the rest of the world alike. In terms of appeal, the development of tourism and the creation of a successful tourism product have often been based on culture and heritage. Extensive tourist movements have mainly been driven by cultural content, which is why it is important to promote cultural values and legacy as part of historical heritage that should be valorised and included in the most current developments of modern tourism. Today, modern cultural tourism is recognised as an important factor of economic and social development. This is reflected in the fact that rich countries, and those that are less rich, improve and develop their tourism strategies, which are, to a large extent, based on promoting cultural values and attractions. Furthermore, one of the main tasks is to identify potentials and limitations in terms of the development of this form of tourism, as well as possibilities for a sustainable utilisation of cultural values.

The term cultural tourism has been present in relevant sources for quite some time, with many definitions of this term that define it in an almost identical manner. It is mainly related to exploring a new region and its residents. The most widely-quoted definition of cultural tourism is that by the author Richards [15], according to whom cultural tourism is "the movement of persons to cultural attractions away from their normal place of residence, with the intention of gathering new information and experiences to satisfy their cultural needs". The same author says that cultural tourism represents "all movements of persons travelling to experience culture through cultural heritage attractions, art and culture events, art, and drama away from their normal place of residence" [16]. Adams [17] describes cultural tourism as "leisure travel for the purpose of personal enrichment", i.e., a much-wanted exploration and quest for something new. Local authors explain cultural tourism as a form of tourism which includes various historical, artistical, religious, ethnic, sporting, recreational, etc. content [18]. According to some authors, cultural tourism is about learning, experience, and recognising resources and activities of other cultures [19]. The World Tourism Organisation also provides a definition of cultural tourism as "movements of persons for essentially cultural motivations such as study tours, performing arts and cultural tours, travelling to festivals and other cultural events, visits to sites and monuments, tending to raise the cultural level of the individual and giving rise to new knowledge, experience and encounters".

All this leads to the conclusion that the concept of cultural tourism encompasses a broad range of material and spiritual dimensions of culture. It includes a multitude of activities such as tours of cultural heritage sites, historical sites and monuments. It additionally includes exhibitions and concerts, participation in traditional customs and festivities, learning about local gastronomy, learning about the lifestyle of local people, etc. [20]. Cultural tourism offers possibilities of learning about different cultures through hands-on experience of such cultures' values and heritage, this possibly making cultural heritage the main drive of tourism industry in Europe. Thorburn [21] deems that Europe's cultural heritage is one of the oldest and most significant generators of tourism, which has to date kept a central role in the European tourism industry, while Bernandini [22] concludes that cultural tourism, in a broader sense, deserves to enjoy preferential attention as a special field of development policies.

Cultural tourism poses multiple challenges, this fact making it very complex. There are also various aspects underlying it (economic, tourismological, educational, and organisational), which define it in different manners (see more in: [23]). Also, to be able to understand it more clearly, Csapo [24] has made a distinction between the most important forms and elements of cultural tourism which are thematically grouped in accordance with desired activities, such as: tourism based on cultural heritage, cultural thematic routes, cultural city tourism, ethnic tourism, events and festivals, religious tourism, and creative tourism.

3. POTENTIALS FOR DEVELOPING AND IMPROVING CULTURAL TOURISM

The Municipality of Prijepolje, in which the Mileševa Monastery compound is situated, possesses diverse and versatile cultural and natural values. Tourism is subject to continuous change, hence it is necessary for it to be well-organised, but what is also required is to strive strongly to enhance and improve our own potentials. Potentials have been recognised by the local self-government and identified as part of relevant documents describing plans for strategic development. The Tourism Development Strategy defines 18 prioritised tourist destinations based on the criteria of infrastructure and suprastructure resources that have been built to date, availability and realised tourism-based turnover, all of these elements being relevant in terms of creating a full range of tourism products. With its cultural and natural content, Prijepolje belongs to the Tourist Region of West Serbia. Bearing in mind its rich cultural and historical heritage, nature attractions, a large number of highly appealing tourist destinations and sites that are located in a small area, tourism represents one of the industries with the strongest potential. To use comparative advantages this region possesses, it is necessary to have a well-devised plan for the development of tourism.

In regards to tourism potentials, this area is rich in cultural and historical heritage. The area used to be at the crossroads of different cultures and civilisations, caravan routes crossed this region, as well as pilgrims. The region stands for a kind of tourist attraction where cultural-historical and nature motifs permeate (the Mileševka River canyon, Mileševa Monastery, the mediaeval town of Mileševac, Sava's hermit cells, the Hisardžik mosque, Sopotnica River cascades, etc., the slopes of Mounts Jadovnik and Zlatar). Apart from the Mileševa Monastery, as the most significant cultural and religious monument, there are some other cultural monuments that must be mentioned due to their importance and value (the Church of Saints Peter and Paul, the Church of Basil of Ostrog, the Church of the Davidovac Monastery, the Church of the Kumanica Monastery, the Catholic church in Prijepolje, the Ibrahim Pasha Mosque in Šarampovo, and the "Big" or Mahmut Bey Mosque). We should also note some cultural structures that commemorate several events from WWII (the Boško Buha Memorial Centre in Jabuka, the ruins of the Partisan hospital, the 4th December Memorial Complex, the Rushdia Museum). The most significant forms of tourism feature the following: cultural-historical, picnic tours, adventure tours, transit tourism, agritourism, there is also religious tourism, rural tourism, tours that focus on special interests and recreational activities in the pristine environment (cycling, trekking, hiking, geo-tours, etc.), cultural events and festivals, etc.

According to the Spatial Planning of the Special Purpose Area document, spatial organisation of offered tourism products and services will be organised in the following tourism zones: zone of

cultural and religious tourism (the Mileševa Monastery, with the mediaeval town of Mileševac, Sava's hermit cells, the Hisarsdžik Mosque), zone of the Special Nature Reserve of the Mileševka River canyon, zone of the Natural Monument Sopotnica Cascades (with a visitor/educational centre, and recreation infrastructure /marked mountain and cycling tracks), and zone of rural tourism [25].
The strongest opportunity for developing and improving cultural tourism of the Mileševa Monastery is to create an integrated tourism offer for this area in which natural and cultural-historical motifs are intertwined, which as such can attract both local and foreign tourist as well as individuals who enjoy recreational activities. It is necessary to encourage development and create thematic mountain and trekking trails that promote cultural-historical heritage of religious structures, archaeological sites, the Mileševka River canyon, Sopotnica River cascades, and other natural values (geological heritage and geodiversity). Development of educational tourism should also be encouraged through presentations and popularisation of cultural and natural values of protected areas (via publications, collaboration with tourist boards, mountaineering and other associations, organised visits, etc.). Also, it is necessary to make use of a reasonably good accessibility to this area via the IB-class state road and international railway, as well as the vicinity of urban centres, such as Prijepolje, Priboj, Nova Varoš, tourist destinations Zlatibor and Zlatar, but also other attractions in the region surrounding this area, as well as some centres in the neighbouring Republic of Montenegro.

4. TOURIST VALORISATION OF CULTURAL HERITAGE

Cultural heritage of a country and its local community is important potential that can be exploited for tourism purposes. With tourist offers of cultural heritage, tourists are provided access to tangible and intangible heritage that has a huge impact on a diversified range of overall tourism offer, but at the same time generates higher revenue in a particular tourist destination [26]. Tourist valorisation of cultural heritage allows for a promotion of cultural heritage as well as economic shift in terms of independent revenue generation of cultural goods [27]. By harmonising tourism and cultural heritage, we encourage a more adequate management of cultural goods, provide a better quality of use, consequently increasing regional and local tourism demand [28].
The main prerequisite for successful tourism and a stronger appeal of the Mileševa Monastery and the surrounding area is a well-devised strategy for tourist valorisation of cultural heritage. Tourist valorisation is an integral part of tourism-geographic research of relative natural and anthropogenous values that are of significance for the development of local and foreign tourism in a location, tourist destination, region, or country. It stands for a complex assessment of mentioned values and it is significant for the science of tourismology and operational capacities [29:5]. The concept of tourist valorisation refers to the appeal of tourist destinations with a broader social significance, which may result in financial benefits, but with the significance they bear, they represent benefit in themselves. Tourist valorisation and tourist appeal are directly connected. This as a rule means: the higher the appeal, the higher the value [30].
For the purpose of performing tourist valorisation of the Mileševa Monastery compound and the surrounding area, one of the options is to apply the quantitative-qualitative method. This is one of the most commonly used methods since it gives ample leeway in terms of research and assessments. It is based on six indicators [31]: tourism-geographic position, artistic values, cultural-historical significance, tourist value of the ambience, tourist appeal and recognisability, design, furnishing and fittings of facilities and their compatibility with tourist potentials, all of which are relative to the assessment of tourist value of complementary motifs at the same destination, for the purpose of determining complementarity or competitiveness of other motifs and consolidating tourism offer.
The result of tourist valorisation stands for tourist value of cultural goods. Based on the above-mentioned indicators, valorisation of said elements is carried out for the purpose of establishing an overall tourist value. Valorisation may be performed with the application of the comparative method [32], it being based on: a comparison of tourist attractions that belong to the same type, establishing elements based on which it will be possible to perform valorisation and comparison. The system of

comparison takes into account the most strongly acknowledged motivations and the application of the principle of complementarity in the form of valorisation and motivations of other types.
On the basis of results to be obtained via tourist valorisation, it would be possible to appropriately rank the Mileševa Monastery and the surrounding area and thus in multiple ways assist and contribute to the implementation of planned cultural tourism in this area and a wider area alike. It would additionally contribute to making cultural tourism more marketable in the local and international tourism markets. This has a decisive role since structures, sites, etc. with the highest determined tourist value become prioritised, especially in terms of investment in accommodation facilities, and hospitality facilities in general, as well as investment in infrastructure facilities. Once analysis has been performed and tourist value of a particular structure has been established, further directions for the development of tourism will be defined. A noteworthy fact is that the use value of tourism facilities, sites, etc. is not a clear economic indicator, but rather a basis for applicative action, after which economic effects ensue [31].

5. CONCLUSION

The Mileševa Monastery is one of the most significant cultural-social monuments, which reflects the identity of the local community and our country. We should note the fact that there is no real cultural tourism at the Mileševa Monastery and the surrounding area. The strongest limitation in this context is that it belongs to cultural goods for which there is no developed programme with a cultural content, nor is there a comprehensive range that includes both cultural and natural values in the surrounding area, which could attract a higher number of both local and foreign tourists. The task and the objective of tourist valorisation of the Mileševa Monastery is to ensure, via evaluation, classification and ranking of tourist values in the market, that cultural tourism becomes self-standing. Furthermore, the objective is to promote and present values of Mileševa's contractive zone, to define the content of tourist stays, improve material furnishings, and adjust to the local environment. Tourism values, along with the views of the local community and visitors alike, do have a rightful place in the tourism market and, each in their own way, contribute to the accomplishment of social and economic effects of receptive tourism. In terms of their number, cultural-historical and artistic importance, monasteries in Serbia account for the most important category in Serbia's cultural heritage. They tell stories of events of historical significance, events that were significant for national identity and culture of all peoples who lived in this region [33]. Therefore, the Mileševa Monastery deserves to be the leader of tourist offer and cultural tourism on a much larger scale than has been the case until now.

Funding for researches presented in this paper has been provided by the Ministry of Science, Technological Development and Innovation of the Republic of Serbia. ref. no.: 451-03-68/2023-14/200006.

Abstract: *In Serbia, rural development is an integral component of the economic, social, and environmental growth of numerous regions. Almost half of the population of Serbia lives in rural areas, which make up even three quarters of the country's territory. Braničevo District has an exceptional natural, social and archaeological potential for the development of tourism. Since the Paleolithic, when some of the Homolj caves were inhabited, through a rich prehistory and antiquity, to the Middle Ages, more than a thousand archaeological sites have been registered in this territory. Furthermore, a number of geographical features, cave systems, river sources, historical sites, monasteries, spas, and other resources continue to be underappreciated. The sights of the city of Požarevac – the memorial park Čačalica and the Ljubičevo stud farm – are of special value. According to global trends, rural tourism can significantly reduce poverty and improve quality of life. In this paper, researchers attempted to examine the variety of tourist attractions offered in the Branievo district and to bring attention to less known locations as potential hotspots for tourism and rural development.*
Keywords: Braničevo District, rural development, tourism, arhaeological sites

1. RURAL DEVELOPMENT OF BRANIČEVO DISTRICT

Rural areas can be characterized as places where many people spend most of their working time on farms, with abundant and relatively cheap land, and with high transaction costs associated with remoteness and poor infrastructure to most of these areas [1]. There is a long tradition of classifying rural areas according to agroecological potential, based on the analysis of soil attributes, landforms and climate. In most rural areas, agriculture is the main source of income for the population. One of the pillars of rural development and one of the key sectors with a strong potential for diversification of the Serbian rural economy and rural development is sustainable rural tourism. International trends show that rural tourism has a key roleplay in rural communities in raising the quality of life, social struggle and economic inequalities and degradation. Rural areas can be characteredcan be described as the combination of natural and cultural landscapes, natural and cultural heritage, and activities developed by the local population [2]. For the overall rural development of the Braničevo district, in addition to infrastructure projects, it is necessary to pay more attention to the rich cultural heritage that this region abounds in. Given that the tourist destination is the basic element of tourism development [3]. Braničevo District has a high potential to include tourism as an additional or main

[5]dsaler@atssb.edu.rs

source of income for the population of this region, in addition to agriculture as the primary activity in Serbia.

The Branicevo District is is one of 30 Serbian districts [4]. located in its northeastern part (Figure 1) and covers an area od 6,864km2 [5]. It include eight municipalities (Municipality of Veliko Gradište, Požarevac, Golubac, Malo Crniće, Žabari, Petrovac, Kučevo, Žagubica). It has about 250,000 inhabitants.The seat of the district is the town of Požarevac, a well-known crossroads, through which numerous roads still run today. The cultural sights of Požarevac are: National Museum (the first built after the Belgrade Museum), Tulba Ethnopark (unique museum in nature), Picture gallery of Milena Pavlović - Barili (famous Surrealist painter and poet). The city is also recognizable for the Čačalica Memorial-park as well as the Ljubicevo stud farm (one of the oldest and most famous stud farms in Serbia). In addition to the sights of the municipality of Požarevac, the sights of other municipalities located within the Braničevo region are Viminacium, Belovode, Ram fortress, Golubac fortress, Gornjak and Tumane monasteries, the Kalište, the Margum itc. All this shows of the enormous potential of this region, which is located among the great rivers along which cultures have changed over the centuries. The Braničevo district is home to the largest number of archaeological sites in Serbia [6]. Lower areas occupy the north-western part, the valleys of the rivers Danube, Velika Morava, Mlava and Pek. The biggest part of the area is covered by hills and lower mountains (200–1000 m), of which the highest is Mt. Beljanica (above 1000 m), occupying the southeastern part of the province [7].

2. VIMINACIUM – THE HEART OF THE ROMAN UPPER MOESIA

Viminacium is an archaeological site and a cultural property of exceptional importance for the Republic of Serbia and specially for the Branicevo District. This archaeological site is located on the right banka of Mlava river, near the Danube, in the field of Stari Kostolac and Drmno villages [6]. This ancient Roman city and military encampment covers an area of 220 hectares in the inner city, extending to over 450 hectares in the wider city region [8]. It is located today under cultivated arable land and artifacts and fragments of objects from Roman times are scattered in the furrows of agricultural fields. In the 2006 Viminacium Archaeological Park was established and 2009. entire area of the fortified ancient city and legionary fortress, along with its close surroundings, was defined as a site was borders and protections regimes. Located on cultural routes and the most important European corridrs, the Viminacium Arhaeological park is the main promoter of tourism development in the Požarevac area today [9]. The old Roman city of Viminacium was created in the period around

the new era, the Roman culture flourished, with the Roman conquests. The peak of that period was when Viinachium was the capital of the province of Upper Moesia. What is important for the archaeological heritage of Braničevo is the fact that Viminacium was the starting point of the great road that led to Constantinople. The archaeological site "Viminacium" located near the church has been attracting a lot of attention from archaeologists and art lovers from all over the world in recent years [6]. On the banks of the Danube in Kostolac, a port for large passenger ships, established in 2006, transports tourists from all over the world [10]. Given that the popularity and archaeological importance of Viminacium is still in its infancy, it is expected that with the continuation of the excavation of this imposing locality, the development of this rural area will flourish.

3. BELOVODE - THE LARGEST SITE OF VINČA CULTURE IN EUROPE

The prehistoric archaeological site of Belovode, from the time of the Vinča culture, dates back to the 5th and 6th millennium BC and is one of the largest sites in Europe from that period. It is located in the territory of the municipality of Petrovac na Mlava, in the atar of the village of Veliko Laole, it covers an area of 100 ha. The settlement existed from 4500 BC to 3800 BC when it was destroyed by fire. According to numerous indicators, copper ore was smelted and processed for the first time in European history in prehistoric Belovode, so this locality is considered the cradle of European metallurgy [6, 11,12].

4. KALIŠTE - ROMAN FORTRESS IN STIG PLAIN

Near today's village of Kališta, in the municipality of Malo Crniće, on the right bank of the river Vitovnica, there are the remains of a large Roman city, which was recorded on old Roman maps as Municipium, is preserved. Today, this city is covered by layers of the fertile Stig plain. The city was eighteen Roman miles from the ancient metropolis of Viminacium, located at the confluence of the Mlava River and the Danube. It was located on the route of the main Roman road that connected Viminacium with Nis (ancient Nais), the hometown of Emperor Constantine. The traces of that Roman road can still be followed today through Stig from Stari Kostolac, through Drmn, Bradac, Bratinac, Salakovac, Crnić, Batuša and Kališta. Numerous cult icons made of stone and metal were found in the City itself, which testify to a developed spiritual life. In the wider area of the site, Roman cemeteries were discovered, in which a variety of archaeological material was found, which testifies to the complex funeral rituals and the lively trade connections of this part of the Empire with other parts of the empire. The archaeological complex in Kališta is still waiting for researchers who will extract the gems of the past from the depths of the centuries [6].

5. MARGUM - ROMAN CITY

The Roman city of Margum is located near its confluence with the Danube, near the present-day village of Dubravica. During the time of the emperor Marcus Aurelius, Margum was given the status of a municipium, and numerous objects from prehistory, antiquity and the Middle Ages were found in German. A large amount of jewelry, made of gold, silver, bronze and semi-precious stones, has been found at the Margum site. Throughout history, cultures have changed in Margum, from prehistory, antiquity, to the Middle Ages [6].

6. THE FAMOUS RAM FORTRESS

The remains of the medieval Ram fortress is located in the village of Ram on the Danube bank, between Veliko Gradište and Kostolac, near an erstwhile, Roman military camp and urban settlement of Viminacium.The fortress was built by Turkish sultan Bajazit II in 1483 and possessed a major strategic importance from the ancient times [13,14] and is one of the best examples of military architecture from Turkish period [15]. Ram fortress had great strategic importance until 1521, when

the borders of the Turkish empire expanded far to the north.In 2019, this fortress was restored and thanks to it, the small town of Ram, located on the right bank of the Danube, regained its tourist importance.

7. THE GOLUBAC FORTRESS - WHERE THE DANUBE IS THE WIDEST

Despite the fact that the Golubac region is positioned in the widest part of the Danube and has a prominent medieval Golubac fortress at the entrance to the Đerdap gorge, the largest on the river, the population and development of this region have been declining for decades. The municipality has lost more than 55% of its population since the end of the Second World War [16,17,18]. The Golubac fortress is one of the best-preserved Serbian medieval fortresses and one of the most beautiful and famous on the Danube. Under it, the remains of the Roman road are still visible today. This fortress was built on a place of strategic importance, where even traces from prehistory and antiquity have been preserved [6]. It is presumed that the fortress was built in the 14th century on the earlier military-defensive ancient Roman fortification, whose visible remains are at the base and in the immediate surroundings of the fortress. Golubac Fortress was proclaimed a cultural monument of exceptional importance in 1979, under the protection of the Institute for the Protection of Cultural Monuments [19]. Taking in account the previous facts regarding natural and cultural heritage in Golubac area, the potential for its use in tourist economy is obvious.

8. GORNJAK AND TUMANE MONASTERIES - ORTODOX SHRINES

In recent years, with the increasing popularity of religious tourism in the world, religious objects of the Republic of Serbia have gained importance [20]. Ždrelo Monastery, later called Gornjak, is located on the banks of the Mlava, under the steep cliffs of Ježevac Mountain, and is the endowment of the Serbian Prince Lazar. It was built in the period 1376-1380. Due to its specific geographical position, in the Homoljska region, located a little off the main roads, the features of old culture, folk customs and traditional architecture have been preserved. It is considered that the history of the monastery is also the history of this region - it was demolished and burned, its valuables were looted, but it sprung up again [6]. The Tumane Monastery is located in the Braničevo diocese, 9 kilometers from Golupac, in a picturesque area area, surrounded by a forest, in front of which the clear river flows Tuman river. It is suitable for the development of not only religious tourism, but also other types of tourism such as: geotourism, event tourism, excursion tourism, etc. [21].

9. KRUPAJSKA AND MLAVA RIVERS - THE MOST BEAUTIFUL SOUND OF HOMOLJE

The sources of two rivers in the Braničevo region are particularly interesting: the source of the Mlava river, in Žagubica itself, at the place where the northern section of Beljanica descends into the Homoljska basin, and the source of the Krupajska river, about 35 kilometers from Žagubica. Both springs were protected in 1979 as nature monuments of national importance. The Krupajska river once flowed out of the cave with a strong force accompanied by a roar, and today it is blocked by a concrete constitution for the needs of the mill that is still working today. As a result, a pond was created in front of the cave partially submerged her opening. Near the source is a strong thermal spring with a water temperature of 26.5˚C [22].

10. CEREMOŠNJA CAVE - THE PEARL OF THE HOMOLJE MOUNTAINS

The region of Eastern Serbia is a highly dominant karst terrain with numerous geological and geomorphological features, especially caves. Ceremošnja cave is located in the Homolje mountains, of eastern Serbia, which are parts of the larger Carpato-Balcanian mountain range. The cave is divided into five halls, with the Strugar Stream running through it. The Strugar Stream connects the Ceremosnja Cave with the nearby Bigar Cave. In addition to these two caves, the Ravnistarka cave

also contributes to the speleological wealth of this region. The speleotourism potential of these caves still remains fully unrevealed. [23, 24].

11. MEMORIAL PARK ČAČALICA - GREEN URBAN LUNGS OF POŽAREVAC CITY

Memorial Park Čačalica which was originally planned and designed in memory of patriots who laid their lives for the people of Braničevo District during the WWI and WWII, has become a green oasis of Požarevac city [25]. In the last few decades Čačalica with 26.6 ha of green areas and with over 28.000 of trees and undergrowth has been providing the inhabitants of Požarevac with clean air and at the same time it has been preserving plant and animal diversity [26]. Today, Čačalica is a real small arboretum which 17 species of tall conifers, 6 species of low and ground cover conifers, 70 tall medium-sized deciduous trees, 24 deciduous shrubs, 3 evergreen shrubs and 3 roses [27]. The ecological association "Friends of Čačalica" has big conceptual plans for its arrangement as a Mountain house, recreational center and observation point, drainage canals restoration, aquatic biotopes preservation and plant diversity protection [26].

12. LJUBIČEVO STUD FARM - THE PRIDE OF THE CITY OF POZAREVAC

Ljubičevo stud farm is one of the oldest in the territory of Serbia. It is located on the right bank of the Great Morava, 5 km from the town of Požarevac. It was founded in 1860 by order of Prince Miloš. It was created with the aim of improving horse breeding from the best horse breeds. Later, Prince Miloš's son Mihailo named this 300-hectare property "Ljubičevo", after his mother, Princess Ljubica. The stud farm is connected with the tourist and sports event "Ljubičevské Equestrian Games", a traditional event that is held every year at the Požarevac Hippodrome in the first week of September and which regularly gathers a large number of domestic and foreign visitors [28].

13. CONCLUSION

Rural tourism is one of the main branches of rural development. It can be said that rural tourism in Serbia is still in the development phase. In addition to the continuous presentation of new products and rural tourism destinations, it is necessary to work on the marketing of the already known ones. Braničevski region certainly represents one of the largest archaeological sites in the world, but on the other hand, insufficiently used rural tourism inevitably leads to weak rural development in this region. Greater promotion of both the natural and cultural assets is necessary because they still represent its greatest untapped potential.

PROTECTION, DEVELOPMENT AND MANAGEMENT IN A PROTECTED NATURAL ASSET - ANALYSIS OF THE PETNIČKA CAVE

Marija Perić[1], The Academy of Applied Technical Studies Belgrade
Ben Mladenović[2], The Academy of Applied Technical Studies Belgrade

Abstract: *The tourist potential of the a protected natural asset Petnička cave is an obvious. The imposing long subterranean karst relief from with the Banja spring, and significant archaeological traces from the younger stone and bronze age represent a well-known tourist destination in the wider area of the Valjevo mountains. Staying in a part of preserved and unpolluted nature creates suitable conditions for the development of scientific, educational, sports, recreational, cultural, transit and excursion tourism. The paper used the index of recreational potential and rating, which is a suitable for the geoecological evaluation of landscapes that are important for tourism, sports and recreation. The essence of this method is that when valuing the Petnička cave we have an initial value in points to which points are added or subtracted that express the quantitaive and qualitative characteristics of the protected biological property. The cave is a classified based on the obtained balance of points into from one of 10 categories (the most valuable part of the landscape to extremely unfavorable parts). It is determined on the basis of physical characteristics, aesthetics, educational and scientific values, carrying capacity of accommodation, and accessbility of space. Based on the research results, the Petnička cave has a category value of 152 points and is considered the most valuable part of the relief.*
Key words: Protected natural asset, Index of recreational potential and rating, Petnička cave

1. INTRODUCTION

The Petnička cave with the hot spring Banja is among the first speleological objects in Serbia that were the subject of geomorphological and archaeological research by many researchs. The first written document about this cave can be found in the works of Joakim Vujić, who visited the cave in 1826, and already noticed the intermittent character of the hot springs and "figures of animals" [1,2,3]. After him, numerous authors describe more detailed research and systematic presentations in their works: Vladimir Karić [4], Jovan Cvijić [5], Branislav P. Jovanović [6,7,8], Kuzmanović [9], Milojević [10] and Kličković [11,12,13]. Vrelo Banje, due to its values and specificity, was included in the Geoheritage Objects Inventory of Serbia (2005), within the list of Hydrogeological objects. In the immediate vicinity, significant archaelogical traces were discovered that testify to the exictence of a human settlement during the stone and bronze ages. Water phenomena are an integral part of the natural environment, and their representative forms are geoheritage objects. Based on previous experiences, considerations, and studies in the available literature, the hydrological properties of numerous geolocalities have been incompletely processed and evaluated as a separate or unique phenomenon. In the Inventory of Geoheritage Objects of Serbia, hydrological phenomena are classified into two groups: geomorphological and hydrogeological. Based on this, the idea to

[1] mperic@atssb.edu.rs
[2] bmladenovic@atssb.edu.rs

create a new independet group, which would bear the commom name - Objects of hydrological heritage [14].
The Natural Monument "Petnička cave" has a total area of 8.10 ha, of which private property (7.82 ha), state property (0.25 ha), and village property (0.03 ha). It was protected for the first time in 1950. It belongs to the second category of a protected area of great importance, and according to the classification of the International Union for Conservation of Nature (IUCN) to the third category of natural monuments or phenomena [15].
The Petnička cave is located southeast of the town of Valjevo (7.5 km) in Valjevo Podgorina, on the very border of the villages of Klinci and Petnica. The speleological system is presented with two entrances and the total length of the examined channels is about 580 m. It consits of two main speleomorphological units, which are determined according to their position and size: Lower (Big) and Upper (Small) caves. With the expansion of the urban settlement, in partially becomes a part of the new urban entity, but it has still preserved the characteristics of a village/rural setllement. It was created by the erosive work of the underground flow of Banja, i.e. the abyssal part of the Zlatarski stream, which in the first stages of the morphological evolution of the cave stood out at the opening of the Upper cave, and then descended with all its erosive force towards the surronding terrain [16,17]. A significant role in the morphological shaping of cave channels was played by the processes of collapsing the ceiling and walls. This is how the vigleds in the Concert hall were created, although according to Branislav P. Jovanović [6] they are of a combined way of origin. He believes that the wiglleds originally represented the point of emergence of the underground river and that they got their present appearance and physiognomy through the later processes of flooding. During that period of construction, two opposite processes operate simultaneosly in the channel: erosive and accumulative. On the side, rolling away rock pieces and blocks, the cave channel grows in width and height. On the other hand, rock blocks and rock fragments occupy more space on their new bed than on the primary bed, and because of this, the cavity of the channel is reduced and there is backfilling. All together with the construction of saliva, stalactites and stalagmites and the introduction of other material from the surface of the terrain threatens to bury the cave channel [6].

2. NATURAL AND ANTHROPOGENIC TOURIST VALUES

About 400 m from the entrance to the Petnička (Upper) cave, you come across the gate of the newly built water factory (Vujić). To the right of the main entrance to the cave is the Church of the Assumption of the Blessed Virgin Mary. On both sides are arable fields under corn, wheat and small vegetable/orchards. The slopes of the limestone elevation of the Osoja hill, which rise to the south of the cave, are covered with bushes and forest. The banks of the river Banja overgrown with three trunks, and on the left side there is a captured spring for the needs of the Research Station Petnica. The small bridges were built, the first is at the very entrance to the vaulted part of the Lower cave, and the second is downstream from the water mill. Nearby there is a board with a small guide about the cave and a staircase leading to the Upper cave. An archaeological site was discovered in that place, which was protected by the state in 1949 [17].
In 1988, the Petnička cave was arranged for tourist visits. A pedestrian path with a total length of 550 m was built, of which 414 m is in the cave itself. The path enables a circular tour of the cave from the entrance to the Lower cave to the Concert hall, then through Visoka to Medveđa hall, then to the exit from the Upper cave, in order to reach the starting point of the Lower cave through the steep slope of the hill. The narrowing formed between the area of the Lower cave and the Concert hall is protected by metal gates to prevent air flow. In the meantime, the cave and the immediate surroundings were neglected and devastated under the influence of the anthropogenic factor. The importance of revising the protection of Petnica cave is reflected in the preservation of natural/primary and cultural/created values, the affirmation and presentation of this space based on the principles of coordinated development for wider social communities, the scientific public and other interested parties [17,18].

The Natural Monument "Petnička cave" includes the second protection regime. The following activities are prohibited: entering the cave without a proper permit (a certain number of tourist/visitors), breaking, removing and damaging cave jewelry (stalactites and stalagmites), destroying cave fauna and flora (biodiversity), building infrastructure/superstructure, industrial, commercial, residential and tourist facilities, use of toxic chemical substances (in liquid and solid state) of oil derivatives and other dangerous substances, change of the existing morphology/physiognomy and physical - geographical features of the terrain, hot springs of Banje and capturing of springs for water supply needs of individual households. The manager of the protected natural property "Petnička cave" is the hotel tourist joint - stock company "Sloga" AD Valjevo, which through its activities so far has shown the ability to handle business.

The torust potential of the protected nature area is evident. The underground karst form (cave/pit) of intersting morphology/physiognomy and considerable/imposing length with the hot spring Banja, signifacant archaeological traces from the younger stone and bronze age represent a well-known tourist origin of the wider area of the Valjevo mountains. Staying in a part of preserved and unpolluted nature near the district center of Valjevo creates favorable conditions for the development of scientific, educational, sports, recerational, cultural, transit and excursion tourism. What will really be the socio-economic effects of the development and the concept of sustainable use of the area of the Natural Monument "Petnička cave" depends on the interests, motivation, engagement and ability of the local community, i.e. the resident population to unerstand the availability of an area of exceptional natural features (authenticity, recognition and representativeness). If cooperation, connection and engagement are absent, only people from science and the profession, casual visitors and local (domicile) population will known the Petnička cave. From the hospitality facility "Vujić", which is located in front of the entrance to the Lower cave, during the season (spring, sumer and autmun), when visits are more frequent and a larger number of visitors come, the existing infrastructure cannot fully meet the needs and demands of tourists. It is necessary to build similar of larger capacities at a slightly greater distance from the hot springs of Banja and cave. This would not endanger the aesthetic part and damage the natural environment of the Nature Monument. Due to its morphological, physiognomic, physical, geographical and hydrological characteristics, the cave represents an underground form of karst relief that is of particular importance for tourism, relaxion, nature conservation, science and education enthusiats (in the immediate vicinity of the Research Station Petnica, which is known outside border of our Earth).

Paleontological/geomorphological and archaeological traces found in its immediate vicinity/surroundings represent the cultural identity and authenitcity of this area. The assessment of the value of a protected natural asset is carried out on the basis of the main characteristics (originality, representativeness, rarity, diversity, integrity, attractiveness and preservation), function and importance. Petnička cave and its immediate surroundings represent a unique combination of all the mentioned features and according to most criteria have a high ranking in the evaluation scale. The concept of protection and sustainable development of tourism of the Natural Monument "Petnička cave" is based on the maintenance and improvement of primary characteristics, landscape features and coortinated/balanced "ecological" development. The basic functions are: educational, health/healing - recreational, scientific - research, tourism and development.

The *educational function* is based on raising the awareness of the population (local/domicile) about the importance of the protected area of nature and its potential, i.e. resources (natural and anthropogenic).The most effective way is the establishment of the Center for Sustainable Development, which is locted in the town of Valjevo and represents the training of the local (domicile) population and their active involvement in protection, promotion, marketing, formation of tourist services/content and sustainable management through education and educational programs (workshops, fairs, congresses/conferences). The *health/healing - recreational function* implies a stay in a preserved part of nature that possesses natural and cultural values i.e. primary and created. Favorable climatic characteristics (climatic elements and factor) are a condition for the development of sports and recreational tourism (visits by speleologists, adventures and enthusiasts) and

excursions/transit tourism. The *scientific research function* of a protected natural asset should represent a polygon of complex scientific research with the aim of tourism valorization/evaluation and monitorin of natural and created values. The *development function* is detrmined by the boundaries of the protected natural property and the established protection regime, which are in accordance with the preservation of natural landmarks.

3. METHODOLOGY IN WORK

The application of general methods will make it possible to determine the interdependence of tourism and the environment, that is, the connection between autochthonous (untouched) nature on the one hand, and tourist trends and their consequences in the study area itself, on the other hand. Tourism is significantly more than any other economic (branch) activity conditioned by the quality and preservation of the environment, i.e. natural and anthropogenic tourist values as the basic motives and indicators for attracting tourists and presenting on the tourist market. The analytical method consists in the mental disassembly of complex forms of knowledge into their simple and simple constituent parts, contents and elements. It includes the analysis of the existing bibliography and reference literature (domestic and foreign) related to tourism in protected natural resources and includes criticism of existing literature and work procedures, as well as the determination of elements/factors that are significant for solving certain problems. The synthesis method is the final stage or part of the complete (overall) analytical-synthetic method of knowledge. A closer connection between analysis and synthesis consists in the fact that analysis and synthesis not only complement each other, but they also pass into each other, that is, one cannot do without the other. The synthesis method defines the links, connections and relationships between the analyzed phenomena processes in the studied area and in this way conclusions are formed and proposals are made about the role of protected goods in the overall tourist offer of the northwestern part of Central Serbia.
The index of recreational potential and raiting is a method that is suitable for the geoecological evaluation of landscapes that are important for tourism, sports and recreation/relaxation. The essence of this method is that when evaluating the Petnička cave, we have an initial/base value in points which points are added or subtracted that express the quantitative and qualitative feautures of the landscape, i.e. the protected area. The cave is classified, based on the obtained balance of points, into one of 10 categories (the most valuable part of the landscape to extremely unfavorable parts) [19]. The recreational potential and bonitation index method is based on geological, geomorphological and hydrological data.

Table 1. Evaluation of Natural Monument "Petnička cave"
Source: *Authors, 2020*.

Starting points 100			Assessment category
Physical - geographical (natural/original) characteristics Petnička cave	Length of the cave in m/km	10	
	Terrain morphology and physiognomy	10	
Aesthetic, educational, scientific and educational characteristics	Cave jewelry (stalactites and stalagmites)	8	
	Other (soils, wiggleds, ceilings, water regime, climatic characteristics)	8	
Carrying capacity	Total number of tourists who do not endanger the protected nature object/limited number of tourists/visitors	9	
Accessbility to the main entrance and auxiliary entrance	passable/impassable ground	7	
Access to the cave	Distance from national/regional/local road	–10	
	Cave slope/terrain configuration	5	
	Access/arrangement/information boards (regional/local path)	5	
Total points		152	10

The recreational potential and bonitation method is determined based on physical characteristics, aesthetics, educational, scientific and educational value, carrying capacity, accessbility and availability. The Petnica cave has a category value of 152 points and is considered the most valuable part of the relief. Based on a survey of visitors and local residents, it also has significant aesthetic values (stalactities and stalagmities, see the spring Vrelo).

4. CONCLUSION

Speleotourism represents an affirmative/specific type of tourism, which includes visiting underground facilities, organized and unorganized caves. Since ancient times, caves have an extremely strong attractive power for people. It lies not only in their appearance and beauty, but in the totality of the subjective experience of each person individually. Organized visits to caves in Serbia, and thus the begininngs of the development of speleotourism, date well before the first arrangement of caves for tourist visits [20].

Petnička cave represented solid tourist potentials that must be valorized and promoted at the national, regional and local level (fairs, seminars, conferences and congresses). Greater investment in infrastructure/superstructure and participation in the development of projects, strategies, studies and spacial plans of special purpose areas is necessary. In order to clearly define the goals and objectives of the planned development of tourism of the protected natural asset Petnička cave, the concept of sustainable development (ecological, socio-economic and cultural) is apllied. Through training, improvement and education programs, it is important to inform the decision makers about preoorganized (program and plan) ecotourism, because otherwise due to unplanned, irresponsible and not excessive lack of interest, the degradation and devastation of the landscape, i.e. discruption of the natural environment, which is impossible to bring to the primary/base state. The positive experiences of protected natural resources should represent an example for the future development of environmental tourism in Petnička cave, which must be planned long-term on an integral basis and adapted to the characteristics of the environment.

Activities to protect the natural environment should be seen in the following priorities: measures to prevent and suppress harmful disturbances, degradation, devastation in natural environments and the wider environment, maintenance of natural resources and their rational, realistic and objective use. As a result, it is necessary to take a closer look at the problem and come up with solutions and conlusions for each appropriate space individually. Of course, the best protection is the one that causes the least degradation and devastation of the area, i.e. air, water and soil pollution, but the principle of the concept of active protection can be implemented and applied during more intensive tourism development, especially in the planning phase of tourist flows, shops and activities [21,22].

THE FAUNAL DIVERSITY OF MEMORIAL PARK ČAČALICA

Marija Perkunić[1], The Academy of Applied Technical Studies Belgrade
Tatjana Sekulić[2], The Academy of Applied Technical Studies Belgrade
Markola Saulić[3], The Academy of Applied Technical Studies Belgrade
Vladanka Stupar[4], The Academy of Applied Technical Studies Belgrade

Abstract: *The Previous studies on the fauna diversity were included only the identification and determination of the presence of phytophagous insects based on the traces on leaves and tree bark. Forest litter was not investigated. To gain a better understanding of the fauna diversity this study included the research which was conducted on forest litter and the surface layer of soil in order to determine the presence of living organisms in this forest stratum because this was the only way to obtain a more comprehensive picture of the biodiversity of this microhabitat. As the aim of this Paper is to collect and analyze various species of invertebrate and vertebrate fauna in order to create a preliminary list of species present at several locations within Memorial Park Čačalica, the scientific material was collected by using various research methods. Identified species that belongs classes Insecta, Diplopoda, Chilopoda, Malacostraca, Gastropoda and Aves are shown further in this work.*
Keywords: Memorial Park Čačalica, Faunal diversity, Biodiversity, Species

1. INTRODUCTION

Biodiversity is a concept that, since its inception until today, has been attracting increasing attention, not only from the scientific public, but also from a wider perspective. Thanks to negative phenomena such as "erosion of biodiversity", the protection and preservation of biodiversity represent a necessary need of humanity as an irreplaceable resource that ensures the survival of the human species. Despite the negligence towards the environment in general, it is nature that makes every effort to restore balance in its system. The authors discover a place in the immediate vicinity of the city of Požarevac where faunal diversity develops spontaneously - the Memorial Park Čačalica. Memorial Park Čačalica, which was originally planned and designed in memory of the patriots who laid down their lives for the residents of Braničevo District during the I and II WW, has become a green oasis over time. For the last several decades, Čačalica has provided the citizens of Požarevac with clean air and at the same time preserves plant and animal diversity.

2. THE FAUNA OF MEMORIAL PARK ČAČALICA

2.1 Materials and methods

During September, October and November in 2022, analyses were conducted at several locations at Memorial Park Čačalica in order to collect samples for determining the diversity of fauna. Images of the locations including microhabitats and coordinates are shown further in this work. (Figures 1&2).

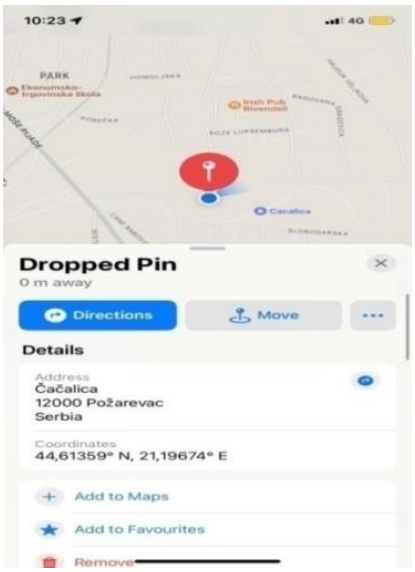

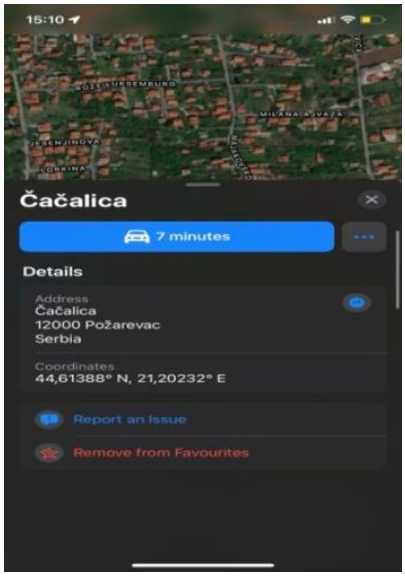

Figures 1.&2. Location coordinates where the research was conducted
Source: Original author's work

Faunistic quantitative and qualitative parameters for assessing species diversity include the following: Richness (S), Rarefied richness (ES), Abundance (N), and Shannon-Wiener diversity index (H') [1]. An inventory of fauna diversity is carried out using the relative method and the number of animal populations in a certain transect is determined. The micro-, meso- and macrofauna of invertebrates in the forest litter and the surface layer of the soil are collected, and by setting traps with different groups of pheromones and attractants, the species of vertebrates present are determined. Modern methodological procedures for examining biodiversity provide a comprehensive overview of all types of fauna living on Čačalica. The scientific material was collected by using various research methods [2, 3, 4]:

1. Collecting faunistic material manually under the rocks, fallen and upturned trees, in crevices in rocks and cracks in the soil, as well as in other potential microhabitats that could serve as a refuge for invertebrates.
2. Sampling the surface layer of soil together with fallen leaves and vegetation (soil litter) and sieving it through larger mesh sizes on a white background.
3. Setting traps with pheromones – 10-15 traps (plastic cups) were placed about 5 meters apart at each examined location and they were emptied once a month.
4. Using entomological nets in order to collect flying insect groups.
5. Setting traps with various attractants for larger invertebrates as well as vertebrate species.
6. The collected and identified material was preserved in 70% alcohol or 4% formaldehyde.

2.2 The Results and Discussion

The soil fauna as an important component of Earth's biocenosis is extremely rich in most ecosystem types and constitutes a significant portion of overall biodiversity [5].The soil fauna includes macrofauna, mesofauna and microfauna. Spatial distribution of soil macrofauna and mesofauna communities is influenced by both abiotic and biotic factors [6, 7].
Insect identification was carried out according to Mihajlović, 2015; Schwenke (edit.), 1970; Pavićević et al., 2015. After the determination of collected material, it was observed that the highest prevalence of macrofauna representatives from the phylum Arthropoda and Mollusca was found at all examined locations and the species from the phylum Annelida were also collected. Among arthropods, the largest number of species belongs to the class Insecta, with the following orders: Hymenoptera, Diptera, Hemiptera, and Coleoptera. Determination was done at the taxonomic level up to the species level and the results are presented in Table 1.

Table 1. Overview or representatives of Arthropod
Source: Original author's work

Class Insecta	ordo Hymenoptera *Formica rufa*, Linnaeus, 1761 (Formicideae) *Vespa crabo*, Linnaeus, 1758 (Vespideae) *Apis melilifera*, Linnaeus 1758 (Apideae)
	ordo Diptera *Musca domestica*, Linnaeus, 1758 (Muscideae)
	ordo Hemiptera *Aelia acuminata*, Linnaeus, 1758 (Pentatomideae) *Pyrrhocoris apterus*, Linnaeus, 1758 (Pyrrhocorideae)
	ordo Coleoptera *Zabrus tenebroides*, Goeze, 1777 (Carabideae) *Coccinella septempunctata,* Linnaeus, 1758 (Coccineillidae) *Ips amitinus,* Eichhoff, 1871 (Curculionidae) *Phaenops cyanea*, Fabricius, 1775 (Buprestideae) ordo Dermaptera *Forficula smyrnensis*, Audinet-Serville, 1839 (Forficulideae)
Class Diplopoda	ordo Julida *Julus terrestris*, Linnaeus, 1758 (Julideae) *Pachyiulus hungaricus*, Karsch, 1881 (Julideae)
	ordo Glomerida *Glomeris marginata*, Villers, 1789 (Glomerideae)
Class Chilopoda	ordo Geophilomorpha *Geophilus flavus*, De Geer, 1778 (Geophilideae)
Class Malacostraca	ordo Isopoda, Laterille, 1817

All the collected arthropod species are characteristic of surface soil horizons, forest litter and the A horizon (up to 10 cm depth). What has been observed and significantly emphasized is the presence of several groups of phytophagous pests and predators, typically found in agroecosystems - *Aelia acuminata*, Linnaeus, 1758, *Zabrus tenebroides*, Goeze, 1777, and *Coccinella septempunctata*, Linnaeus, 1758. There area large number of yards, private gardens, as well as agroecosystems in the immediate vicinity of the examined locations, which clearly involve the occurrence of these groups of organisms. Additionally, on the basis of pedological analyses conducted in 2020 as a part of the project "Project Program and Management Basics for Memorial Park Čačalica", a deficiency of nutrient elements in the soil and increased acidity were determined. Such characteristics are not a contributing factor to the growth of conifers in the examined locations, which makes them more vulnerable and easily susceptible to parasite attacks.

The species *Aelia acuminata*, Linnaeus, 1758, is a characteristic parasite on most representatives of the Poaceae family, especially the genera *Festuca*, *Poa*, *Agrostis*, *Dactylus*, *Lollium*, and *Bromus*. The *Carabidae* family, with its large number and functionality, represents a dominant group involved in reducing the number of pests in agroecosystems [8, 9]. A typical representative of this family observed at the location of Memorial Park Čačalica is *Zabrus tenebroides*, Goeze, 1777.

One of the most significant economic pests native to Europe and prevalent in Memorial Park Čačalica is *Ips amitinus*, Eichhoff, 1871. The species was collected at the examined locations around the black pine and it primarily parasitizes spruces (*Picea spp*.) and pines (*Pinus spp*.), sporadically firs (*Abies spp*.) and European larch (*Larix spp*.). It is prevalent and cosmopolitan in 16 European countries. This species is listed on Annex IIB Directive 2000/29/EC as a protected species in Ireland, Greece, and the United Kingdom.

The family Coccinellidae, Latreille, 1807, are natural enemies of aphids and play an important role in agroecosystems in ecologically grown crops [10]. The species from this family, which is in the protected category, *Coccinella septempunctata* was observed beneath the pine trees bark (Figure 4). The predatory species *Forficula smyrnensis* was also collected beneath the pine bark.

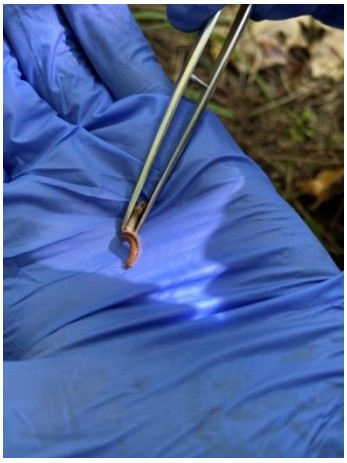

Figure 3. *Julus terrestris*
Source: Original author's work

Figure 4. *Coccinella septempunctata*
Source: Original author's work

All the collected species of millipedes from the classes Diplopoda and Chilopoda (Figure 3) are a characteristic population of the macrofauna in the surface soil layer. From the phylum Annelida, the presence of the species *Lumbricus terrestris*, Linnaeus, 1758, was observed at the examined locations. Considering the recorded representatives of the order Hymenoptera, it is important to mention the cosmopolitan species *Formica rufa*, Linnaeus, 1761. Ants are numerous , diverse and widely distributed from arctic to tropical ecosystems and they are one of the dominant groups of faunal biomass on the planet constituting about 10% of it [11]. Representatives of the phylum Mollusca are shown in Table 2.

Table 2. Overview of Mollusca Representatives
Source: Original author's data

Class Gastropoda	*Helix pomatia*, Linnaeus, 1758 (Helicideae) *Cepaea hortensis*, O.F. Müller, 1774 (Helicideae
	Arion hortensis, A. Férussac, 1819 (Arionideae)

The widely distributed species of snails, *Helix pomatia*, Linnaeus, 1758 were observed at all examined locations. It is a protected species and it is on the Red List of European Fauna (IUCN, CORINE) [12].
It is essential to emphasize that as a part of the results of this study, a species of slugs from the family Arionidae, *Arion hortensis*, A. Férussac, 1819, was identified. The mentioned species represents a significant pest as well as an invasive species in agricultural production and most of the damage to cereal grains in cultivated crops in Europe is caused by the species *Arions sp* [13].
Even more favorable conditions have been created for the ornithofauna because birds are easier to care for and self-sustain as the forest matures and grows.
The recorded presence of bird fauna is shown in Table 3.

Table 3. Overview of Ornithofauna Representatives
Source: Original author's data

Class Aves	ordo Passeriformes *Turdus merula*, Linnaeus, 1758 (Turdidae) *Garrulus glandarius*, Linnaeus, 1758 (Corvidae) *Corvus cornix*, Linnaeus, 1758 (Corvidae) *Parus major*, Linnaeus, 1758 (Paridae)

	ordo Columbiformes *Columba palumbus*, Linnaeus, 1758 (Columbidae)
	ordo Galliformes *Phasianus colchicus*, Linnaeus, 1758 (Phasianidae)
	ordo Piciformes *Dendrocopos major*, Linnaeus, 1758 (Picidae) *Fringilla*, Linnaeus, 1758 (Fringillidae) *Passer domesticus*, Linnaeus, 1758 (Passeridae) *Hirundo rustica*, Linnaeus, 1758 (Hirundinidae) *Delichon urbicum*, Linnaeus, 1758 (Hirundinidae)
	ordo Accipitriformes *Buteo buteo*, Linnaeus, 1758 (Accipitridae)
	ordo Falconiformes *Falco tinnunculus*, Linnaeus, 1758 (Falconidae)

According to the observations made by using the visual method, the most numerous species are *Delichon urbicum* (urban swallow) and *Hirundo rustica* (barn swallow), *Passer domesticus* (house sparrow), *Dendrocopos major* (great spotted woodpecker), which thrives in this location, *Corvus cornix* (hooded crow), *Columba palumbus* (wood pigeon) and others. The beauty of this man-made environment is enhanced by the songs of bird species like *Fringilla* (finch), *Turdus merula* (blackbird), *Parus major* (great tit) and *Garrulus glandarius* (Eurasian jay). Due to the proximity of agroecosystems, the presence of *Phasianus colchicus* (pheasant) is also noticeable. Among more interesting inhabitants of this forest complex are certainly *Buteo buteo* and *Falco tinnunculus*. *Buteo buteo* (common buzzard) is the most common bird of prey in Serbia. The conservation status of kestrels (*Falco tinnunculus*) is “nearly threatened” (IUCN 3.1) [14, 15].

3. CONCLUSION

Due to the diverse and rich diversity, the established research staff and students of the Academy of Applied Technical Studies Belgrade (Department of Applied Engineering Science Požarevac) in cooperation with the Ecological Society "Friends of Čačalica" intensively conduct numerous scientific researches of biodiversity. It is planned to continue the started research, the results of which are presented in this Paper, with the aim of a more comprehensive inventory of the entire faunal biodiversity of this area. One of the advantages of this type of analysis model is, of course, monitoring, that is, continuous monitoring of the existing state and possible changes, all with the aim of protecting and improving this natural place and conserving the biodiversity that inhabits it.

CULTURAL HERITAGE OF ITALY

Sara Ilanković[1], Faculty of Philosophy, University of Novi Sad

Abstract: *The topic of this paper is the cultural heritage of Italy, which is important not only for Italian culture, but also for the entire world cultural heritage. In this, the three crowns of Italian literature are mentioned, namely Dante Alighieri, Francesco Petrarch, and Giovanni Boccaccio. They create the foundations of the Italian language and literature. The importance of the contribution of the three crowns is shown because with them the development of the national language in Italy begins, and until then Latin was the only one in use. The issue of language was very important for the Italian people, and with the works of Dante, Boccaccio and Petrarch, the issue of language began to be resolved, which significantly influenced the further development of culture, literature, and language in Italy. In addition, the paper will clearly show how important the works of the three crowns are for the whole world and represent a universal cultural heritage until today.*
Keywords: Literature, Culture, Dante, Petrarch, Bocaccio

1. INTRODUCTION

In the *trecento*, that is, in the 14th century, communal society disintegrated, and the vernacular entered into literature. Dante Alighieri, Giovanni Boccaccio, and Francesco Petrarch are the most important for the beginning of the Italian language, who were the first to use a language that would be understandable and accessible to everyone. Namely, until that moment Latin was the language spoken on the Apennine peninsula, and there were, as today, many dialects, understandable only to people in the regions where they are spoken. The three crowns of Italian literature will significantly influence the development of the Italian language.

Figure 1. *Dante, Petrarca, Boccaccio*
Source: www.ravennatoday.it

[1] saramat97@gmail.com

2. DANTE ALIGHIERI

Dante Alighieri was born in 1265 in Florence and died in 1321 in Ravenna. He was the greatest poet of the Middle Ages and represented the culmination of the medieval worldview and the basis of the modern Italian language. If we look at the late Middle Ages, most poetry was in Latin and was only available to the rich and educated. Dante was the first to advocate for writing in the *volgare*, which is why his works *The New Life* and *The Divine Comedy* stand out because they were published in Tuscan. The *New Life* is a work he wrote when he was inspired by the platonic love of Beatrice, and it was written in the spirit of the sweet new style (*dolce stil nuovo*).
Dante's *Comedy* represented plurilingualism in language and contained about thirty thousand words. As Dante was key to the formation of the modern Italian language, many called him the father of the Italian language precisely because of this. In addition, in Italy he is addressed as *il sommo poeta* - the supreme poet. *The Divine Comedy* depicts the holy trinity as it consists of three parts: Hell, Purgatory and Paradise. The poet gave the name comedy because it is a narrative work in verse that begins sadly and ends happily. The very attribute divine was added by Boccaccio. Dante is the most important name in the history of Italian literature because he was the first to study the *volgare*, that is, the vernacular. The key work, besides the *Divine Comedy*, is *De volgari eloquentia*. It was written in Latin and in this work, Dante defended the Vulgar. In addition to literature, Dante was also politically active. In order to be able to do the same, Dante started to study as a pharmacist and doctor. At the age of 18, Dante met Guido Cavalcanti, Cino da Pistoia and Brunetto Latini. Together they became representatives of *dolce stil nuovo*.

Figure 2. *Dante Alighieri*
Source: www.worldhistory.org

Dante's importance is also reflected in the fact that he combined religious themes with historical-political ones. By combining these two themes, Dante has placed himself in the position of an observer of this world. In this way, Dante represents the link between heaven and earth [1].
It is noted that Dante possesses stylistics that were not seen in any European language until then. His ability is reflected in the fact that he brings these stylistic figures into mutual relation. Although there were writers before Dante, his language that he used really left a mark and from the very beginning he composed a richer and better expression than his predecessors, which left a mark on the further development of the Italian language [2].

Dante is the name that mentions it as the beginning of the development of the *volgare*, that is, the Italian language that will be accessible to everyone and that everyone will be able to understand. With that, he opened the door to his successors who followed his path and thus reached their goals and made literature accessible to all layers of society.
His goal was for the reader to see what he saw then, and that's why his language is very simple. He uses very few metaphors. He mostly used allegory because he wanted to convey his thoughts to other countries, outside of Italy itself, and this method of allegory contributed to his simple expression being heard as far as possible [3].

3. FRANCESCO PETRARCA

Francesco Petrarch was born in 1304 and died in 1347. He was an Italian poet who wrote in the vernacular and in Latin. He was crowned with a laurel wreath in Rome and thus became *poeta laureatus*. He also dealt with the problem of language, like Dante. Most of his works are in Latin because he believed that these were more sublime works and that he would be most famous for them. He was a distinct perfectionist and re-read his works and revised what had already been written. His most important work is the Canconiere, which is a collection of songs and is a characteristic of the Renaissance. Petrarch had a great influence on the entire epoch and on later generations who were called Petrarchists. In relation to Dante, Petrarch had unilingualism in his work. He was looking for an ideal form and threw out all the forms that he considered not useful for one grammar and one poetry. Like Dante, Petrarch also had his muse. Her name was Laura de Noves.

Figure 3. *Francesco Petrarca*
Source: www.florenceitaly.org

Petrarch was a writer who was driven and inspired by love. His great influence can be seen in the refinement of language and poetry. He used different forms, but he was still recognizable by it. He significantly influenced the development of Italian poetry, including his later followers – Petrarchists [1].
Petrarch is certainly the poet who most influenced the development of Humanistic and Renaissance culture. He becomes the first great court poet in Italy. Although he was in favor of Humanism, he often turned to the Middle Ages and looked for answers in classical Roman culture [4].
Canconiere represents the intertwining of the real and the ideal, the instinctive and the spiritual, and despair and hope alternate. Petrarch conveyed his love for Laura through the poetic word, through the poetic myth. In his work, the aesthetic function and the very method of the creative process can be observed [5].

4. GIOVANNI BOCCACCIO

Giovanni Boccaccio was born in 1313 and died in 1375. He was a writer and humanist. Petrarch had a great influence on Boccaccio's spiritual development and literary work. His works are important because in them he combines life in castles with the city environment. Boccaccio is the progenitor of Italian prose. He was a great admirer of Dante, and thus Boccaccio turns to multilingualism, i.e., a variety of language that adapts to the interlocutor. Through his works, Boccaccio also shows the realistic society of the three-year-old and in this way, he simultaneously praises and criticizes.
The Decameron is the first Italian narrative work. The plot begins with a description of the black plague in Florence, which raged in 1348.

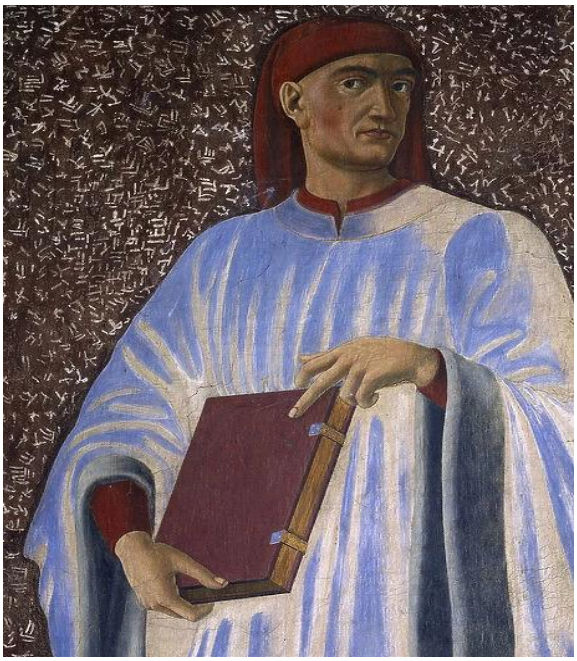

Figure 4. *Giovanni Boccaccio*
Source: www.brown.edu

Unlike the others, Boccaccio is the first to master sensory phenomena. He has a conscious understanding of art and encompasses it in one language. Boccaccio's linguistic art is based on the rhetorical shaping of prose, and the style borders on the poetic. Boccaccio created Italian artistic prose and the first prose of post-antique Europe. Through his work, Boccaccio presents teachings about love and nature. He represents real characters in his work who live on earth [2].
If we look at it from the genre side, it can be concluded that Boccaccio introduced many genres through his work, such as legends, parables, Provençal novels, Italian Novellino, chronicles, novels of chivalry. In addition, he introduced ancient and folk traditions. Thanks to his humanistic position, a broader view of the world emerges [6].
As it all began with the story of the spread of the national language, Boccaccio's Decameron is presented as a realistic depiction of a society in various aspects of life. That world is real and earthly, and thus the work itself is closer to the readers. The greatest value of his work is reflected in the harmony between the material and the moral, which was transformed into poetry [4].

5. CONCLUSION

The paper shows the importance of the three crowns of Italian literature, Dante, Petrarch and Boccaccio. From the data already mentioned, it is clear that these three great men significantly influenced the creation of the Italian vernacular, but not only that, but they also left a significant mark on other European literatures.

In the fourteenth century, it was very brave to come forward with the view that Latin should be reduced in use and that a language that would be understandable and accessible to all should be used more. The Church had a great influence in that period, and its official language was Latin, which is still maintained in the Catholic Church today. In addition, Dante, who started writing in the vernacular, was remembered for his beginnings and struggles that proved to be worth every effort.
It was very brave and ahead of its time to fight for the *volgare* and look for a common language. These three writers represent the Italian spirit that has lasted until today. Not only the language is learned from their works, but they brought us closer to the period of life in which they lived and thus left their mark in history, culture and literature.
Dante, Petrarch and Boccaccio represent a turning point in the creation of the Italian language as unique and comprehensible to all, and that is why their work is of exceptional value and importance, both for Italian and for all European literature, because they proved that literature is the best way to reach all people.

ITALIAN CINEMATOGRAPHY

Sara Ilanković[1], Faculty of Philosophy, University of Novi Sad

Abstract: *The paper presents Italian cinematography through different historical periods. Each period significantly influenced the further development of both film and other cultural spheres in art. The work talks about the important representatives of each movement of Italian cinematography and gives the essential characteristics of that creative period. Similarities or differences in film art throughout the centuries were determined by the comparative method. The paper highlights the most important names of Italian cinematography, especially directors and actors who have left a mark on culture even today, which significantly influences contemporary cultural creations. The aim of the work is to bring closer the importance of film in Italy, but also in the world, and thus point to an important sphere in the development of everyone. The work is based on historical facts that describe certain eras, but also on different attitudes and opinions regarding topics that appear in Italian cinematography.*
Keywords: Italy, cinema, film, culture, history

1. INTRODUCTION

Italy represents many cultures. The Apennine peninsula is responsible for many cultural treasures that have left their mark on the whole world, starting from early history and continuing to the present day. Italy possesses all seven arts and from each we can extract world famous and important works.

Figure 1. *Mole Antonelliana, Torino*
Source: www.museocinema.it

Here is also the film as an art that has made Italy famous all over the world. Different genres, actors and directors had a great influence on the development of film and this is reflected even today. The importance and traces of Italian cinema can be seen in many productions. Also, it is important to note that Piedmont is one of the regions that has great importance for the development of the film industry. Thus, the capital of this region, Turin, has the Museum of Italian Film, Mole Antonelliana, which even in modern times revives all those artists who are important for the identity and development of Italian cinema. Movies are certainly sources of various information and illustrate the life of a nation, state or a certain era in which it was lived. Italian film represents a unique core and deals with expressive processes that are connected by forms, expressions, general places and myths. Italian cinematography shows that it has no desire to be industrialized, nor to conquer the future, but connects time with the present and other arts such as literature, theater and other artistic traditions [1].

[1] saramat97@gmail.com

2. LANGUAGE OF ITALIAN FILM

When looking at the language of the film, that linguistic material can be divided into three categories:

1. The language of the film - the oral material is on its own;
2. Language in the film - shows the degree of influence of everyday language on the film;
3. Language from the film - the contribution of the film to everyday speech.

In addition to this, there are also divisions of languages through historical periods. In those years, changes occur from a linguistic point of view, and thus it can be divided into three parts:

1. Oral film (1896-1905);
2. Written film (1905-1930);
3. Reproduced film (from 1930 onwards).

Oral film is primarily associated with films that were intended for entertainment in the squares. This custom dates to the 19th century when there was still no sound and subtitles were read publicly. The second period, i.e., the written period, is characterized by the insertion of written text during film scenes. If the films were shown throughout the country, there were subtitles in Italian [2].

3. FILM AND TELEVISION

Because historical and social reasons, film and television in Italy are very closely related. The need to find a common language required the showing of television content, including foreign content, in Italian. When television was created, there was also an explosion of film offerings, which was greater than in other countries. In the 1960s, the film received a place of honor on television. Many authors have proven themselves at their best by documenting on television. There are Bernardo Bertolucci, Ugo Gregoretti, Gianni Amelio, Ljiljana Cavani and many others. At that time, Rai also allowed directors from the theater to show themselves on television and Strehler and Skvarcina became famous there. Some directors come to television just from the movies and there are Renato Castellani, Vittorio Cotafavi, Roberto Rossellini, Franco Rossi. In the 1970s, the first television films appeared, such as *Stregone di città, Semmelweis* [2].

Figure 2. *La vita è bella (1997)*
Source: www.britannica.com

If we talk about topics that appear on television content, they are usually topics that will be interesting and close to the viewers. The viewership of certain content depends on who it is intended for and how much it will interest the viewers. From the very beginning of cinematography, it was important to choose a theme that would be seen every day and that would make viewers look forward to the sequel.

Screenwriters do not possess any scientific instrument with which they can really study a society. The creators of the feature program adopt descriptions and behaviors in society and translate them into current stories and thus directly transmit social circumstances through television [2].

4. THE IDENTITY OF ITALIAN CINEMA

The screen becomes an opportunity to change the history and geography of the nation. Thanks to D'Aanuncio, Gavacconi, Caserini, Gallone and Pastrone, the historical film starts to conquer the world audience. These films conveyed Italian history and culture, but also talked about the coming war period. In the period between 1912 and 1915, the films Last Days Of Pompeii, Cleopatra, Salambo, Julius Caesar, Spartacus were made [2].

Figure 2. *Gli Ultimi giorni di Pompei*
Source: www.raiplay.it

Italian producers set out to conquer the audience using the combined power of masters of literature and art: Dante and Gabriele Rossetti, Giotto and Dore, Manzoni and Pietro Cosa, Shakespeare and Puccini, Verdi and Verga and many others. The combination of literature and film gives success to Italian cinematography, and it develops rapidly. Literature and other arts become vehicles for better success [2].
If we look at neorealism, its goal was to cover the territory of Italy. With this step, he strives for universality. The protagonists then become people who were invisible until then. It is believed that the film can tell all the stories of everyday life and describe the different lives of people found throughout Italy [2].

5. CONCLUSION

The work shows the beginnings of Italian cinematography. It talks about the origin and development of film, television and the film industry in general in Italy. This is a topic that can be viewed from multiple angles, a topic that has many names that have influenced Italian film and television. This

work shows only some of the important producers who were important for further development. The importance of literature and other arts that are connected with the film and thus make it special is shown.

The importance of Italian cinema can be seen even today because, both in Italy and in the whole world, the first names of Italian cinema left their mark. Movies are the best way to learn about the culture and mentality of a people, and they are still very important in this regard.

TOWARDS A THEORY OF DIGITAL TWINS: FUNDAMENTAL DEFINITIONS

Andrea Matta[1], Dept. of Mechanical Engineering, Politecnico di Milano, Italy
Mohsen Jafari[2], Dept. of Industrial and Systems Engineering, Rutgers University. USA

Abstract: *Digital twins are not simply conceived as simulation models of their physical counterparts, differently they are developed as means for better understanding and control of the physicsl entity. A unifying theory that systematically defines the core functions bridging the gap between the digital and physical entities is missing. This absence represents the main limitation of digital twins and is also cause of misunderstandings. This work describes 17 fundamental definitions of digital twins to fruitfully work in close interaction with their physical counterparts. Functions are described in terms of scope, inputs, and outputs.*
Keywords: digital twin, simulation, smart manufacturing, industry 4.0

1. INTRODUCTION

The variety of functionalities that digital twins can potentially offer is very large encompassing different application fields from aerospace to urban traffic [1]. This extremely large spectrum of digital twin use cases has caused a multitude of scientific contributions and market studies from several disciplines, each one with its own terminology, models, and approaches [2,3]. Also, digital twins are subject to international standardization efforts [4]. However, a general theory describing the relationships among digital and physical twins is still missing. Despite the rapid proliferation of digital twin applications across various domains, a significant gap exists in the form of a comprehensive theoretical framework that depicts the services of digital twins and their physical counterparts. This absence becomes more critical in light of the diverse terminologies, models, and disciplinary approaches that currently characterize the emerging paradigm on digital twins. Thus, this paper aims to define the fundamental functions that establish the connection between physical entities and their digital counterparts. In this work, we try to be as general and independent from any application domain with the aim to start building the theoretical background of a digital twin theory. The structure of this paper is shortly described. Next section contains a set of general definitions to delineate digital twins and their physical counterparts in their main characteristics. Section 3 describes the functions that digital twins use to provide their services. Conclusions and outlook are drawn in the last section. Readers with interest in deeper knowledge of the features, models, and services of digital twins are referred to the recent advanced tutorial contained in [5].

2. GENERAL DEFINITIONS

This section introduces the fundamental concepts of physical entities and digital twins, establishing the foundational understanding necessary for the subsequent theoretical development.

2.1 Physical entity

Digital twins were conceived to enhance the management of tangible real-world objects. To better define the boundary the physical counterpart of a digital twin, the following definition is proposed:

[1]andrea.matta@polimi.it
[2]jafari@soe.rutgers.edu

*Definition 1 (**Physical entity**). A physical entity is a material object that evolves or operates with time.*

A physical entity encompasses products (e.g., engines, valves), systems (e.g., machine tools, production systems, logistic systema), environments (e.g., buildings, lakes), and biological systems (e.g., parts of the human body, plants). Broadly, digital twins model resources. Although immaterial entities like stock markets could potentially benefit from digital twins, we exclude them from this study for the sake of simplicity. This definition extends the ISO standard [5] by incorporating the concept of temporal evolution or operation of the physical entity. Indeed, a physical object that remains static does not necessitate the support of a digital twin.

Physical entities, or simply entities hereafter, possess properties or attributes that characterize them, as detailed in the following definition:

*Definition 2 (**Property**). A property of a physical entity is the information about its characteristics.*

Properties encompass geometrical attributes (e.g., shape, macro and micro dimension), physical attributes (e.g., weight, colour), chemical attributes, mechanical attributes, etc, depending on the entity's nature. For sake of generality, properties include variables, attributes, and constant parameters. As per Definition 1, entities can be time-dependent due to degradation, interaction with other entities, or internal processes. This implies that entities may modify some of their properties and behavior over time; observing the same entity at different time intervals may reveal variations.

A pivotal concept useful for distinguishing among different situations of the same entity is the concept of state:

*Definition 3 (**State**). The state of a physical entity is the information encapsulating its dynamic status through a set of variables, attributes, and parameters.*

The state of a physical entity can change continuously with time or discretely according to its nature. For instance, a tank's liquid level changes continuously, while a robot's software reconfiguration could be a singular event.

Observing a physical entity's state is challenging due to location and cost constraints. Satellites orbiting in space and offshore wind towers cannot be easily accessed. In manufacturing, halting a production line for machine degradation assessment might not be efficient. To overcome these constraints, sensors are typically employed to infer the entity states. Sensors are devices that observes and measures a physical property of a natural phenomenon or process and converts that measurement into a signal [5]. For standard digital twin applications, assuming fully observability of the state is often impractical, making partial observability the norm. When the state is not observable, the term *latent state* is also used to indicate the lack of observability. Simple digital twin applications benefit from accurate sensors, enabling continuous state assessment of physical entities.

In general, the physical entities relevant for digital twins provide functions for the external environment. For instance, electric motors generate shaft torque, manufacturing systems produce goods, city buses provide transportation. Throughout their operation or natural evolution, entities release traces of information, referred to as the footprint of the physical entity as introduced in the following definition:

*Definition 4 (**Footprints**). The footprints of a physical entity are the information regarding its manifestations.*

Examples of footprints are the heat dissipated by the electric engine and the torque it provides, the number of parts produced by the manufacturing system with their quality measure, the carbon emissions of the bus with the time to reach the destination.

Depending on the nature of the physical entity, footprints may be sensed, collected, and digitized for analysis. The subset of the acquired footprint is termed observable as specified in the following definition:

*Definition 5 (**Observations**). Observations are the sensed footprints of a physical entity.*

Observations are clearly a subset of footprints, and not all the footprint of a physical entity can be observed, nor they need to necessarily be observed. When the state is observable or partially observable, sensor measurements of the state are part of the observed footprint.

2.2 Digital twin

Grieves (2014) introduced the first concept of digital twin in the early 2000s [6]. In the proposed concept, the main features were the continuous synchronization between physical entity and digital twin, the granularity of the analysis level, and the long term coupling of the two twins along the whole entity's lifecycle. Since then, many other definitions have been proposed in recent literature to emphasize specific digital twin features such as the integration and interconnections of digital twin's elements, the digital counterpart, the predictive capabilities, and the descriptive power. Barricelli et al. classified 75 papers according to their digital twin definitions from manufacturing, aviation, and healthcare domains [7]. Other definitions of digital twins that are more customized for manufacturing, aviation, and healthcare domains can be found in [8,9,10]. A simple and context independent definition of digital twin is proposed in the following:

Definition 6 (***Digital Twin***)*: a temporally updated digital representation of the physical entity*.

This definition comprises the three fundamental features of digital twins [5]:

- *Digital*. The increase in computational power, data accessibility, and availability of modeling software environments, have created the ideal conditions to develop digital representations of physical systems affordable with cost and time. This feature is universally recognized by literature, i.e., the digital twin is a set of instructions coded in a computer program to describe the physical system behavior.
- *Descriptive*. The main purpose of the digital twin is to provide information and knowledge about the physical entity, e.g., about its state, its emerging behavior, its trends, or anything that may help the manager of the physical entity to understand and improve its performance.
- *Synchronous to physical*. The digital twin should be able to describe the physical entity at any moment. This feature implies the state changes of the physical entity being transferred to the digital twin in real time.

Digital twins are used to emulate the behavior of physical entities in specific conditions, to make predictions, estimate future performance, and more in general to enhance the control of entities. This process is a computer experiment in which the digital twin uses its models for producing quantitative results. These results are termed emulation results as delineated in the following definition:

Definition 7 (***Emulation results***)*: The emulation results are the output of the digital twin obtained through the replication of the physical entity behavior in a controlled digital environment*.

In essence, digital twins are software applications that manipulate sensed data collected from the physical entity, use digital models to make analysis, and communicate their response to entities and environment. Thus, digital twin models must be multidimensional encompassing the current knowledge about the physical entity, the digital representations that can be used to provide functions, the data and the communication for their transfer [5]. The following definitions delineate the dimensions of a digital twin model.

Definition 8 (***Knowledge model***)*: A knowledge model comprises the information concerning the characteristics and behavior of the physical entity*.

Knowledge models represent the most updated understanding of physical entities. Digital twins help to improve these models through the observations and analysis collected and performed throughout the operation or natural evolution of physical entities. This knowledge can be used entirely or partially to represent the behavior of physical entities in digital models depending on the granularity requested by the analysis. The following definition is taken from the ISO standard [4]:

Definition 9 (***Digital model***)*: A digital model is a data element representing a set of properties of an observable physical entity*.

The most intensive use of digital models is for simulating the entity behavior in specific contexts. In general, multiple digital models can be used to describe the physical entity, each dedicated to a specific behavior. The choice of which model to use depends on the purpose of the analysis. Digital models produce quantitative analysis of possible entity behaviors. Parameters fitted using knowledge models are used in digital models.

An element that physical entities and digital twins have in common is data. In fact, physical entities generate data through their emitted and sensed footprints. Digital twins make use of entity observations to build the knowledge necessitated by digital models to replicate the behavior of physical entities. As a consequence, a data model is needed and a concise definition is needed:
Definition 10 (***Data model***)*: A data model is a structured representation of data and the relationships between data elements in a digital twin*.
Since data flow from physical to digital and in most advanced applications from digital to physical, the presence of a communication model in digital twins is mandatory.
Definition 11 (***Communication model***)*: A communication model is a structured representation of how information is transmitted, received, and interpreted between the physical entity and the digital twin.*
The communication model comprises the connection protocols for data transfer, and it largely depends on the application context. The frequency of connection can be high in the guide of autonomous vehicles, medium in a fish farm, or low in a production scheduling of a cast iron plant. Cybersecurity must also be taken into account because sensible data may be exposed to malware during their transferring.

3. FUNCTION DEFINITIONS

This section provides definitions for the functions characterizing physical entities, digital twins, and their interactions.

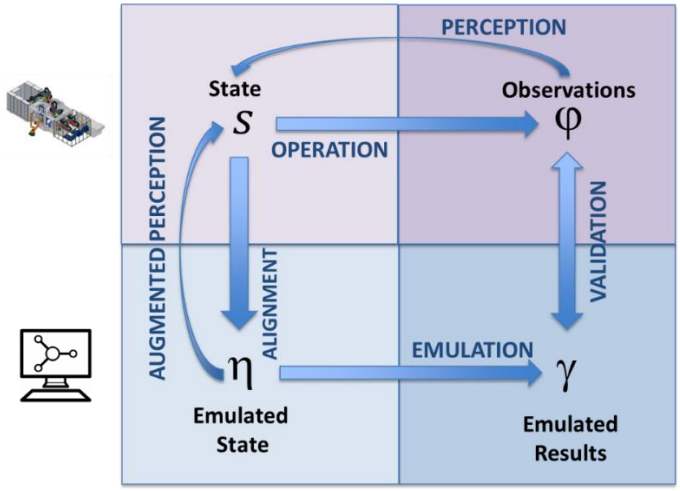

Figure 1. *Functions of physical entity (top) and digital twin (bottom).*

3.1 Physical entity

The functions in this section only characterize physical entities and are typically used without digital twin applications.
Definition 12 (***Operation***)*: The operation function f models the evolution of the physical entity that releases observed footprints φ from a specific state s. Formally, $\varphi = f(s)$.*
Through the support of the digital twin it is possible to control the physical entity, this is represented with the control variable u. To consider that physical entities frequently interact with the external environment, variable d is used to capture disturbances and noises from the environment. Making explicit controls and disturbances in the operation function can be useful for a better understanding of the physical entity $\varphi = f(s; u, d)$.
From the definition, it is evident that the non-observable footprints are not of interest, or are costly to observe, or may not be measurable at all. For these reasons, only φ rather than the whole footprint appear in function f. Key performance indicators such as cost, quality, efficiencies, and effectiveness

can be calculated using the emitted observations. If the state, or part of it, is observable then it can be added to the observation vector φ.
Modifying function f means changing the physical entity. When modification is made to maximize a performance indicator of the physical entity, we say the physical entity is improved. Optimization and control are embedded in variable u. For instance, a pure reinforcement learning approach uses observations φ to find optimal values for u. Using digital models in optimization and control corresponds to simulation-based approaches.
Definition 13 (***Perception***)*: The perception function h models the process of state inference based on the observed footprints φ. Formally, $\hat{s} = h(\varphi)$ where φ is used to infer the latent state s.*
Specifically, function h helps to make a guess about the actual state s of the physical entity. Perception is typically used in robotics and agent theory to infer the status based on observations.

3.2 Digital twin

A major use of digital twins is to replicate the physical entity behaviors for retrospective analysis, online optimization and control, and predictions. The following definition delineates the emulation function of digital twins:
Definition 14 (***Emulation***)*: The emulation function g models the process of physical entity replication in a controlled digital environment. Formally, $\gamma = g(\eta)$ where η is the emulated entity state and γ the emulated results.*
Modifying function g means changing the digital models of the digital twin. When modification is made to maximize a performance indicator of the physical entity, we say the digital twin is used to simulate changes of the physical entity in the digital environment. A model of noises and disturbs might be necessary to better emulate the behaviors of the physical entity. To consider the control of the entity, digital models make explicit the control variable u and this can also be reflected in the function together with the disturb $\gamma = g(\eta; u, d)$.
Emulation is the main pillar of digital twins. Through emulation, computer experiments can be executed in the digital world. This avoids experimenting with the physical entity and prevent from performance losses. Benefits can be knowledge improvement (the knowledge model is improved as the digital twin learns), control, and optimization of the physical entity.
Construction of emulation functions can be automated leveraging techniques such as system identification and process mining that build formal models from observations φ. With the same purpose, machine learning approaches builds nonlinear regression functions that explain the observations released by physical entities.

3.3 Interaction physical entity vs digital twin

The functions in this section only characterize the interactions between physical entities and digital twins. Synchronizing digital to physical is mandatory for digital twins because it allows a continuous alignment of the digital entity with the physical one. The following defines the alignment function:
Definition 15 (***Alignment***)*: The alignment function l synchronizes the state of the digital twin to the entity's state s. Formally, $\eta = l(s)$.*
Since the entity's state might be non-observable, the alignment can be executed using the perceived state $\hat{s}$ instead of the latent state s. If the entity's state can be observed, even after having incurred a cost, then the observed state is used for synchronization [11].
Digital twin models must always be valid to avoid jeopardizing its contribution. A validation function is needed to execute online validation of the digital twin models:
Definition 16 (***Validation***)*: The validation function checks the validity of digital models by comparing observations φ to emulated observations γ.*
Validation encompasses digital models, parameters, and variables used by the digital twin for emulation.

Digital twins can also be used for perception through execution of computer experiments as described in the following definition:
Definition 17 (***Augmented Perception***)*: The augmented perception function* m *uses the digital twin emulation to perceive the entity state. Formally,* $\hat{s} = m(\eta)$ *where* η *is the emulated state.*
An improved state perception leads to a better control and for this reason augmenting perception can be relevant in some applications.
These interactions between the physical entity and the digital twin underline the synchronization, alignment, and validation processes that ensure the accuracy and effectiveness of the digital twin's emulation capabilities.

4. CONCLUSION

This paper is a seminal work for putting the basis of a digital twin theoretical framework. The main result is a set of 17 definitions that comprise general concepts as well as the fundamental functions that are used by the digital twin to provide services. These definitions will help to better develop digital twins and their related services. The main limitations of this work are the lack of an illustrative example that would help to transfer the contents and the absence of details in the description of the functions. These limitations will be tackled in future works together with a description of related research challenges.

This research was supported by the by the Horizon Europe Project "Auto-Twin" [grant number 101092021].

AN ANALYSIS OF A PROCESS OF DECENTRALIZED CONTROL OF A ROBOT POWERED BY A DIRECT CURRNET MOTOR

Đorđe Dihovični[1], The Academy of Applied Technical Studies Belgrade

Abstract: *The subject of this paper is the analysis of the process of decentralized control of the movement of the joint of a robot powered by a direct current motor. In the case of this control, a double integrator with local speed coupling is used. In the control facility itself, more control variables are observed and such control is called cascade where the inner loops have the best regulation, while the speed decreases when going to the outer loops. After the calculation, the transfer function of the coupled ratio of the internal contour is obtained, and then the analysis of the transition process was performed through the display of relevant indicators. Regardless of which automatic control synthesis method is applied, it is important to know the poles of the system that are closest to the imaginary axis, i.e. the dominant poles. The transfer function of the control object is analyzed from the point of view of determining overshoot, delay time, rise time, fall time, the moment of overshoot occurrence, oscillation period, phase lead and gain lead.*
Keywords: Robotics, Direct current motor, Mechatronics, Control systems, Synthesis

1. INTRODUCTION

Making the movement of the robot has a lot of specifics, unlike the control of other automatic control systems. When it comes to controlling the movement of the robot, it can be free, for example when the top of the robot moves freely in space, and contact when the robot maintains contact with the environment during movement, [1]. Compared to linear equations with one input and one output that occur in automatic control models, the dynamic model of robot motion is far more complex and is represented by a second-order matrix differential equation, [2-3]. The dynamic model of the robot's movement is highly non-linear, and in case the robot has rotary joints, then the fields in the matrices contain trigonometric expressions as a function of the current position of the joints [4-5], as well as the positions of the joints' speed, which represent centrifugal and centripetal forces, i.e. Carioles forces. It should be taken into account that since the robotic mechanism changes its inertia during its movement and represents a kinematic chain, the movement of any joint has an impact on the load on the other joints. All these mentioned factors, as well as the fact that the joints of the robotic system move simultaneously, indicate that the management of a robotic system of the kinematic chain type is one of the most complex management tasks. When moving the top of the robot regardless of whether it is carrying a tool or not, internal and external coordinate management is used. When controlling the internal coordinates, a closed system of automatic control is formed, and in the return branch there is a measuring device that measures the positions of the joints, based on which an error signal is created, which should be as small as possible in order to achieve the desired movement of the joints, i.e. the top of the robotic system. The disadvantage of this approach is manifested in the fact that the position vector of the top of the robot is not measured directly because it does not participate in the formation of the error signal, which can be overcome if the management by external coordinates is applied, where the error signal is formed on the basis of the given reference movement and the measured realized movements of the top of the robot.

[1]djdihovicni@atssb.edu.rs

In this paper it is applied the analysis of the process of decentralized control of the movement of the joint of a robot powered by a direct current motor.

2. DECENTRALIZED MODEL OF ROBOT DYNAMIC

In the literature [6-7], the model of the robot system which is usually presented includes only the dynamics of the mechanical structure of the manipulator, where the driving forces and moment represent the input to the model, and the output is the position of the joints. A dynamic model of actuators in the form of electric motors or pneumatic or hydraulic cylinders is used to create driving forces and moments, [8-9].
The actuators are placed directly in the joints, or they are placed in those positions where the dynamic properties of the robotic system will be preserved. The robot as an object of a closed system of automatic control consists of three subsystems, which are the actuator, transmission and manipulator, [10-11]. The transmission from the actuator to the joint of the robot is carried out via belt transmission, screw spindle and similar forms of transmission, [12].
A complex mathematical model of robot behaviour, in addition to the manipulator model, should also contain actuator and transmission models, whereby the output from the model represents the joint position vector denoted by q(t). In the literature, it is often the case when a direct current motor with a permanent magnet is used for the actuator, that it is placed directly in the joints of the robot, where the energy is transferred from the motor to the joint via a reducer. When applying the reducer, the dynamics model is linear and stretched, and the dynamics of the engine becomes dominant in relation to the joints. In the decentralized control of an industrial robot by joint movement, the system itself is considered linear, while the nonlinear coupled part is viewed as a disturbance, and the control of the robot is reduced to n individual joint control tasks, so that the management of a multivariable system is reduced to the management of a single joint with one input and one output.
The decentralized robot dynamics model is given by the following equation, [6]:

$$\tau = \bar{H}\ddot{q} + F_v\dot{q} + d(q, \dot{q}, \ddot{q}) \tag{1}$$

where $\tau(t)$ is vector of generalized forces or moments, $\bar{H}$ is constant diagonal matrix containing the averaged values of the joints' own inertias, $q(t)$ is vector of generalized coordinates, $\dot{q}(t)$ is vector of generalized speed, $\ddot{q}(t)$ is vector of generalized acceleration, and F_v is the diagonal matrix containing the coefficients of viscous friction for each joint of the manipulator.
Equation (1) represents a linear uncoupled system, and the problem of controlling an industrial robot is reduced to n individual tasks aimed at controlling one joint. Taking into account that $q(t)$ represents the coordinates of the joint position of the robot, when displaying the structural block diagram of the linear model of one joint, it is observed that the feedback loop is closed according to the achieved position of the joint.
The desired value of the joint position in a closed automatic control system is a reference value in the mark $q_{ref}(t)$, the part of the system that is framed by a broken line is an object, and the influence of the rest is seen as a disturbance and is marked with d.
Structural block diagram of the linear model of one joint is shown in Figure 1, [6].

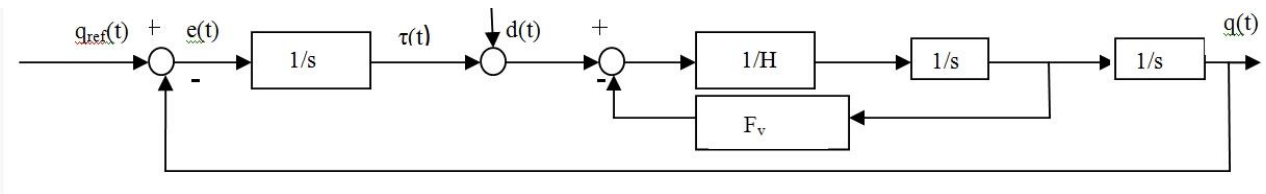

Figure1. Structural block diagram of the linear model of one joint [6]

The transfer function of an object can be shown in the form:

$$W_o(s) = \frac{K_0}{s(1+sT_0)} \tag{2}$$

where K_o is the gain and T_o is the time constant of the object:

$$K_o = \frac{1}{F_v}, T_o = \frac{\bar{H}}{F_v} \tag{3}$$

The transfer function of the entire system is shown by the following formula:

$$W(s) = \frac{W_{gg}(s)}{1+W_{gg}(s)} = \frac{\frac{K_o K_p}{T_o}\left(s\frac{K_D}{K_p}+1\right)}{s^2+s\frac{K_o K_p+1}{T_o}+\frac{K_o K_p}{T_o}} \tag{4}$$

where K_p is the proportional and K_D is the differential action gain. It is observed that the denominator of the transfer function of the system is of the second order and that the coefficients depend on the parameters of the PD regulator.

3. ASSESSMENT OF DYNAMIC BEHAVIOUR IN THE TIME DOMAIN

Primarily, a certain quality of dynamic behaviour is required from technical systems, which is manifested through bounce and/or frequency response indicators. The poles of the transfer function of the system that are closest to the imaginary axis in the complex plane *s* have a decisive influence on the appearance of the transition process, and they are called dominant poles, and if the system is of a higher order, then the influence of the poles, whose real part is six times greater in absolute value from the real part of the dominant poles to the transitional process can be ignored.
Dominant pole pair for robot system is:

$$s = -2 \pm j8 \tag{5}$$

The complex number *s* can be represented as follows:

$$s = \sigma + jw, j^2 = -1 \tag{6}$$

where σ represents the real part and *w* the imaginary part of the complex number *s*.
In polar coordinates, if the Euler form of the complex number is used, it can be written:

$$|s| = \sqrt{R_e^2(s) + I_m^2(s)} = \sqrt{\sigma^2 + w^2} = w_n^2 \tag{7}$$

where w_n is the natural frequency of the system.
Considering equations 5, 6 and 7, the natural frequency of the system can be expressed as:

$$w_n = \sqrt{\sigma^2 + w^2} = \sqrt{4 + 64} = 8.24s^{-1} \tag{8}$$

and the system damping is given by:

$$\varsigma = \frac{\sigma}{w_n} = \frac{2}{8.24} = 0.242 \tag{9}$$

The dominant time constant T_d is:

$$T_d = \frac{1}{|\sigma|} = \frac{1}{|-2|} = 0.5s \tag{10}$$

and the time of calm T_s is:

$$T_s = \frac{4}{\varsigma w_n} = \frac{4}{0.242 \cdot 8.24} = 2.0s \tag{11}$$

The moment of occurrence of the leap is:

$$t_{\Pi} = \frac{\pi}{w_n\sqrt{1-\varsigma^2}} = \frac{\pi}{8.24\sqrt{1-0.242^2.}} = 0.392s \tag{12}$$

The oscillation period is:

$$T = 2 \cdot t_{\Pi} = 0.785s \tag{13}$$

4. CONCLUSION

The aim of this paper is the analysis of the process of decentralized control of the movement of the joint of a robot powered by a direct current motor. It is presented the decentralised model of robot dynamic and a double integrator with local speed coupling is used. The problem of controlling an industrial robot is reduced to *n* individual tasks aimed at controlling one joint. Structural block diagram of the linear model of one joint is shown and the transfer function of industrial robot is calculated. After the calculation, the analysis of the transition process is performed through the display of relevant indicators. The dominant poles are chosen, and the analysis is presented from the point of view of determining overshoot, delay time, rise time, fall time, the moment of overshoot occurrence, oscillation period, and phase lead and gain lead. The obtained values are within satisfactory limits for this stable industrial robot system.

Abstract: *The choice of mechanical power transmissions is one of the key tasks in robotics engineering. Their characteristics largely affect the final performance of industrial robots. Since each axis has a specific function, each one of them needs a different gearbox. This paper analyses the main factors to be considered when selecting gearboxes for a 6-axis robot.*
Keywords: 6-axis industrial robots, high precision gearboxes, selection criteria

1. INTRODUCTION

The fourth industrial revolution brought about tectonic changes in large industrial systems, especially in electronic, automotive and metal processing systems, where robots perform various tasks such as material transport, machine servicing, welding, polishing, painting, assembly, control, packaging, sorting, palletizing... [1,2,3,4]. In order to perform most of these tasks, the robot needs to have six degrees of freedom, three for positioning and three for orientation of the end effector in space [5]. Since the rotational speed of the actuator is high compared to much slower mechanical rotation of the joints, it is necessary to significantly reduce the rotational speed and increase the torque. This is achieved using gearboxes, which greatly affect the final performance of industrial robots. According to available research data, gearboxes account for as much as 35% of the total robot costs, actuators account for 20%, and controllers only for 15% [6].
Since parts of a robot are in continuous motion, speeding up and slowing down, gearboxes in joints need to provide not only high rated torque and emergency stop torque but also high acceleration. In industrial robots, positioning accuracy and repeatability are very important. Positioning accuracy is the difference between the requested and the obtained position, while repeatability is the ability to achieve the same requested position over and over again. Although these two characteristics are interrelated, repeatability differs from accuracy and is usually much more important. In order to achieve a repeatability of ± 0.02 mm for an industrial robot with a reach of up to 700 mm, the robot needs to have an angular repeatability of only ± 5.9 $arcsec$ in the base axis [7]. In order to achieve this level of repeatability without the use of expensive high resolution encoders, it is necessary to use zero backlash gearboxes and not the conventional ones. Another major disadvantage of conventional gearboxes is the limitation of the gear ratio in single-stage gearboxes. In order to have an optimal reduction in rotational speed and increase in torque, i.e. to achieve the reduction ratio of 1:171 or 1:220, as needed in the joints of some industrial robots [8], it is necessary to install multi-stage gearboxes. Furthermore, one should not leave out low efficiency of conventional gearboxes, which has a negative impact on energy efficiency [9].

[3] gnestorovic@atssb.edu.rs

At present, only high precision reducers can meet all the requirements including high accuracy and repeatability, zero backlash, high torsional rigidity, a combination of high torque and low weight (torque density), high efficiency and high gear ratios without taking up much space. The most widely used high precision reducers are rotate vector (RV) reducers, which are based on cycloid gears, and harmonic reducers [10,11]. Both reducers have high gear ratios, but since RV reducers have a higher load capacity they are usually installed in more loaded joints (base, shoulder, elbow). Harmonic reducers are compact and simple in structure hence they are usually installed in less loaded joints (forearm, hand). At the moment, RV reducers make up 60% and harmonic only 15% of all the reducers used in industrial robots [6]. This paper analyses the main factors to be considered when selecting gearboxes for axes of industrial robots.

2. REQUIREMENTS IN SPECIFIC AXES

In industrial robots, each joint can rotate in a specific axis (Figure 1). Generally, in a 6-axis robot, axis 1 allows the robot to move its arm to the left or right, axis 2 (shoulder) provides the ability to move the upper arm back and forth, axis 3 (elbow) allows the forearm to be raised and lowered, axis 4 allows the rotation of the forearm, axis 5 (wrist) enables the raising and lowering of the hand, axis 6 enables the rotation of the hand [12]. Since each axis has a specific function, each one requires a special gearbox.

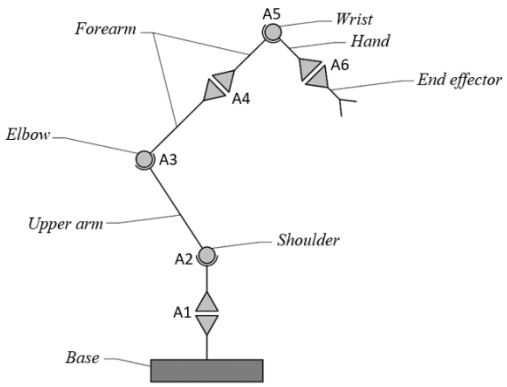

Figure 1. Kinematic structure of a 6-axis robot

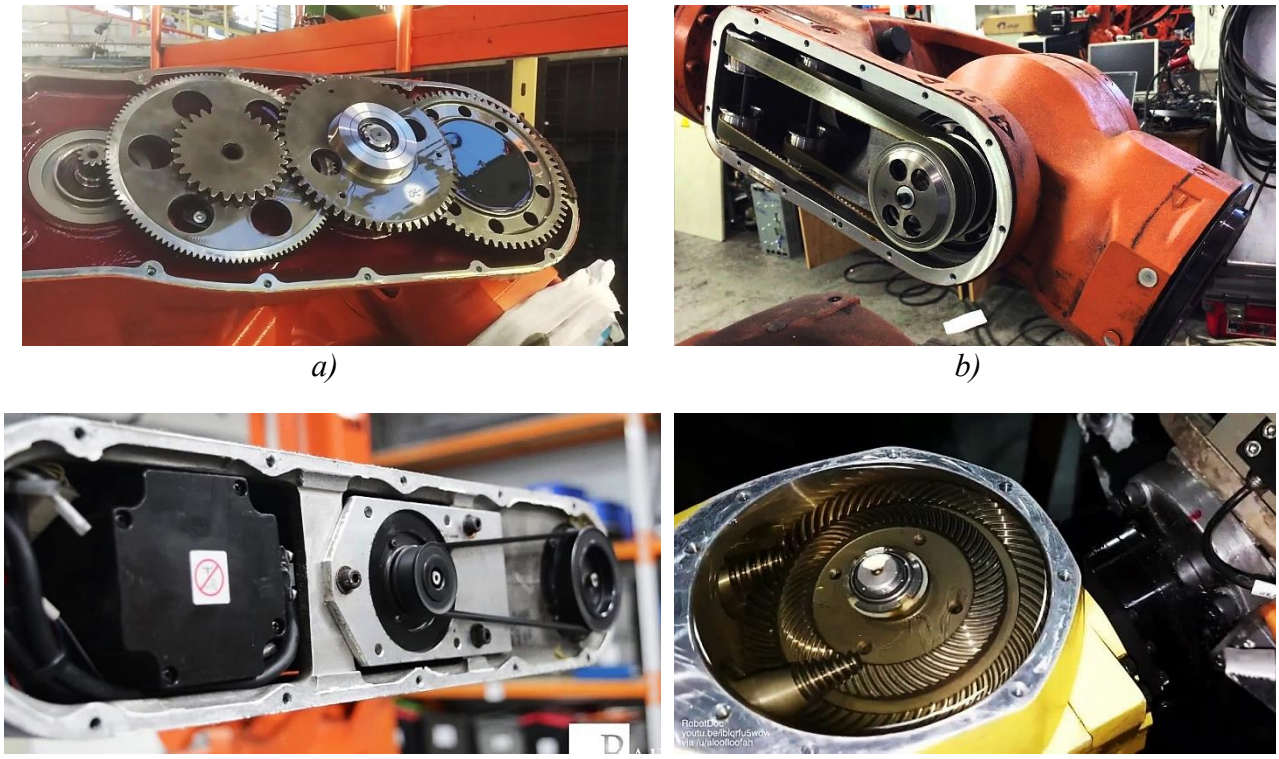
When a load is applied to the end effector of a 6-axis industrial robot, the largest moments occur in the first joints. Due to the large lever arms, the rotation of the first joints have the greatest effect on the end effector positioning errors [13]. Therefore, gearboxes in axis 1 must have solid and robust construction in order to provide the necessary stability at high tilting and bending moments. In order to enable internal routing of power and data cables, as well as of supply hoses for painting or welding robots, it is necessary to use hollow shaft gearboxes.
Since axes 2 and 3 are also subjected to large loads when the robot moves, especially axis 2 which carries 70-75% of the total robot weight [14], their gearboxes need to provide high torques and have high torsional rigidity. Here, the cables and hoses are not routed internally but externally, so hollow shafts are not necessary. Since actuator weights also have negative effects on the load of axes 2 and 3, they are very rarely placed directly next to the gearboxes for axes 4, 5 and 6. For these three axes, they are mounted externally in the direction of axis 4. As a result, there is a need for intermediate transmission systems whose main role is to transfer the torque from the actuators to the remote gearboxes [15]. To date, several different construction solutions have been implemented. They are shown in Figure 2 [16]:

- In *IRB 6620* robots with a payload capacity of up to 150 kg in axis 5 - raising and lowering the hand, *ABB* uses cylindrical gear pairs which provide higher torque but much lower precision (Figure 2.*a*).
- In *KUKA KR5* robots with a payload capacity of up to 5 kg, the actuators and the gearboxes in axes 5 and 6 are connected by toothed timing belts (Figure 2.b).

- In *Yaskawa Motoman MA1400* robots with a payload capacity up to 3 kg, the actuator and the gearboxes are also connected by toothed timing belts, but here the actuators are not too far away from their gearboxes (Figure 2.*c*).
- *FANUC* uses special hypoid gears with a payload capacity of up to 12 kg in *M-10iA* robots (Figure 2.*d*).



a) *b)* *c)* *d)*

Figure 2. Intermediate transmissions from the actuator to the joint gearbox in axes 5 and 6: a) *ABB*; b) *KUKA*; c) *Yaskawa Motoman*; d) *FANUC*

In general, for rotation of the forearm (axis 4), it is necessary to use gearboxes with high torsional rigidity and slightly lower torques. They often need to have hollow shafs to allow installation cables to be passed through the gearbox. For axes 5 and 6, more compact and lightweight gearboxes with solid shafts are used, although in axis 6, it is sometimes necessary to use a hollow shaft, depending on the actuator in the end effector [17].
All these requirements for gearboxes in robot axes are summed up in Figure 3.

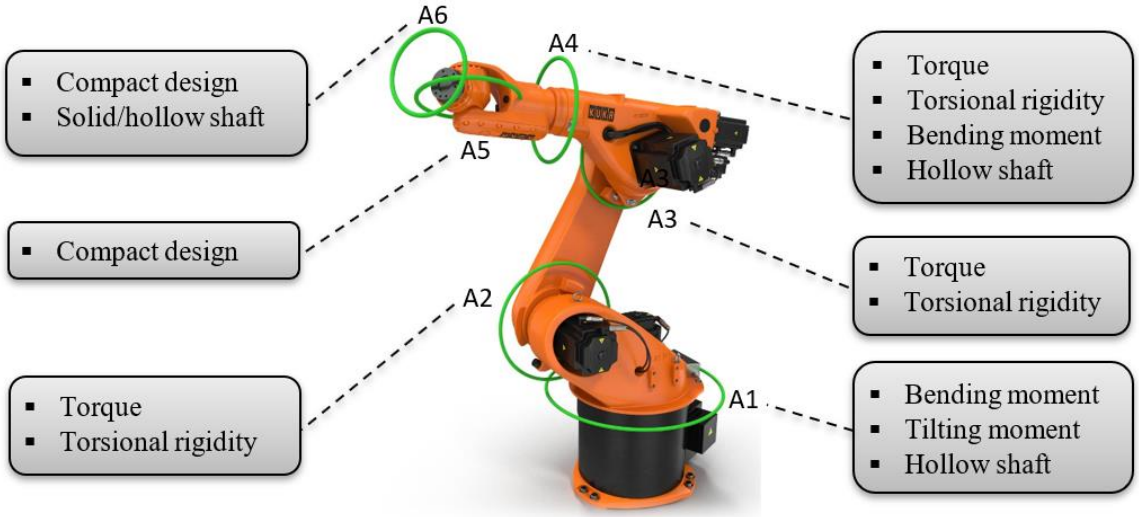


Figure 3. Gearbox requirements for axes of industrial robots *KUKA KR 60-3*

3. A COMPARATIVE ANALYSIS OF CHARASTERISTICS IN SPECFIC AXES

A comparative analysis of the characteristics of a 6-axis industrial robot axes with a payload of up to 150 kg is shown in Figure 4 [17]. Other important robot characteristics include the loss of hysteresis/lost motion below 1 $arcmin$, speed and acceleration above 100 $°/sec^2$, positioning accuracy and repeatability less than 20 $arcsec$. The trend lines are formed based on the mean values of the quantities. It can be seen that the highest torques are required in axes 2 and 3, while the highest torsional rigidity is needed in axis 4.

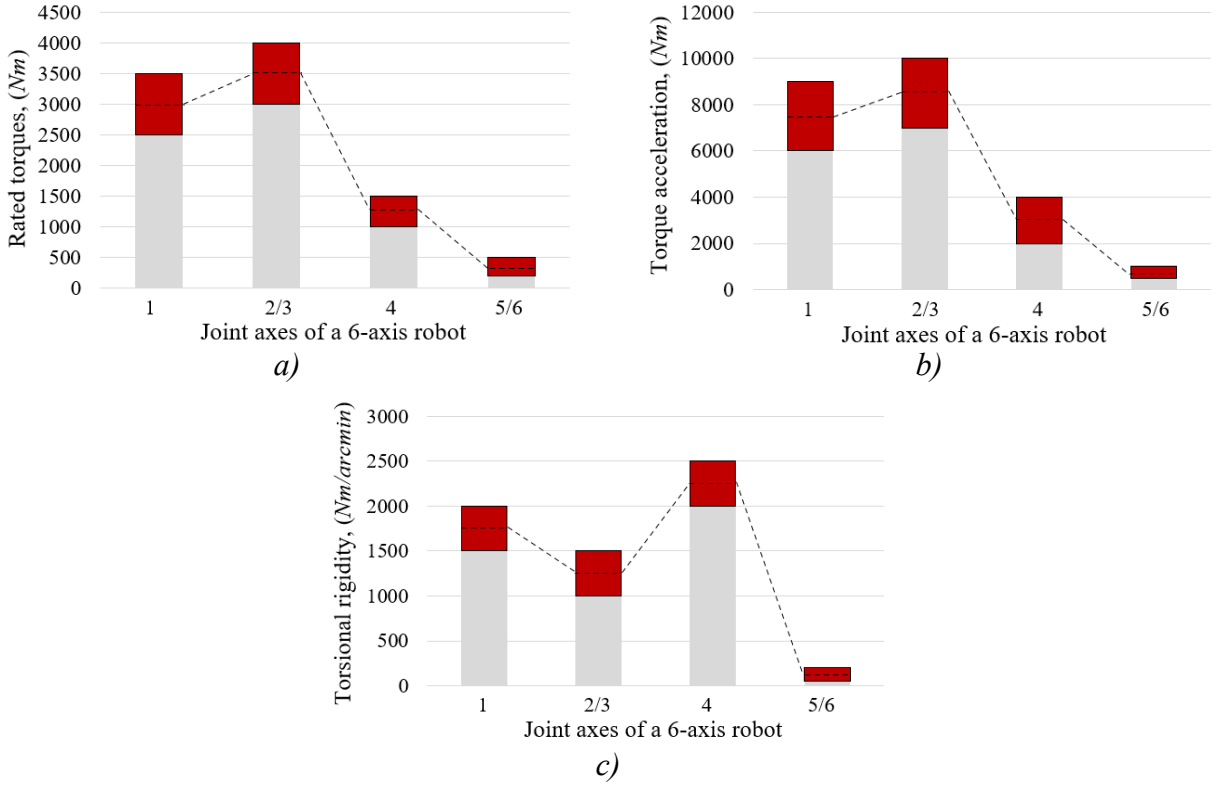

Figure 4. Comparative characteristics of gearboxes in axes: a) rated torques; b) torque acceleration; c) torsional rigidity

4. CONSLUSION

This paper analyses the main factors to be considered when selecting gearboxes for joints of a 6-axis robot. Since gearboxes have a great impact on final performance of industrial robots including speed, acceleration, payload, positioning accuracy and repeatability, the gearboxes generally need to have zero backlash, high torsional rigidity, high torque density, high efficiency and high gear ratios without taking up much space. Each axis has a specific function, therefore, each axis needs a specific gearbox. Considering the fact that the largest loads occur in the first axes: base, shoulder and elbow (especially in the shoulder which carries 70-75% of the total weight of the robot), these axes require gearboxes with high torque density. For other axes, more compact gearboxes can be used, except for axis 4 which requires high torsional rigidity.

Abstract: *MQTT (Message Queuing Telemetry Transport) is the main Machine-to-machine (M2M) communication protocol in Industry 4.0. It provides data exchange within a complex network of remote connected devices. Protocol MQTT represents a completely open source publish/ subscribe communication model, with fast response. It is an application layer protocol, intended for the transmission of short messages and suitable for Internet of Things (IoT). Data transfer to/from the Internet using MQTT is made over the TCP/IP stack. MQTT is a high-performance protocol, which keeps each connection open and reused in scheduled communication when needed. MQTT protocol is a reasonable option for data transfer between small-size devices with low energy consumption, where lower bandwidth has to be utilized. MQTT is used in automotive, manufacturing, telecommunications, oil and gas industry, etc. This protocol is a standard for the IoT data transmission, because it is simple, efficient, scalable, reliable, secure, and well supported. High level of data security can be provided through selective encryption, using the Transport Layer Security and Security Socket Layer or TLS/SSL cryptographic protocols. MQTT in Industrial IoT (IIoT) is a adaptable solution for M2M communication - it enables devices to exchange sensor's data, machine status, or alerts and allows receiving control commands.*
Keywords: MQTT Protocol, Internet of Things - IoT, Industrial IoT - IIoT, Machine-to-machine - M2M Communication, Industry 4.0.

1. INTRODUCTION

Industrial automation is nowadays omnipresent and a commercially viable to be implemented in manufacturing and process industry. Utilization of sophisticated technologies like Internet of Things (IoT) can provide improved performance in practice and better integration of production with business systems. The IoT and Machine-to-machine (M2M) are innovative technologies that require messaging protocols and connectivity to transfer information from and to some remote locations.

MQTT (Message Queue/Queuing Telemetry Transport) is an application layer protocol, primarily aimed to send/receive short data messages. This messaging protocol is supported by main public cloud services: Amazon Web Services, Microsoft Azure and Google Cloud. MQTT protocol is of the open source type and it is suitable for connecting the IoT and Industrial IoT (IIoT) devices. This message protocol enables reliable data transfer over unreliable networks. There is no message queuing. High level of security can be obtained. MQTT protocol has been released in 1999. and is successfully in operation since [1]. MQTT can have stable run in bandwidth-constrained networks.

[2] djdihovicni@atssb.edu.rs
[3]nratkovickovacevic@atssb.edu.rs
[4]sinisa.minic@pr.ac.rs
[5]sanja.jevtic@vzs.edu.rs

MQTT is characterized by the following features: small code footprint, low power consumption, small bandwidth, decreased latency, use of publish/subscribe procedure. Other known protocols, which are not of publish/subscribe type, require new connection to be established each time between networked devices so this two would be able to communicate. The large amount of IIoT applications relies on MQTT. Implemented in a factory such applications usually utilize equipment of various vendors, numerous sensors and devices (called MQTTY clients) networked with a central server as a control unit (referred to as a MQTTY broker). [1, 2]

2. THE IOT AND IIOT

IoT stands for Internet of things, i.e. Internet of dedicated, 'intelligent' devices, called things, deployed and used to exchange real-world data over Internet or other networks without the need of a person to initiate communication. IoT refers to the collection of networked devices that are able to communicate autonomously over the Internet [3]. The IoT operation is enabled through a communication of physical devices over cabled or wireless networks, enhanced with data analytics and advanced cloud computing technology. The basic process of how IoT operates is as follows: a group of physical devices is networked through cables or wireless links, both between each other and to a central area (various network architectures can be used); the devices collect data from the environment using some type of sensors; these data are then stored in the cloud or in a local memory on the device; the data are then processed (often using machine learning - ML, and artificial intelligence - AI); the processed data are used by the same physical devices to perform some predefined actions [3].
The IoT has either consumer or private, enterprise and social implementations. When is used properly, the same enables different industries to accelerate growth, transform economies and achieve higher level of competitiveness and efficiency [3]. With the IIoT, manufacturers can ensure increase of efficiency over the value chain, ranging from operations and engineering to product supply and services. Inherent benefits of the IIoT, include: asset optimization, smart monitoring, a predictive maintenance and most importantly, intelligent and informed decision-making. All these had rapidly made the IIoT an irreplaceable technology. Different technologies, like big data, sensor data, M2M communication, ML, and automation are present and in cooperation in the IIoT [3].

3. INDUSTRY 4.0

Industry 4.0 is a new concept that changed the way companies operate, manufacture, supply products or services and enhance all these processes [4]. With integrated innovative technologies, including IoT, 5G and 6G networks, cloud computing, AI and ML, production and operations can be considerably improved. The so-called smart factories are contemporary plants equipped with sensors, embedded software and robotics with high level of autonomous automation. Collecting and analyzing data from various enterprise systems is utilized and hence more informed decisions can be made. These digital technologies lead to higher automation, enabling predictive maintenance, self-optimization, higher efficiency level and faster responsiveness to customer's requests or needs. Developing smart factories that provide many new opportunities transformed manufacturing industry to Industry 4.0. Exploiting the high-tech IoT devices in smart factories leads to higher productivity and improved quality of end product or service. By applying ML algorithms, it is possible to detect some errors immediately or early, to prevent equipment downtime or losses and make optimized, planed repairs on demand. Industry 4.0 technologies can be applied within almost all industry types, including discrete and process manufacturing, oil and gas, mining and other. [4]
The IoT is the key innovative and supporting technology for transformation of traditional factories into smart factories in Industry 4.0 [5, 6]. The strategy of 4^{th} industrial (r)evolution is focused on implementation and converging information-communication technologies (ICT). The goal is to achieve the intelligent factory (smart factory), which is characterized by adaptability, resource efficiency, and ergonomics, as well as the integration of customers and business partners in business

and value processes [5]. The final result of convergence is the completely smart factory, which can deliver enhanced productivity, flexibility, agility with real-time decision making [4]. Each object is made intelligent (has built-in web server) and can communicate with any other object regardless of application level or function [5]. Industry 4.0 for Process is an initiative for manufacturing operations and process control that applies increasingly more autonomous automation, while integrating it with business information, execution of manufacturing operations, supply chains and retail to achieve overall higher efficiency of the company. The issues in a system are addressable and immediately solved, on any level of application or function. This improves all aspects of production and service availability across relevant environments for greater overall efficiency of the company [5].
Digital technologies, including IoT, robotics, cloud computing, cyber-physical systems and big data are key for the Industry 4.0 implementation [7]. The Industry 4.0 concept implies complete digitization of all production processes and application of the aforementioned digital technologies to create prototypes, fabricate products, organize production, perform manufacturing and process control, make quality inspection and connect with clients and customers to provide better services [7].

4. OPERATION AND PROPERTIES OF MQTT

MQTT is a lightweight messaging protocol that was developed by IBM and first released in 1999. [8] It uses publish/ subscribe ('pub/ sub') pattern and translates messages between devices, servers, and applications. MQTT has a lot of applications in the IoT [8]: telemetry and sensor networks, home automation, IIoT, asset tracking, energy management, healthcare and wearables. When MQTT protocol is used, connected devices known as "clients" communicate over a server referred to as the „broker". The MQTT broker's task is to handle data transmission between clients [1, 8]. Whenever a MQTT client, here called "publisher", wants to distribute information, it will publish to a particular topic [8]. MQTT operation process is presented in Figure 1 [2].

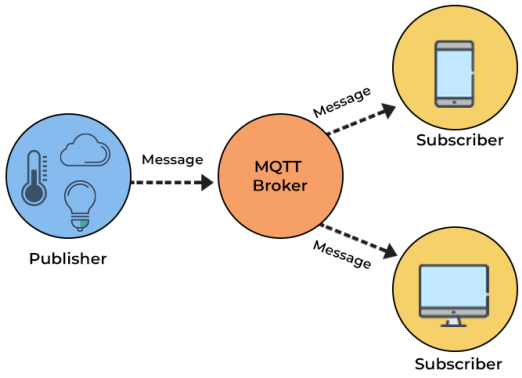

Figure 1. A Diagrammatic Representation of the MQTT Process
Source: https://shorturl.at/AHMNW

The message filtering is a mechanism by which subscribers receive only a subset of all published messages they 'wanted' [9]. There are two forms of message filtering [9]: topic-based and content-based. In topic-based filtering after the message is published the MQTT broker forwards this information to any of the MQTT clients, here called "subscribers" that have subscribed to that topic (Figure 1. [2]). In content-based approach, messages are delivered to subscribers provided that the attributes, or content of the message correspond to the constraints defined by them [9]. Each message sent by MQTT protocol contains a two-byte fixed header [2]. Adding title to it is optional and introducing it makes the message lengthier. The payload of the message is restricted to 256 MB [2].
MQTT is currently available in version 5.0 launched in 2019. [2]. It has on going evolving since its initial development. During this time, significant changes were made, but the primary focus of the protocol has changed from proprietary embedded systems to the open IoT use cases [2]. MQTT is a smart solution for wireless networks that face different levels of latency, due to periodic bandwidth

limitations, or unreliable connections. It's built as a super-lightweight messaging transport, perfect for linking faraway gadgets using minimal code and network resources [2]. MQTT is suitable even for delivery of small code. MQTT is OASIS-recognized standard suitable for IoT communications and data transmission in various industries. The main MQTT applications include [2]: automotive, oil and gas industry, manufacturing, smart cities, remote sensing, home automation, smart farming, wearables, social media platforms, power and ICT. MQTT has been created as a specialized protocol for interfacing with supervisory control and data acquisition (SCADA) systems in the oil and gas industry [2].

MQTT is often used to transport small messages between devices because [2]: it is lightweight and efficient, well-supported, scalable, it provides reliable and secure communication. Message distribution is one-to-many and may scale in terms of customer base without putting publishers or brokers under undue strain [2]. Message queuing can be done by a broker in case of intermittent links. MQTT is utilized in wide range of applications [2], from the IoT and IIoT, to linking cloud environments in the IoT and IIoT. Key reasons why MQTT is well suited for the IoT implementation are [2]: it drives efficiency, enables low network use (as a result of smaller data packets), facilitates efficient data dissemination, unlocks remote sensing and control, delivers messages timely and efficiently, consumes low power, supports multiple modes of communication. MQTT's ongoing development brought significant changes and enhancements to the protocol. In current MQTT version several new features are introduced [2]: message expiry dates, the ability to mask topics, reason codes in case of messaging failure, and load sharing across multiple clients. With MQTT protocol industry is well suited to apply and incorporate IIoT and M2M communication workflows into enhanced IT infrastructure [2].

MQTT uses the TCP protocol for data and message transfer. The three types of messages are usually exchanged by MQTT [2]: connect, publish, subscribe. Both MQTT and Hypertext Transfer Protocol (HTTP) protocols use TCP connections [10], in client-server network architecture. However HTTP servers (unlike MQTT servers) only respond to requests from clients. With MQTT in message exchange, clients can publish and subscribe. Once a connection is established, any number of messages can be sent using MQTT through it, in both directions, data from sensor to back-end, and commands to the end devices [10]. MQTT communication requires [2, 10]: clients (either publishers or subscribers or both), brokers and connections. Clients can't communicate directly - a broker is necessary as a mediator. Each incoming message is filtered by the broker, who then sends it to the appropriate customer[s]/subscriber(s) [2]. MQTT is an application layer message protocol that utilizes TCP/IP stack protocols on the 4th and 3rd ISO/OSI layer (Figure 2. [9]). Reliability of MQTT has three qualities of service [10]: 0 - fire and forget, 1 - at least once, 2 - once and only once. Security can be enhanced by transport-encryption ensured by Transport Layer Security and Security Socket Layer or TLS/SSL protocols [9]. Identity of both sides in communication is assessed by implementing the secure transport protocol. Many IoT devices use TLS with two way authentication to protect sensitive data transmission [9, 10].

MQTT can provide a very high level of security by using TLS/SSL certificates [9]. Again MQTT is run on top of the TCP protocol. MQTT protocol has wide range of applications in contemporary smart factories as well. MQTT communication can be integrated with existing security systems. TLS protocol can provide messages to be sent through a secure channel. MQTT brokers may be enhanced by authorization and authentication. [11]

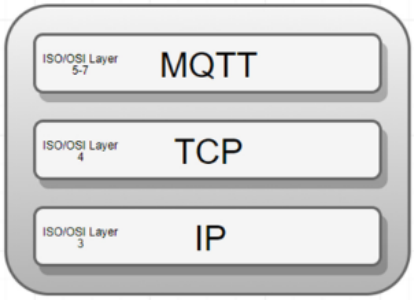

Figure 2. MQTT within TCP/IP communication protocols stack [9]

MQTT can implement intra-factory communications by linking different areas, systems and levels [11]. Intra-factory interactions over MQTT in Figure 3 are represented [11]. Integration of automation and manufacturing, levels 0-3, requires reliable data exchange between various machines, Programmable Logic Controllers (PLCs) and sensors [11]. Further MQTT can be used for exchanging data between SCADA systems and Manufacturing Execution System (MES) [11].

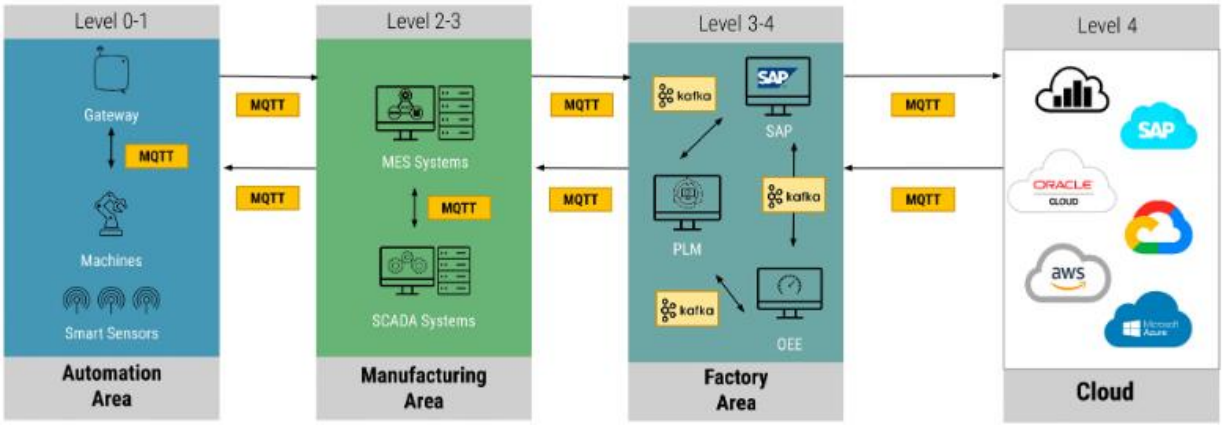

Figure 3. Intra-factory Interactions with MQTT [11]

In the IIoT, there are many sensors and control devices, that exploit unreliable or low-bandwidth networks. It is crucial that MQTT brokers ensure optimal performance and high reliability to meet demands of IoT applications [12]. This is the reason why performance testing is advised. Performance testing is a process of using testing tools to simulate various normal, peak, or abnormal load conditions to test various performance indicators of the system tested [12]. The goal is to verify whether the system can meet the user's expectation, discover performance bottlenecks in the system, and so on. Performance testing of MQTT would establish the relationship between network latency and resulting quality of service (QoS). MQTT is widely used in the various IoT scenarios. It is an asynchronous protocol that implements several types of publishing and subscription [12]: 1-to-1, 1-to-many (fan-out), and many-to-1 (fan-in). There are two main test scenarios for MQTT brokers [12]: 1. Concurrent connection, including number of concurrent connection and connection's rates; 2. Message throughput, for sending and receiving messages, with some performance-affecting parameters, such as QoS, payload size, topic wildcard, etc.

5. CONCLUSION

MQTT is one of the leading protocols suitable for the use in the omnipresent IoT. It is defined as lightweight, flexible network protocol for asynchronous communication. Various devices use MQTT protocol for message exchanges. Messages are of small length, so the data transmission does not overload the network. MQTT relies on publish/subscribe model of communication and requires client(s) (either publisher(s) or subscriber(s)) and server/broker. Publishers send messages regarding specific topics to the broker, while some clients subscribe to selected topics. MQTT performs transmission of messages having one of the three types. All messages are sent to the broker first. MQTT can distribute a published message to many subscribers at the same time. Sending data to commonly applied cloud platforms is also possible.

MQTT protocol is frequently used in M2M communications. This protocol has significant importance in Industry 4.0 implementations. It has features specifically tailored to enable different IoT solutions. MQTT achieves secure communication over networks having constraints. Intra-factory autonomous interactions between machines, devices and software systems are enabled by MQTT on various levels of automation. MQTT provides reliable data exchange in the advanced IoT systems, different services and QoS levels. To achieve specific goals, such as better operation and production management (i.e. process optimization), quality improvements, and predictive maintenance companies need to collect and analyse data and to draw decisions from them.

In the paper MQTT properties, options and applications are elaborated, as well as future trends. It is quite utilized in manufacturing and process control, either in factory's field, or on higher levels of automation and cloud. MQTT has large importance in current and future applications, since it enables sending large amount of data over links with low bandwidth. Moreover it can propel implementations of AI and ML in contemporary production and other industries.

THE POST-QUANTUM CRYPTOGRAPHY AND CHALLENGES IN NETWORK SECURITY AND INDUSTRY 4.0

Srđan Barzut[1], The Academy of Applied Technical Studies Belgrade

Abstract: *This paper highlights the important relationship between Industry 4.0, network security, and the impending quantum computing revolution. The pressing necessity for post-quantum cryptography is explored for securing the massively interconnected networks of Industry 4.0, as quantum computers pose a threat to the fundamentals of current encryption. Examining the vulnerabilities in conventional cryptographic systems, identifying the challenges in implementing quantum-resistant solutions, and emphasizing the value of preventative measures were the objectives. Preserving data confidentiality and integrity is of the utmost significance in the era of Industry 4.0.*
Keywords: Post-quantum Cryptography, Quantum-Resistant Cryptography, Quantum Attacks, Network Security, Industry 4.0

1. INTRODUCTION

The goal of the fourth industrial revolution, or Industry 4.0, is to create an environment in the manufacturing sector that supports autonomous systems, smart factories, and real-time manufacturing ecosystems. Information technologies like cyber-physical systems (CPS), the Internet of Things (IoT), operational technology (OT), cloud computing, automation, big data, and artificial intelligence (AI) are used in Industry 4.0-related initiatives. These initiatives are being carried out in response to the necessity to deal with digital transformation and the rise in competition [1]. A high level of interconnectedness across different equipment, systems, and devices is essential to Industry 4.0. Because of the increasing complexity brought about by this interconnection, it is challenging to monitor and secure all entry points and potential vulnerabilities. Malicious actors have a greater attack surface when there are more linked devices [2]. Organizations in Industry 4.0 need to take a comprehensive approach to network security to solve these problems. This entails making significant investments in reliable cybersecurity solutions, carrying out frequent risk assessments, educating staff members about cybersecurity best practices and new threats, and keeping up with industry developments. Industry, government, and academic cooperation are also necessary to create and exchange information and tactics for preserving Industry 4.0's future. CPSs are a common means by which physical and digital systems are brought together in Industry 4.0. The physical ramifications of attacks on these systems make security lapses even more dangerous [3]. Industry 4.0's widespread use of IoT and OT devices raises several security issues. These devices are often resource-constrained, so security is unlikely to be the producers' first concern. Attackers may use them as points of entry. Threat actors are becoming more sophisticated and are using advanced techniques such as AI and machine learning for cyber-attacks [4]. Detecting and defending against these threats requires equally advanced security measures. Everything mentioned represents a rather contemporary field of research. However, it is necessary to anticipate the future security challenges brought by post-quantum computers and post-quantum cryptography.

A quantum computer is a kind of computer that does computations based on the principles of quantum mechanics. Quantum computers employ quantum bits, or qubits, which can exist in several states concurrently, in contrast to classical computers, which use bits that can only be either 0 or 1. Because

[1]sbarzut@atssb.edu.rs

of this qubit characteristic, certain kinds of computations can be completed by quantum computers far more quickly. For example, factoring huge numbers is one of the mathematical problems that quantum computers can handle that is computationally impossible for classical computers. Although they are still in the experimental stage, quantum computers are not yet commonly accessible. However, creating prototypes and showcasing their prospective capabilities has advanced significantly in recent years. They can completely transform a lot of industries, including machine learning, cryptography, and optimization. Before quantum computers can carry out real computations on a large scale, there are also important technological and practical issues to resolve. However, concerns regarding the security of classical cryptography systems, which rely on the complexity of specific mathematical problems, like discrete logarithms and integer factorization, have been raised by the emergence of quantum computing. This mathematical complexity could be effectively resolved by quantum computers, making many popular encryption techniques insecure. Many of the cryptographic systems in use today, including those that are frequently used to encrypt internet and network communications, could be broken by quantum computers. The goal of post-quantum cryptography (PQC) i.e., quantum-resistant cryptography, is to provide cryptographic algorithms, that will remain resistant to attackers possessing quantum capabilities.

2. FUNDAMENTALS AND CHALLENGES IN POST-QUANTUM CRYPTOGRAPHY

2.1 Review of Conventional Cryptographic Algorithms in Practical Application

In the current digital era, data storage and transmission security has become essential. Cryptographic algorithms have long served as the foundation of information security, ensuring the confidentiality, integrity, and authenticity of sensitive data. The continuous assessment of these algorithms is vital as the digital environment changes, in order to respond to new threats and preserve the privacy and security of data across a variety of applications, such as financial transactions, communication, and data storage. Among the most well-known applied algorithms are: Data Encryption Standard (DES), Advanced Encryption Standard (AES), Rivest-Shamir-Adleman (RSA), Elliptic Curve Cryptography (ECC), and the Rivest Cipher (RC) family. These algorithms illustrate the evolution of cryptographic techniques and their adaptation to practical use cases. When DES was first released in the 1970s, it became the standard symmetric key algorithm. Its significance lies in pioneering the use of encryption for data security. A 56-bit key and a Feistel network structure have been employed in the basic version of the DES algorithm. Later, Triple Data Encryption Standard (3DES) was developed, which increases security by applying the DES algorithm three times to each data block using separate keys. Due to advances in computer power and its vulnerability to brute-force attacks, DES has been replaced in many applications; however, legacy systems in government and financial organizations continue to utilize it to secure legacy data. Although data security was first made possible by DES, AES has proven to be a robust and versatile choice for modern purposes. Since its introduction in the early 2000s, AES has proven to be extremely adaptive to a wide range of security requirements. It provides key lengths of 128, 192, and 256 bits. AES has become the de facto standard for encrypting data in modern applications. It is frequently used to protect data-at-rest in storage devices, secure internet connection via SSL/TLS, and preserve sensitive data in databases. It is appropriate for a wide range of applications, such as online banking, e-commerce, and secure communications, due to its practicality and robust security. RSA is a popular asymmetric cryptography technique that is known for its pivotal role in securing data transmission, digital signatures, and key-exchange. RSA was created in 1977 by Ron Rivest, Adi Shamir, and Leonard Adleman, and its security is based on complexity of the mathematical properties of large prime numbers and modular arithmetic. ECC is an asymmetric cryptographic algorithm that has gained prominence for its high-security properties and efficiency, especially in situations with limited resources like those found in mobile and IoT devices. The difficulty of solving the Elliptic Curve Discrete Logarithm Problem (ECDLP) provides the foundation for the security of ECC. In simple terms, this problem involves finding the discrete logarithm of a point on the curve. The size of the key and the curve selection affect the security of

ECC. Because it is possible to have smaller key sizes without compromising security, ECC is a popular option in situations where efficiency and performance are essential. Due to its effectiveness, ECC is particularly well-suited for devices with constrained bandwidth and processing power. A typical key length for ECC may be 256 bits, which provides security comparable to a 3072-bit RSA key. RC4 and RC6 are members of the RC family and have been used in a variety of applications. For secure email communications and disk encryption, RC6 has been accepted, whereas RC4 is utilized in the WEP and WPA wireless security protocols. The stream cipher known as RC4 became well-known due to its effectiveness and ease of use. It is utilized in applications like VPNs and wireless communication security that call for quick encryption and decryption. Block cipher RC6 provides a high degree of security and adaptability. It is suitable for applications where data needs to be securely stored and transmitted, such as in enterprise-level data protection and file encryption. With its various members, the RC family provides alternatives that strike a compromise between performance and security, making them appropriate for particular uses where speed or data protection is a priority.

2.2 Post-Quantum Cryptography Algorithms and Standardization Process

Among the most well-known and innovative quantum algorithms is Peter Shor's algorithm [5]. It is frequently referred to as Shor's Algorithm and was created in 1994. The ability of this technique to factor huge numbers efficiently has important ramifications for contemporary cryptography. Large composite numbers are mostly intended to be factored into their prime factors. To put it another way, it can divide a big number N into the prime numbers that, when added up, equal N. Large number factoring is a tough computing issue that serves as the foundation for many cryptographic systems, such as RSA. The security of RSA is based on the presumption that factoring huge semiprime numbers is computationally impossible. However, Shor's Algorithm has the potential to efficiently factor such numbers, posing a significant threat to traditional public-key cryptography. The use of quantum period-finding is Shor's Algorithm's primary invention. It makes use of a quantum computer's capacity to assess several values at once in order to determine a modular function's period. Shor's Algorithm deciphers the factors of the number with efficiency by determining the period, which breaks RSA encryption and related techniques. Shor's Algorithm has raised concerns about the security of widely used public-key cryptography systems. For example, the security of RSA-based encryption may be jeopardized by Shor's Algorithm, which theoretically exploits the difficulties of factoring big semiprime numbers. The mathematical characteristics of error-correcting codes served as the foundation for the 1978 proposal of the McEliece cryptosystem, a public-key encryption technique [6]. Consequently, it ranks among the first public-key cryptosystems. Unlike many other public-key encryption schemes, the security of RSA and ECC is not based on number theory, but rather on the difficulty of solving specific mathematical problems that arise in coding theory. The Goppa codes in particular are difficult to decode, and it is believed that decoding a randomly chosen Goppa code in polynomial time is practically unfeasible, even with powerful computing power. This complexity provides the foundation for the security of the McEliece cryptosystem. It is considered safe from quantum attacks even with the introduction of large-scale quantum computers. The larger key sizes utilized in McEliece compared to RSA or ECC can be a disadvantage in terms of key management and storage. Furthermore, compared to other public-key cryptosystems, encryption is less efficient in terms of message size, since it produces comparatively large ciphertexts. These issues have limited its deployment to academic and research settings. Compared to other encryption techniques, it hasn't been widely used in real-world applications, despite providing post-quantum security. Though McEliece continues to be a contender for strong encryption in a world when quantum computers might pose threats to already-existing cryptographic systems, there has been a resurgence of interest in post-quantum cryptography in recent years. However, research is ongoing to address its limitations and make it more practical for real-world applications.

In recent years, there has been an increase in both the quantity and quality of PQC research [6]. Research focuses on candidate algorithms for standardization that have been accepted via each stage.

One of the most promising approaches in the post-quantum era is lattice-based cryptography. It depends on how challenging some lattice-related tasks are, like the Learning with Errors (LWE) problem. NTRUEncrypt and Kyber are two well-known lattice-based encryption methods. The foundation of code-based cryptography is error-correcting codes, which take advantage of the difficulty of deciphering random linear codes (McEliece principles). Distinguished instances of multivariate polynomial cryptography are the Rainbow and HFE schemes. This method makes use of difficult-to-solve systems of multivariate polynomial equations. The Merkle signature scheme and other hash-based cryptography schemes depend on the characteristics of hash functions to offer protection from quantum attacks. Isogeny of Elliptic Curves cryptosystems rely on the property of congruent graphs of elliptic curves over finite fields, or super anomalous congruence graphs, to create a secure system. This is the basis of a number of particular schemes, including the CSIDH key exchange system, which serves as a substitute quantum attack candidate for the Diffie–Hellman key exchange method. The current level of PQC research is succinctly described by the Venn diagram in Figure 1, where the numbers in the circles indicate the number of corresponding references, the red words are the names of potential algorithms, and the circles containing blue words represent the basic principles of encryption.

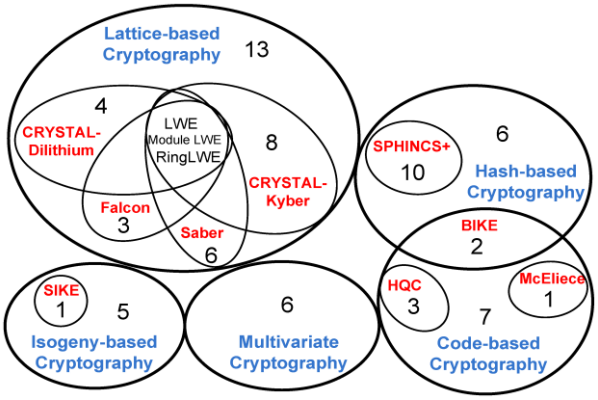

Figure 1. The Venn diagram describes the fields of PQC research
Source: https://www.mdpi.com/2410-387X/7/3/40 [7]

Following several stages of development for cryptography, National Institute of Standards and Technology (NIST) proposed in the 1970s to select a cipher to serve as the nation's common standard. This selected cipher was DES algorithm, launched with a relatively modest key size. That shortcoming led NIST to issue another call for proposals in 1997, which resulted in 50 algorithm proposal for new block codes. The AES algorithm was selected in 2000 and is still commonly used as the industry standard for symmetric encryption. However, the existence of ciphers based on mathematical complexity is now at risk due to the development of quantum computers and quantum cryptography algorithms. Algorithm standardization is a significant post-quantum cryptography challenge. In order to guarantee security and interoperability, NIST started a new process in 2017 to choose and standardize post-quantum cryptography algorithms in an effort to discover algorithms that can withstand the power of quantum computing. NIST has initiated a process to solicit, evaluate, and standardize one or more quantum-resistant cryptographic algorithms [8,9]. Currently, the NIST standardization process is in its fourth round. For the majority of use cases, NIST primarily suggests the CRYSTALS–KYBER (key establishment) and CRYSTALS–Dilithium (digital signatures) algorithms. Furthermore, a standardization of the signature schemes FALCON and SPHINCS+ is proposed. In a fourth round of assessment, candidates BIKE, Classic McEliece, HQC, and SIKE will all continue for further study [9].

2.3 Challenges in Post-Quantum Cryptography

Compared to conventional cryptography algorithms, post-quantum cryptography methods often require more computer resources. It's extremely challenging to maximize their performance while preserving security. The process of switching from classical to post-quantum cryptography is intricate

and needs to be carefully planned and coordinated in order to maintain the security of current systems. While certain cryptographic systems may include quantum-safe features, they haven't been thoroughly examined. It is difficult to ensure their security in practice. The field of quantum-resistant encryption is still developing. Future research might concentrate on enhancing the security and effectiveness of current post-quantum algorithms. Another line of inquiry is how secure communication might be enabled by quantum cryptography. Understanding the potential and constraints of quantum computers in terms of cryptographic system attacks will be essential for developing safe post-quantum algorithms as these machines grow in power. Research is still being done to create useful policies and instruments for using post-quantum cryptography in practical applications.

3. CONCLUSION

This paper has addressed the paramount issue of network security in the context of Industry 4.0, recognizing the imminent threat posed by quantum computing to contemporary cryptographic systems. A comprehensive survey of the weaknesses of conventional cryptography algorithms against quantum attacks, fundamental principles, algorithms, challenges, process of standardization and future directions in post-quantum cryptography has been provided. The advent of quantum computers presents a clear and present danger to the security of data and networks, necessitating a paradigm shift towards post-quantum cryptography. In order to protect the integrity and confidentiality of data in the Industry 4.0 ecosystem, the necessity of taking a proactive stance and pushed for the creation and use of quantum-resistant encryption techniques is emphasized. As the field continues to advance, collaboration between researchers, industry stakeholders, and policymakers will be essential to ensure the security of our digital infrastructure in the post-quantum era.

Abstract: *The paper explores key challenges faced by bees within their hives when exposed to unfavorable temperature and humidity conditions. High humidity inside beehives can lead to an increased risk of diseases and moisture condensation, while high temperatures can induce stress among the bees and potentially harm the combs. Simultaneously, small and weak bee colonies face additional challenges in addressing these issues due to their limited resources and capacities. This paper presents an innovative approach to addressing these problems using artificial intelligence and sensor modules. Through thorough research and implementation, a system has been conceptualized to monitor conditions within beehives and automatically react using fans to maintain optimal levels of temperature and humidity. Through conceptual testing and analysis, the system effectively assists bees in coping with adverse conditions, particularly applicable to small and weak bee colonies. This approach significantly contributes to the preservation of bee populations and the proper functioning of bee communities. The paper emphasizes the importance of applying technological solutions to improve bee health, which has broader ecological and economic implications.*
Keywords: Artificial Intelligence, Temperature, Humidity, Optimization, Beehive

1. INTRODUCTION

The bee colony, with its intricate and delicate ecosystem, is susceptible to the influence of numerous factors, among which air temperature and humidity within the beehive are of essential significance. These factors play a crucial role in regulating the behavior and health of bees. It is evident that two factors, temperature and humidity, are central triggers of changes within the bee society and potential issues when they reach critical values. High humidity within the beehive poses a severe threat to the bee colony. When humidity exceeds the tolerance threshold, bees become extremely vulnerable. Problems resulting from high humidity include an increased risk of various diseases, disruptions in daily activities, and disturbances in their nourishment. Elevated humidity can create a favorable environment for the development of pathogenic organisms, which can cause significant harm to the bee society. Furthermore, high humidity can lead to moisture condensation inside the beehive, further complicating the situation and inducing stress among the bees.
On the other hand, high temperature also represents a significant threat to the bee colony. An increase in temperature above a certain level can lead to severe disruptions, including alterations in reproductive behavior, reduced honey yields, and, ultimately, endanger the survival of the bees.

[3]dradakovic@atssb.edu.rs
[4]dmilovanovic@atssb.edu.rs
[5]ssuljovic@atssb.edu.rs

In this context, research and the development of systems for monitoring and controlling humidity, along with temperature within beehives, become a priority for the preservation of bee populations and the enhancement of their health. This study focuses on the development of an innovative solution using artificial intelligence technology and the Internet of Things (IoT) to efficiently regulate environmental parameters in bee hives, ensuring optimal conditions for the bees and contributing to their survival. Through a combination of technical innovations and scientific approaches, this study aims to achieve a deeper understanding and practical solutions for the complex challenges faced by bee populations in ever-changing environmental conditions.

2. RELATED RESEARCH

The relevance of air temperature and relative humidity parameters is highlighted in numerous studies, including [1], which point to the causal relationships these parameters have within the beehive. High temperatures within the beehive can cause a range of problems crucial to the survival of the bee colony. Critical temperature values may vary depending on the bee's developmental stage and activities, but it is generally considered that temperatures exceeding 36°C are critical and negatively affect bee life. High humidity within the hives can lead to various problems for the bees and their social structures. Critical humidity values also depend on the bee colony's developmental stage, but humidity exceeding 80% is usually considered a serious issue. The development of IoT-based monitoring systems used to track and gain insight into the health of bee colonies and beehive management systems [5] allows for instant insights into bee colony activities and the ability to regulate and manage specific parameters to optimize conditions that may cause stress to bee colonies. There is also a wide range of applications for hive control and management [9].

3. BEEHIVE TEMPERATURE AND HUMIDITY REGULATION PROBLEM

Thermoregulation within the beehive is crucial for maintaining optimal conditions for various processes in the bee colony. Bees are capable of maintaining the temperature within the hive in a narrow range, usually between 32°C and 36°C. High temperatures above this range can lead to several issues, such as bee stress and comb melting. An increase in temperature beyond 36°C can cause stress among the bees, resulting in increased energy consumption, reduced productivity, and decreased lifespan of worker bees. At extremely high temperatures, the wax used to build the comb can begin to melt, leading to comb deformation and loss of food storage cells, which can be catastrophic for the bee colony.Problems arising from high humidity may include an increased risk of pathogenic diseases, condensation inside the hive due to high humidity, reduced productivity, and bee colony survival. Elevated humidity can facilitate the growth of pathogenic organisms. Humidity can lead to condensation within the hive, potentially damaging the hive's interior and the bee food stores. Bees may lose access to food due to such issues. Bees are susceptible to stress at high humidity levels, reducing their productivity and longevity, which can ultimately jeopardize the survival of the colony.

3.1 Challenges of small and weak bee colonies

Small and weak bee colonies face particular challenges in addressing problems related to high humidity and temperature. They have a lesser capacity to regulate and are at a higher risk of bee colony collapse. Small bee colonies have fewer resources and worker bees, making them less capable of regulating hive conditions. Weak bee colonies are more susceptible to temperature and humidity issues due to their limited problem-solving capacity. In this context, the application of artificial intelligence and sensor modules can be crucial. A system that automatically monitors conditions within the beehive and adjusts them using fans can be of significant assistance to small and weak bee colonies.

4. IMPLEMENTATION OF SENSOR MODULES, BIDIRECTIONAL FANS, AND MICROCONTROLLERS

Sensor modules on the perceptual layer are positioned at key locations to detect air temperature and relative humidity within the beehive. Sensors are symmetrically positioned at both upper and lower positions to ensure the data's relevance and comparability. In the same manner, we monitor differences in measured values that provide inputs for fan activation. Fans are positioned parallel to the frames to achieve a greater optimization effect. The beehive has two fans that are symmetrically positioned and can operate synchronously or asynchronously, thus acting in opposite or the same direction, depending on the effect they need to achieve (Figure 1). This way, we achieve regulation, specifically for temperature and relative humidity.

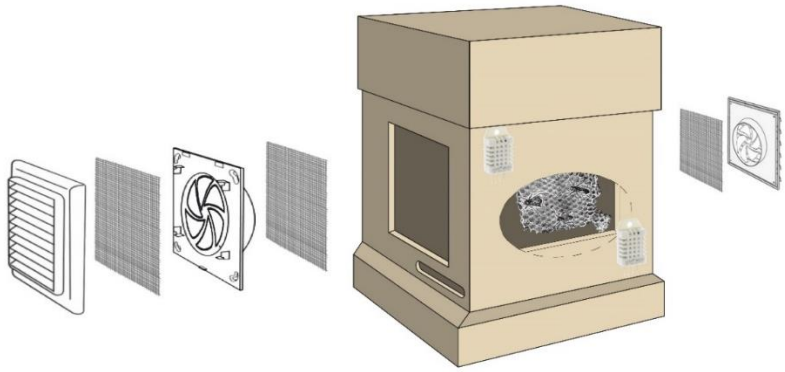

Figure 1. Positions of fans and sensors

The microcontroller module based on the ESPRESSIF ESP32 chipset regulates the operation of sensor modules and fans through relays (Figure 2). Thanks to the possibility of implementing artificial intelligence at lower layers of the IoT architecture, machine learning models are applicable. TensorFlow libraries can be installed on these modules, allowing machine learning models to be applied for monitoring parameters and controlling fan intensity to achieve optimal values inside the beehive.

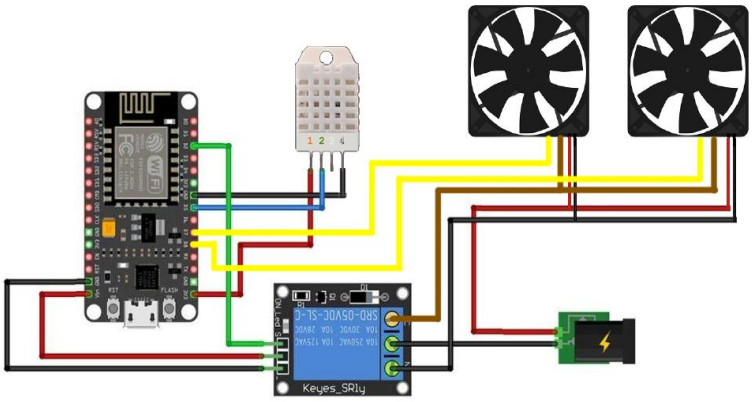

Figure 2. Fritzing connection diagram

4.1 Application of Artificial intelligence modules

The application of artificial intelligence at the EDGE layers of the IoT architecture optimizes the hardware resources' load for beehive health monitoring systems. ESP32 modules meet these requirements with their impressive hardware performance. In this way, self-regulation and predictive control of the beehive can be achieved, especially if the system is controlled via cloud services and application software with alarm features. By using predictive models for preventing unwanted events, the system can be automated, expanding the technology's applications.Based on data collected from the perceptual layer (DHT22 sensor measures temperature and relative humidity), an artificial intelligence model based on recurrent neural networks, an LSTM model, has been created to predict

parameter trends. If the model predicts critical values for a specific parameter, increased temperature or humidity, it activates the fan's movement in a specific direction depending on the parameter and adjusts the fan's intensity and speed. The model makes predictions based on average values within intervals of 20 minutes. As critical values for these two parameters may occur at different times and may overlap, the model recognizes trends and activates the fan's direction and intensity.The LSTM model of recurrent neural networks for time series prediction has already shown excellent results in previous studies. The ability to adjust hyperparameters and include hidden layers, as well as memory cells, provides a significant advantage in modeling predictive values with these models.

5. CONCLUSION

During the test phase with an empty beehive, the system succeeded in optimizing humidity values by 6 percent, while in the regulation of temperature values, it succeeded in optimizing by 4 degrees. Of course, this is a conceptual model, and testing in different times of the day and seasons is yet to come. Testing will also be performed in various situations of the bee colony's activity, different periods of food collection, etc.The fan's operating mode is based on the combination of airflow directions in the beehive, finding the best operating model during value optimization. The results of future research will help develop more precise models and better parameter optimization.

Abstract: *In this paper, an expression for the channel capacity (CC) of the combined L-branch (SC) selection receiver is derived in the presence of Rayleigh small fading and co-channel interference (CCI) also by Rayleigh distribution. Rayleigh fading occurs when there is a large number of objects between the transmitter and receiver on which the signal scatters. Analytical results for CC will be performed in closed form and then graphed for channel capacity. In addition, a machine learning approach based on ChatGPT is introduced to recognize the type of fading based on channel capacity measurements, which is further leveraged for quality of service (QoS) adjustment tuning the corresponding parameters on receiver's side.*
Keywords: ChatGPT, SC combining, Rayleigh fading and interference, QoS, GPU.

1. INTRODUCTION

Wireless communication systems are designed to deliver a message over a wireless channel. The messages sent from the transmitter include a random source and the messages received cannot be predicted with certainty. In addition, wireless channel impairments including thermal noises are expressed as random factors. The characteristics of such a channel change over time, making it difficult to design reliable systems with guaranteed performance. The random process is a very useful model to describe an information source, transmission, and noise. In wireless communication systems, the received signal may be subject to short-term and long-term fading (shadowing). Short-term fading is the result of multi-layered propagation and shadowing of large obstacles and large deviations of the terrain profile between transmitter and receiver [1]. Shadowing is the weakening of the signal due to the specifics of the propagation environment (vegetation, residential areas, ...). As these objects are stationary, the attenuation of the received signal is relatively slow. Thus, the mobile communication channel can be modeled as a Gaussian channel with slow non-selective Rayleigh fading (received signal amplitudes have a Rayleigh distribution) and with a shadow effect, where the distribution of the mean value of the signal-to-noise ratio, SNR, is lognormal) [2].
One of the best techniques for improving the reliability of communication over wireless channels is combining diversity. With this technique, if the signal on one path weakens at one moment, it can be stronger on the other path, so due to the existence of a larger number of paths, the current and average SNR can be significantly increased, and thus the performance of the system improves. There are two

[1]gnestorovic@atssb.edu.rs
[2]v-petrovic@hdl-dh.com
[3]nandrijevic@atssb.edu.rs
[4]nenad.petrovic@elfak.ni.ac.rs
[5]ssuljovic@atssb.edu.rs

types of diversity techniques: micro and macro diversity. Microdiversity eliminates short-term fading. In this case, several non-correlated (fading) components are received at the same base station and combined in a certain way, whereby the non-correlation condition is ensured by a distance between the receiving antennas that is greater than λ/2 (e.g. at frequencies greater than 1 GHz, sufficient is a distance of 15 cm). There are various methods of extracting a useful signal, such as: selection of the signal with the highest SNR value (selective diversity SC), phase equalization of all signals and their addition, where each signal is multiplied by a fading parameter determined by measuring the SNR of each signal, i.e. maximum-ratio (MR) combining, and a method that is a special case of the previous one, where all signals are taken with the same weight, better known as equal gain (EG) combining. The simplest of these methods is selective diversity (SC) where, at the reception of L diversity branches, the one with the highest SNR ratio is selected [3]. Macrodiversity reception techniques are represented by spatially separated radio ports (base stations), which serve one cell, receive fading signals with different long-term attenuation. As the attenuation due to the shadow effect at certain ports must be independent, they are located at distances greater than 1 km [4].
This paper presents a micro diversity receiver with an L branch that works through a Rayleigh multiple fading channel and interference also present in the channel. For that case, the channel capacity is calculated at the output of the receiver. The main vision of mobile networks is to achieve massive data transfer with the highest data transfer speeds. The idea is to enable people and machines to access information and services at all times and in all possible situations, leading to enormous improvements in productivity and sustainability in the modern world of communications.

2. CC OF SIGNAL TO INTERFERENCE RATIO AT THE OUTPUT OF SC RECEIVER

In this part, the outage probability of wireless communication system with SC receiver with L branches (L=2, 3…..n) are considered. The received signal experiences Rayleigh fading and the interference on the co-channel channel. The receiver model is shown in Figure 1:

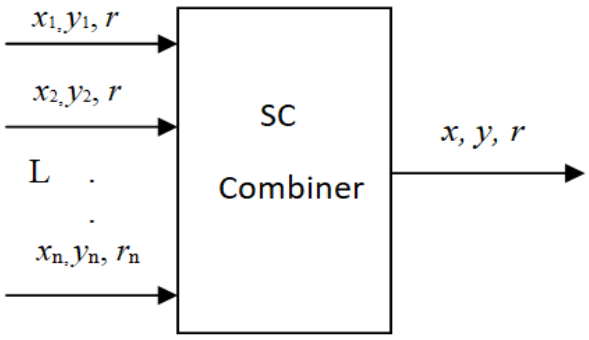

Figure 1. Model of the considered *SC* combiner with *L* branches

The signal envelopes at the receiver inputs are marked with x_1, x_2, …, x_L. The SC combiner selects the signal marked x from the antenna with the highest SNR. The co-channel interference envelopes are marked with y_1, y_2,..., y_L, at each of the L inputs of the SC receiver, where L=2….n, while the corresponding output signal is y. The signal envelopes x_i follow the Rayleigh distribution [5]:

$$p_{x_i}(x_i) = \frac{2x_i}{\Omega_i} e^{-x_i^2/\Omega_i}; x_i \geq 0, i = 1, 2...n \quad (1)$$

where Ω_i is the mean value of the signal power. The signal y_j of the co-channel interference follows Rayleigh distribution and probability density function (PDF) of y_j is:

$$p_{y_i}(y_i) = \frac{2y_i}{s_i} e^{-y_i^2/s_i}, y_i \geq 0, i = 1, 2..n \quad (2)$$

where s_i is the mean value of the interferers power:

$$\Omega_i(x_i) = \bar{x}_i^2, s_i = \bar{y}_i^2 \tag{3}$$

The ratio of desired signal envelope and co-channel interference at inputs of SC receiver is:

$$r_i = x_i / y_i, \; x_i = r_i y_i \tag{4}$$

The probability density function (PDF) of the signal r_i is given by [6]:

$$p_{r_{ij}}(r_{ij}) = \int_0^{+\infty} dy_{ij} y_{ij} p_{x_{ij}}(y_{ij} r_{ij}) p_{y_{ij}}(y_{ij}) = \frac{2 r_{ij} \Omega_i s_i}{\left(\Omega_i + s_i r_{ij}^2\right)^2} \tag{5}$$

Cumulative distribution function (CDF) of r_i is [7]:

$$F_{r_i}(r_i) = \int_0^{z_i} \mathrm{d}t p_{z_i}(t) = \left(\frac{s_i r_i^2}{\Omega_i + s_i r_i^2} \right) \tag{6}$$

At the output of the SC receiver, the ratio signal to interference where i=1,3,…n is equal $r = \max(r_1, r_2 \ldots r_i)$. The probability density function (PDF) of the r at the out-put of the SC receiver with L branches can be calculated by using expression [7]:

$$p_{r_i}(r) = L p_{r_i}(r_i)\left(F_{r_i}(r_i)\right)^{L-1} = \frac{2L r_i^{2L-1} \Omega_i s_i^{\,L}}{\left(\Omega_i + s_i r_i^2\right)^{L+1}} \tag{7}$$

One of the most important measures of system performance is the channel capacity, which, according to Shannon, represents the theoretical upper limit for the maximum data transfer rate at an arbitrarily low bit error probability, without any delay complexity constraints [8]:

$$\frac{C}{B} = \frac{1}{\ln(2)} \int_0^{\infty} \ln(1+r) p_{r_i}(r) dr \tag{8}$$

where C is Shannon capacity given in bits/s, B denotes denotes transmission bandwidth given in Hz. Using the form for the logarithm function [9]:

$$\ln(1+x) = \sum_{i=0}^{\infty} (-1)^i \frac{x^{i+1}}{(i+1)!} \tag{9}$$

we get that the capacity of the channel:

$$\frac{C}{B} = \frac{2L}{\ln(2)} \left(\frac{s_i}{\Omega_i} \right)^L \sum_{i=0}^{\infty} \frac{(-1)^i}{(i+1)!} \int_0^{\infty} \frac{r_i^{i+2L+1-1}}{\left(1 + (s_i / \Omega_i) r_i^2\right)^{L+1}} dr \tag{10}$$

Using form [10; 3.251]:

$$\int_0^{\infty} \frac{x^{\mu-1}}{\left(1+\beta x^p\right)^v} dx = \frac{1}{p} \beta^{-\frac{\mu}{p}} B\left(\frac{\mu}{p}, v - \frac{\mu}{p} \right) \tag{11}$$

where B is the beta function, we get that the channel capacity is:

$$\frac{C}{B} = \frac{L}{\ln(2)} \sum_{i=0}^{\infty} \frac{(-1)^i}{(i+1)!} \left(\frac{\Omega_i}{s_i} \right)^{\frac{i+1}{2}} B\left(\frac{i+2L+1}{2}, \frac{1-i}{2} \right) \tag{12}$$

Numerically obtained results from the expression (12) where w=Ωi/si are shown graphically in Figure 2, which shows the C/B of the signal-interference ratio in relation to the crossing threshold (γ_{th}) at the output of the SC receiver (*i*=2,3. .*L*).

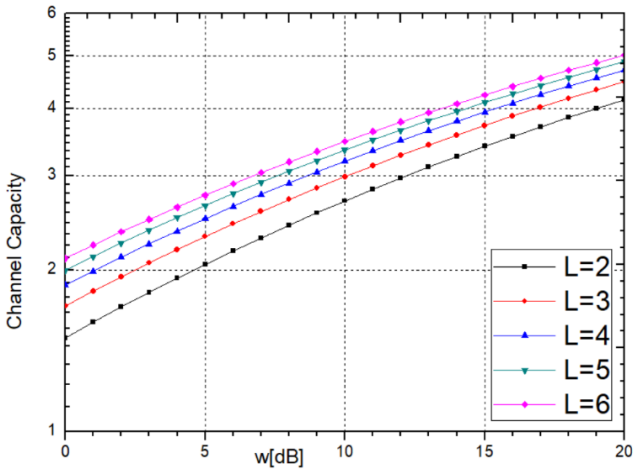

Figure 2. Normalized channel capacity for different values number of branches *L*

Fig. 2 show the channel capacity normalized by channel bandwidth B, depending on the w=Ω/S (dB). If the parameter L increases, the channel capacity increases and the system has better performance.

3. CHATGPT-BASED FADING TYPE CLASSIFICATION FOR QoS TUNING

Furthermore, this paper explores how the trending ChatGPT conversational agent based on Large Language Model (LLM) can be leveraged in order to recognize the type of fading within a given mobile network environment, based on channel capacity measurements. This information is used for Quality of Service (QoS) improvment by appropriate receiver type selection and parameter tunning. The problem is treated as classification, considering that the output is the number which corresponds to fading type. Based on our previous works, several types of fading are covered [11]: η-μ, k-μ, Weibull, Rayleigh and Nakagami-*m*. The proposed workflow is depicted in Fig. 3.

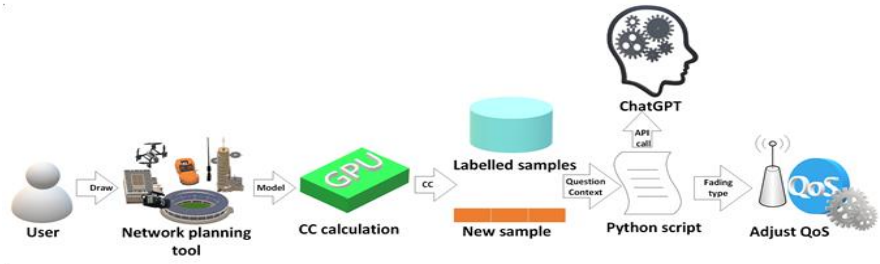

Figure 3. ChatGPT-driven workflow for QoS adjustment based on fading type classification

First, CC is calculated for given mobile network scenario, relying on our mobile network planning and simulation environment [12]. In order to speed up the CC calculations, we make use of GPGPU-based approach relying on graphics hardware for loop paralleliztion, reaching up to 70 times speed up compared to traditional CPU approach [13]. After that, the previously calculated CC value is used among the other input variables: receiver type (such as SC, MG, EG) and measured signal strength at the input of the reciever (x).

Chat Generative Pre-trained Transformer, known to publicity as ChatGPT, represents LLM-driven solution acting as chatbot with capability of dialogue, where users pose questions for given context. Context might include more specific information or additional facts which serve as „hint“ to ChatGPT, considering that the underlying LLM was trained on enormous amount of textual data. It was released publicly in late 2022 by OpenAI organization. Quickly, the curiosity of its users has shown that it is much more caable thatn basic question answering, showing outsanding results for variety of tasks –

from poertry writing and playing board games to program code generation and debugging [12]. Additionally, it has shown potential in area of basic supervised machine learning tasks [14], as it requires much smaller amount of data for training for adjustment than training a model from scratch, as it was already trained on almost whole World Wide Web.
Problem solving based on ChatGPT consists of forming prompts which provide the additional information as context and sending them via REST API to the online service itself. In this case, we make use of Python API, building upon code used for prompt construction and service invocation, as desribed in [14]. In our case, we provide labelled examples for known fading type generated using calculations using expressions, as the one derived in this paper. Context is given in the following form, representing the labelled data samples:

$$LabelFadingType_i = \left(ReceiverType_i CC_i \; X_i \right) \tag{13}$$

When it comes to p rompt itself, we define it as:

$$Classify\left(ReceiverType_i CC_i \; X_i \; BS_i Area_i \right) \tag{14}$$

Problem solving based on ChatGPT consists of forming prompts which provide the additional information as context and sending them via REST API to the online service itself. In this case, we make use of Python API, building upon code used for prompt construction and service invocation, as desribed in [14]. In our case, we provide labelled examples for known fading type generated using calculations using expressions, as the one derived in this paper. Context is given in the following form, representing the labelled data sampl.
Finally, Table 1 gives evaluation results, considering the following aspects: 1) processing time – time needed for classification of a single new observation; 2) minimal context size – least number of labelled examples within context in order to perform classification; 3) accuracy – correct classification ratio per 10 records for given minimal size of context expressed as percentage.

Table 1. ChatGPT Approach to fading type determination : Evaluation Results

Aspect	Result
Execution time	2.21 s
Minimal context	15
Accuracy	85%

According to the achieved results, the proposed apporach seems promising as it performs with satisfiable accuracy for quite small number of labelled examples, giving the additional flexibility of data analysis, considering that model re-training is not required for each small modification of dataset layout (such as introducing additional input variables).

4. CONCLUSION

In this paper, we analyzed the L-branch SC receiver in the presence of Rayleigh fading and co-channel interference. For such a scenario, in this paper, an expression for the capacity of the channel for a signal that is subject to the influence of fading and interference is mathematically derived and graphically presented. Based on the graphic display, we determined that the system has the best performance when the number of system branches is greater than 2. Using the obtained expressions, the probability of the SIR output of the SC receiver for a system with L branches is effectively estimated. Also, in the second part of our work, we showed that the optimal choice of base station minimizes the total costs and provides the best possible quality of service (QoS). According to the obtained results, it is evident that the cost reduction achieved in this way is significant, and it depends on the specific example of the smart city model.

In the second part of the part of the paper, we proposed a novel workflow for QoS adjustment on receiver's side leveraging fading type classification based on trending ChatGPT. According to the achieved outcomes, this approach exhibits satisfiable prediction accuracy even for small number of labelled examples.

The paper has been supported by the Ministry of Education, Science and Technological Development of the Republic of Serbia.

Abstract: *In this paper, we conducted an analysis of the probability of outage (P_{out}) at the receiver output with selection combining (SC) with L branches of a wireless communication system in the presence of Nakagami-m fading and Nakagami-m co-channel interference (CCI). The mathematical form of the function for P_{out} in terms of the normalized signal-to-interference ratio (SIR) was derived, on the basis of which a graph was drawn for different values of fading and CCI parameters. In the second part of the paper, we propose a classification-based approach implemented in Weka to estimate the QoS level using the P_{out} of the observed system as one of the inputs*.
Keywords: Outage probability (P_{out}), Selection Combining (SC), Nakagami-*m* fading and co-channel interference (CCI), Weka, machine learning.

1. INTRODUCTION

In wireless communication systems, the three main channel impairments are: short-term fading (multipath propagation), long-term fading (shadowing), and the corrupting effect of co-channel interference. Shading or long-term signal variation follows a Lognormal distribution, while short-term signal variations can be described by several other distributions such as Hoit, Rayleigh, Rice, Nakagami-*m*, and Weibull, and others. Considering that interference is significant in today's wireless networks, the channel model in communication systems ignores the effect of receiver noise on system performance. Short-term fading refers exclusively to temporal changes of the communication channel due to the movement of the mobile unit or surrounding objects. In long-term fading, the impulse response of the channel changes much more slowly than the transmitted signal, so that the channel can be considered invariant for the duration of a few symbols of the transmitted signal. The speed of movement of the mobile unit (or objects in the channel) and the rate of signaling determine whether the transmitted signal will be subject to fast or slow fading [1].
The Rayleigh channel model is used in situations where there is no direct optical line visibility LOS (line of sight - los) between the transmitter and receiver, which is typical for urban environments. In intercity zones and suburban areas are used the Rice model, which includes the existence of a los component. Variations in current received signal strength in urban areas can be described quite well by Nakagami and Weibull distribution. Nakagami-*m* model is used to describes the mobile radio

channel, to model the attenuation of multipath wireless signals and to study the effect of fading channels on wireless communications [3].
In order to improve system performance in case of pronounced fading, the diversity technique is applied. Diversity techniques it is based on the principle of using a large number of copies of the sent signal, which are statistically independent. Most commonly used signal combining techniques after application various techniques are: Selection Combining (SC)-which implies the choice of a branch with with the most favorable signal-to-noise ratio, Maximum Ratio Combining (MRC) – combining with maximum signal- to-noise ratio, Equal Gain Combining (EGC) – combining with equal contribution of all branches, Switch and Stay Combining (SSC)–simple switching combining, as well as various hybrid techniques combining signals[4].
The most commonly used performance indicators are diversity receivers in fading environments are the mean value output signal-to-noise ratio (SNR) or signal-to-interference (SIR), as well as the probability of system outage (P_{out}) and bit error probability (BER). Outage probability-denoted by P_{out} is the probability that the instantaneous error probability exceeds a specified value or equivalently the probability that the output SNR or SIR falls below a certain specified threshold γ_{th} [5].
In this paper chosen channel model Nakagami-*m* was for describing the statistics of multipath fading, due to its simplicity and frequent application. The parameter m is called the fading parameter and can take any value in the interval (1/2, +∞). For *m*=1 the Nakagami distribution becomes Rayleigh's, and for *m*>1 Rice's distribution [6]. On the other side, the second part of this paper considers leveraging the previously derived outage probability expression for purpose of proactive Quality of Service (QoS) estimation, based on classification model implemented using Weka in Java programming language.
The structure of this paper is as follows. After the introductory part (Section I), the analysis of P_{out} of the transmission channel affected by the Nakagami-*m* fading will be presented (Section II) by deriving the closed-form expressions for PDF, CDF, and P_{out} and numerical analysis of the P_{out} for multiple combinations of the fading parameters and different numbers of branches *L* of the SC receiver, will be conducted and results discussed. QoS estimation using classification in Weka will be presented in Section III. The conclusion of the paper is given in Section IV.

2. OUTAGE PROBABILITY OF THE SIR AT THE OUTPUT OF SC RECEIVER

The system considered in Figure 1 is an *L*-branch SC receiver when Nakagami-*m* fading and Nakagami-*m* co-channel interference are present. At the input of the *L*-branch SC receiver (*L*=2, 3,..., *n*) there are *n* copies of the useful signal: x_1, x_2, ..., x_n. Also, at the inputs to the SC combiner, signal components originating from the CCI y_1, y_2, ..., y_n appear. The SC receiver from the *L*-branch selects the signal with the highest SIR from the input antennas.

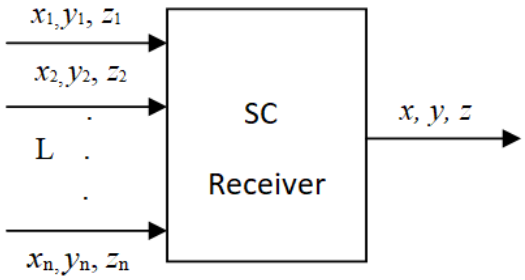

Figure 1. Model of the considered *SC* combiner with *L* branches

Signals at the receiver input have a probability density function (PDF) modeled by Nakagami-*m* distribution [7]:

$$p_{x_i}(x_i) = \frac{2}{\Gamma(m_1)}\left(\frac{m_1}{\Omega_i}\right)^{m_1} x_i^{2m_1-1} e^{-\frac{m_1}{\Omega_i}x_i^2},\ x_i > 0,\ i = 1, 2, ..n \qquad (1)$$

where m is the Nakagami-m short-time fading severity parameter, Ω represents the average SNR represents the average SNR, and $\Gamma(\cdot)$ denotes the Gamma function. The co-channel interference follows Nakagami-m distribution:

$$p_{y_i}(y_i) = \frac{2}{\Gamma(m_2)}\left(\frac{m_2}{s_i}\right)^{m_2} y_i^{2m_2-1} \mathrm{e}^{-\frac{m_2}{s_i}y_i^2},\ y_i > 0,\ i = 1,2,..n \tag{2}$$

where s_i represents the power of interference: $\Omega_i(x_i) = \bar{x}_i^2, s_i = \bar{y}_i^2$. The ratio z_i of the desired signal and the co-channel interference at the i^{th} branch at the SC receiver input is: $z_i = x_i / y_i, x_i = z_i y_i$.
The SC receiver chooses the signal with the highest SIR of all signals (i=2,3,..n) and forwards it to the output: $z = \max(z_1, z_2 ... z_i)$. On each branch at the entrance to the SC receiver, the PDF of the SIR-z_i relationship is [8]:

$$p_{z_i}(z_i) = \int_0^\infty \mathrm{d}y_i y_i p_{x_i}(z_i y_i) p_{y_i}(y_i) = \frac{2z_i^{2m_1-1}\Gamma(m_1+m_2)}{\Gamma(m_1)\Gamma(m_2)}\left(\frac{m_1}{\Omega_i}\right)^{m_1}\left(\frac{m_2}{s_i}\right)^{m_2}\left(\frac{\Omega_i s_i}{m_1 s_i z_i^2 + m_2\Omega_i}\right)^{m_1+m_2} \tag{3}$$

The cumulative distribution function (CDF) of z_i is [8]:

$$F_{z_i}(z_i) = \int_0^{z_i} \mathrm{d}t p_{z_i}(t) = \frac{2(\Omega_i m_2)^{m_2}(s_i m_1)^{m_1}\Gamma(m_1+m_2)}{\Gamma(m_1)\Gamma(m_2)} \int_0^{z_i} \mathrm{d}t \frac{z_i^{2m_1-1}}{\left(m_1 s_i z_i^2 + m_2\Omega_i\right)^{m_1+m_2}} \tag{4}$$

The integral in (4) can be solved by using [9]:

$$\int_0^\lambda \frac{x^m}{\left(a+bx^n\right)^p}\mathrm{d}x = \frac{a^{-p}}{n}\left(\frac{a}{b}\right)^{\frac{m+1}{n}} B_z\left(\frac{m+1}{n}, p-\frac{m+1}{n}\right), z = \frac{b\lambda^n}{a+b\lambda^n}, a>0, b>0, n>0, 0<\frac{m+1}{n}<p \tag{5}$$

where, $B_x(p,\mathrm{q})$ is Incomplete Beta function [10; 8.39] we get that the CDF of z_i is:

$$F_{z_i}(z_i) = \frac{\Gamma(m_1+m_2)}{\Gamma(m_1)\Gamma(m_2)} B_{\frac{m_1 s_i z_i^2}{m_2\Omega_i + m_1 s_i z_i^2}}(m_1, m_2) \tag{6}$$

When interference is present in the environment, P_{out} is defined as the probability that the output SIR of the used combiner will fall below the defined protection ratio, which depends on the applied modulation technique and expected grade of service (GoS). On the receiver output SC with L branch, P_{out} is [11]:

$$P_{out}(z<\gamma_{th}) = \left(F_{z_i}(z_i)\right)^L = \left(\frac{\Gamma(m_1+m_2)}{\Gamma(m_1)\Gamma(m_2)} B_{\frac{m_1 s_i z_i^2}{m_2\Omega_i + m_1 s_i z_i^2}}(m_1, m_2)\right)^L \tag{7}$$

In order to analyze the influence of the SIR parameters on the performance of the considered system, we drew a graph for P_{out} from the expression (7), shown in Figure 2. One of the assumptions is that there is no correlation between the input branches in the SC receiver. Figures were created using Wolfram Mathematica and Origin.

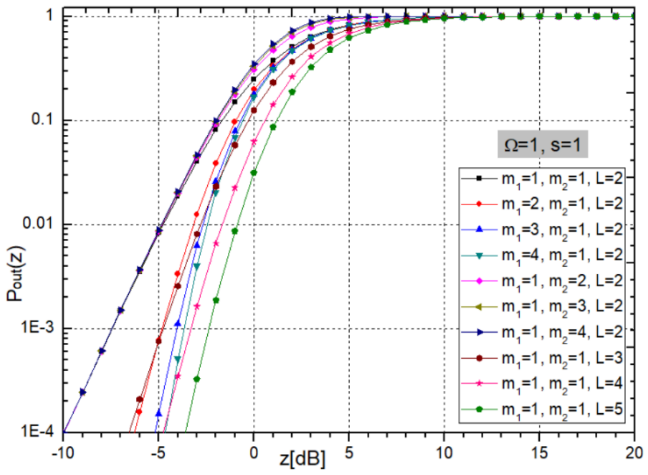

Figure 2. P_{out} of L-branch SC receiver for different values of fading parameters m_1, m_2 and the number of diversity branches L.

From Figure 2, we see that with the increase of parameters m_1 and m_2, the outage probability (P_{out}) of the system decreases and the performance of the system improves. Also, the outage probability of the system decreases with the increase in the number of diversity branches L at the input of the SC combiner, and the system performance improves.

3. QoS ESTIMATION CLASSIFICATION IN WEKA

The potential of artificial intelligence adoption and predictive models has been identified among the key-enablers contributing to progress towards the next generation wireless and mobile networks [12]. This paper introduces an approach to Quality of Service (QoS) prediction leveraging machine learning algorithms, considering the previously calculated P_{out} among the input variables of predictive model. Furthermore, there are also other input factors included: 1) identifier of observed smart city area 2) number of active service users for the area 3) identifier of base station covering the area of interest 4) season number, depicting the period within a year.
On the other side, the target of predictive model represents categorical outcome which illustrates QoS level. This value is a label and has several possible values: "1"–failure or anomaly occurred; "2"–low/insufficient; "3" –normal, "4"–"maximum". Considering that, we treat the prediction problem as multilabel classification. Table 1 depicts the header layout of the training dataset which was generated leveraging our simulation environment [13].

Table 1. QoS Level Dataset Header

Area id	Pout	Num Users		Bs id	Num Season	QoS [1-4]

When it comes to predictive QoS level predictive model implementation, we make use of free to use (under GNU public license) library - Waikato Environment for Knowledge Analysis (Weka) [14] aiming Java programming language. It includes a set of machine learning technique implementation, together with additional features, enabling convenient data preparation, management and visualization. Regarding the algorithms aiming supervised machine learning trained on samples with known outcome (label), it includes several classification approaches - decision tree, decision stump, ID3 and k-nearest neighbors.
In Table 1, summarized evaluation results focused on two aspects–prediction performance (as accuracy – correct sample classification percentage) and processing time required for training of classification model on laptop with given configuration: CPU - Intel Core i5-10300H quad-core 2.50GHz; RAM - 24GB DDR4 and storage - 512 GB SSD. Observed dataset of 50 000 samples was divided into set for training (75%) and test (25%).

In Fig. 3, the full workflow of the underlying approach is depicted. In the first steps, users-defined network models are created based on tools from our previous works [12, 14]. After that, calculation of outage probability is done with respect to this model. Additionally, for this step we make use of NVIDIA CUDA kernels [13] with aim to parallelize loops which gives around 60 times speed-up compared to CPU-only implementation. Once the outage probability values are known, they are used together with variables for training of Weka-based predictive model. Weka's predictive model workflow includes several phases: 1) importing CSV dataset 2) conversion of CSV values to Weka instances 3) target variable selection 4) classification model object instantiation 5) model training 6) model evaluation. After all these steps, the model is finally ready to make predictions on unseen inputs. Finally, based on prediction outcomes, decisions can be taken regarding the operator infrastructure parameter tuning with goal of proactive QoS improvement.

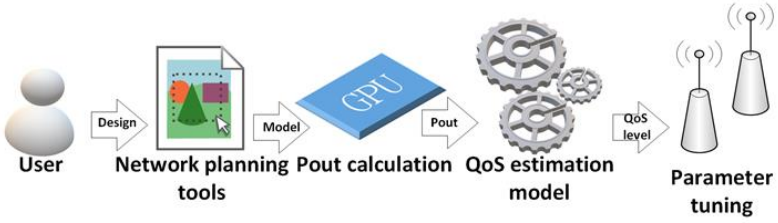

Figure 3. Classifiication-based macihne learning QoS level prediction workflow relying on Weka

TABLE 2. EXPERIMENTS AND EVALUATION RESULTS

Method	**Training** [s]	**Accuracy** [%]
DecisionTable	39.8	96.4
J48	9.1	91.1
DecisionStump	11.5	86.3
iBk	2.4	89.3
Average prediction time [s]	0.08	

Observing the achieved results from Table 2, it can be noticed that DecisionTable method shows the best performance compared to others in terms of prediction quality expressed as accuracy. On the other side, training time required for this approach is the longest among the compared techniques. Moreover, ID3-based J48 method is the second when it comes to prediction accuracy, but training phase is much faster. Additionally, DecisionStump requires the shortest amount of time to be trained, while it exhibits the worst accuracy performance. However, iBk based on k-NN shows slightly better results, but the required training time is longer. Finally, average prediction time for a single prediction for all the methods does not exceed 0.1 s.

4. CONCLUSION

In this paper, the expression for the outage probability (P_{out}) is derived as one of the important measures for the quality of transmission in wireless networks. Numerical results showed that increasing the fading parameters m_1 and interference m_2 leads to a decrease in P_{out} and the system works better. We also concluded that increasing the number of SC diversity branches reduces the level of P_{out} and the performance of the system is better. Additionally, we have proposed the software environment for simulation of P_{out} for the observed Nakagami-*m* fading system, leveraging the calculated value as one of inputs for classification-based method aiming QoS estimation. According to the achieved experimental outcome, the proposed workflow shows both promising accuracies, quite fast training and single prediction execution times.

The paper has been supported by the Ministry of Education, Science and Technological Development of the Republic of Serbia.

Dragana Đurić[4], Academy of Applied Technical Studies Belgrade

Abstract: *Computer devices (desktop and portable computers, tablets, mobile phones ...) are used daily for creating documents and for various forms of communication. The user controls the computer (or "communicates with it") through a special set of programs called the operating system, through graphical elements and text in different languages, including Serbian in Cyrillic or Latin script. This paper deals with the level of using the Serbian language usage for communication with computers, as well as the creation of documents in the Serbian language. There is an overview and description of using computer techniques in Serbian on various devices and operating systems, such as Windows, Linux, Android, iOS. The specifics of using the Cyrillic and Latin letters scripts are covered, also as well as combining and converting one letter script to another (transliteration). A pilot study was conducted on users' familiarity with the possibilities of using computers in the Serbian language, the ways in which they use them and their views on the necessity of observing language standards. Measures were proposed to improve the level of language culture when using computer devices, especially in educational institutions.*
Keywords: computer use, Serbian language, Cyrillic script, Latin script

1. INTRODUCTION

In the transition period from the 20th to the 21st century, there was a rapid increase in the use of computer devices in Serbia. In that period, there was no adequate support for the use of computers in the Serbian (operating systems and document creation) This support is mainly related to the lack of hardware and software components, inadequate training of teachers and, consequently, unsatisfactory training of users. The situation is further complicated by the fact that two scripts are used in the Serbian (Cyrillic and Latin), while only Cyrillic is recognized internationally. That is why manufacturers of computer devices and software have taken different positions regarding the use of both the Cyrillic and Latin alphabets. This led to the creation of bad habits among users: excessive use of the English language in communication with computer devices, acceptance of poorly adjusted devices and non-respect of Serbian spelling, etc. Overall, the result is low productivity and low-quality documents in the Serbian language, while the considered support has not been significantly improved so far. The aim of this paper is to point out the currently available possibilities and shortcomings of available computer devices (hardware and software) and to propose measures to complete the support for the use of computers in the Serbian language.

2. KEYBOARDS

As a rule, text entry is performed using the keyboard. Keyboards can be a separate peripheral device or a dedicated part of the screen. One key is activated by clicking the mouse or touching a finger on touch screens (virtual keyboards). Physical keyboards enable faster and more productive text input and editing. Physical keyboards are mostly used on desktop and laptop computers, and virtual keyboards on mobile devices (tablets and mobile phones). Programs for managing keyboards determine the arrangement of characters on keys and the way to change the keyboard. All keyboards allow the entry of special characters and characters of different world alphabets through the dedicated management programs.
Physical keyboard are separated computer peripherals. A physical keyboard for a language or script means that the keys are arranged according to the appropriate standard and that the corresponding letters of that language or script are visible on the keys. Physical keyboards for the Serbian language on the Serbian market exist mostly only for the Latin alphabet. The authors were able to find only one type of Cyrillic keyboard in three online stores (for example [1]). Regardless of the fact that there are Latin keyboards, Serbian users often use some other keyboards, most often English, to write text in the Serbian language. If there is no suitable Serbian keyboard, users have the following options:

1. Use the keyboard you have, set the Serbian Cyrillic or Latin alphabet in the software, learn by heart where each letter or character is located (and often make mistakes). This kind of thing is mostly practiced when the Serbian Latin keyboard is used to enter text in Cyrillic.
2. Improvise. Write a letter or stick a label on the characteristic keys, Figure 1 [2]
3. Obtain and stick sets of stickers for one or two languages or letters that the user will use the most Figure 1 [3].

Figure 1. Improvised key labelling and Keyboard with a set of stickers
Source: *https://urlis.net/jzjoht8y & https://urlis.net/g1m3m1zp*

Using multiple languages/scripts on one computer also requires an efficient way to change wih. For example, the more efficient Win+Space or Accent Grave (`) can be added to the usual Alt+Shift in Windows.
Virtual keyboards are special programs (tools) built into operating systems and software packages. Virtual keyboards exist for all types of devices and operating systems, but are mainly used for portable devices with a touch screen; they exist for both Cyrillic and Latin. English keyboards for the Latin alphabet have keys for every letter of the English alphabet, and letters containing diacritical marks (for the Serbian alphabet šđčćž) are typed by long pressing the corresponding key to get a menu with all available letters with diacritical marks. This is also the case with the Serbian Latin keyboard for the iOS operating system (Figure 2). This method greatly slows down text input, so users often type only the basic character: c for c, č and ć; s for s and sh; z for z and ž, as well as dj instead of đ – the so-called clipped Latin alphabet. Users who acquire such a harmful habit also often apply it to keyboards, physical and virtual, which have keys for all the necessary letters. Cyrillic keyboards have a corresponding key for each letter of the Serbian alphabet (for example Figure 2, also for iOS), as well as, for example, the GBoard and Swift Key keyboards, which are available for several operating systems.

All keyboards have a lot of techniques that make it easier to type text, including giving suggestions for finishing the started word - these techniques, however, require a lot of adjustment and getting used to, so beginners often don't apply them. Some keyboards, such as Gboard, have the ability to convert speech into text for the Serbian language. For the Android operating system, the functionality is good, but for iOS, our country/region is not supported! Overall, there are good options for converting speech to text for Android, while the iOS Serbian language is not supported at the level of the operating system.

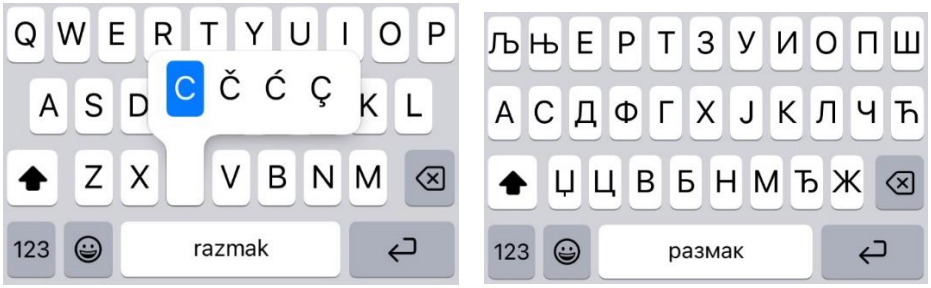

Figure 2. Virtual Keyboard for iOS
***Source**: original copyright*

3. TEXTUAL INTERFACE OF OPERATING SYSTEMS AND APPLICATIONS

Most operating systems have a predominantly graphical interface, but also with a lot of text for command names and messages. It is similar with applications of various types such as office applications, web browsers and open source software. All operating systems except iOS and on all devices support the Serbian Cyrillic and Latin interface, as well as most of the listed applications (except those for iOS). Figure 3 shows an example of the application interface in the Serbian language.

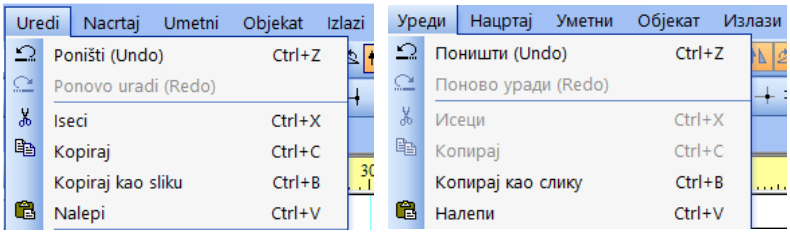

Figure 3. User interface example in Serbian
***Source**: original copyright*

4. LANGUAGE TOOLS FOR SERBIAN LANGUAGE

Spellchecking involves comparing a written word with words in the dictionary. The user is prompted for an error, offers options for replacing or adding a new word to the dictionary. The ability to add a new word is especially important for the Serbian language, since different cases and other words with different suffixes in spellcheckers are treated as separate words. However, in the application, one user quickly refills the list of words and the spelling check is quite functional. The most commonly used word processing programs have built-in spellchecking for Cyrillic and Latin script, with a corresponding adjustment, which is not quite simple so it is often absent. Most e-mail programs have spell checking, often through additional programs and settings. For example, online Gmail has a good spell checker for Cyrillic. Other language tools: hyphenation, thesaurus, automatic word correction, grammar checking - in principle they also exist for the Serbian language, but not with a mostly incomplete word pool, but with the possibility of adding it. Language tools for Serbian language are numerous for web browsers, but mostly are not widely used and sufficiently developed. Interesting is the language tool [4] which allows irregular and unacceptable typing of text in Latin script (Dosli su saptaci. – Figure 4) to be converted into correct text in Cyrillic – Дошли су шаптачи.

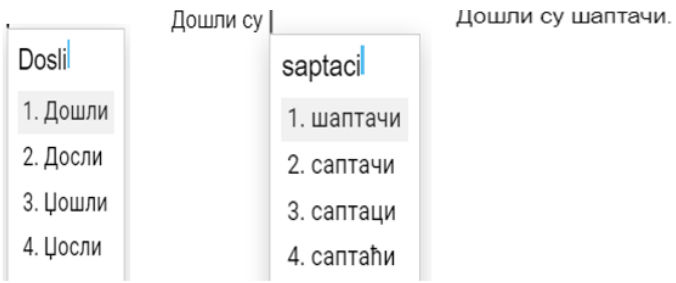

Figure 4. Example of language tools
***Source**: original copyright*

Document templates (DTs) are predefined documents that serve as the basis and starting point for creating new ones. DT is read only file, so an ordinary user can hardly modify them, but can easily create new ones. DTs contain a variety of language (e.g. script language) and national settings (e.g. date and paper format), and may contain parts of the content. There is usually a basic default DT (e.g. called Normal). If DT for Serbian language is not already installed, users should adapt the basic DT to the Serbian language and the usual documents. If, for example, DT for English instead of for Serbian is used, typical errors can occur such as: using Letter paper instead of A4, displaying dates 12/03/2023 incorrectly as 12/03/2023 or, worse, 03/12/2023 and, typically, the conjunction "i" transformed into "I" (English personal pronoun) through autocorrect options.

5. TRANSLITERATION

Transliteration (preslovljavanje in Serbian) is the process of transferring a word from the alphabet of one script to another. Problems in transliteration Cyrillic to Latin and vice versa arise from the fact that in Latin for some letters two characters are used: lj for љ, nj for њ, as well as irregular but often used dj instead of đ for ђ.
Table 1 shows examples of errors in the conversion of Cyrillic to Latin and Latin to Cyrillic. Colour and bold letters indicate converted or misspelled words. The first example refers to the conversion of the letter pair n-j in which the letter nj can also be denoted in the Latin alphabet. The second and third examples refer to the appearance of Latin letters in the dominant Cyrillic text: Roman numerals and units of measurement. The fourth and fifth examples show the correct and incorrect input of the Latin letter đ as dj. All of these irregular conversions should be recognized by the spellchecker, but the conversion is not automatic and requires additional user involvement. Another way would be to extend transilleration programs with vocabulary words that need to be excluded from conversion. From the table it can be seen that the conversion from Cyrillic to Latin alphabet is always correct, while with reverse conversion there are errors. Plugins and web services for transliteration are mostly created by individuals or open source communities, so they are often not maintained or upgraded. The authors do not know that there are such tools created by a state institution or one of the manufacturers of word processors. Thus, transliteration users are reduced to the conversion of smaller wholes of text and careful proofreading, while the transcription of entire documents is generally more complicated. In general, it can be recommended that for texts that should be published in both Latin and Cyrillic, first make a text in Cyrillic, and then convert into Latin. In addition, it is necessary to encourage the organization and state institutions to create appropriate programming tools for transliteration.

6. SURVEY

In the electronic survey on computer devices and the Serbian language conducted from April to August 2023, 111 respondents participated, of which 90% have higher education and five have secondary education; 32% are 25 to 40 years old and 64% are 40 to 65 years old. So, it is mainly about the active population where 32% work in the public service or public company, 10% are teachers at some of the levels of education, 6% are IT specialists and students 4%. 45% of respondents aged 25 to 40 assessed the level of training they had for the use of computer devices in Serbian as satisfactory at the primary and secondary level of education; and 50% on higher education (offered answers were: satisfactory, unsatisfactory and without training). For a population of 40 to 65, satisfactory training had 20%. It is possible that there was an interesting situation that the second mentioned population trained the first!

92% to 96% of respondents know that the interface of computer devices can be in Serbian (mostly for mobile phones). About 2/3 of the respondents use the English interface, one-third serbian, for all devices except mobile phones, where it is the other way around. For word processing, e-mail, and web browsing, 55% of respondents use the interface in Serbian and 45% in English. For SMS and social networks, this relationship is 77% for Serbian and 23% for English. These results suggest that only mobile phone providers and partly mobile phone vendors sell phones that are already set up for use in Serbia. Setting up for Serbian language with vendors of other devices, as well as setting up in companies and institutions (including those required by law to use the Cyrillic alphabet) – is largely absent. Correct Latin script is mostly used for writing texts in Serbian, except for official correspondence, where Cyrillic script dominates (Figure 5). The mutilated Latin script is mostly used for short messages that are mostly written on a mobile phone.

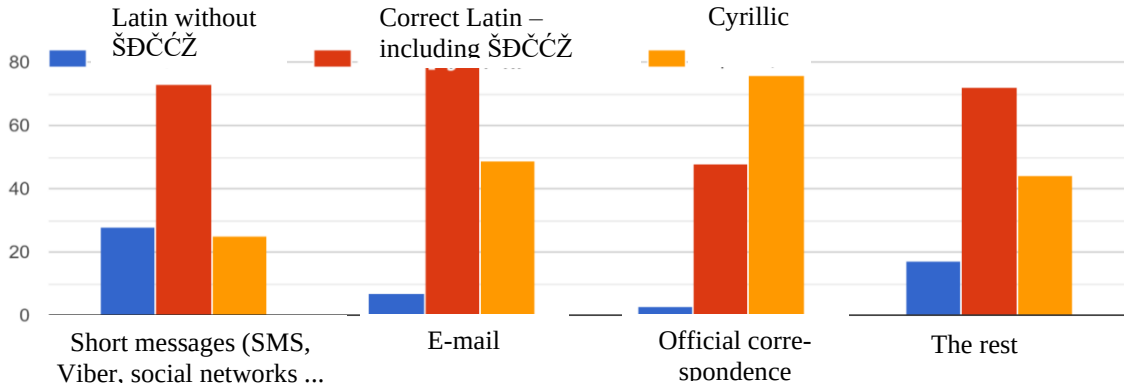

Figure 5. Script used for texts in Serbian language
***Source**: original copyright*

Respondents were able to cite a number of reasons: **A)** Why English is more suitable for communicating with computers – offered answers with the possible addition of new answers. The following answers were obtained (given by more than 10% of respondents): 29% - English is not more suitable; 41% - due to habit; 39% - because most computers are set up for English; 29% - I know computer terms in English very well; 11% - because most keyboards are for English. **B)** Why writing without SĐČĆŽ is more suitable for them to write. The following answers were obtained: 63% - do not approve of such writing; 15% - because computers are often not set up for Serbian; 12% - due to habit; 11% - the letters šđčćž are not visible on mobile devices. **C)** Why Cyrillic is more suitable for writing. The answers are: 20% - I believe that writing in Cyrillic is not suitable (we already have Latin alphabet); 54% - Cyrillic script is primarily Serbian script; 15% - because it always uses only one key to write one letter.

37% of respondents believe that learning to use computer programs would be easier if the interface language was Serbian, 22% believe that this would not be the case, and 41% of respondents are not sure. Respondents were asked to assess the extent to which it is important to properly use the Serbian language on computer devices. Ratings of 1 to 10 are offered, where 10 corresponds to the highest importance. 50% of respondents gave a score of 10, 86% from 6 to 10, and as many as 5% to grade 1.

In short, the survey was conducted on a sample of a population that actively uses computer devices in Serbian. In the relevant group of respondents aged 25 to 40 years, only 50% were satisfied with the training for using computers and writing in Serbian. Although practically all respondents know the interface of computer devices can be in Serbian, only about 2/3 of respondents use the English interface, one-third use Serbian, for all devices except mobile phones, where it is the other way around. The above indicates poor training and setup of devices (hardware and software) for computer use and the production of documents in Serbian. This led to the fact that most computers are set up for use in English, and that texts in Serbian are difficult to write and often misspelled incorrectly.

7. RECOMMENDATIONS

In order to improve the production of documents in the Serbian language, it is necessary that institutions, especially educational and ministries, as well as companies, systematically implement the following steps:
1. **Training for the use of computers** with a Serbian interface and preparation of documents in the Serbian language, as a rule Cyrillic Script. **A)** Train teachers at all levels of education, with appropriate training checks – upon employment and periodically. **B)** Train the IT professionals who configure the computers, with the prior creation of a precise configuration specification. **C)** Pupils and students should be trained exclusively to work on computers with a Serbian interface and for the production of documents in the Serbian language with clear requirements. It is especially important that young children use only devices with an operating system in the Serbian Cyrillic alphabet from the beginning, since literacy also begins in the Cyrillic alphabet.
2. **Hardware.** Oblige computer sellers to have Serbian Latin and Cyrillic keyboards as a basic offer – as two separate devices and as a single device.
3. **Software. A)** Oblige sellers to sell all software in wide use already set for the Serbian language. **B)** Encourage the creation of a program for Transliteration as well as templates for documents in the Serbian language and make them available free of charge to sellers and users. **C)** Encourage the development and improvement of other tools, such as hyphenation, thesaurus, automatic word correction, grammar checking.
4. **Regulation.** Enact appropriate regulations related to the previous points.

8. CONCLUSION

The paper deals with hardware components and software tools for using computer devices in the Serbian language - possibilities and availability on the market. The results of a survey on the use of computers in the Serbian language were presented. It has been shown that the main causes of non-productivity and errors in the preparation of documents and texts in the Serbian language are: inadequate training, poor adjustment of computer devices and inadequate offer on the market, as well as already created bad habits among users. Specific measures that institutions and companies should undertake in order to improve the productivity and quality of writing texts and documents in the Serbian language are proposed. These measures are primarily related to encouraging and obliging, above all, educational institutions to conduct training with correctly selected and adjusted software and to pass appropriate regulations. Also, development and improvement of appropriate software tools should be encouraged and their free use should be enabled for all users.

LIDERI GENERACIJE

Projekat zapošljavanja Lideri generacije namenjen je studentima završnih godina visokih škola i fakulteta ili postdiplomcima bez radnog iskustva. Kandidatima nudimo plaćeno zaposlenje u trajanju od 6 meseci, uz pojedinačan rad sa stručnim mentorom tokom čitavog trajanja projekta. Nakon isteka perioda od 6 meseci, najboljima nudimo mogućnost da ostanu u našoj kompaniji i nastave sa razvojem u oblastima koje ih interesuju.

Projekat podrazumeva prolazak kroz 5 krugova selekcije, tokom kojih vršimo profesionalnu orijentaciju i zajedno pronalazimo najbolji sektor za svakog kandidata. Aktuelne informacije o projektu možete pratiti na našoj Instagram stranici **@liderigeneracije**.

GRAFIKUM

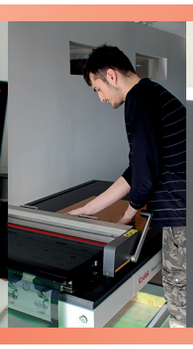
Kompanija Grafikum je prisutna više od 15 godina na srpskom tržištu nudeći opremu, repro materijal i softvere prestižnih brendova.

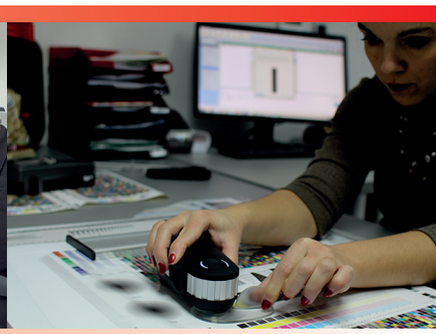
KODAK miraclon CGS HYBRID SOFTWARE

Böttcher TECHKON® GLUNZ & JENSEN

Sa više od 150 klijenata, uglavnom sa tržišta ofset i flekso štampe, Grafikum je dobro poznato ime i simbol za ponudu dobrih proizvoda, vrhunskih tehnologija i softvera.

Prepoznajemo potrebu da podržimo naše klijente i sa servisne strane. Zahvaljujući stručnosti naših servisera imamo veliki broj potpisanih ugovora o servisiranju naših CTP uređaja. Ovakvim pristupom, naši klijenti su sigurni u svojim procesima znajući da će u svakom trenutku imati našu podršku.



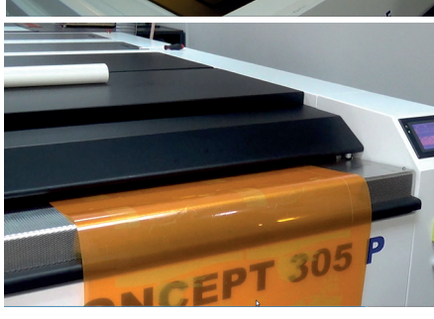


Kodak Flexel NX sistem, lider u procesu izrade flekso ploča, samo je jedan sa liste naših odličnih proizvoda.

Gradeći sopstveni Demo Flexel NX Studio, sa kompletnim procesom izrade ploča, Grafikum nudi tržištu mogućnost korišćenja NX ploča i istraživanja ove sjajne tehnologije sa svim njenim prednostima.

Pokazujući šta NX flekso ploča donosi štampi, stičemo puno poverenja u flekso industriji i uspostavljamo jake veze.

Studio je takođe opremljen workflow softverom (Kodak Prinergy Wokflow), mernim uređajima (Techkon) i sistemom za izradu probnog otiska (CGS ORIS) kako bi kupci, kako stari tako i novi, mogli da vide naše proizvode na delu i upoznaju se sa svim beneficijama koje oni nude.



Grafikum je partner, a ne samo dobavljač svojim klijentima.

Naši glavni ciljevi su:

- Ponuditi najbolja rešenja za svaki deo grafičke industrije
- Podrška postojećim klijentima uslugama, posetama, konsaltacijama itd.
- Pomoć kompanijama da rastu u svom poslovanju.

SHIMADZU
Excellence in Science

Doprinos nauci kroz znanost i tehnologiju

Svojom tehnologijom, Shimadzu omogućuje korisnicima iz različitih industrija, ali i medicine, razvoj novih proizvoda i rešenja za unapređenje i zaštitu zdravlja i života ljudi, ujedno podupirući zaštitu životne sredine na globalnom nivou.

Naša rešenja!

GC/MS AOC 6000

Shimadzu gasna hromatografija spregnuta s masenom detekcijom te dodatno kombinovana s gotovim instrumentalnim metodama predstavlja celokupno rešenje za analizu pesticida, PBC, BTX te mnogih drugih kontaminanata i analita od interesa.

UV1900i

Najbrži UV-VIS spektrofotometar svoje klase na tržištu, uz veliki izbor dodataka i načina merenja u analizama životne sredine s velikom tačnošću i mogućnosti detekcije komponenata niskih koncentracija.

TOC-L

Svetski vodeći TOC analizator omogućava analize jednog od najvažnijeg parametra za procenu organskog onečišćenja životne sredine. Toc-L analizator s principom izgaranja katalitičkom oksidacijom podržava svaku vrstu primene - od čiste vode do visoko kontaminirane vode.

ICPE-9800

Visokoosijetljivi instrument koji simultano određuje sve elemente periodnog sistema u niskim i visokim koncentracijama. Omogućit će vašoj laboratoriji brze, tacne i pouzdane rezultate u svega nekoliko koraka.

ZAJEDNO DO BEZBEDNOSTI

BEZBEDNOST. Kompanija Albo je vodeći snabdevač ličnom zaštitnom opremom kompanija i tržišta Srbije. Naš asortiman obuhvata kompletnu ponudu lične zaštitne opreme - radnu i zaštitnu odeću, obuću, rukavice, zaštitu glave, lica, sluha i disajnih oragana. Nudimo i dodatni asortiman - opremu za hitne slučajeve, profesionalne hemikalije za higijenu radnih prostora, papirnu galanteriju i opremu za bezbednost radnog mesta.

SNAGA. Zahvaljujući našim proizvodnim kapacitetima i individualnom pristupu svakom klijentu, nudimo i mogućnost personalizacije radne opreme i njenog usklađivanja sa korporativnim identitetom kompanije.

U našem asortimanu možete pronaći sertifikovanu zaštitnu opremu svetski poznatih brendova, kao i privatne robne marke naše komapnije, čime našim kupcima osiguravamo dostupnost najboljih i najadekvatnijih proizvoda koji odgovaraju njihovim potrebama.

Ono što nas čini liderima je naše znanje i iskustvo stečeno radom dugim 30 godina, širina i dostupnost asortimana, kao i savetodavna pomoć kupcima pri odabiru zaštitne opreme, brzina isporuke i kompletna postprodajna usluga. Sve ovo omogućava naš tim od preko 200 zaposlnih koji ima istu misiju, a to je maksimalna bezbednost na radu naših klijenata.

PARTNERSTVO. Naši klijenti su pre svega naši partneri. Cilj naše kompanije je da im pružimo celovito rešenje za bezbedan rad, u svrhu čega obezbeđujemo i neophodne obuke o upotrebi određenih zaštitnih sredstava.

Sa našim kupcima razvijamo odnose uzajamnog partnerstva koje nas vodi ka zajedničkom cilju - svetu bez povreda na radu.
